cartography. On the resulting antigenic maps, Thailand DENV1-4 strains were more centrally located than strains from other countries, indicating greater sensitivity to heterotypic immunity. Generalized additive models of antigenic distances from the map center revealed that DENV1-4 had become more antigenically similar to one another between 1994-2003, followed by a period of increasing antigenic dissimilarity. The dip in antigenic distance for Thailand DENV1-4 remained when we only analyzed strains from 1994-2006, extended observations through 2014, and analyzed each DENV type separately. We tested whether DENV type-specific incidence in Bangkok correlated with antigenic distance and found the months with the largest epidemics were those during which DENV types were most antigenically central on the antigenic maps. Finally, within DENV type, antigenic and genetic distance increased linearly up to ~20 amino acid differences, whereas strains separated by greater genetic distances were actually more antigenically similar. Thus, we find DENV1-4 circulating in a highly endemic area can oscillate in antigenic similarity across time and genetic space and that antigenic similarity correlates with dengue epidemics. These findings raise new questions about paths to viral antigenic evolution and may help explain why DENV vary antigenically within type without divergence of the DENV types.

Introduction: Dengue fever (Df) is known to be one of the most common Arthropod-borne viral infectious disease of public health importance. The disease is now endemic in more than 100 countries in Africa, the Americas, the Eastern Mediterranean, Southeast Asia and the Western Pacific with an estimated two fifths of the world's population being at risk. The notable endemic Viral Hemorrhagic Fevers (VHFs) found in West Africa, including Yellow fever, Lassa fever, Rift Valley fever, Dengue fever and until recently Ebola have been responsible for most outbreaks with fatal consequences. These VHFs usually produce unclear acute febrile illness, especially in the acute phase of infection. Aim: We set out to investigate and characterize the presence of Df and other arboviral agents in archived residual clinical specimens of serum 150 patients clinically suspected of Ebola virus disease during the Ebola Virus Disease (EVD) outbreak in West Africa. Methods: Through a surveillance system set up as part of an EVD preparedness and response plan to detect and rapidly respond to cases, clinical specimens of serum/plasma from patients suspected of EVD were submitted and tested for EVD as well as known endemic VHFs including Yellow fever, Lassa fever West Nile and Dengue fever. Results: In this study we detected the presence of 2 different serotypes (DENV-2 and DENV-3) of Df virus in 4 sera of the patients clinically suspected of EVD during the outbreak in West Africa with the use of serological and molecular test assays. The phylogenetic analysis of the envelope gene showed that the DENV-3 had close homology with serotype from Senegal and India. Conclusion: This study documents molecular evidence of an indigenous Dengue fever viral infection in Ghana and therefore necessitates the need to have an efficient surveillance system to rapidly detect and control the dissemination of the different serotypes in the population which has the potential to cause outbreaks of Dengue Hemorrhagic fevers.

MAPPING THE CLONAL AND FUNCTIONAL DIVERSITY OF DENV-ELICITED HUMORAL IMMUNITY USING HIGH THROUGHPUT SINGLE CELL RNA SEQUENCING

Adam T. Waickman[1], Wiriya Rutvisuttinunt[1], Gregory D. Gromowski[1], Kaitlin Victor[1], Hayden Siegfried[1], Tao Li[1], Abhinaya Srikanth[1], Benjamin Gabriel[2], Anon Srikiatkhachorn[2], Stefan Fernandez[3], Alan Rothman[2], Richard G. Jarman[1], Jeffery R. Currier[1], Heather Friberg[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*Institute for Immunology and Informatics and Department of Cell and Molecular Biology, University of Rhode Island, Providence, RI, United States,* [3]*Department of Virology, Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Tracking the development and maturation of virus-specific humoral immunity is a highly complex technical challenge. However, the importance of understanding the isotype distribution and relative abundance of type-specific or cross-reactive antibodiesis becoming increasingly apparent, especially in the setting of complex pathogens such as dengue virus (DENV). In order to close this functional gap in our understanding of viral-specific humoral immunity, we utilized high-throughput single cell RNA sequencing to capture individual B cell plasmablasts circulating in response to both primary and secondary natural DENV infection. At least two time points with circulating plasmablasts were captured per subject (within days pre- and post- viral clearance), allowing for the temporal resolution of antibody maturation and clonal turnover. Paired full-length heavy and light immunoglobulin chains were identified for ~90% of captured plasmablasts, and monoclonal antibodies were synthesized and tested for virus binding and neutralization capacity from multiple time points per subject. Plasmablasts circulating in response to a secondary DENV infection were found to predominantly express IgG class-switched antibodies that were broadly cross-reactive to all four DENV serotypes and were extensively hypermutated. In contrast, plasmablasts circulating in response to a primary DENV infection were predominantly IgA expressing and were specific for the infecting viral serotype or weakly cross-reactive to all DENV serotypes. The observation that primary - but not secondary - DENV infection was associated with a IgA biased-humoral response was confirmed by serum ELISA, where significant levels of DENV-reactive IgA were found in early-convalescent samples in subjects with primary DENV infections, but not those with secondary DENV infections. These results highlight the utility of unbiased molecular analysis of acute virus-elicited humoral immunity, and also suggest a previously unappreciated role for IgA in controlling - or responding to - primary DENV infection.

816

PRIMARY AND SECONDARY DENGUE VIRUS INFECTIONS ELICIT SIMILAR MEMORY B CELL PROFILES BUT CROSS-REACTIVITY TO ZIKA VIRUS IS HIGHER IN SECONDARY DENGUE

Paulina Andrade[1], Josefina Coloma[1], Angel Balmaseda[2], **Eva Harris**[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*

Dengue virus (DENV) exists as four serotypes that differ antigenically; Zika virus (ZIKV) shares high protein sequence homology with DENV. Little is known about the development of polyclonal memory B cells (MBCs) during DENV infection and the relationship of these responses to DENV and ZIKV cross-reactivity. Here we analyzed MBCs from peripheral blood mononuclear cells collected ~2-4 weeks or ~6 months after RT-PCR-confirmed DENV1, DENV2 and DENV3 infections from primary (1°) and secondary (2°) cases in a pediatric hospital study in Nicaragua. Analysis of activated MBCs was performed using a Multi-color FluoroSpot assay that enables measurement of immunoreactivity of B cells to DENV1-4

and ZIKV at a single-cell level. During 1° DENV infections, type-specific (TS) responses accounted for 37.9±15.5% (mean ± standard deviation) of total antigen-specific responses, DENV cross-reactive (CR) responses for 49±16%, and DENV&ZIKV cross-reactivity for 13±8.4%. During 2° infections, TS responses represented 26±17% and reacted to the infecting serotype but also to heterotypic serotypes from previous exposures. DENV CR responses represented 55.9±13% and DENV&ZIKV CR responses 23±10% of antigen-specific responses. Thus, CR responses were significantly higher than TS responses in both 1° and 2° infections. Interestingly, when comparing TS responses during 1° vs. 2° infections, no significant differences were observed, similarly to CR responses. However, DENV&ZIKV cross-reactivity was significantly higher during 2° infection compared to 1° infections (p=0.017), suggesting that the breadth of MBC antibodies increases after more than one DENV infection. Finally, we compared DENV&ZIKV CR responses from DENV-immune Zika patients before and after their ZIKV infection and found that these responses were similar between both temporal groups. Overall, the frequency of DENV- and DENV&ZIKV-specific responses among total antibody-secreting cells reflected antigen-specific data. These results improve our knowledge of memory B cell responses during DENV infection and their implication for the development of DENV and ZIKV cross-reactivity.

Four serotypes of dengue virus (DENV1-4) circulate in human populations, and immunity to one serotype does not confer long-lasting immunity to the others. Rather, pre-existing DENV immunity may actually increase the risk of severe dengue after exposure to a second serotype. The possibility of antibody-mediated enhancement has complicated vaccine development because of the need to induce robust immunity to all 4 serotypes simultaneously. After a primary infection, type-specific (TS) antibodies to individual serotypes of DENV is thought to be associated with robust, life-long homotypic protection, but the full repertoire of primary neutralizing antibody epitopes in each DENV serotype remains incomplete. Currently, the only DENV3 TS neutralizing human monoclonal antibody (mAb) is 5J7, which recognizes a complex quaternary epitope spanning 3 monomers of the envelope (E) glycoprotein. Importantly, several studies in natural DENV-infected cohorts suggest only a fraction of the polyclonal response targets the 5J7 epitope and there are additional neutralizing epitopes. To test this hypothesis, we immortalized memory B cells from DENV3-infected individuals with secondary DENV infections from a cohort in Nicaragua. New DENV3 TS neutralizing mAbs were identified that do not compete with 5J7 in competition assays. We designed a panel of 4 chimeric DENV3/1 viruses containing increasingly larger transplants of the DENV1-specific 1F4 and 14c10 epitopes into the DENV3 E protein along with chimeric DENV1/3 viruses containing increasing portions of domain I of DENV3 transplanted into DENV1. Using the panels of DENV3/1 and DENV1/3 chimeras along with an existing panel of 5 recombinant viruses containing DENV3 genotype E protein swaps, we mapped 14 new human mAbs to 4 distinct areas of the E protein. When tested in mice, several of the new mAbs were highly effective in reducing viral load when challenged with DENV3. These findings provide new insights into the mechanism of DENV3 neutralization and will lead to new tools for defining the primary neutralizing epitopes associated with DENV3 protective immunity following natural infection or vaccination.

818

SEROLOGICAL CHARACTERIZATION OF HOMOTYPIC AND HETEROTYPIC REPEAT DENGUE VIRUS INFECTIONS IN A LONG-TERM COHORT STUDY

Parnal Narvekar[1], Ciara Gimblet-Ochieng[2], Magelda Montoya[1], Paulina Andrade[1], Daniela Valente Andrade[1], Leah Katzelnick[1], Sandra Henein[2], Angel Balmaseda[3], Aravinda de Silva[2], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Department of Microbiology and Immunology, University of North Carolina, Chapel Hill, NC, United States,* [3]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*

Dengue is the most common mosquito-borne viral disease, affecting an estimated 100 million people annually worldwide. It is caused by one of 4 related dengue virus serotypes (DENV1-4), and it is thought that infection confers lifelong immunity to the homologous serotype. However, cases of homotypic reinfection have been documented and may be more common than currently appreciated. Here, we identified instances of homotypic and heterotypic DENV repeat infections and analyzed memory B cell (MBC) and antibody responses. We selected individuals with consecutive annual samples from a 15-year on-going community-based cohort study in Nicaragua with evidence for repeat infections based on paired annual inhibition ELISA (iELISA) titers. We then conducted flow cytometry-based neutralization assays to DENV1-4 reporter virus particles using Raji-DC-SIGN cells in each annual sample and calculated NT_{50} titers. Based on a >4-fold increase in NT_{50}, we identified potential repeat infections as homotypic (increase to the previous infecting serotype only) or heterotypic (increase to >1 serotype). We also selected a control group of subjects with primary infection only. Depletion of DENV antibodies specific to all but one serotype was carried out using magnetic beads coated with purified DENV virions in 4 distinct combinations (DENV1/2/3; DENV1/2/4; DENV1/3/4; DENV2/3/4). Successful depletion was confirmed by binding ELISA, and the type-specific (TS) antibody response generated by every infection was compared at each timepoint. Homotypic repeat infections showed no evidence of a TS response from a different serotype even when increased iELISA and NT_{50} titers indicated an infection had occurred. We confirmed TS and cross-reactive MBC responses using a Multi-Color B-cell FluoroSpot that enables measurement of reactivity to DENV1-4 at a single-cell level. Using these discriminating methods, we document cases of homotypic as well as heterotypic infections in the cohort. We are currently developing simplified assays to characterize larger numbers of samples to determine the proportion at which homotypic DENV infections occur at a population level.

819

PERSISTENCE OF ANTI-ZIKA VIRUS ANTIBODIES OVER TIME IN PEDIATRIC AND ADULT COHORT STUDIES IN NICARAGUA USING DIFFERENT SEROLOGICAL ASSAYS

Magelda Montoya[1], Fausto Bustos[1], Damaris Collado[2], Tatiana Miranda[2], Guillermina Kuan[3], Angel Balmaseda[4], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Sustainable Sciences Institute, Managua, Nicaragua,* [3]*Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua,* [4]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*

The Zika epidemic in 2015 began in Brazil and then spread throughout the Americas. Zika virus (ZIKV) entered Managua, Nicaragua, in January 2016 and caused an explosive epidemic that peaked in July-September 2016. ZIKV seroprevalence was estimated in two different groups, a pediatric (*n* = 3,740) and an adult cohort (*n* = 1,047) in Managua, with seroprevalence values of 36% and 56%, respectively. There is debate regarding the differential stability of anti-ZIKV antibodies in both children and adults. Here, we use two serological tests, the ZIKV NS1 Blockade-of-Binding (BOB) ELISA (measuring total anti-ZIKV NS1 antibodies and highly specific

vs. anti-dengue virus [DENV] antibodies) and a ZIKV Inhibition ELISA (iELISA; measuring total anti-ZIKV antibodies). In the ZIKV NS1 BOB ELISA, a 1:10 dilution of serum is competed against a ZIKV-specific monoclonal antibody, and the % of antibody blocking is calculated, with a cut-off of 50%. In the iELISA, 4 serial 10-fold dilutions are tested, and the titer at which 50% inhibition occurs is estimated. Here, we apply these 2 assays to the Nicaraguan pediatric and adult cohorts over a 3-year timeframe: 8 months (2017), 20 months (2018) and 32 months (2019) after the peak of the Zika epidemic. This period experienced no ZIKV circulation and scant DENV infections, which can elicit cross-reacting antibodies. Using a 4-fold decrease in titer as a decay cutoff, 23.5% of iELISA titers decayed from 2017 to 2018 in the pediatric cohort. However, ZIKV NS1 BOB ELISA blocking percentages appear quite stable (1.6% sero-reversion from >50% to <50%) in the pediatric cohort study over the same time-frame, suggesting that the large decay in iELISA titers could reflect both the presence of cross-reactive anti-DENV antibodies and true anti-ZIKV antibody titer decay. Thus, conclusions from serological assays must account for the type of antibodies being measured and their respective stability. The decay rates in the adult versus pediatric cohorts over the 8-32 months post-epidemic is being compared. Our results provide insights into the stability of anti-ZIKV antibodies over time and inform future epidemiological studies.

THE GLOBAL BURDEN OF DENGUE FROM 1990-2017

Anum Najeem Khan, Harrison Chase Gottlich, Taren Gorman, Steph Zimsen, Martina Vargas, Amanda Deen, Jeffrey Stanaway, Robert C. Reiner, Jr., Elizabeth Cromwell

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Dengue is a mosquito-borne infectious disease with the potential to develop into severe dengue, a lethal complication and one of the leading causes of disability and fatality. The global incidence of dengue has grown drastically in all regions during recent decades, with almost 50% of the world's population now at risk. Dengue incidence is also known to be underreported and many cases are misclassified. In this analysis, we estimate mortality due to dengue disease, as well as incidence and prevalence of dengue fever, severe dengue fever (dengue hemorrhagic fever & dengue shock syndrome) and post-acute chronic fatigue due to dengue from 1990 to 2017 as part of the Global Burden of Disease study. National level data were modeled using a multi-level mixed effects negative binomial model, adjusted for spatial distribution, temporal trends, and global dengue death rate. We then adjusted results for under-reporting and modeled age and sex-specific dengue incidence and prevalence. Overall, global estimates for dengue incidence, prevalence, deaths and associated Disability Adjusted Life Years (DALYs) have increased from 1990 to 2017, and we estimate 40,467 (95% Uncertainty Interval (UI): 17,620 to 49,779) deaths due to dengue in 2017. We estimate 1,388,995 (95% UI: 27,306 to 3,119,291) prevalent cases and 23,283,274 (95% UI: 453,181 to 51,840,670) incident cases in 1990, 2,061,222 (95% UI: 295,550 to 3,863,987) prevalent cases and 34,459,672 (95% UI: 5,144,944 to 62,137,081) incident cases in 2000 and 6,267,410 (95% UI: 3,416,131 to 10,611,908) prevalent cases and 104,771,911 (95% UI: 63,759,019 to 158,870,031) incident cases in 2017. In 2017, the prevalence of dengue is highest among children aged 5-14, with majority of cases estimated in India, Indonesia and Brazil. Also, in 2017, burden of dengue in DALYs is highest in India (1,480,679; 95% UI: 744,422 to 2,087,713), followed by Indonesia (666,598; 95% UI: 304,378 to 821,767) and Philippines (227,152; 95% UI: 317,742 to 112,608). Given the rise in dengue incidence, we highlight the need to improve methods that account for under-reporting to better estimate the true burden associated with dengue.

821

RE-EMERGENCE OF DENV-2 IN THE STATE OF SAO PAULO, BRAZIL

Expedito J. Luna, Gerusa M. Figueiredo, Sergio R. Campos, Jose E. Levi, Walter M. Figueiredo, Angela A. Costa, Alvina C. Felix, Nathalia S. Souza, Claudio S. Pannuti

Universidade de Sao Paulo, Sao Paulo, Brazil

A cohort study has been set up to determine the incidence of dengue in a mid-level endemicity town, Araraquara, located in the central region of the state of Sao Paulo, Southeastern Brazil. A cluster randomized sample of children and adolescents, from 2 to 16 years of age was selected and invited to participate. Parents or legal guardians that agreed to participate provided a written consent. A baseline blood sample was collected for dengue serologic diagnosis. Families have been contacted weekly for fever surveillance. If the participant reports a febrile episode, the study's nurse visits the household to collect a blood sample for dengue diagnosis. Acute cases were confirmed according to their PCR and NS1 results. Confirmed dengue cases underwent full medical examination. Yearly blood samples were collected for serology. Participants were recruited from Sept 2014 to March 2015. 3,514 participants were enrolled in the cohort. A large dengue outbreak occurred in 2015. There were 290 confirmed cases among the participants in 2015 and 14 in 2016 (cumulative incidence of 8.3% and 0.48% respectively). All cases were confirmed as DENV1. No confirmed cases were observed in 2017. By the end of the transmission season in 2018 (April - June) three cases of DENV2 were diagnosed. In the beginning of the current transmission season (Nov 2018) new cases were confirmed as DENV2. So far, 35 DENV2 cases have been confirmed in this season, a cumulative incidence of 1.3%. Of them, 10 had had previously a DENV1 confirmed diagnosis during the cohort follow up, and 57% had an IgG reagent result in their last serology before the dengue episode. The cumulative incidence was significantly higher among the previously exposed to dengue (2.27%) than among the non-exposed (0.85%), which suggests a heterogeneous exposure to the disease. So far, no severe cases have been observed among the cohort participants. After two years of record low incidence, and ten years of predominance of DENV1, a new dengue outbreak is under way in some regions of Brazil.

822

GROWING EVIDENCE THAT THE WORLD MOSQUITO PROGRAM'S *WOLBACHIA* METHOD REDUCES DENGUE TRANSMISSION

Katherine L. Anders, Cameron P. Simmons

Monash University, Clayton, Australia

The World Mosquito Program (WMP) is a not-for-profit initiative which aims to provide a safe, sustainable, and cost-effective new tool for preventing transmission of *Aedes aegypti*-borne diseases, including dengue, chikungunya and Zika. WMP's method involves introgression of *Wolbachia* bacteria into *Ae aegypti* mosquitoes. The resultant *Wolbachia* infected *Ae aegypti* have significantly reduced transmission potential for dengue, Zika and chikungunya viruses. Field releases in 9 countries have demonstrated successful and sustained *Wolbachia* establishment in local *Ae aegypti* populations. The public health impact of WMP's *Wolbachia* method is being evaluated through a suite of epidemiological studies in global field sites. A cluster-randomized controlled trial is underway in Indonesia and due to report in 2021, and a non-randomized prospective clinical study in Colombia in 2020. Consistent with predictions from mathematical modelling, pragmatic field effectiveness studies in Australia, Brazil, Colombia, Indonesia, Vietnam, and the Western Pacific have demonstrated that dengue outbreaks have ceased in locations where *Wolbachia* has been established. We used controlled interrupted time series analysis of surveillance data to quantify the reduction in dengue incidence in *Wolbachia*-treated areas, compared with historical time series and (in most sites) an untreated control area. Using segmented negative binomial regression to model monthly dengue case counts before and after *Wolbachia* deployment, with an offset for population size and

controlling for seasonal and interannual dengue variability using flexible cubic splines, we show that dengue incidence is significantly lower in *Wolbachia*-treated populations. Point estimates of the reduction in dengue incidence for the 5 sites with ≥6 months post-intervention by end 2018 ranged from 46-97%, with significance at the 0.05 level for 4/5 sites. These results, together with the efficacy trials and cost-effectiveness studies, strengthen the evidence that WMP's *Wolbachia* method can deliver large and sustained reductions in the burden of dengue in endemic and non-endemic countries.

823

COST-EFFECTIVENESS OF *WOLBACHIA* TO REDUCE DENGUE BURDEN IN MAJOR INDONESIAN CITIES

Oliver Brady[1], Lauren Carrington[2], Emilie Hendrickx[1], Dinar D. Kharisma[3], Ida S. Lakswanawati[4], Kathleen O'Reilly[1], **Donald S. Shepard**[3], Cynthia Tschampl[3], Nandyan N. Wilastonegoro[5], Laith Yakob[1], Wu Zeng[3]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam,* [3]*Brandeis University, Waltham, MA, United States,* [4]*Dr Sardjito General Hospital, Yogyakarta, Indonesia,* [5]*Universitas Gadjah Mada, Yogyakarta, Indonesia*

Dengue is among the world's fastest growing vector-borne diseases, costing US$18 billion globally in 2016. Releasing mosquitoes infected with *Wolbachia* is a promising strategy to control dengue, chikungunya and Zika. As *Wolbachia* are passed on to the next generation of mosquitoes, the process is self-sustaining and generally entails minimal ongoing costs. A 24-cluster randomized trial and observational studies with *Wolbachia* are underway in Yogyakarta, Indonesia. Here we assess the cost-effectiveness over a 10-year present-value horizon of extensions to two potential sites: (1) the current control clusters of Yogyakarta (population 225,313); (2) densely populated parts of Indonesia's top 7 cities in number of predicted dengue cases (Jakarta, Surabaya, Bandung, Medan, Semarang, Palembang, and Makassar, population 37 million). We based costs (in 2018 US$) on budgets from Yogyakarta and disease impact on a dengue transmission model calibrated to entomologic data. We projected that the first site would cost US$4.4 million (with a 95% uncertainty interval of $2.9-$6.7 million) and avert 534 (138-1,213) DALYs per year, a 97.4% reduction. The incremental cost-effectiveness ratio (ICER) was $1,123 per DALY averted on a gross basis (counting only program costs), but -$82 on a net basis (i.e., showing a net savings due to medical costs averted). The second site would cost $480 ($306-$746) million, or $13.1 ($8.4-$20.3) per person protected, and avert 48,454 (12,582-110,074) DALYs annually. Its gross and net ICERs were $1,335 and -$4 per DALY, respectively. These results suggest *Wolbachia's* ICER is lower (i.e., even more cost-effective) than other widely-accepted public health interventions in Indonesia. For example, Didik Setiawan et al. estimated the ICER for visual inspection with acetic acid and human papillomavirus vaccination for girls at $1,863 per DALY averted. Because *Wolbachia* costs depend primarily on the area covered, this strategy is most cost-effective for large urban areas. If epidemiologic results confirm entomologic data, the extension of *Wolbachia* to major cities appears highly cost-effective, and perhaps cost saving.

824

LABORATORY EVALUATION OF A NOVEL MICROFLUIDIC NANOPARTICLE-BASED IMMUNOASSAY FOR THE DETECTION OF DENGUE VIRUS NS1 ANTIGEN IN A DENGUE-ENDEMIC SETTING

Michelle Ylade, Jedas Veronica Daag, Kristal An Agrupis, Leidenia Castro, Riacarl Alpay, Jacqueline Deen, Anna Lena Lopez

University of the Philippines Manila National Institutes of Health, Manila, Philippines

Dengue is an important public health problem in Asia and Latin America. There are four serotypes; individuals living in endemic areas may experience repeat dengue infections. Since dengue has non-specific manifestations, an accurate rapid diagnostic test would be useful. The flavivirus nonstructural 1 (NS1) protein is an important biomarker for early diagnosis of disease. A study evaluating commercially-available NS1 RDT kits for diagnosis of acute dengue found sensitivities ranging from 40 to 59% and specificities of 76 to 80% compared to RT-PCR and/or virus isolation. A better performing NS1 RDT, particularly with improved sensitivity, would be useful. We evaluated the performance of a novel kit, ViroTrack acute dengue NS1 antigen test used with the BlueBox reader (BluSense Diagnostics, Copenhagen, Denmark). The ViroTrack test consists of a microfluidic disc with magnetic nanoparticles coated with high-affinity monoclonal antibodies against NS1. The presence of NS1 antigen in the specimen triggers agglutination and nanocluster formation that is detected using an optomagnetic readout in the BluBox. We tested 100 stored samples from Filipino children with acute febrile illness for dengue RNA by RT-PCR and for dengue NS1 by a commercial RDT (SD BIOLINE Dengue NS1 Ag, Abbott) and the ViroTrack test. Compared to RT-PCR, the overall sensitivity and specificity of SD was 35.29% and 87.76% and Virotrack was 41.18% and 87.76%. Using RT-PCR as the gold standard, we found similar specificities but a slightly higher sensitivity of the ViroTrack test compared with the SD NS1 RDT. A larger study is ongoing to assess the performance of ViroTrack at the point-of-care.

825

GENOME MICROEVOLUTION OF DENGUE VIRUS TYPE 2 CAUSING OUTBREAKS IN THE KENYAN COAST, 2014-2017

Solomon Kipngetich Langat, Fredrick Eyase, Albert Nyunja, John Distelhorst, Rosemary Sang

U.S. Army Medical Research Directorate-Africa, Nairobi, Kenya

Dengue virus (DENV) is an important arbovirus pathogen with significant disease burden and risk potential globally. An estimated ^{390} million yearly infections occur throughout the tropical and subtropical regions. In Kenya, the virus has been associated with outbreaks since ^{1982}, especially in the Coastal towns of Malindi, Kilifi and Mombasa. DENV^{2} has been implicated on the majority of those outbreaks, with DENV^{1} and ^{3} also being reported. DENV epidemics in Kenya have increased over the recent past in terms of the frequency and severity of the disease. Information on the evolutionary dynamics of DENV in Kenya is still lacking. In this study, therefore, we complemented previous sequencing efforts of DENV^{2} by performing complete genome sequencing of samples covering the periods between ^{2014} and ^{2017}, and subsequently performed viral microevolutionary analysis of this important pathogen which has caused outbreaks at the Kenyan Coast between these periods. Newly generated DENV^{2} genomes, combined with previously published genomes resulted in a dataset of ^{19} complete and near-complete sequences isolated between ^{2014} and ^{2017}. Our findings show that DENV^{2} in Kenya is undergoing a rather rapid lineage turnover, characterized by replacement of earlier strains. The most recent outbreak strains are genetically distinct and they have acquired unique amino acid changes in the NS^{1}, NS^{2}A and NS^{2}B genes. The observed lineages do not appear to be as a result of importation of new strains, rather they appear to have arose In Situ through elaborate evolutionary processes acting on the DENV^{2} genome. Our findings suggest an interplay of natural selection and genetic drift in this process. This study demonstrates the importance of evolution in the emergence of DENV^{2} as a significant human pathogen in Kenya.

THE TETRAVALENT DENGUE LIVE ATTENUATED VACCINE TV003 ELICITED A CROSS-REACTIVE MEMORY B CELL REPERTOIRE IN FLAVIVIRUS-NAÏVE SUBJECTS

Huy A. Tu[1], Usha K. Nivarthi[2], Matthew Delacruz[2], Kristen Pierce[1], Stephen Whitehead[3], Beth Kirkpatrick[1], Aravinda Desilva[2], Sean Diehl[1]

[1]*University of Vermont, Burlington, VT, United States,* [2]*University of North Carolina School of Medicine, Chapel Hill, NC, United States,* [3]*Laboratory of Infectious Disease, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States*

Dengue, caused by any of the four dengue virus serotypes (DENV-1, 2, 3, 4), is the leading mosquito-borne viral disease worldwide, with approximately 400 million new infections annually. The lack of direct treatment and increasing rate of transmission result in an urgent need for safe and efficacious vaccines to protect populations living and traveling in endemic areas. The tetravalent DENV live attenuated vaccine candidate TV003 protected 100% of the subjects from clinical symptoms and viremia upon an attenuated DENV-2 challenge, and recently DENV-3 challenge. Toward the goal of defining novel correlates of protection for improved evaluation of vaccine efficacy, we interrogated the antibody response following TV003 immunization. Using longitudinal samples acquired during the six-month period following immunization, we assessed the plasmablast and memory B cell response induced by TV003. In healthy, naïve adult subjects, TV003 induced a plasmablast response within three weeks following immunization, averaging 3.0% of peripheral B cells. The magnitude of this plasmablast response was correlated to duration and level of vaccine-related viral replication, and was associated with development of serum neutralizing antibodies. At 6-month post-immunization, we estimated 0.15% of the memory B cell pool to be DENV2-specific. The majority of these DENV-2-specific memory B cells showed cross-reactivity against multiple DENV serotypes, which reflected the tetravalent nature of the TV003 formulation. Given the vaccine's ability to confer protection, our findings suggested that TV003-induced immunity may involve cross-reactive antibodies along with other immune mechanisms. In addition, the connection between vaccine-related viremia and the early plasmablast response may be further explored to determine its applicability as an immunologic parameter to inform vaccine efficacy evaluation.

ARBOVIRAL VULNERABILITIES OF ECUADOR: CHIKUNGUNYA ORIGINS AND NOVEL DENGUE INTRODUCTIONS FOLLOWING THE INCREASED INFLUX OF VENEZUELAN AND COLOMBIAN CITIZENS

Irina Maljkovic Berry[1], Wiriya Rutvisuttinunt[1], Rachel Sippy[2], Katherine Figueroa[1], Abhinaya Srikanth[1], Anna M. Stewart-Ibarra[2], Timothy Endy[2], Richard G. Jarman[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*SUNY Upstate Medical University, Syracuse, NY, United States*

In recent years, Ecuador and other South American countries have experienced an increase in arboviral diseases. A rise in dengue infections and severe forms of the disease was followed by introductions of chikungunya and Zika, two viruses never before seen in the country. This, coupled with the latest socioeconomic and political instability in Venezuela and the mass migration of its population into the neighboring countries, has given rise to concerns of infectious disease spillover and escalation of arboviral spread in the region. Our analyses of dengue virus (DENV) and chikungunya virus (CHIKV) genomes sampled from a surveillance site in Ecuador in 2014-2015, along with genomes from the surrounding countries, revealed several DENV introductions from Venezuela and Colombia (in years 2010, 2011 and end of 2013), some of which were subsequent to an increase in the influx of Venezuelan and Colombian citizens into Ecuador. However, we show that Venezuela has historically been a major source of DENV dispersal in this region, even before the massive contemporary exodus of its population, suggesting already established paths of viral distribution. Like DENV, CHIKV was introduced into Ecuador at multiple time points, but unlike DENV, these introductions were associated with the Caribbean strains. Findings indicate no direct CHIKV dispersal between Ecuador, Colombia, and Venezuela as of 2015, suggesting that CHIKV was not following the paths of DENV spread despite the viruses sharing a common vector in this region. Finally, our results reveal that Ecuador is vulnerable to arbovirus import from many geographic locations, highlighting the need of continued surveillance and more diversified prevention strategies.

828

CLINICAL PROFILE OF PATIENTS HOSPITALIZED WITH DENGUE DURING AN EPIDEMIC IN PUERTO RICO

Laura Divens Zambrano[1], Brenda Torres-Velasquez[1], Laura E. Adams[1], Tyler M. Sharp[1], Janice Perez-Padilla[1], Vanessa Rivera-Amill[2], Stephen H. Waterman[1], Gabriela Paz-Bailey[1]

[1]*Centers for Disease Control and Prevention, San Juan, PR, United States,* [2]*Ponce Health Sciences University, Ponce, PR, United States*

Dengue is endemic in Puerto Rico and typically causes outbreaks every 3-5 years. An epidemic dominated by dengue virus (DENV)-1 occurred during 2012-2013. Among other criteria, WHO recommends hospitalizing patients with severe dengue and warning signs to closely monitor disease progression and manage fluid intake. To assess adherence to the current WHO clinical management guidelines, we evaluated symptoms associated with hospitalization among dengue patients in 2012 and 2013 with onset of fever within 7 days prior to presentation at two sentinel sites in southern Puerto Rico. We analyzed demographic and clinical data from initial clinical assessments among patients with DENV infection detected by RT-PCR or IgM ELISA. Adjusted prevalence ratios comparing the proportion of hospitalized patients with severe dengue and dengue with warning signs was determined through log-binomial regression. Of 916 confirmed dengue patients during the outbreak period, 412 (45%) were hospitalized. Of all dengue patients, 13% (n=117) had severe dengue, 80% (n=736) had one or more dengue warning signs, and 6.9% (n=63) had dengue without warning signs. Of patients with severe dengue, 71% (83/117) were hospitalized, compared to 43% (318/736) of patients with warning signs and 18% (11/63) of dengue patients without warning signs. Compared to patients without warning signs, the likelihood of hospitalization was twice as high with warning signs (aPR: 2.19, 95%CI: 1.29-3.72) and over 3 times as high (aPR: 3.64, 95%CI: 2.08-6.39) with severe dengue. Despite their higher frequency of hospitalization, some patients with severe dengue and warning signs were not admitted. The subjectivity of key self-reported and observed severity indicators, particularly for lethargy and abdominal pain, could contribute to misclassification. Review of hospitalization practices can optimize triage of dengue patients. These data underscore the importance of sensitizing clinicians to published clinical guidance. Evaluation of existing guidance and methods used to identify warning signs predictive of severe dengue may improve dengue case management algorithms.

829

LABORATORY DIAGNOSIS ZIKA IN NEUROLOGICAL CASES DURING ZIKA OUTBREAK 2016 AND 2018

Leda Parham, Kimberly García, Isis Figueroa, **Ivette Lorenzana**

Centro de Investigaciones Genéticas, Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras

Since 2016 Zika outbreak that occur in Latin America, it has been confirmed its relationship to complications such as Guillain Barré Syndrome and other neurological manifestations, representing a considerable impact to global public health.In 2016, Honduras it was reported 32,132 Zika suspected cases,corresponding to more than 45% of Arboviral infections and 167 of neurological cases.Since then, efforts have been done for laboratory evidences of Zika infection and its association neurological.We aim to describe the laboratory results obtained in neurological cases since

the introduction of Zika in Tegucigalpa, Honduras(year 2016 to 2018). Analysis of 150 neurological cases. Plasma and/or urine were tested by qRT-PCR, as reported previously. A comparison was performed between plasma and urine in a subgroup of subjects (n=82). Plasma samples from 135 cases were tested for IgM antibodies for Zika&Dengue EIA-CDC methods. A 6% (9/150) of positivity for Zika by qRT-PCR & 36% (49/135) by Zika IgM antibodies. Distribution by year: 2.5% (2/79, CI95% 1 ± 9%) for 2016 and 11.2% (7/62, CI95% 6 ± 22%) for 2018 by PCR; 59% (43/73, CI95% 49 ± 69%) for 2016 and 9.8% (6/62, CI95% 5 ± 20%) for 2018 by serological means. In 2017 only 9 cases were reported and none was positive in the molecular assays, neither by serology. About 82 cases tested in both urine&plasma, a 7.3% (6/82, CI95% 3 ± 15%) positivity was found only in urine; 3.6%(3/82, CI95% 1 ± 10%) positivity only in plasma. The temporal distribution had two peaks, first in February and then in June during the two years. A Higher frequency of was observed in young people (less than 30 years of age)&males.The strong association between Zika in neurological cases considered a real challenge because of the low probability of detecting viral RNA after acute infection, nevertheless it was possible to determine it in 6% of neurological cases by molecular means.Urine and plasma samples contribute an added value for the ARN detection of Zika virus in neurological cases.The positivity could increase to 36% if serology is used, though one must keep in mind that Dengue is endemic in Honduras and some could be due to cross reactivity

830

ENSO PHENOMENON, THE FLOW OF THE RIVER AND THE PREVALENCE OF DENGUE CASES IN PIURA-PERU. 2013.01-2017.12

Victor Raul Ocana Gutierrez, Jorge Gonzales, Luis Varona

National University of Piura, Piura, Peru

We study for the dynamics of temporal behavior of cases of Dengue virus (DENV) as well as explain the causal relationships between ENSO and the prevalence of cases of DENV in the Piura-Peru Region, for the period 2013- 2017. The Distributed Autoregressive Recesses (ARDL) model that explains the impact of ENSO on the behavior of the prevalence of DENV in the Piura Region. The limit test accepts the long-term relationship of the model variables, which is adjusted in the short term by 38% per month. Two rainy scenarios are presented with ANIÑO indicators greater than zero and regular flow of the Piura River with DENV cases over 2466 and another scenario for a dry period that tends to zero the three variables. The model with the variables of ENSO and flow of the Piura River explain the variations in the prevalence of DENV by 83%. The model is useful for the analysis of future trends in DENV or other arboviruses transmitted by *Aedes aegypti.* For health prevention, the timely design of public policies before ENSO and the monitoring of water resources to reduce and mitigate endemic or epidemic levels is recommended. The rainy scenario with ANIÑO indicators greater than zero and flow of the Piura River with DENV cases causes higher DENV and another scenario for a dry period that does not.

831

THE BURDEN OF DISEASE DUE TO DENGUE IN THE DISTRICT OF COLOMBO, SRI LANKA

M. B. Azhar Ghouse[1], Hasitha A. Tissera[1], Yeşim Tozan[2]

[1]*Epidemiology Unit, Ministry of Health, Sri Lanka,* [2]*New York University, College of Global Public Health, NY, United States*

Dengue is endemic in all districts in Sri Lanka, and the incidence of dengue has risen significantly during the last decade. The highest proportion of cases are reported from Colombo district, which is the most populated and urbanised district in the country. Assessing the underlying dengue disease burden in Colombo is key to policy decision making on the introduction of a successful vaccination strategy in the future. We evaluated the dengue disease burden by estimating the disability-adjusted life-years (DALYs) using an incidence-based approach of morbidity and mortality surveillance data from 2015 to 2017 in Colombo district and at the national level. In 2015 and 2016, the dengue incidence in Colombo was 473.5 and 742.4, while the incidence for the whole country was 128 and 242 cases per 100,000 population. In 2017, when a severe dengue outbreak was experienced in all parts of Sri Lanka, with an incidence rate of 883 cases per 100,000 population, the incidence in Colombo increased to 1,901 cases per 100,000 population. The dengue disease burden in Colombo district was estimated at 918 DALYs (39.49 per 100,000 population) in 2015, 978 DALYs (42.08 per 100,000 population) in 2016, and 2,203 DALYs (133.84 per 100,000 population) in 2017. The national disease burden was estimated at 1,918 DALYs (9.42 per 100,000 population) in 2015, 3,270 DALYS (16.06 per 100,000 population) in 2016, and 13,635 DALYs (66.97 per 100,000 population) in 2017. This is the first study on the dengue disease burden in Sri Lanka, and our findings show a significant increasing trend over time, particularly following the massive dengue outbreak in 2017. The findings of this research serve as a catalyst for future countrywide disease burden assessments and have the potential to inform the implementation of a future dengue vaccination strategy

832

GENOTYPIC DIVERSITY IMPACTS DENGVAXIA DENV4 ANTIBODY RESPONSES AND PROTECTIVE IMMUNITY

Emily Gallichotte[1], Sandra Henein[1], Usha Nivarthi[1], Matthew Delacruz[1], Matthew Bonaparte[2], Ralph Baric[1], Aravinda de Silva[1]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*Sanofi Pasteur, Allentown, PA, United States*

Dengvaxia, Sanofi-Pasteur's licensed tetravalent dengue vaccine, has completed two large phase III trials in Latin America and Southeast Asia. While overall vaccine efficacy varied depending on baseline dengue (DENV) immune status and DENV serotype, efficacy was highest against serotype 4 (DENV4) (~77%). Recent genetic epidemiological studies revealed that two DENV4 genotypes circulated during the trials, genotypes I and II. Additionally, these studies found that vaccine efficacy was substantially higher against vaccine-matched genotype II DENV4s (83%), than vaccine-mismatched genotype I viruses (47%). Importantly, this phenomenon was not observed when only looking at older individuals, who are likely pre-immune to DENV, suggesting a difference in vaccine-elicited antibody (Abs) responses in naïve versus pre-immune individuals. In our study, using chimeric genotype I and II DENV4 viruses, we find that sera from naïve vaccinated individuals more potently neutralize DENV4 genotype II viruses than genotype I, whereas pre-immune vaccinees cross-neutralize both genotypes similarly. Using depletion techniques, we find this is driven by differences in quality of vaccine-elicited Abs. Naïve vaccinees generate high levels of DENV4 serotype-specific Abs that more potently neutralize vaccine-matched genotype II, whereas pre-immune vaccinees have lower levels of DENV4-specific Abs, revealing cross-reactive Abs are primarily responsible for DENV4 neutralization. Additionally, we map five specific amino acids within the viral envelope glycoprotein that differ between genotype I and genotype II viruses, which are responsible for the differential neutralization between the genotypes. These results suggest that the immune response to Dengvaxia vaccination is measurably different between naïve and pre-immune individuals, and that these differences in responses might allow for vaccine-mismatch genotype breakthrough infections. Additionally, these results highlight the importance of antigenic variation within DENV serotypes, and possibly provides a molecular explanation of heterotypic reinfection.

833

LINKING DENGUE VIRAL GENOMICS AND HOST CELL TRANSCRIPTOMICS IN SINGLE CELLS

Felix J. Hol, Fabio Zanini

Stanford University, Stanford, CA, United States

Viral infections originate from one or a handful of virions infecting a single host cell, yet in the laboratory this process is generally studied at vastly larger scales. Recent advances in sequencing technologies, however, enable the characterization of the host cell and its infecting pathogen at

an unprecedented level of molecular detail. Using virus-inclusive single cell RNAseq data, we present an analysis of hundreds of human cells infected with dengue virus (DENV) and characterize the joint dynamics of the host transcriptome and viral population genetics at the single-cell level. Our analysis reveals a strong heterogeneity in the viral genetic diversity generated in individual host cells, and the distribution of single nucleotide variant (SNV) frequencies across cells indicates that DENV replicates geometrically, implying an accelerated accumulation of SNVs compared to a 'stamping machine' replication mode. Detailed analysis of mutational profiles shows that the frequency and type of SNVs vary along the genome. Connecting the genetics of the infecting virus to the transcriptome of the host cell shows that standing genetic variation in the parental DENV strain and de novo mutations result in different clusters of host cells with linked viral genomic variation and distinct host transcriptional patterns. This study provides an exploratory proof-of-concept of simultaneous viral genomics and host transcriptomics in single cells at high throughput, and can be extended to virtually any virus and host cell type.

834

EVALUATION OF THE LARVAL INDEX RAPID ASSAY FOR *AEDES AEGYPTI* (LIRAA) AS A PREDICTOR OF DENGUE EPIDEMICS

Andrew William Enslen, Antonio S. Lima Neto, Marcia C. Castro

Harvard TH Chan School of Public Health, Boston, MA, United States

To retrospectively examine whether the LIRAa larval survey served as a useful tool in predicting the occurrence of future dengue epidemics within Brazilian municipalities from 2009-2015. Weighted sensitivity and specificity analysis were used to determine the validity of the LIRAa predictor in predicting epidemics across Brazil from 2009-2015. Models were stratified by year, by geographic macro-region, by municipality-population size, and temporal interval between LIRAa survey and epidemic outcome. Between 2010 and 2015, the LIRAa survey had an overall weighted sensitivity of 25.07% (CRL: 22.67, 27.47), a weighted specificity of 73.45% (CRL: 71.97 - 74.52), a weighted PPV of 42.57% (CRL: 39.84 - 45.31) and weighted NPV of 55.27% (CRL: 53.84 - 56.70) in predicting future dengue epidemics across all municipalities in Brazil. The LIRAa survey was a poor predictor of future dengue outbreaks within municipalities throughout Brazil. The marginal increases in sensitivity associated with northern macro-regions, heavily populated municipalities, and for the month following the LIRAa survey as compared to 6-months post-survey suggest that usage of LIRAa scores on a national scale requires further investigation. The Brazilian Ministry of Health, PAHO, and the WHO should re-consider widespread recommending LIRAa implementation or reevaluate strategies to optimize its use in order to better respond to future Dengue epidemics.

835

CHARACTERIZATION OF GENETIC VARIATION BETWEEN ZIKV ASIAN AND AFRICAN STRAINS

Camila R. Fontes-Garfias[1], Bruno Nunes[2], Chao Shan[1], Antonio Muruato[1], Scott C. Weaver[1], Pedro F. Vasconcelos[2], Daniele B. Medeiros[2], Pei-Yong Shi[1]

[1]*University of Texas Medical Branch, Galveston, TX, United States,* [2]*Evandro Chagas Institute, Ministry of Health, Brazil*

Zika virus (ZIKV) Asian lineage is responsible for recent epidemics in the Americans causing neurological complications and is associated with sexual transmission. However, ZIKV African lineage has not been associated with the recent epidemic outbreak or severe disease manifestations. However, in laboratory settings, the African strains seem to be more virulent than the Asian strains. To identify the determinants of virulence between the two ZIKV lineages, we engineered chimeric viruses by swapping the structural and non-structural regions between the African (DKR) and Asian (FSS) strains. We observed differences *in vivo* and *in vitro* that indicate the structural genes (C-prM-E) are responsible for the increased viral replication and virulence of the African over the Asian strain. We investigated the effect of the variations of the structural genes of the DKR strain by constructing structural chimeric viruses; in which each virus contained one structural gene from DKR strain in the backbone of FSS strain. In mouse models, the DKR prM structural gene enhanced virulence and neurovirulence. Additionally, we investigated the role of amino acid differences between the two strains located in the structural regions. We generated recombinant viruses by introducing single mutations, present in the DKR strain, into the FSS infectious clone. We identified the single mutation as one of the major determinants for neurovirulence in the CD1 mice, as evidenced by mortality, the mutant and DKR viruses caused 100% mortality at days 13 and 10 p.i., respectively. In contrast, infections FSS strain resulted in 20% mortality. Collectively, the results have identified the virulent determinant (s) between the African and Asian ZIKV lineages.

836

PERFORMANCE OF TWO ZIKA VIRUS NEUTRALIZING ANTIBODY TITER CLASSIFICATION SCHEMES AGAINST ZIKA NS1 BLOCKADE-OF-BINDING ASSAY DURING THE 2015-2016 EPIDEMIC IN GUATEMALA

Daniel Olson[1], Molly M. Lamb[2], James W. Huleatt[3], Matthew Bonaparte[3], Maria Alejandra Paniagua-Avila[4], Alma Zacarias[4], Neudy Rojop[4], Andrea Chacon-Juarez[4], Muktha Natrajan[5], Jesse Waggoner[6], Maria Renee Lopez[7], Celia Cordon-Rosales[7], Edwin J. Asturias[1]

[1]*University of Colorado School of Medicine, Aurora, CO, United States,* [2]*Colorado School of Public Health, Aurora, CO, United States,* [3]*Sanofi Pasteur, Swiftwater, PA, United States,* [4]*Fundacion para la Salud Integral de los Guatemaltecos, Los Encuentros, Guatemala,* [5]*Emory Vaccine Center, Atlanta, GA, United States,* [6]*Emory University School of Medicine, Atlanta, GA, United States,* [7]*Universidad del Valle de Guatemala, Ciudad de Guatemala, Guatemala*

Neutralizing antibody (NAb) tests, including microneutralization (MN) and plaque reduction neutralizing tests (PRNT), are commonly used to determine Zika (ZIKV) and dengue virus (DENV) serostatus, though they can exhibit cross-reactivity. The ZIKV anti-NS1 blockade-of-binding (BoB) ELISA has high sensitivity (Sn) and specificity (Sp) in determining ZIKV serostatus, when evaluated against PCR. We created two ZIKV/DENV serostatus classification schemes ('Expanded' and 'Simple'), which consider various combinations of ZIKV and DENV NAb titers (<15, 15 to <100, 100 to <500, and >500) concurrently to categorize individual ZIKV and DENV serostatus into ZIKV- and DENV- 'positive,' 'possible,' 'negative,' or 'indeterminate.' Using available serum samples obtained from randomized cross-sectional, pediatric seroprevalence surveys in Guatemala during the ZIKV epidemic (Oct. 2015-Feb. 2016), we performed ZIKV/DENV 1-4 MN testing and ZIKV NS1 BoB testing on all samples. We then evaluated the performance of each NAb classification scheme (Expanded and Simple) against ZIKV NS1 BoB positivity (50% inhibition of NS1 Mab binding, titer >10 [1/dilution]). A total of 389 subjects had samples available for testing (mean age 9.9 years, 56% female), and 92 (24%) were ZIKV-seropositive by ZIKV NS1 BoB. ZIKV serostatus was classified as positive, possible, negative, and indeterminate by the two NAb schemes as follows: Expanded, 59 (15%), 48 (12%), 279 (72%), 3 (<1%); and Simple, 59 (15%), 19 (5%), 308 (79%), 3 (<1%). The Sn/Sp for positive ZIKV categorization in the Expanded and Simple schemes, compared to ZIKV NS1 BoB ≥10, were 76%/99% and 71%/99%, respectively; the Sn/Sp for positive *or* possible ZIKV categorization were 80%/89% and 75%/97%, respectively. In summary, the Expanded and Simple NAb categorization schemes for classifying individual ZIKV and DENV serostatus performed well against the ZIKV NS1 BoB assay (Sn 71-80%, Sp 89-99%), and therefore may be useful in classifying individual ZIKV/DENV serostatus. Accuracy of these schemes should be corroborated using late convalescent phase sera from PCR-confirmed ZIKV/DENV cases.

837

ZIKA VIRUS INFECTION INDUCES DETECTABLE METABOLIC ALTERATIONS IN HUMANS

Nathaniel M. Byers[1], Bryna L. Fitzgerald[1], Lyle R. Petersen[1], Amy C. Fleshman[1], Barbara Graham[2], Rebekah C. Gullberg[3], Rushika Perera[2], Michael P. Busch[4], Mars Stone[5], Claudia R. Molins[1]

[1]*Division of Vector-Borne Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States,* [2]*Colorado State University, Fort Collins, CO, United States,* [3]*Stanford University, Stanford, CA, United States,* [4]*Vitalant Research Institute and University of California San Francisco, San Francisco, CA, United States,* [5]*Vitalant Research Institute, San Francisco, CA, United States*

Cutting-edge untargeted metabolomics techniques can detect alterations in relative quantities of thousands of metabolites during infection, providing detailed insight into metabolic pathway disturbances indicative of disease progression. Metabolic profiling provides an orthogonal approach to nucleic acid and serologic methods and can circumvent the limitations of commonly used diagnostics. To develop metabolic biosignatures of Zika virus (ZIKV) infection, we applied liquid chromatography-mass spectrometry to well-characterized longitudinal plasma samples obtained from asymptomatic blood donors in the US (n = 53) positive for ZIKV RNA at index collection. We selected molecular features with at least two-fold changes or with statistically significant ($p < 0.05$) differences in concentrations between sample groups. Approximately 300 molecular features differentiated samples collected during the adaptive immune response to ZIKV (5-30 days post index collection) from samples post-ZIKV clearance (> 150 days post index collection). Longitudinal samples allowed us to evaluate the abundance changes of these molecular features over time and to correlate metabolic alterations to the progression of ZIKV infection. In comparing our results to findings from similar studies on dengue, we preliminarily identified several lipid metabolites that were perturbed in both infections, indicating conserved host-virus metabolic interactions between these flaviviruses. Ultimately, this study aims to understand fundamental metabolic changes occurring in ZIKV-infected patients and inform the development of novel biosignatures to predict complicated clinical outcomes of ZIKV, such as congenital Zika syndrome and Guillain-Barré syndrome.

838

CHARACTERISTICS OF A HIGH THROUGHPUT, SPECIES-INDEPENDENT PLATE-BASED ZIKA REPORTER VIRUS PARTICLE (Z-RVP) NEUTRALIZATION ASSAY

Kelly Bohning[1], Melissa Zahralban-Steele[1], Hui-Ling Chen[1], Greg Hather[2], Tim Powell[1], Hetal Patel[1], Stephanie Sonnberg[1], Hansi Dean[1]

[1]*Takeda Vaccines, Inc., Cambridge, MA, United States,* [2]*Takeda Pharmaceuticals, Inc., Cambridge, MA, United States*

Zika virus is a Flavivirus, transmitted via *Aedes* mosquitos, that causes a range of symptoms including Zika congenital syndrome. Zika has posed a challenging situation for health, public and economic sectors of affected countries. To quantitate Zika neutralizing antibody titers in serum samples, we developed a high throughput plate-based Zika reporter virus particle (RVP) assay that uses an infective, non-replicating particle encoding Zika virus surface proteins and capsid (CprME) and a reporter gene (*Renilla* luciferase). This is the first characterization of a Zika RVP assay in 384-well format using a Dengue replicon *Renilla* reporter construct. Serially diluted test sera were incubated with RVPs, followed by incubation with Vero cells. RVPs that have not been neutralized by antibodies in the test sera entered the cells and expressed *Renilla* luciferase. Quantitative measurements of neutralizing activity were determined using a plate-based assay and commercially available substrate. The principle of limiting the infection to a single round increases the precision of the assay measurements. RVP EC_{50} titers correlated closely with titers determined using a plaque reduction neutralization test (PRNT) (>95%). The plate-based Zika RVP assay also demonstrated excellent precision, reproducibility and throughput. The assay employs identical reagents for human, rhesus macaque and mouse serum matrices. Spiking studies indicated that the assay is species-independent, producing equivalent titers to monoclonal antibodies irrespective of the serum species. The assay is conducted in 384-well plates and can be automated to simultaneously achieve high throughput and high reproducibility.

839

SEX AS A BIOLOGICAL VARIABLE IN A POWASSAN VIRUS INFECTION MODEL

Erin Reynolds[1], Paul T. Massa[1], Steven G. Widen[2], Saravanan Thangamani[1]

[1]*SUNY Upstate Medical University, Syracuse, NY, United States,* [2]*University of Texas Medical Branch, Galveston, TX, United States*

Powassan Virus (POWV) is a tick-borne Flavivirus endemic to regions of the United States, Canada, and Russia. Following initial isolation of POWV from a fatal case in 1958 there has been relatively few confirmed cases in the US, although the rate of infection in the past few years appears to be increasing. The majority of POWV cases are presumed to be asymptomatic or present with mild to moderate symptoms but severe neuroinvasive disease has also been reported. In severe cases the fatality rate is approximately 10% and over 50% of survivors develop severe, long-lasting neurological sequelae. Animal models are often used to study human disease and a well-designed experiment can improve our understanding of the pathogenesis of infectious agents. Poor model selection or experimental design may lead to erroneous results while wasting animal lives. As advances are made in our understanding of the human body and how it responds to disease, as well as our understanding of animal models, it has become increasingly apparent that sex is an important biological variable. The Balb/C mouse is often used as a model for POWV infection but published research often used only one sex or has not fully evaluated differences in pathology or immune response in both sexes. To evaluate these potential differences, groups of male and female Balb/C mice were injected with either media or POWV. Animals were monitored for signs of clinical disease and blood was collected to determine viremia. At the end of the study, brains were harvested and split into two equal halves. RNA was extracted from one half for viral load and RNA-Seq analysis while the other half was sectioned and used for histopathology analysis via H&E and IHC staining. Our preliminary analysis indicates that there are differences in the temporal infection pattern of POWV in brain. We are currently investigating the pathology and immunological response to POWV infection. The outcome of this work will determine if sex is a biological variable for POWV infection and clinical outcomes, and will also provide valuable information in using male and female mice for future POWV infection and pathogenesis studies.

840

LEVERAGING MULTIPLE DATA TYPES TO ESTIMATE THE TRUE SIZE OF THE ZIKA EPIDEMIC IN THE AMERICAS

Sean M. Moore[1], Rachel J. Oidtman[1], K. James Soda[1], Amir S. Siraj[1], Robert C. Reiner, Jr.[2], Chris M. Barker[3], T. Alex Perkins[1]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*University of Washington, Seattle, WA, United States,* [3]*University of California Davis, Davis, CA, United States*

Since the first Zika virus (ZIKV) infection was confirmed in Brazil in May 2015, several hundred thousand cases have been reported across the Americas. This figure gives an incomplete picture of the epidemic, however, given that asymptomatic infections, imperfect surveillance, and variability in reporting rates complicate the interpretation of case report data. The infection attack rate (IAR)-defined as the proportion of the population that was infected over the course of the epidemic-has important implications for the longer-term epidemiology of Zika in the region, such as the timing, location, and likelihood of future outbreaks. To estimate the IAR and the total number of people infected, we took advantage of multiple Zika case data types from 15 countries and

territories where subnational data was publicly available. Datasets included confirmed and suspected Zika cases in pregnant women and the total population, Zika-associated Guillan Barré syndrome cases, and cases of congenital Zika syndrome. We used a hierarchical Bayesian model with empirically-informed priors that leverages the different case report types to simultaneously estimate national and subnational reporting rates, the fraction of symptomatic infections, and subnational IARs. The estimated country-level IAR ranged from 0.08 (95% CrI: 0.07-0.10) in Peru to 0.36 (95% CrI: 0.21-0.51) in Ecuador. There was significant subnational variability, with median IAR estimates ranging from 0.02 to 0.84 in Brazil and 0.03 to 0.83 in Colombia. Recently published seroprevalence estimates from Nicaragua, Ecuador, and Brazil all fell within the 95% credible intervals of our subnational model estimates. Totaling these infection estimates across the entire region, our results suggest that 118.7 million (95% CrI: 79.1-246.9 million) people in the Americas have been infected by ZIKV since 2015. These estimates represent the most extensive attempt to date to determine the size of the Zika epidemic in the Americas, and they offer an important baseline for assessing the risk of future Zika epidemics in this region.

STATISTICAL MODELS TO ESTIMATE THE NUMBER OF INFECTIOUS DENGUE AND ZIKA VIRUSES USING A REAL-TIME PCR

Steev Loyola, Dina Popuche, Alfredo Huaman, Zonia Rios, Maria Silva, Carolina Guevara

U.S. Naval Medical Research Unit No. 6, Lima, Peru

Dengue (DENV) and Zika virus (ZIKV) represent a major public health problem worldwide. The evaluation of the viral infection kinetic is necessary to predict clinical outcomes and to monitor the disease course. Real-time reverse transcription polymerase chain reaction (RT-PCR) is a molecular test routinely used for diagnosis and follow-up for infected patients providing a rapid viral load approximation in hours. The plaque assay method is used for the quantification of infectious viral particles. However, this assay is associated with high costs and requires resources that would not be available in developing nations. Statistical models to infer the infectious viral load in resource-limited laboratories with no access to cellular assays are required. Here, we report the correlation between the RT-PCR and plaque assay results for DENV and ZIKV and propose models to estimate the infectious load in plaque forming units (PFU) of DENV and ZIKV using the cycle threshold (Ct) value obtained from the RT-PCR. We conducted two *in vitro* infection experiments with three biological replicates each, using Vero76 cells with DENV and ZIKV inoculums, representing 38 and 32 samples, respectively. Daily, 200μL of supernatant from each replicate was collected until cells displayed a cytopathic effect of>75%. Specific RT-PCR assays for DENV and ZIKV were performed to quantitate the viral load through the Ct value. Plaques were counted and used for calculating the PFU per mL (PFU/mL). PFU/mL values were transformed to log10 (PFU/mL) for data analysis purposes. The overall correlation of the RT-PCR and plaque assay was excellent for both viruses (R>0.9580, p-value<0.001). The coefficients of determination for the DENV and ZIKV models were 0.9342 (p-value< 0.001) and 0.9178 (p-value<0.001), respectively. Additionally, both models displayed statistically significant betas coefficients. Our findings suggest that the RT-PCR could be used as a reliable infectivity assay in samples with unknown load of infectious viral particles. The proposed regression models could be used in locations with limited resources and without access to cell culture assays.

842

DETECTION OF ZIKA VIRUS IN PATIENTS WITH ACUTE FEBRILE RESPIRATORY SYMPTOMS

Dina Popuche[1], Steev Loyola[2], Zonia Rios[1], Julia S. Ampuero[1], **Carolina Guevara**[1]

[1]*U.S.Naval Medical Research Unit No 6, Lima, Peru,* [2]*Asociacion Benefica PRISMA, Lima, Peru*

Over the past 19 years the U.S. Naval Medical Research Unit No. 6 has collaborated with local authorities and universities throughout Latin America to characterize acute febrile and exanthematous illness in throughout the region. Zika virus (ZIKV) is an emerging flavivirus transmitted by *Aedes* mosquitoes and is currently circulating in the Caribbean and Central and South America. In 2016, ZIKV was declared a Global Emergency by the World Health Organization, a classification that recommends ZIKV-vulnerable countries to establish and maintain capacity to detect and confirm cases of ZIKV infection. Detection and isolation of ZIKV from blood can be challenging. In order to overcome this challenge we decided to look for the virus in other types of specimens, such as oropharyngeal swabs, as an alternative method for virus detection. Therefore, we retrospectively selected 21 respiratory samples collected during 2016-2018 from subjects presenting with a febrile illness with respiratory symptoms. All corresponding serum samples tested negative for DENV and ZIKV. All swabs were inoculated in mosquitoes cells (C6/36) and human epithelial cells (A-549) and evaluated for the presence of cytopathic effect (CPE) daily. One sample in A-549 cells produced a cytopathic effect (CPE) of 1+ on day 6 with no CPE in C6/36 cells. A second sample in C6/36 cells a produced CPE of 1+ on day 4 with no CPE in A-549 cells. Both samples were harvested and reacted with Polyclonal Flavivirus pool and MoAb4G2 when tested in immunofluorescence assays. Furthermore, supernatants from both samples tested positive by RT-PCR for ZIKV, we went back to the original oropharyngeal swab samples and both were positive by RT-PCR for ZIKV. Our results indicate that ZIKV can be isolated from oropharyngeal swabs as an alternative to identification in serum or other body fluids Most ZIKV infections are asymptomatic and detection of infectious ZIKV particles in oropharyngeal swabs may represent a person-to-person transmission, and the possibility that ZIKV transmission may not involve vectors in all cases.

843

SEROSURVEILLANCE USING A MICROSPHERE IMMUNOASSAY AND PHYLOGENETIC ANALYSIS OF FLAVIVIRUS INFECTION IN THAILAND - 2002-2014

Vivek R. Nerurkar[1], Lauren L. Ching[1], Akanitt Jittmittraphap[2], Siriporn Chattanadee[2], Jasmine Padamada[1], Narin Thippornchai[3], Madhuri Namekar[1], Axel Lehrer[1], Pornsawan Leaungwutiwong[3]

[1]*University of Hawaii at Manoa, John A. Burns School of Medicine, Department of Tropical Medicine, Honolulu, HI, United States,* [2]*Mahidol University, Faculty of Tropical Medicine, Department of Microbiology and Immunology, Bangkok, Thailand,* [3]*Mahidol University, Faculty of Tropical Medicine, Department of Microbiology and Immunology, Bangkok, Thailand*

Thailand is endemic for dengue virus (DENV), with serological evidence of Zika virus (ZIKV) as early as 1954 in a serosurveillance study conducted using sera collected from military personnel stationed in Bangkok, and epidemiological evidence of human transmission since 2011. In this study we employed a laboratory-developed flavivirus multiplex microsphere immunoassay (MIA) using color-coded fluorescent microspheres covalently coupled with ZIKV, DENV and Japanese encephalitis virus (JEV) nonstructural protein 1 (NS1), and human IgG conjugated to streptavidin peroxidase. The flavivirus MIA was used to evaluate for presence of flavivirus antibody in serum samples from two Thai cohorts of patients who presented with dengue-like symptoms, however were DENV negative by RT-PCR. The first cohort included archival samples from hospitalized patients in rural northeast Thailand collected between 2002 and 2004 (n=300). The second cohort of serum samples was collected at the

Hospital for Tropical Diseases in urban Bangkok in 2014 (n=50). In the setting of high DENV endemicity, we detected 3% (n=11) serum samples reactive for only ZIKV NS1 antibodies as early as 2002. Overall ZIKV NS1 antibodies were detected in 41% (n=142) of the serum samples, some of which were also positive for DENV (56%, n=80), JEV (3%, n=4), or DENV and JEV (33%, n=47) NS1 antibodies. When stratified by geographic location, ZIKV seropositive serum samples were found more frequently in the rural cohort, 41% (n=124), as compared to the urban cohort, 36% (n=18), while DENV (71%; n=249) and JEV (18%; n=63) seropositivity remained constant throughout the country. ZIKV phylogenetic tree was constructed using eight samples collected from febrile patients from Bangkok in 2017 with confirmed ZIKV infection. Sequence analysis of the *env* gene showed the circulating 2017 ZIKV strains in Bangkok clustered with the Asian linage of ZIKV, specifically those originating from Singapore in 2016. These data suggest transmission of ZIKV in Northeastern Thailand as early as 2002 and warrants further surveillance of ZIKV in mosquitoes and humans across Thailand to understand virus transmission.

844

ZIKA VIRUS-LIKE-PARTICLE VACCINE DEVELOPMENT BASED ON IMMATURE AND MATURE PARTICLES

Danielle Thompson[1], Lo Vang[1], Carla Uranga[2], Diego Espinosa[3], Ben Guenther[1], Jason Mendy[1], Darly Manayani[4], Shannon Beaty[1], Jon Smith[5], Eva Harris[3], Jeff Alexander[6]

[1]*Emergent BioSolutions, San Diego, CA, United States,* [2]*J. Craig Venter Institute, San Diego, CA, United States,* [3]*University of California Berkeley, San Diego, CA, United States,* [4]*CA, United States,* [5]*ClearPath Vaccines with RRD International, Rockville, MD, United States,* [6]*JL Alexander Research & Development Consulting LLC, Greater San Diego Area, CA, United States*

Zika virus (ZIKV) is a mosquito-borne flavivirus that causes an acute febrile disease with neurological complications in adults and developing fetuses. To date, there are no licensed vaccines against ZIKV infection. When overexpressed in mammalian cells, the surface structural proteins of ZIKV, pre-membrane protein (prM) and envelope protein (E), self-assemble into virus-like particles (VLPs). VLPs have a physical structure comparable to that of the native virus, with conformationally intact surface epitopes that elicit strong B and T cell responses. Since VLPs are replication incompetent, they may provide a safer alternative to attenuated and inactivated vaccines throughout manufacturing and use. Genetic sequences encoding the surface structural ZIKV proteins from a Brazil outbreak strain (insert strain designation) were selected to construct our lead VLP candidate. In addition, we also generated and characterized a VLP candidate that contains a single point mutation (residue F108A) in the fusion loop of the E protein. We hypothesized that mutation of the F108A residue would increase VLP production and indeed particle yield of the F108A mutant was approximately twice that of the lead candidate. Both constructs induced VLPs that were found to be highly immunogenic, however, the F108A mutant conferred weaker *in vivo* protection against a lethal ZIKV challenge compared to the lead candidate. The F108A mutant displayed uncleaved prM protein in purified VLP material, an indicator of particle immaturity. Previous studies on dengue virus (DENV), a related flavivirus, have shown particle immaturity to be correlated with antibody dependent enhancement (ADE). Here, we used a cell-based ADE assay to evaluate post-boost immunization sera for enhancement of ZIKV infection. Consistent with previous work on DENV enhancement, antibodies induced by the immature F108A particles enhanced ZIKV uptake *in vitro*. Together, these results indicate that there is a relationship between particle immaturity and ADE in ZIKV infection.

PREDICTORS OF ZIKA VIRUS SEROPOSITIVITY AMONG RURAL GUATEMALAN CHILDREN EARLY IN THE 2015-16 EPIDEMIC, USING RAPID ACTIVE SAMPLING SURVEYS AND THE ZIKV NS1 IGG BLOCKADE-OF-BINDING ASSAY

Molly M. Lamb[1], Maria Alejandra Paniagua-Avila[2], Alma Zacharias[2], Neudy Rojop[2], Andrea Chacon[2], James W. Huleatt[3], Matthew I. Bonaparte[3], Maria Renee Lopez[4], Celia Cordon-Rosales[4], Edwin J. Asturias[5], Daniel Olson[5]

[1]*University of Colorado School of Public Health, Aurora, CO, United States,* [2]*Fundacion para la salud integral de los guatemaltecos, Los Encuentros, Guatemala,* [3]*Sanofi Pasteur, Swiftwater, PA, United States,* [4]*Universidad del Valle de Guatemala, Guatemala City, Guatemala,* [5]*University of Colorado School of Medicine, Aurora, CO, United States*

Zika virus (ZIKV) swept through Central America in 2015-2016, infecting a large proportion of the pediatric population, often before surveillance systems could be established to evaluate risk factors and clinical outcomes. Rapid identification of risk factors for ZIKV infection in children could have directed public health efforts to limit transmission in children and their caretakers. We tested 383 available samples for ZIKV seropositivity using a ZIKV NS1 blockade-of-binding (BoB) ELISA assay, obtained from two cross-sectional seroprevalence surveys conducted in children (mean age: 9.9 years, 56% female) in the lowlands of rural southwest Guatemala early in the ZIKV epidemic. Multivariable generalized linear regression was used to test the following socio-demographic and epidemiologic factors for association with ZIKV seropositivity: age, gender, ethnicity, presence of standing water on property, house type and water source (socio-economic indicators), primary caregiver literacy, household crowding, number of small children in house, and school attendance (children ≥ 6 years). Overall, 89 (23.2%) children tested positive for ZIKV infection: 20/197 (10.2%) in Survey 1 (Oct-Nov 2015), and 69/186 (37.1%) in Survey 2 (Jan-Feb 2016). Older age (Prevalence Ratio (PR) for each year in age: 1.12, 95% Confidence Interval (CI): 1.07-1.17) and primary caregiver literacy (PR: 2.8, CI: 1.3-6.06) were identified as independent risk factors for ZIKV seropositivity. The results from these cross-sectional RAS Surveys in a ZIKV-naive population suggest that older children were at greater risk of ZIKV seropositivity early in the epidemic, which may be due to increased exposure to *Aedes* mosquitoes due to daily activities, or greater cross-reactivity in the ZIKV BoB assay due to cumulative DENV infections. Primary caregiver literacy may be a proxy for urban household setting, which is associated with increased risk of ZIKV exposure. These findings suggest that RAS Surveys may be a useful tool to identify risk factors for infection with emerging pathogens early in the course of an outbreak, which may then be used to direct public health messaging.

846

RECENT ZIKA INFECTION AMONG WOMEN OF REPRODUCTIVE AGE IN GUATEMALA, 2017-2018

Carol Y. Rao[1], Manuel de Jesus Sagastume[2], Carolina Martinez[3], Mireya Palmieri[3], Maria Elena D. Jefferds[1], Olga L. Henao[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Ministry of Health, Guatemala City, Guatemala,* [3]*INCAP, Guatemala City, Guatemala*

Zika infections were declared a public health emergency of international concern in the Americas in 2016. Zika infection during pregnancy can cause severe brain defects. In 2016, Guatemala reported 3,214 cases of Zika infections; 549 Zika infections were reported in 2017 with most cases reported in the first half of the year. Although official reports of Zika infections had decreased in Guatemala, Zika virus was still a potential risk for pregnant women. SIVESNU (Sistema de Vigilancia Epidemiológica de Salud y Nutrición) routinely monitors health and malnutrition among women and children in Guatemala. In the 2017 round of data collection for SIVESNU, we added questions on Zika-like symptoms and tested serum for recent Zika infection among women of reproductive age (WRA). Between July 2017 and March 2018, SIVESNU collected data

from a nationally representative sample of WRA (between 15 and 49 years of age). We administered a standardized questionnaire which asked about demographics, pregnancy status, symptoms of Zika infection in the last year and possible risk factors for infection. Venous blood was collected and sent to Instituto de Nutrición de Centroamérica y Panamá in Guatemala City for analysis. Serum was tested for IgM antibodies for Zika (Inbios ZIKV Detect 2.0). Of the 1,738 WRA enrolled in the project, 18% reported severe rash in the past 12 months. Ninety-nine women were pregnant at the time of the interview; 15.8% received information on preventing Zika infection during pregnancy. Of the WRA enrolled in the project, 1,504 participants provided a blood sample. One hundred and sixty five were IgM positive for recent Zika infection (165/1,504 = 11.0%). Seven were IgM positive for other flavivirus infection (7/1,504 = 0.5%). Although the official reports of Zika infections in Guatemala had waned considerably by late 2017, Zika infections among women of reproductive age were occurring in late 2017/early 2018. The majority of pregnant women, however, did not receive Zika prevention messaging from a healthcare provider. Countries endemic for Zika should remain vigilant in preventing Zika infection among pregnant women.

847

ASSESSMENT OF COMMUNITY SUPPORT FOR VECTOR CONTROL INTERVENTIONS IN A SOUTHERN PUERTO RICO COHORT

Emma M. Little[1], Liliana Sánchez-González[1], Laura E. Adams[1], Matthew Lozier[1], Brenda Torres-Velasquez[1], Marianyoly Ortiz[2], Grayson Brown[2], Angela F. Harris[1], Roberto Barrera[1], Ryan Hemme[1], Carmen Pérez[1], Steve Waterman[1], Vanessa Rivera-Amill[3], Gabriela Paz-Bailey[1]

[1]*Division of Vector-borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States,* [2]*Puerto Rico Vector Control Unit, San Juan, PR, United States,* [3]*Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, PR, United States*

Public support is vital to the successful implementation and sustainability of vector control interventions (VCI). Identifying factors that influence acceptance of VCI is necessary to maximize public support and inform community education campaigns. Communities Organized to Prevent Arboviruses (COPA) is a cohort study in communities with historically high rates of arboviral disease in Ponce, Puerto Rico. During 2018-2019, half (N=1,215) of adult participants were interviewed in their homes on their opinions about six VCI, including if they had heard of them and whether they would support or oppose implementation in their community. VCI included traditional (larviciding and indoor residual spraying [IRS]) and novel (autocidal gravid ovitraps [AGOs], genetically modified [GMO] mosquitoes, *Wolbachia* suppression, and *Wolbachia* replacement) methods. Binomial logistic regression with the log link was used to compute prevalence ratios (PR) with 95% confidence intervals (CI) to identify associations between support for VCI and participant demographics, practices, knowledge, and opinions on mosquitos and breeding site prevention. Overall, 51% of respondents had heard of larviciding, 35% of IRS, 26% of AGOs, 16% of GMO mosquitoes, and 5% of *Wolbachia*. Support for traditional VCI methods was high; 85% supported IRS and 90% supported larviciding. Support for AGOs was high (97%), but support for other novel methods was lower: GMO mosquitos (62%), *Wolbachia* replacement (64%), and *Wolbachia* suppression (68%). Older participants tended to be less likely to support novel VCI. Participants aged 41-50 years were less likely to support *Wolbachia* suppression (PR 0.90; 95% CI 0.82-0.99) and *Wolbachia* replacement (PR 0.80; 95% CI 0.70-0.93) than those aged 21-30 years. Greater support for *Wolbachia* suppression was found among participants that indicated arboviruses were a problem in the community (PR 1.09; 95% CI 1.001-1.19) as well as those who used store bought insecticide (PR 1.13; 95% CI 1.04-1.23). Ongoing community engagement and education efforts targeted toward specific age groups is necessary to increase community acceptance of novel VCI.

848

THE EFFECTS OF INCREASED INOCULUM ON ORAL ROTAVIRUS VACCINE TAKE AND IMMUNOGENICITY AMONG INFANTS IN DHAKA, BANGLADESH

Benjamin Lee[1], Dorothy Dickson[1], Masud Alam[2], Sajia Afreen[2], Abdul Kader[2], Faria Afrin[2], Tania Ferdousi[2], Christina Damon[1], Soyeon Kim[1], Monica McNeal[3], Daniel Bak[1], Mona Tolba[1], Marya Carmolli[1], Mami Taniuchi[4], Rashidul Haque[2], Beth Kirkpatrick[1]

[1]*University of Vermont, Burlington, VT, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States,* [4]*University of Virginia, Charlottesville, VA, United States*

Oral rotavirus (RV) vaccines have reduced immunogenicity in low-income countries, where interventions to improve vaccine performance remain elusive. Increasing vaccine inoculum might improve Rotarix vaccine immunogenicity, but this has not been formally evaluated in a low-income setting. Therefore, we performed a double-blind, randomized controlled trial among infants in Dhaka, Bangladesh randomized 1:1 to standard-(10^6 FFU) or high-dose ($10^{6.3}$ FFU) Rotarix at 6 and 10 weeks of age. Plasma RV-specific IgA (RV-IgA) was measured by EIA. Seroconversion was defined as pre-immunization RV-IgA <20 U/mL converting to seropositive (≥20 U/mL) 4 weeks post-immunization. Stool was collected 3, 7, and 14 days after each dose to detect vaccine shedding, defined as real-time qRT-PCR detection with sequence confirmation of vaccine-strain virus in any post-vaccination specimen. The primary outcome was vaccine take, defined as either seroconversion or vaccine shedding. PCR-positive specimens were also tested by stool EIA. Secretor status was determined by saliva EIA. 189 children completed the study per-protocol (97 standard-dose, 92 high-dose). Seroconversion was 49% vs 51% in the standard- vs high-dose arms (P=0.6). Post-vaccination RV-IgA geometric mean concentration was 22.6 U/mL vs 30.4 U/mL in the standard- vs high-dose arms (P=0.2) and 76.8 U/mL vs 107.9 U/mL, respectively (P=0.3), among seropositive infants. Vaccine shedding was 61% vs 55% in the standard- vs high-dose arms (P=0.4). Vaccine take was 70% vs 66% in the standard- vs high-dose arms (P=0.6). More children in the high-dose arm were non-secretors (40.2%); secretor status did not affect the primary outcome, but secretor-positive phenotype was associated with increased seroconversion (P=0.03) and vaccine take when shedding was determined using EIA-positive stools (P=0.01). Vaccination with an increased inoculum of Rotarix at 6 and 10 weeks of life did not increase seroconversion, vaccine shedding, or vaccine take among infants in Bangladesh. Larger dose increases may be effective, but limited by cost-effectiveness. Secretor status appeared to affect vaccine response.

849

DEVELOPMENT OF LASSA VIRUS GLYCOPROTEIN IMMUNOASSAY TO AID IN LASSA FEVER SURVEILLANCE AND VACCINE DEVELOPMENT

Duane Bush[1], Diana Nelson[1], Irina Aimukanova[1], Megan Rowland[2], Megan Heinrich[2], Kathryn Hastie[3], Mambu Momoh[4], Francis Baimba[4], Eghosa Uyigue[5], Adeyemi Kayode[6], John Aiyepada[5], Benevolence Ebo[5], Testimony Olumade[6], Patience Akhilomen[5], Grace Okonofua[5], Michael Airende[5], Blessing Osiemi[5], Ekene Muoebonam[5], Ikponmwosa Odia[5], Augustine Goba[7], Onikepe Folarin[6], Erica Ollmann Saphire[3], Luis Branco[2], Donald Grant[8], Christian Happi[6], John Schieffelin[9], Matthew Boisen[1], Robert Garry[9]

University, Ede, Nigeria, [7]Kenema Government Hospital, Kenema, Nigeria, [8]Ministry of Health and Sanitation, Freetown, Sierra Leone, [9]Tulane University, New Orleans, LA, United States

Lassa fever (LF) is a severe, often fatal, febrile disease endemic to West Africa. The etiologic agent is Lassa virus (LASV; family Arenaviridae) encodes several viral proteins including a membrane glycoprotein (GP) that mediates entry into host cells. The Lassa GP undergoes post-fusion conformational changes to complete cell invasion. Efforts to develop effective Lassa fever vaccines have focused on eliciting Lassa GP immune responses however these vaccine candidates have not addressed conformational stability in the prefusion state that the host must recognize for successful viral neutralization and protection. Recently point mutations have been optimized that successfully stabilize the Lassa GP in the prefusion conformation. Zalgen Labs and collaborators from the Viral Hemorrhagic Fever Consortium have utilized these stabilized prefusion GP antigens to develop the ReLASV Pan-Lassa Prefusion GP IgG/IgM ELISA to aid in the development of viable LF vaccine candidates and improve LF surveillance. The GP ELISA incorporates three recombinant prefusion GP representing LASV lineage II, III, and IV into a stabilized microwell coating for the capture of Lassa specific IgG or IgM. A Lassa GP specific human monoclonal antibody is included as an IgG Calibrator to provide a semi-quantitative estimate of anti-Lassa GP antibody in the clinical sample. Limit of detection of the IgG Calibrator is 50ng/mL. This assay was field tested during the 2018 and 2019 LF outbreaks in Nigeria and found Lassa specific IgG seroprevalence to be 22% and 25%, respectively. Long-term follow-up of Lassa survivors has demonstrated IgG reactivity at endpoint dilutions between 1:400 and 1:12,800. These results were confirmed 97.4% (38/39) positive agreement with a Lassa GP pseudovirus neutralization assays. The ReLASV Pan-Lassa Prefusion GP IgG/IgM ELISA has proven capable of detecting Lassa GP specific IgG and IgM in early convalescent LF patients and long-term LF survivors. The assays utility in LASV vaccine development and LF surveillance will provide a valuable medical countermeasure for countries affected by LF.

850

LASSA FEVER SEROPREVALENCE IN PLATEAU STATE, NIGERIA

Rashidat Adeyemi[1], **Matthew Boisen**[2], Elijah E. Ella[1], Maryam Aminu[1], Benevolence Ebo[3], John Aiyepada[3], Testimony Olumade[4], Olusola Ogunsanya[5], MacDonald Onyechi[6], Johnson Etafo[6], Matthew Afam Eke[7], Philomena Eromon[4], Andrew Hoffmann[8], Brandon Beddingfield[8], Onikepe Folarin[4], Simji Gomerep[9], Robert Garry[8], Christian Happi[4]

[1]*Ahmadu Bello University, Zaria, Nigeria, [2]Zalgen Labs LLC, Aurora, CO, United States, [3]Irrua Specialist Teaching Hospital, Irrua, Nigeria, [4]Redeemers University, Ede, Nigeria, [5]University of Ibadan, Ibadan, Nigeria, [6]FMC Owo, Owo, Nigeria, [7]FMC Abakaliki, Abakaliki, Nigeria, [8]Tulane University, New Orleans, LA, United States, [9]Jos University Teaching Hospital, Jos, Nigeria*

Lassa fever (LF) is a severe, often fatal, febrile disease endemic to West Africa. Nigeria has experience significant increases of confirmed LF in 2018 and 2019. While endemic in Nigeria, the majority of the LF cases has occurred in the southern states of Ondo, Edo, and Ebonyi. In January 2019, we conducted a LF seroprevalence study in a cohort of febrile patients admitted to two hospitals in Jos, Plateau State. While not a high transmission area, these febrile patients did satisfy the case definition of LF. Collected samples (n=278) were taken to the Africa Centre Of Excellence for Genomics of Infectious Diseases (ACEGID) laboratories at Redeemers University, Ede, Osun State, for screening of Lassa-specific IgG and IgM. Serum samples were tested using ReLASV Pan-Lassa Antigen ELISA and IgG/IgM ELISAs specific for nucleoprotein (NP) or glycoprotein (GP). Samples exhibiting antigen reactivity were also tested by ReLASV RDT and RealStar Lassa Virus RT-PCR Kit 2.0 (Altona Diagnostics GmbH, Germany). Samples exhibiting IgG or IgM reactivity were tested for endpoint titers against LASV lineage specific antigens to assess strain specificity. LASV GP pseudovirus neutralization was performed to confirm Lassa-specific antibody reactivity. One sample was positive by ReLASV Antigen ELISA and RDT (IgG, IgM ELISA negative) but was not confirmed by Altona 2.0 qPCR. Lassa NP-specific IgG seroprevalence was 6.1% (17/278; 95th% CI 3.6 - 9.6%) and GP-specific IgG seroprevalence was 20.5% (57/278; 95th% CI 15.9-25.7). Endpoint titer testing exhibited cross-reactivity toward antigen from LASV Lineage II, III, and IV with endpoint typically in the range of 1:1600 to 1:6400. Lassa-specific antibody reactivity was confirmed in a small subset of samples by LASV pseudovirus neutralization but further confirmation testing is needed using this reference method. The Lassa antigen cross-reactivity observed in this study group is consistent with findings in southern Nigeria and could facilitate an integrated LF surveillance program utilizing standardized LF diagnostics.

851

RESPIRATORY AND FEBRILE ILLNESSES IN CHILDREN DUE TO HUMAN PARAINFLUENZA VIRUS TYPE 4 (HPIV4) AND HUMAN CORONAVIRUS (HCOV) OC43 IN DHAKA, BANGLADESH

Mohammed Ziaur Rahman[1], Md. Muzahidul Islam[1], Md. Shaheen Alam[1], Mariya Kibtiya Sumiya[1], Doli Rani Goswami[1], Mustafizur Rahman[1], W. Abdullah Brooks[2]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Human parainfluenza virus (HPIV) and human coronavirus (HCoV) are globally recognized viral pathogens causing more than 15% of the overall respiratory tract infections. In Bangladesh, respiratory viral studies were mostly linked to the epidemiological and clinical impact of Influenza, RSV, HPIV-1, 2, 3, hMPV and adenovirus. However, information regarding HPIV4 or HCoV infections, its specific clinical syndromes, age distribution, seasonal patterns and the extent of genetic variation among the strains are limited. A total of 200 samples (20%) were randomly selected out of 1022 archived nasopharyngeal wash (NPW) specimens that were tested negative for a panel of viruses (Influenza, RSV, HPIV-1, 2, 3, hMPV, adenovirus). These specimens were collected under an urban rural surveillance for pneumonia, diarrhea and febrile illness among children under five years old in between 2014 and 2015. In order to detect novel paramyxoviruses, semi-nested RT-PCR was performed to amplify large polymerase (L) gene fragment and for detection of HCoV, samples were also subjected to RdRp (RNA Dependant RNA Polymease) gene nested RT-PCR followed by Sanger sequencing. Upon PCR based direct nucleotide sequencing, 10 samples were positive for either HPIV4 (n=4) or HCoV (n=6). The HPIV4 strains were phylogenetically belonged to HPIV4a (n=3) and HPIV4b (n=1) having sequence similarity of >98% with the other globally circulating strains. The sequence analysis of the RdRp gene fragment revealed that all the 6 samples that were positive for HCoV belonged to HCoV-OC43 with the sequences similarity of >99%. This study results may help to identify the contribution of HPIV4 and HCoV, causing respiratory and febrile illness in children and their circulating pattern among Bangladeshi children.

852

INCIDENCE OF FEBRILE ILLNESS EPISODES AND ASSOCIATED OUT-OF-POCKET COSTS AND SCHOOL AND WORK ABSENCES REPORTED IN A SOUTHERN PUERTO RICO COHORT

Liliana Sanchez-Gonzalez[1], Dania Rodriguez[1], Emma Little[1], Robert Rodriguez[2], Nicole Medina-Lopes[1], Olga Lorenzi[1], Janice Perez-Padilla[1], Laura E. Adams[1], Stephen H. Waterman[1], Luisa I. Alvarado[2], Vanessa Rivera-Amill[2], Gabriela Paz-Bailey[1]

[1]*Centers for Disease Control and Prevention - Dengue Branch, San Juan, PR, United States, [2]Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, Puerto Rico*

Fever is one of the most common reasons for seeking health care. Delay in health care can occur when out-of-pocket and time costs are high. Communities Organized for the Prevention of Arboviruses (COPA) is a community-based cohort study in southern Puerto Rico that measures the incidence of arboviral diseases through annual serosurveys using serologic

and virologic testing. Participants aged 1-50 years (y) were recruited in 2018-2019 from randomly selected households. We administered a questionnaire to assess febrile illness, and out-of-pocket expenses. We present demographic characteristics, and time and out-of-pocket costs for persons reporting fever in the previous year. Among 3,644 participants, 15% were positive for Zika IgM, 0.4% for dengue IgM, 0.6% for chikungunya IgM, and 31% were chikungunya IgG positive. Overall, 987 (27%) reported at least one episode of fever during the last year. Most participants (60%) were female and the median age was 26y (interquartile range 17-40). Participants 31-40y and 41-50y were less likely to report fever (23% and 24% respectively, $p<0.005$) when compared with those 1-10y (32%). Reports among participants 11-20y (30%) and 21-30y (30%) were similar to those 1-10y. More than half reported seeing a doctor (58%). Viral syndrome was the most common reported diagnosis (14%) followed by influenza (7%). Reports of dengue, Zika and chikungunya diagnoses were rare (4 each). Among participants who reported fever, missed days of work among those employed were reported by 55% (207/373), median of 3 (range 0.5-80) days missed. Among students, missed days of school were reported by 45% (175/388), median of 3 (range 1-21) days missed. Most (70%) reported out-of-pocket expenses. The median out-of-pocket expense was $20 (range $1-$4,000). Episodes of febrile illness were common in this population, and resulted in a median of 3 days of school or work missed. The economic burden of disease will likely increase in areas endemic for arboviral diseases during outbreaks. Effective control and prevention strategies are needed to decrease common causes of fever such as arboviral diseases and its associated economic impact.

COLD BLOOD: REPTILES AND AMPHIBIANS AS RESERVOIR AND OVERWINTERING HOSTS FOR ARBOVIRUSES

Izabela K. Ragan, Airn Hartwig, RIchard A. Bowen

Colorado State University, Fort Collins, CO, United States

Arthropod-borne pathogens continue to have a significant threat to animal and human health. A majority of these pathogens are maintained in enzootic cycles where the pathogen cycles between an animal reservoir and hematophagous arthropods. Animal reservoirs like ectothermic vertebrates are ubiquitous in the environment and may be important in the maintenance and overwintering of viral pathogens. Viremia in ectothermic vertebrates has been demonstrated for emerging arthropod-borne viruses (arboviruses) like Zika, Chikungunya and West Nile virus. However, there is a limited understanding of the viral pathogenesis in ectothermic vertebrates under various environmental conditions. Our objective is to better understand the role of amphibians and reptiles in the maintenance, overwintering and amplification of arboviruses. We initially screened a diverse range of arboviruses (Zika, Dengue, Mayaro, Yellow fever, Venezuelan equine encephalitis, and Rift Valley fever virus) for infectivity and viremia in four genuses of ectothermic vertebrates (frogs, toads, snakes, iguanas). Our results show that infectious virus was detected in blood from frogs (*Lithobates)* infected with Zika virus and from toads (*Rhinella)* and iguanas (*Iguana)* infected with Venezuela equine encephalitis virus; however, the magnitude of viremia was low. Additionally, antibodies were detected in sera against Yellow fever virus in frogs and against Zika virus in iguanas. The screening of snakes (*Thamnophis)* are ongoing. After the screening, selected arbovirus-ectotherm host models will then investigate the influence of temperature changes on pathogenesis. Lastly, an artificial ecosystem will evaluate arbovirus transmission cycles among ectothermic vertebrate hosts and arthropods (mosquitos). The knowledge gained from these studies will significantly enhance our understanding of ectothermic vertebrates as reservoir hosts for several arboviruses with significant public health consequences. This in turn will aid in developing global measures to reduce or eliminate the disease risk associated with these pathogens.

PLACENTAL TROPHOBLASTS AND GIANT CELLS ARE TARGETED FOR INFECTION IN A RODENT MODEL OF CONGENITAL RIFT VALLEY FEVER

Devin A. Boyles, Cynthia M. McMillen, Amy L. Hartman

University of Pittsburgh, Pittsburgh, PA, United States

Rift Valley fever virus (RVFV) is endemic to Africa and infects livestock via mosquito bite. Severe cases in animals can lead to fatal hepatic necrosis and "abortion storms" that result in the loss of up to 90-100% of pregnancies. Human infection occurs from contact with livestock and manifests as a febrile illness that can advance to hemorrhagic fever, liver disease, and encephalitic disease. Two published cases of human vertical transmission resulted in fetal viremia and death. The first established rodent model of vertical transmission observed that RVFV was able to bypass the antiviral protections of the reproductive system and infect the offspring. Significant damage was observed in the maternal decidua and placental trophoblasts. Even asymptomatic dams that survived to give birth produced stillborn pups with severe abnormalities. Little is known about the mechanism of viral infection in the placenta and the resulting fetal pathology. We sought to further characterize the cellular and molecular mechanisms of congenital RVF. Pregnant Sprague-Dawley rats were inoculated at embryonic day 14. Maternal and fetal tissues were processed for RNA *in situ* hybridization of RVFV RNA and immunohistochemical (IHC) staining of immune cell markers in order to identify inflammatory cell infiltrates and resulting pathologies of infected rat tissues compared to that of pregnant uninfected controls. RVFV-infected rats showed signs of liver and placental inflammation and necrosis and contained high viral titers; however, tissues from survivors displayed evidence of tissue repair. Infected pregnant rats were more susceptible to tissue pathologies than non-pregnant rats. Infection of trophoblasts, giant cells, and infiltration of neutrophils were identified by using IHC. RVFV was found in the brains and peritoneal cavities of pups from dams that succumbed while pups from survivors exhibited fetal resorption or extreme deformities. This study gives insight into RVFV cellular targets during pregnancy which can be further investigated for development of antiviral therapies.

TECOVIRIMAT, A NEW FDA-APPROVED DRUG FOR TREATMENT OF HUMAN SMALLPOX - SUPPORTING PRECLINICAL DATA

Peter M. Silvera[1], Aklile Berhanu[2], Jonathan Prigge[3], Kady Honeychurch[2], Doug Grosenbach[2], Dennis Hruby[2]

[1]*Advanced Bioscience Laboratories, Rockville, MD, United States,* [2]*SIGA Technologies, Inc., Corvallis, OR, United States,* [3]*US Army Joint Program Office, Frederick, MD, United States*

The etiological agent for human smallpox is variola virus (VARV), a highly infectious virus with an estimated case mortality rate of 30%. In 1980, the WHO declared eradication of smallpox - this resulted in a cessation of routine vaccinations in the US during the 1970s. Consequently, a large proportion of the population remains unprotected in the event of a potential release of VARV as an act of biowarfare or bioterrorism. To address this biosecurity concern, the US government has procured smallpox vaccines (ACAM2000 and IMVAMUNE) into the Strategic National Stockpile. Tecovirimat (registered trade name, TPOXX®), a small molecule with antiviral activity against orthopoxviruses was developed by SIGA Technologies as a post-exposure therapeutic. Here, we present a snapshot of preclinical data that supported advance development of TPOXX® utilizing the macaque monkeypox virus (MPXV) model. Experiments were designed to simulate a potential exposure scenario in a real-life situation. Thirty-two cynomolgus macaques were randomized into four treatment groups and exposed to a lethal intravenous challenge ($5x10^7$ PFU) with MPXV, Zaire strain 79 on study day 0. On study day 3 post-infection, groups of macaques were either mock-vaccinated or vaccinated with ACAM2000 via percutaneous scarification. Oral treatment with 10 mg/kg TPOXX® or placebo was initiated on study days 3, 4, 5 or

6 post-infection and continued for 14 consecutive days. Subsequently, all animals were monitored for survival, clinical signs of disease, fever, weight loss, MPX viremia, formation of pock lesions, and development of humoral and cell-mediated immune responses. Results demonstrated that post-exposure administration of ACAM2000 alone failed to provide protection against severe MPXV disease or mortality. In contrast, post-exposure treatment with TPOXX® alone or in combination with ACAM2000 provided 100% protection. Additionally, delaying TPOXX® treatment until day 4, 5, or 6 post-infection provided 83% (days 4 and 5) and 50% (day 6) protection. These data supported the New Drug Application and subsequent approval (2018) of TPOXX® for the treatment of human smallpox.

EXPERIMENTAL INFECTION OF JAMAICAN FRUIT BATS (*ARTIBEUS JAMAICENSIS*) WITH BUKAKATA ORBIVIRUS, A NOVEL VIRUS FROM A UGANDAN BAT

Anna C. Fagre[1], Alex Byas[1], Ashley Malmlov[2], Nicholas Bergren[1], Erin M. Borland[1], Lauren Rice[3], Tony Schountz[1], Rebekah Kading[1]

[1]*Colorado State University, Fort Collins, CO, United States,* [2]*Colorado Parks and Wildlife, Fort Collins, CO, United States,* [3]*University of Colorado School of Medicine, Aurora, CO, United States*

In 2013, a novel orbivirus (*Reoviridae: Orbivirus*) was isolated from an Egyptian fruit bat (*Rousettus aegyptiacus*) in Uganda. To further study the effects of infection with Bukakata orbivirus in a bat host, 9 male and 5 female captive Jamaican fruit bats (*Artibeus jamaicensis*) bats were inoculated intraperitoneally with 5.3 $\log_{10}$ pfu Bukakata orbivirus and monitored daily for signs of clinical disease. One male and 1 female bat were humanely euthanized and tissues collected for processing at day 0, and the same was done for two males and one female bat at days 2, 5, 10, and 15. Organs were collected and processed for qRT-PCR, quantification of viral load in multiple organs by plaque assay, histopathology, and immunohistochemistry. Blood, rectal swabs, and oral swabs were also collected to assess viremia profiles and shedding potential. Gross pathologic findings included hyperemia in the skin, pulmonary congestion, liver pallor, and injected vasculature on serosal surfaces of abdominal organs. Histopathologic lesions included vasculitis, hemorrhage, and vacuolar changes in multiple organ systems. Further, immunohistochemistry supports antigen localization in areas of inflammation and hemorrhage. The female bat euthanized at day 15 was discovered to be late in gestation, and the fetus was collected for processing following approval by the CSU Institutional Animal Care and Use Committee. Serology is being performed to confirm seroconversion, and qRT-PCR and viral titration (PFU/mL) are being performed to assess relative abundance of virus in various organ systems. This model provides an opportunity to examine pathology induced by an arbovirus in bats, and these data are critical in the assessment of the potential role of bats as reservoirs for arboviruses.

857

A RECOMBINANT SUBUNIT LASSA VIRUS VACCINE ELICITS A STRONG ANTIBODY AND CELL-MEDIATED RESPONSE

Albert To

University of Hawaii at Ma¯noa, Honolulu, HI, United States

Lassa virus (LASV) is classified as a Category A Priority Pathogen by the NIAID and NIH due to its high mortality rate, ease of dissemination, and for lack of preventive countermeasures. The accretion of LASV infections in Nigeria eariler this year is a clear characteristic of an emerging pathogen. Due to the epidemic potential and high case fatality rate, the WHO has declared the development of a LASV vaccine as a high priority for preventative use in endemic regions. The recombinant subunit vaccine platform offers a safe, non-replicating alternative to live-attenuated and chimeric vaccine candidates. In this study, we generated recombinant LASV glycoprotein (GP) using an insect cell expression system and tested the immunogenicity of an adjuvanted antigen in an outbred mouse model. Briefly, stably transformed *Drosophila* S2 cell line excreting LASV GP was scaled up in a multi-liter bioreactor and the clarified culture supernatant containing soluble GP was purified using a single-step immunoaffinity chromatography (IAC) purification method. Coomassie blue staining of SDS-PAGE gels showed that IAC using a GP1 specific-antibody yielded protein with a high level of purity. The eluted LASV GP was composed of GP1 and GP2 subunits, the GP1-2 heterodimer, as well as trace amounts of oligomer on a Western blot. Swiss Webster mice immunized intramuscularly with 3 doses of purified recombinant LASV GP formulated with an adjuvant showed a maximal, GP-specific antibody response after two immunizations. Low neutralizing antibody titers, and a robust cell-mediated response was observed after the 3rd dose. We have successfully developed an immunoaffinity-based method to produce highly purified, insect-cell expressed recombinant LASV GP capable of eliciting high antibody titers when formulated with a suitable adjuvant after only two doses. These results indicate the potential for recombinant GP to be an efficacious vaccine candidate. Further structural enhancments and a in-detail characterization of antibody and cell-mediated responses induced by this recombinant subunit LASV candidate vaccine are the next steps towards preclinical development.

IMMUNOGENICITY AND EFFICACY OF RECOMBINANT SUBUNIT FILOVIRUS VACCINES IN NON-HUMAN PRIMATES AND DEVELOPMENT OF THERMOSTABLE FORMULATIONS

Axel T. Lehrer[1], Michael M. Lieberman[1], Teri Ann S. Wong[1], Chih-Yun Lai[1], Eleanore Chuang[1], Oreola Donini[2], Kendall Neuberger[3], Theodore W. Randolph[3], Thomas W. Geisbert[4]

[1]*University of Hawaii, Honolulu, HI, United States,* [2]*Soligenix, Inc., Princeton, NJ, United States,* [3]*University of Colorado Boulder, Boulder, CO, United States,* [4]*University of Texas Medical Branch, Galveston, TX, United States*

Ebola (EBOV), Marburg (MARV) and Sudan (SUDV) viruses are three filoviruses that have caused the most fatal cases in humans. Transmission from animals into the human population typically causes outbreaks of limited scale in endemic regions. In contrast, the 2013-16 outbreak in several West African countries claimed more than 11,000 lives revealing the true epidemic potential of filoviruses. This is further emphasized by the continuing difficulty in controlling the largest ever outbreak of EBOV in the DRC. Despite significant progress with the clinical development of several EBOV vaccine candidates and therapeutics during and after the West African outbreak, no vaccines targeting EBOV have received regulatory approval. Moreover, protection of a monovalent EBOV vaccine against other filoviruses has never been demonstrated in primate challenge studies. We are developing a trivalent vaccine based on recombinant filovirus glycoproteins (GP) from EBOV, MARV and SUDV produced using the *Drosophila* S2 platform. The highly purified recombinant subunits elicit potent immune responses in mice, guinea pigs and non-human primates (NHPs) and consistently produce high antigen-specific IgG and virus neutralizing antibody titers. Candidate vaccines show full protection against EBOV infection in rodent and NHP challenge models. Similarly formulated monovalent MARV or SUDV vaccine candidates can protect cynomolgus macaques completely against infection with lethal doses of MARV or SUDV and combinations with the EBOV vaccine can be formulated yielding multivalent vaccines retaining efficacy. Ongoing formulation optimization in our laboratory focuses on thermostabilization of recombinant subunits by lyophilization. Current data suggest that shelf stability of at least three months at 40°C is feasible for each of the three antigens individually. Most importantly, formulations of antigens lyophilized in the presence of adjuvant are also stable, which should enable clinical development of safe and efficacious, field-deployable vaccine candidates for protection against Ebola, Marburg and Sudan Virus Disease.

HOST GENES ARE DIFFERENTIALLY EXPRESSED IN DENGUE COMPARED TO INFLUENZA INFECTIONS

L. Gayani Tillekeratne[1], Sunil Suchindran[1], Emily R. Ko[1], Elizabeth A. Petzold[1], Champica K. Bodinayake[2], Ajith Nagahawatte[2], Vasantha Devasiri[2], Ruvini Kurukulasooriya[2], Megan E. Reller[1], Bradly P. Nicholson[1], Micah T. McClain[1], Thomas Burke[1], Ephraim L. Tsalik[1], Ricardo Henao[1], Geoffrey S. Ginsburg[1], Christopher W. Woods[1]

[1]*Duke University, Durham, NC, United States,* [2]*Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka*

The host response to viral infections such as dengue and influenza is largely characterized by interferon-related pathways. Identifying other gene sets that are variably expressed in specific viral infections may be useful in the development of diagnostics and therapeutics. We searched for genes that may be differentially expressed in patients with dengue compared to influenza, the most common viral infections resulting in hospitalization in southern Sri Lanka. We enrolled patients admitted with acute febrile illness in Sri Lanka from July 2012- May 2013 and collected nasopharyngeal samples, serum, and blood in PAXgene RNA tubes. We confirmed influenza using multiplex polymerase chain reaction (PCR; Luminex NxTAG) and dengue using a combination of virologic (PCR and virus isolation) and serologic techniques. Total RNA was extracted from peripheral blood and RNAseq was performed from samples confirmed as acute dengue or influenza. We aligned reads to a reference transcriptome (hg38) using Bowtie2, quantified at the isoform level using Express version 1.5.1, and normalized using trimmed-mean normalization. The voom method, an empirical Bayes method designed for RNA-sequencing data, was used to test for differential expression. Sequencing batch was entered as a covariate and the Benjamini-Hochberg method was used to control for multiple comparisons. Among 39 patients confirmed to have dengue and 43 patients confirmed to have influenza, the Enrichr gene-set-analysis tool was used to characterize pathway enrichment. Overall, 447 transcripts achieved a false discovery rate (FDR) less than 1%. Genes associated with T-cell chemotaxis, apoptotic cell clearance, cellular triglyceride homeostasis, and natural killer cell activation and chemotaxis were enriched among genes considered differentially expressed (adjusted p-value enrichment <0.05). We identified genes that were differentially expressed among patients infected with dengue and influenza. Further studies are required to determine if such differences may translate to diagnostics or therapeutics for these viral illnesses.

PLUG AND DISPLAY VIRUS-LIKE-PARTICLE VACCINES FOR OUTBREAK PATHOGENS

Iona J. Taylor[1], Yu Zhou[1], Yuanyuan Li[1], Cheryl Lee Yi-Pin[2], Siti Naqiah Amrun[2], Olga Dolnik[3], Arianna Marini[1], Stephan Becker[3], Lisa F. P. Ng[2], Sumi Biswas[1]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*Singapore Immunology Network, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,* [3]*Institute of Virology, Philipps University of Marburg, Marburg, Germany*

A fast and effective response to emerging and outbreak diseases requires a vaccine platform that is adaptable, highly immunogenic, rapidly produced and has a previously demonstrated safety profile. The SpyCatcher/SpyTag biochemical superglue technology enables the rapid and efficient development of highly immunogenic virus like particle (VLP) vaccines against target pathogens. VLPs are a platform technology that is used to produce vaccines against many different diseases. These technologies are particularly suited for the induction of strong antibody responses, which are achieved through presentation of an ordered antigen array to the immune system. The SpyCatcher/SpyTag technology has been used to establish a novel chimeric VLP vaccine platform technology for rapidly and irreversibly decorating VLPs simply by mixing with protein antigen in a "Plug-and-Display" manner. This approach overcomes the well-described challenges of producing VLP carriers with complex antigens genetically-fused on their surface, or low conjugation efficiency often reported when using chemical conjugation. The SpyTag-SpyCatcher technology has been used previously to enhance humoral immunogenicity by displaying malaria antigens on VLPs. The application of this technology for the development of vaccines against Ebola and Zika viruses will be discussed. Immunogenicity and neutralisation data from mice immunised with glycoproteins from both viruses will be presented along with further investigation into the protective efficacy of the Zika virus vaccine using a murine challenge model. Examination into the dose sparing effect of the VLP displayed antigens using both viruses further demonstrates the versatility and applicability of the platform to generate vaccines against new epidemics and emerging infections.

861

HEPATITIS A & E AMONG HOSPITALIZED PATIENTS: DISEASE MAPPING FROM A NATIONWIDE SURVEILLANCE IN BANGLADESH

Md. Taufiqul Islam

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Hepatitis A virus (HAV) and hepatitis E virus (HEV) are transmitted by the fecal-oral route and are responsible for epidemic and sporadic outbreaks of acute hepatitis in low-income countries like Bangladesh. The purpose of this study was to determine the burden of acute hepatitis due to HAV and HEV in different districts of Bangladesh. The nationwide foodborne illness surveillance started in 2014 at 10 different hospitals which covered seven divisions of Bangladesh. Blood samples of acute hepatitis cases were collected and transported to the central laboratory twice a week. Cases were screened for the presence of IgM specific to HAV and HEV using enzyme-linked immunosorbent assay (ELISA). Multivariate logistic regression was performed to assess the association between HAV and HEV infection with different risk factors. A total of 1016 patients were enrolled during the study period where 998 samples were tested for both HAV and HEV. Among the tested samples, 19% (191/998) were identified as HAV positive and 10% (103/998) were HEV positive. The median age was 12 years and 25 years for HAV and HEV positive patients, respectively. The prevalence of HAV was higher among the females (24.9%), whereas HEV was higher among males (11.2%). The highest occurrence of HAV was observed among children while HEV was most prevalent in the 15-60 years age group (12.4%). Through our nationwide surveillance, it is evident that infection with enteric hepatitis viruses is common in Bangladesh. These data will be useful towards planning preventive and control measures by planning future vaccination strategies in Bangladesh.

862

A SEROLOGICAL ASSAY FOR DIFFERENTIATING RIFT VALLEY FEVER (RVF) NATURALLY INFECTED ANIMALS FROM ARMP12 NSM DEL VACCINATED ANIMALS

Linda Peniel Salekwa[1], Douglas Watts[2], George Bettinger[2], Pedro Palermo[2], Mirende Matiko[1], Philemon Wambura[1]

[1]*Sokoine University of Agriculture, Morogoro, United Republic of Tanzania,* [2]*University of Texas, Texas, TX, United States*

Rift Valley fever virus (RVFV) is the cause of Rift Valley fever (RVF), a significant public health and veterinary problem in Africa and the Arabian Peninsula. An effective vaccine is needed to prevent RVF in livestock, preferably a vaccine with a biomarker to distinguish naturally (virulent) infected from vaccinated animals (DIVA). Therefore, the goal of this study is to evaluate a live attenuated recombinant RVFV vaccine with deleted the non-structural nucleotides deleted from the M RNA segment (NSm) to serve as a biomarker to distinguish RVF vaccinated from animals infected with virulent RVFV. An indirect ELISA was developed using NSm protein as a capture antigen for detecting NSm-antibody in samples from naturally infected and for possible non-detection of NSm antibody in animals vaccinated with the NSm genes deleted RVF vaccine arMP-12ΔNSm21/384.

Sera samples from animals previously infected with virulent RVFV were obtained from Kenya and Tanzania, and from experimental challenge study in Canada. Also, samples from animals vaccinated with parent RVF MP-12 and the arMP-12ΔNSm21/384 vaccine were obtained from virology laboratory at Sokoine University of Agriculture. All sera from animals infected naturally with virulent RVFV or from the challenge study had a geometric mean optical density (OD) reading of 0.88, thus demonstrating that animals were infected with virus containing the NSm antigen induced a detectable antibody response to this antigen. In contrast, animals vaccinated with RVF arMP-12ΔNSm21/384had an OD reading of only 0.17, or negative for antibody, thus demonstrating that animals vaccinated with RVF arMP-12ΔNSm21/384 can be distinguished from animals infected with virulent RVFV.

863

ENTOMOLOGICAL INVESTIGATIONS AND LABORATORY DETECTION OF A RIFT VALLEY FEVER OUTBREAK IN HUMAN POPULATIONS IN OL KALAU SUB-COUNTY OF NYANDARUA COUNTY, KENYA, 2019

Samson Limbaso Konongoi[1], Allan Ole Kwallah[2], Kizito Lubano[3], Joel Lutomiah[1], Rosemary Sang[1]

[1]*Center for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya,* [2]*Production Department, Kenya Medical Research Institute, Nairobi, Kenya,* [3]*Centre for Clinical Research, Kenya Medical Research Institute, Nairobi, Kenya*

Rift Valley fever (RVF) is an acute mosquito-borne viral disease affecting ruminants and humans. It's associated with negative economic impacts due to abortions in animals, high mortality in young animals and trade restrictions. In the last two decades, parts of East Africa have experienced RVF epidemics. The last major outbreak of RVF in Kenya occurred in 2006/2007. Since then there have been sporadic detections in selected localities and an outbreak in Northeastern Kenya in mid-2018. Between February and March 2019 there were reports of livestock abortions in Olkalau sub-county, Nyandarua County in Central Kenya. Suspected human cases associated with close contact to sick animals were reported in health facilities and blood samples sent to the KEMRI Viral hemorrhagic fever laboratory. Real-time PCR and immunoglobulin M enzyme linked immunosorbent assay (IgM ELISA) were used to detect acute cases and the presence of IgM antibodies against RVFV. Entomological investigations were done in areas with reported human cases. A total of 139 human samples were collected and tested.12.9 % (n=18) were positive for RVF by real-time PCR while 1 tested positive for RVF IgM antibodies. A total of 2,259 mosquitoes were collected and identified to 8 diverse species, predominated by *Culex theileri*, 40% (n=903), *Cx.zombaensis*, 20.2% (n=456), *Anopheles squamossus,* 16.6% (n=375), *Cx.pipiens,* 12.6% (n=285), *Cx.vansomereni,* 7.2% (n=163), *Aedes tricholabis,* 1.5% (n=34) and others 1.9 %(n=43). Laboratory analysis is ongoing to determine infectivity. This is the first documentation of human RVF cases in Nyandarua; occurring during the dry season. Initial investigations indicate that the outbreak was of lower magnitude and severity compared to previous outbreaks in Kenya with no human mortalities reported and was quickly contained. Preliminary findings indicate that none of the mosquito species sampled belonged to the group known as primary vectors of RVF, yet there was active RVF transmission. There is need to monitor spatial and temporal vector densities and virus activity and detect changes in the epidemiology of RVF occurrence in Kenya and the region.

864

PROTOCOL FOR THE SURVEILLANCE STAGE OF A COMMUNITY-BASED RSV (RESPIRATORY SYNCYTIAL VIRUS) MORTALITY STUDY IN KARACHI, PAKISTAN

Abdul Momin Kazi[1], Asad Ali[1], Nazia Ahsan[1], Waliyah Mughis[1], Saima Jamal[1], Beryl Guterman[2], Fauzia Aman Malik[2], Saad Bin Omer[2]

[1]*Aga Khan University, Karachi, Pakistan,* [2]*Emory University, Atlanta, GA, United States*

RSV is a respiratory pathogen with potentially moderate to high disease burden in LMICs - it is estimated to annually cause 34 million episodes. This pathogen is a potential target for maternal immunization strategies to prevent disease and early death in young infants. However, due to lack of evidence, role of RSV in early mortality in young infants and neonates in LMICs is not confirmed. Most current studies estimate burden of disease in terms of hospital-based deaths, there is a knowledge gap regarding proportion of community-based deaths due to RSV. Primary study objectives are to assess and analyze the burden and determinants of RSV mortality in infants in 4 low-income settlements of Karachi and to provide a cause of death consultation for the enrolled families of deceased neonates. This is an observational surveillance study, with primary outcome measures including a laboratory (rPT-PCR) confirmed RSV and pertussis infection report for nasopharyngeal swab sample collected from deceased infant. From August 2018 to March 2019, 80 specimens have been obtained (out of 324 criteria-eligible neonatal deaths, and 161 timely death alerts) from catchment areas of Ibrahim Hyderi, Ali Akbar Shah Goth, Bhains Colony & Rehri Goth in Karachi. Field team consists of nurses (trained in nasopharyngeal swab collection and grief support), field site supervisors and site-specific community health workers and mobilizers (who engage with the community and bereaved parents and offer grief support). Following a 3-month advocacy phase (exploring the acceptance of study procedures within communities, assessing benefits to families of deceased infants for enrolling), project is currently in its 9-month pilot surveillance phase, which is expected to be phased into a 12-month scale-up surveillance. There are many challenges in generating evidence for the burden of disease, specifically for RSV, such as lack of resources for hospital and community surveillance and diagnostics, and difficulty in obtaining specimens. Religious community acceptance and obtainment of *fatwas* or religious rulings for medical research have aided the successful specimens collection.

865

GRIEF SUPPORT TRAINING FOR COMMUNITY HEALTH WORKERS AND NURSES WORKING WITH BEREAVED PARENTS ENROLLED IN A COMMUNITY-BASED RSV MORTALITY STUDY IN KARACHI, PAKISTAN

Waliyah Mughis[1], Saima Jamal[1], Ayesha Mian[1], Nargis Asad[1], Fauzia Aman Malik[2], Saad Bin Omer[2], **Abdul Momin Kazi**[1]

[1]*Aga Khan University, Karachi, Pakistan,* [2]*Emory University, Atlanta, GA, United States*

A community-based study on burden of respiratory syncytial virus (RSV) on infant mortality is being conducted in 4 catchment areas of Karachi. The study purpose is to collect nasopharyngeal specimen from deceased infants under 6 months, in order to analyze burden of RSV as cause of neonatal deaths in Pakistan. Upon receiving a death alert, community health workers, mobilizers and nurses approach household to obtain parent consent to collect nasopharyngeal sample from deceased infant before bathing/funeral process. The field team is completing training in grief support skills, conducted by project psychologist. The health workers apply these skills in follow-up home visits with enrolled infants' parents, acting as referral pathway to psychologist, who conducts grief counseling for bereaved parents with complicated grief or mental health issues that require specialist intervention. The grief support training curriculum is broadly divided into modules on mental health first aid skills, communication skills, differentiating between complicated/uncomplicated

grief; covering listening skills, counseling strategies, screening for mental health issues, and utilizing appropriate social-emotional support to prevent the development of complicated grief. The staff are trained to conduct grief support home visits for bereaved parents; during these visits (at 1, 2, 4 and 8 weeks after infant's death), CHW/nurses enquire about the infant's caretakers about their mental health and their experience of grief surrounding infant's death. From August 2018 to March 2019, 80 specimens have been obtained and over 90 sets of parents supported and counseled in their grief. Grief from bereavement often presents as a clinical disorder such as depression, anxiety, OCD, PTSD. Training field staff (the first responders) to screen for issues that could lead to complicated grief is imperative. Community-based models of social support require further examination to understand how grief support can prevent the need for counseling for complicated grief to arise.

866

NIPAH VIRUS INFECTION IN 2018-19 NIPAH SEASON IN BANGLADESH

Nipah virus (NiV) has been identified as one of the most dangerous emerging pathogens by the World Health Organization, due to infections resulting in high case fatality and person-to-person transmission potential. A hospital-based Nipah encephalitis surveillance began in 2006 and event-based surveillance in 2008 in Bangladesh, identifying Nipah outbreaks and sporadic cases every year. Presently icddr,b in collaboration with Government of Bangladesh is conducting active surveillance at five medical college hospitals (Rajshahi, Rangpur, Faridpur, Chattogram, and Khulna). Through the surveillance, 521 suspected encephalitis cases were enrolled during the 2018-19 Nipah season (December to March). We collected blood and throat swab samples from the enrolled cases, tested for PCR (serum and throat swab) and serology (serum). Four laboratory confirmed Nipah (both Nipah PCR and IgM positive) cases were identified, three from Rajshahi and one from Rangpur. The Rangpur Nipah case which was detected by our surveillance was the final case in an outbreak consisting of five fatal cases. Two of the Rangpur cases were missed by our surveillance staff, as the cases were admitted to the facility in the evening after surveillance staff had gone home. These cases had fever and headache, and their condition deteriorated rapidly and they died shortly after hospital admission. Among the five Rangpur cases, four had very close contact with the first case and were his caregivers. Each became infected and subsequently died within 14 days of the death of the first case. These subsequent four cases likely developed secondary NiV infection and the first four cases were identified as probable cases. We sampled all contacts (74) of the cases (8) who became ill with fever and who had direct contact with the case's body fluids, and none had evidence of Nipah antibodies. In the 2018-19 season, we found a total of eight (four lab confirmed and four probable) cases with 87% case fatality. NiV remains an ongoing threat in Bangladesh and in other sites in Asia. Continued investment in surveillance can monitor for threatening changes in epidemiology and transmission.

867

IDENTIFICATION OF ORTHOBUNYAVIRUSES CO-CIRCULATIN DURING A RIFT VALLEY FEVER OUTBREAK IN RWANDA 2018

Marie Fausta Dutuze[1], Angélique Ingabire[2], Isidore G. Mapendo[2], Solange Uwituze[3], Manassé Nzayirambaho[4], **Rebecca C. Christofferson**[1]

[1]*Louisiana State University, Baton Rouge, LA, United States,* [2]*Animal Research Resources and Transfer Technology Department, Kigali, Rwanda,* [3]*Rwanda Agriculture Board, Kigali, Rwanda,* [4]*University of Rwanda, Kigali, Rwanda*

Bunyamwera (BUNV), Batai (BATV), and Ngari (NRIV) are arboviruses of the *Bunyaviridae* family, genus Orthobunyavirus. NRIV is a recombinant of the other two. All three cause disease in domestic ruminants and humans, presumably sharing ecological niche and clinical symptoms with Rift Valley Fever Virus (RVFV). In Rwanda, RVFV is the only Bunyavirus regularly surveilled. In 2018, there was an historic outbreak of RVFV in Uganda, Rwanda, and Kenya. Cattle showing clinical signs of RVFV were diagnosed, with few molecular confirmations. We hypothesized that clinical-based diagnosis of RVFV in Rwanda eclipses the occurrence of these Orthobunyaviruses. From May to July 2018, 185 blood samples from acutely ill cattle were collected from Rwanda. cDNA was synthesized from vRNA and amplified by conventional PCR using specific primers for RVFV. RVFV-negative samples were then tested for these Orthobunyaviruses. 56 (30.3%) were positive for RVFV by PCR and we identified BUNV and BATV for the first time in Rwanda. 7 samples (3.8%) were positive for undifferentiated Orthobunyaviruses; two samples were positive for BATV, and two were positive for BUNV. The remaining three were positive for both BUNV and BATV, which means that they were either co-infected with these two viruses or some combination of BUNV/BATV and NRIV. This is the first report of Orthobunyaviruses in Rwanda and the second report of BATV in Africa, and suggests that these may contribute to the burden of disease in cattle in the region.

NIPAH VACCINE TRIALS- ASSESSING THE FEASIBILITY BASED ON PREVIOUS OUTBREAKS IN BANGLADESH

Birgit Nikolay[1], Henrik Salje[1], Marc Lipsitch[2], Stephen P. Luby[3], Simon Cauchemez[1], Emily S. Gurley[4]

[1]*Institut Pasteur, Paris, France,* [2]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [3]*Stanford University, Stanford, CA, United States,* [4]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Nipah virus is an emerging, bat-borne pathogen that can be transmitted from person-to-person. Vaccine candidates are currently being developed for Nipah virus, and studies are funded to evaluate the safety and immunogenicity of these vaccines, so that they could possibly be used to contain large outbreaks. An important unanswered question is whether it will be possible to evaluate the efficacy of these vaccine candidates in phase III clinical trials in a context where spillovers are infrequent and associated with outbreaks that are small and often detected late. Ring vaccination strategies were used in trials of Ebola virus vaccines; however Nipah virus transmission, with few exceptions, results in short transmission chains. The objective of this study was to investigate the feasibility of conducting a phase III trial for Nipah vaccines in Bangladesh, the only country reporting regularly Nipah cases. We used simulations based on previously observed Nipah spillovers from Bangladesh, and an assumed vaccine efficacy of 90%, to compare two vaccine trial scenarios: (i) ring vaccinations including contacts of Nipah cases and contacts of contacts; and (ii) cluster-randomized trials in the two most affected districts in Bangladesh. The simulations showed that it would take approximately 160 years (1,230 rings per arm) to carry out a ring vaccination trial with 80% power to detect a difference between the arms. It would take about 50 years for a cluster-randomized trial (cluster size 10,000; 140 clusters by arm). Without a change in the epidemiology of Nipah, ring vaccination or cluster randomized trials will be impractical. Other trial designs such

as a vaccine campaign for all residents of the two most affected districts, followed by a case-control design, should be explored. Efforts to increase case detection through enhanced surveillance efforts would also be beneficial as the limited number of cases currently reported is the primary driver of the feasibility of these studies.

Fever is the leading cause of paediatric outpatient consultations in Sub-Saharan Africa. Although most are suspected to be of viral origin, a putative causative pathogen is not identified in over a quarter of these febrile episodes. This study includes sera from 692 febrile children (aged 2-59 months) and plasma from 77 febrile adults recruited at outpatient clinics in Tanzania. These blood products were screened for novel viruses using a de novo assembly sequencing approach. We report the presence of RNA from a dicistrovirus (DicV) in 15.4% of the paediatric cohort. In contrast, DicV RNA was only detected in 1/77 (1.3%) plasma samples from febrile Tanzanian adults, suggesting that children could represent the primary susceptible population. The virus is novel to human tissue and phylogenetic analysis of the capsid region in the three full-length genomes obtained showed the presence of two clusters representing a tentative novel genus. Estimated viral load across all samples by specific quantitative real-time RT-PCR assay ranged from < 1.32E3 to 1.44E7 viral RNA copies/mL serum. Although DicV-positive cases were detected throughout the year, a significantly higher positivity rate was observed during the rainy season. Dicistrovirus is part of a family of RNA viruses that have been detected in some hematophagous insects that are known vectors of parasitic disease in humans (such as triatomes). However, these viruses have never before been detected in human blood. This study reveals that novel DicV RNA is frequently detected in the blood of Tanzanian children and works to encourage further investigations to determine whether DicV may be a novel infectious agent in humans.

870

DORMANCY OF PLASMODIAL SPOROZOITES

Miles B. Markus

University of the Witwatersrand, Johannesburg, South Africa

Hypnozoites in the primate liver appear to be derived from dormant sporozoites. Can the equivalent stage of *Plasmodium* also persist elsewhere in the body, such as dermally or in the lymphatic system, and be a source of recurrent malaria? *Plasmodium* has certainly been seen in these particular sites in the early phase of infection (references will be given on the poster). Hypnozoites of some non-plasmodial apicomplexan coccidia can persist not only in the liver, but elsewhere too. Both light and electron microscopic images of these extrahepatic hypnozoites, derived from the presenter's laboratory research (which resulted in his discovery of the apicomplexan hypnozoite in the 1970s), will be used to illustrate the point. This question of whether persisting, quiescent, extrahepatic sporozoites occur in the life cycle of primate *Plasmodium* species should be intensively investigated in both primates and primatized mice - *inter alia*, by using modern imaging techniques. Detection of any such latent forms would necessitate assessment of the implications for the elimination of malaria parasites in human populations as well as the drug treatment of malaria in individual patients.

871

PLASMA TAU AND OTHER BLOOD-BASED BIOMARKERS OF BRAIN INJURY IN CEREBRAL MALARIA AND SEVERE MALARIAL ANEMIA

Dibyadyuti Datta[1], Katrina Co[1], Peter F. Castelluccio[2], Andrea L. Conroy[1], Robert O. Opoka[3], Paul Bangirana[4], Andrew J. Saykin[5], Chandy C. John[1]

[1]*Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Department of Biostatistics, Indiana University School of Medicine, Indianapolis, IN, United States,* [3]*Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda,* [4]*Department of Psychiatry, Makarere University, Kampala, Uganda,* [5]*Indiana Alzheimer Disease Center and Department of Radiology and Imaging Sciences, Indiana University School of Medicine, Indianapolis, IN, United States*

In children with cerebral malaria (CM), elevated admission cerebrospinal fluid (CSF) concentrations of tau, an axonal injury marker are associated with disease severity and worse long-term cognitive outcomes. In the present study, we sought to determine if brain injury markers were present in admission plasma samples of children with severe malaria (CM or severe malarial anemia (SMA)), and to determine their association with disease severity and long-term cognitive outcomes. Plasma concentrations of 4 markers of neuronal/axonal injury produced exclusively in the CNS – tau, neurofilament-light (NFL), glial fibrillary acidic protein (GFAP), and ubiquitin carboxyl-terminal hydrolase isoenzyme L1 (UCHL1) – were assessed in 183 Ugandan children with CM, 162 with SMA, and 123 community children (CC), using the Human Neurology 4-Plex Assay on a single molecule array (Simoa) instrument. Plasma tau, NFL, and UCHL1 concentrations in children with severe malaria were higher than in CC, and plasma tau and UCHL1 concentrations were higher in CM than SMA (all $P<0.001$). In children with CM, elevated tau, NFL, and UCHL1 concentrations were associated with acute kidney injury (all $P<0.05$), elevated NFL concentrations were associated with prolonged coma duration ($P=0.001$), and elevated tau and UCHL1 concentrations were associated with number of convulsions in hospital (all $P<0.03$). After adjusting for confounders, elevated $\log_{10}$-transformed plasma tau concentrations in children with CM correlated with worse z-scores over 2-year follow-up for overall cognition (β coefficient [95 % CI]) (-0.77 [-1.31,-0.24]) in children <5 years at the time of testing, and attention (-0.64 [-1.23,-0.04]) and memory (-0.72 [-1.35,-0.08]) in children ≥5 years at the time of testing. In children with SMA, plasma tau concentrations correlated inversely with scores in cognition, attention, and memory, but no significant associations were detected. Plasma tau concentration is a promising prognostic marker for disease severity and worse cognitive outcomes after CM and possibly other forms of severe malaria.

872

LACTIC ACID SUPPLEMENTED MEDIA STIMULATES GAMETOCYTOGENESIS IN *PLASMODIUM FALCIPARUM* CULTURE

Rachel M. West, David J. Sullivan

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Malaria infection by *Plasmodium falciparum* continues to afflict millions of people worldwide, with transmission maintained by the definitive

host mosquito. Transmission is dependent upon mosquito ingestion of the gametocyte stage of the parasite. These sexually committed stages develop from the asexual stages, yet the factors behind this transition are poorly understood. *In vitro* studies have revealed that extracellular factors, such as LysoPC, present in different media and cellular environments influence gametocytogenesis. Parasites readily produce metabolites such as lactic acid in millimolar concentrations during malaria infection. We hypothesize gametocytogenesis is induced through molecular factors found in parasite- or reticulocyte-rich environments. We have demonstrated that lactic acid supplemented media significantly influences gametocytogenesis in an NF54 strain *P. falciparum* infection. Parasites exposed to different exposure times of lactic acid were monitored throughout gametocyte development *in vitro*. We found that continuous lactic acid supplementation increased parasitemia and gametocytemia after 72h and 168h, respectively. Using reverse-transcriptase qPCR, we also found that gametocyte specific gene expression was increased after 240 hours in lactic acid supplemented cultures. In a mosquito infection, we found that gametocytes continuously exposed to lactic acid were more infectious to *Anopheles stephensi* mosquitoes, increasing prevalence of infection but not oocyst density. Further, we found that gametocytes produce lactic acid throughout development, and produce it at higher levels than controls when supplemented with lactic acid. We then adapted a gametocyte-specific quantitative Pfs16 promoter luciferase assay to examine the effects of media environment on gametocyte development. Lactic acid supplemented media significantly increased gametocyte equivalent numbers after 72 hours of incubation, counted by luciferase assay. We will continue to test various acids produced by parasites or reticulocytes in a dose and time dependent to determine their effects on gametocytogenesis.

873

SEVERE ANEMIA IS ASSOCIATED WITH SYSTEMIC INFLAMMATION IN YOUNG CHILDREN PRESENTING TO A TERTIARY HOSPITAL IN UGANDA

Robert O. Opoka[1], Andrea L. Conroy[2], Ali Waiswa[3], Ronald Wasswa[3], James K. Tumwine[1], Charles Karamagi[1], Chandy C. John[2]

[1]*Makerere University, Kampala, Uganda,* [2]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,* [3]*Global Health Uganda, Kampala, Uganda*

There are multiple causes of severe anemia (SA) but the etiology and prevalence of risk factors varies from region to region. We carried out a cross sectional study in which a range of etiological factors and biomarkers of host response were evaluated in children aged 0-5 years in Jinja Regional referral hospital, Uganda. Study participants included 284 children with SA (Hb < 5.0 g/dl), 63 admitted children with acute illness without severe anemia (Hb > 9.3 g/dl) and 53 healthy community controls. Descriptive statistics were used to categorize the etiological factors in the SA children, and appropriate logistic analysis performed to determine factors associated with SA. Amongst SA children, common etiological factors were *Plasmodium falciparum* (Pf) parasitemia 106 (36.4%), hemoglobinuria 93 (32.7%) and vitamin B12 deficiency 30 (10.6%). Human Immunodeficiency Virus infection, bacteremia, hookworm infection, severe acute malnutrition and folate deficiency were uncommon (each accounting for < 8%). The factors found to be associated with SA included (adjusted odds ratio (OR); 95% Confidence Interval [CI]); Pf parasitemia (OR, 3.9; 95% CI, 1.3 to 11.5), total white blood count (OR, 1.3; 95% CI, 1.1 to 1.4), C-reactive protein (OR, 1.7; 95% CI, 1.2 to 2.3), and ferritin (OR, 2.7; 95% CI, 1.9 to 3.9). There are multiples etiological factors that contribute to SA in young children in Jinja Hospital. Elevated inflammation was associated with SA in the study population. There is need for studies to confirm the immuno-pathogenic pathways of SA in malarial endemic areas in order to target intervention strategies.

874

CHARACTERIZATION OF A *PLASMODIUM FALCIPARUM* ARMADILLO-TYPE REPEAT PROTEIN

Philip Ilani[1], Emmanuel Amlabu[1], Grace Opoku[1], Prince B. Nyarko[1], Evelyn Quansah[1], Laty G. Thiam[1], Manfred Anim[1], Reuben Ayivor-Djanie[1], Ojo-ajogu Akuh[1], Henrrieta Mensah-Brown[1], Julian C. Rayner[2], Gordon A. Awandare[1]

[1]*West African Centre for Cell Biology of Infectious Pathogens, Department of Biochemistry, Cell and Molecular Biology, University of Ghana, Accra, Ghana,* [2]*Wellcome Sanger Institute, Wellcome Genome Campus, Hinxton, Cambridge, United Kingdom*

Nearly half of the genes in the *Plasmodium falciparum* genome have not yet been functionally investigated. We used homology-based structural modelling to identify multiple copies of Armadillo repeats within one uncharacterised gene expressed during the intraerythrocytic stages, PF3D7_0410600, subsequently referred to as P. falciparum Armadillo-Type Repeat Protein (PfATRP). Soluble recombinant PfATRP was expressed in a bacterial expression system and used to screen plasma samples from malaria endemic areas in Ghana, which revealed that malaria-infected children have naturally acquired PfATRP-specific antibodies, with prevalence varying across transmission areas. Affinity-purified α-PfATRP human and rabbit antibodies specifically recognised both native and recombinant parasite proteins. Immunofluorescence imaging established that PfATRP is a component of the inner membrane complex (IMC) and its associated microtubules, consistent with its differential solubility. Size exclusion chromatography suggests PfATRP forms part of a larger-order protein complex, the composition of which could potentially play a role in its sub-cellular distribution.

875

ANALYSIS OF NATURAL ANTIBODY RESPONSE TO NOVEL *PLASMODIUM FALCIPARUM* MEROZOITE PROTEINS

Grace Opoku, Ojo-ajogu Akuh, Prince Nyarko, Damata Ibrahim-Dey, Gordon A. Awandare, Emmanuel Amlabu

West African Centre for Cell Biology of Infectious Pathogens, Department of Biochemistry, Cell and Molecular Biology, University of Ghana, Accra, Ghana

Despite the enormous research into the biology of the malaria parasite, our understanding still remains limited. A panel of novel merozoite proteins that could play essential roles during erythrocyte invasion were identified using data-mining analysis of published transcriptome and proteome of the parasite combined with protein-informatics approach. Time-resolved real-time PCR analysis for the genes coding for these proteins indicated that they were optimally expressed at early to late schizogony. To produce these proteins in bacteria system with optimum recovery, codon-optimisations and gene synthesis were performed. These recombinant proteins were expressed and purified in their active forms and used in a systematic serological screen with plasma samples from malaria-exposed children. We observed that the patterns of antibody acquisition varied with age and transmission intensities across the different malaria endemic sites in Ghana. Antigen-specific immunoaffinity columns were used to purify human antibodies from the plasma of malaria-exposed children. Immunofluorescence assays using these affinity-purified human antibodies show that three (3) of the merozoite proteins were localised on the parasite surface. We are currently evaluating these antigen-specific human antibodies in invasion assays to establish that these antigens are targets for protective immunity or they are potential bio-markers for malaria exposure.

876

ELEVATED PLASMA SOLUBLE ST2 CONCENTRATIONS ARE ASSOCIATED WITH COGNITIVE IMPAIRMENT IN UGANDAN CHILDREN WITH CEREBRAL MALARIA

Elizabeth Fernander[1], Pontian Adogamhe[2], Katrina Co[1], Dibyadyuti Datta[1], Robert Opoka[3], Chandy John[1]

[1]*Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*University of Wisconsin- Whitewater, Whitewater, WI, United States,* [3]*Makerere University, Kampala, Uganda*

Children who recover from episodes of severe malaria caused by *Plasmodium falciparum* exhibit long term cognitive impairment. The mechanisms that lead to this impairment are unknown. In murine experimental cerebral malaria (ECM), IL-33 and its receptor ST2, can act in both a protective and deleterious manner. IL-33 binding to membrane bound ST2 can lead to pro-inflammatory signaling and recruitment of T cells, which exacerbates ECM. Conversely, IL-33 can act through anti-inflammatory signaling via regulatory T cells and a Th2 response, preventing the development of ECM. Soluble ST2 (sST2) acts as a decoy receptor to neutralize the actions of IL-33 and is elevated in disease states such as sepsis or brain injury. We assessed the role of ST2 in disease severity and neurodevelopmental outcomes in a cohort of Ugandan children 18 months to 12 years of age with cerebral malaria (CM), severe malaria anemia (SMA) or asymptomatic community children (CC). Overall cognitive ability, attention and associative memory were assessed 12 months after discharge. Plasma concentrations of sST2 were measured by ELISA. Among the 515 children studied, plasma concentrations of sST2 were highest in children with CM (median [IQR], 123.23 ng/mL [72.53-177.20]) compared to SMA (81.39 ng/mL [50.17-140.89], p <0.0001) or CC (5.76 ng/mL, [4.14-7.72], p <0.0001). In children with CM who were >5 years of age at the time of testing, elevated levels of sST2 were associated with worse age-adjusted z-scores for overall cognitive ability (beta coefficient [95% CI], -1.56 [-2.72- -0.39], p=0.01) and attention (-1.17 [-2.23- -0.27], p=0.04) 12 months after discharge. Plasma sST2 concentrations increase with disease severity in malaria and are associated with worse neurocognitive outcomes in children >5 years of age. Future research will assess cerebrospinal fluid (CSF) sST2 concentrations and the mechanisms by which plasma or CSF sST2 may affect cognition.

877

DYNAMICS OF HOST CELL SURFACE REMODELING IN *PLASMODIUM* GAMETOCYTES

Priscilla Ngotho[1], Kathleen W. Dantzler[2], Brian R. Omondi[3], Franziska Hentzschel[1], Karl Seydel[4], Miriam Laufer[5], Terrie Taylor[4], Teun Bousema[6], Matthias Marti[1]

As efforts towards malaria elimination intensify, blocking the transmission cycle becomes a crucial component of control programmes. *Plasmodium* transmissible forms, gametocytes, arise during the blood stage cycle of the parasite. A small subset of parasites switches from the disease-causing asexual cycle to produce gametocyte progeny that are taken up by mosquitoes during blood meals, completing the transmission cycle. While asexual parasites sequester in various vascular niches, causing pathology such as cerebral malaria, gametocytes sequester and develop in the extravascular niche of the bone marrow and spleen. We have recently characterized immune responses targeting immature but not mature gametocytes in *P. falciparum* and identified putative target surface antigens. We hypothesize that such antigens play a role in gametocyte sequestration and contribute to acquired transmission reducing immunity. Indeed, we demonstrate that immune sera contain anti-gametocyte IgG that mediate opsonic phagocytosis by macrophages, a plausible mechanism of gametocyte clearance *in vivo*. Interestingly, the dynamics of antigen surface expression, phagocytosis induction and surface membrane remodeling (phosphatidylserine exposure on the outer membrane of host RBC) show the same dynamics during asexual and gametocyte maturation, suggesting that these processes might be interlinked. Moreover, parasite reverse genetics and drug perturbations suggest conserved mechanisms of surface remodeling in asexual and sexual *P. falciparum* stages and across *Plasmodium* species. These findings have important implications for our understanding of parasite biology and novel intervention strategies to simultaneously reduce parasite burden and transmission.

878

IS THAT A REAL OOCYST? IDENTIFICATION OF *PLASMODIUM FALCIPARUM* OOCYSTS FROM MIDGUTS OF *ANOPHELES* MOSQUITOES FED ON INFECTED HUMAN BLOOD IN TORORO, UGANDA

Alex Kashaija Musiime[1], Joseph Okoth[1], Melissa Conrad[2], Daniel Ayo[1], Ismail Onyige[1], John Rek[1], Joaniter I. Nankabirwa[3], Emmanuel Arinaitwe[1], Moses R. Kamya[3], Grant Dorsey[2], Geert-Jan van Gemert[4], Sarah G. Staedke[5], Chris Drakeley[5], Teun Bousema[4], Chiara Andolina[4]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States,* [3]*Department of Medicine, Makerere University College of Health Sciences, Kampala, Uganda,* [4]*Department of Medical Microbiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [5]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

The human infectious reservoir for malaria consists of individuals capable of infecting mosquitoes. Oocyst prevalence and density are typical indicators of infectivity of human-to-mosquito transmission. However, identification of oocysts is challenging, particularly in areas of low malaria transmission intensity where few individuals may infect mosquitoes, and infected mosquitoes tend have few oocysts. Although molecular techniques like polymerase chain reaction (PCR) allow accurate detection of low- level *Plasmodium falciparum* oocyst infections in mosquito midguts, they are expensive, require highly trained personnel and do not allow quantification of oocysts. Here, we explain and illustrate features that differentiate oocysts from other structures seen under light microscope in mosquito midguts that may resemble oocysts to help guide oocyst detection in low transmission settings. In 2014, an infrastructure was developed and equipped with *Anopheles gambiae s.s.* mosquitoes to support infectivity experiments from participants enrolled in a large cohort study in Tororo, Uganda. Venous blood drawn from participants who were naturally infected with malaria parasites was used for membrane feeding assays, using 60-80 mosquitoes per experiment. Approximately 9-10 days after feeding, mosquitoes were dissected, and midguts were stained in mercurochrome and examined by light microscopy for *Plasmodium falciparum* oocysts and similar structures. A total of 16458 mosquitoes were successfully fed on infected blood and dissected of which 330 were infected (2.0%).Oocysts and oocyst-like structures were observed in mosquito midgut walls. Oocysts were characterized by; presence of malaria pigment, clearly defined edge, round shape within the mosquito midgut or on the peripheral tissue and always attached to the epithelium. Distinguishing real oocysts from oocyst-like structures may be challenging for inexperienced microscopists due to overlapping features. The characteristics and guidelines outlined here support identification of oocysts and reliable detection at low oocyst densities.

879

VARIATION IN THE *CD40* PROMOTER PREDICTS LONGITUDINAL SUSCEPTIBILITY TO MALARIAL ANEMIA AND ALL-CAUSE MORTALITY IN KENYAN CHILDREN

Elly Munde[1], Samuel B. Anyona[2], Evans Raballah[3], Qiuying Cheng[4], Christophe G. Lambert[1], Benjamin H. McMahon[5], Collins Ouma[6], Nick Hengartner[5], Douglas Perkins[4]

[1]*University of New Mexico-Kenya Global Health Programs, Albuquerque, NM, United States,* [2]*University of New Mexico-Kenya Global Health Programs, Kisumu, Kenya,* [3]*Masinde Muliro University of Science and Technology, Kakamega, Kenya,* [4]*University of New Mexico Center for Global Health, Albuquerque, NM, United States,* [5]*Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States,* [6]*Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Kisumu, Kenya*

Molecular mechanisms influencing pediatric severe malaria anemia (SMA, Hb<5.0g/dL and any density parasitemia) are only partially defined. Investigation of pathways leading to severe disease has the potential to aid in understanding the complex pathogenesis. Cluster of differentiation 40 (CD40) expressed on immune and non-immune cells can stimulate inflammatory reactions. Therefore, we hypothesized that polymorphisms within the *CD40* promoter will impact on the production of downstream inflammatory molecules and clinical outcomes of pediatric malaria during the development of naturally-acquired immunity. The influence of *CD40* variation [(-580G>A; rs1800686, -245C>T rs752118, and -1C>T rs1883832) on cross-sectional and longitudinal outcomes (over 36 months) were determined in children (n=1,370, aged 6-36mos.)] from Siaya County, western Kenya, a *P. falciparum* holoendemic transmission area. *CD40* genotypes were generated by Taqman® genotyping assays. Transcriptional expression of IL-1β, TNF-α, and IL-6 were determined by qPCR, while protein levels were quantified by ELISA. Bivariate logistic regression analyses (cross-sectional), controlling for anemia-promoting covariates, revealed that inheritance of the *CD40* -580G/-245C/-1C (GCC) haplotype protected against SMA (OR=0.31, 95%CI=0.14-0.67, *P*=0.0030), while carriage of the GCT haplotype enhanced susceptibility to SMA [OR=5.24, 95%=3.31-8.82, *P*<0.001]. Longitudinal analyses showed that carriage of the ATC haplotype increased the risk of malaria (RR=1.09, 95%CI=1.00-1.19, *P*=0.044), and that the GCT haplotype increased the risk of all-cause mortality (HR=2.11, 95%CI=1.08-4.15, *P*=0.030) over a 36month period. Additionally, phagocytosis of malarial pigment (*Pf*Hz) increased the mRNA and protein expression of IL-1β, TNF-α, and IL-6 in human peripheral blood mononuclear cells. Collectively, these results demonstrate that variation in CD40 influences susceptibility to malaria disease outcomes and all-cause mortality, potentially through altering the inflammatory milieu.

880

ARGININE METABOLISM DRIVES THE ADAPTIVE PROLINE RESPONSE TO HALOFUGINONE IN *P. FALCIPARUM*

Lola Fagbami

Harvard T.H. Chan School of Public Health, Boston, MA, United States

We have previously identified the cytoplasmic prolyl tRNA synthetase (cPRS) in *Plasmodium falciparum* as the functional target of the natural product febrifugine and its synthetic analogue halofuginone. HFG treatment triggers a novel mode of drug resistance wherein intracellular proline levels are increased by 30 fold prior to any alteration in the target cPRS gene. This metabolic adaptation, termed the Adaptive Proline Response (APR), persists after drug withdrawal and renders the parasite tolerant to HFG treatment. We investigated the molecular basis of the APR by identifying the source of the increased proline using a multiplexed high-resolution mass-spectrometry (HRMS) based assay. After culturing HFG-induced parasites in the presence of orthogonally labeled proline and proline precursor amino acids (15N proline, 13C-15N arginine, and 13C5 glutamine), we observed predominantly 13C-15N-labeled proline, indicating that arginine is a major contributor. We then probed the essentiality of the arginine biosynthesis of proline by using CRISPR/Cas9 technology to generate independent parasites lines that lack ornithine δ-aminotransferase (PF3D7_ 608800), a key enzyme in this metabolic pathway. Functional analysis of the ornithine δ-aminotransferase (Dd2 ΔOAT) knockout parasites revealed a complete absence of the arginine derived 13C-15N-labeled proline. Dd2 ΔOAT parasites exposed to HFG remain sensitive to drug and do not increase their intracellular proline levels. This observation that ornithine δ-aminotransferase knockout parasites do not activate the APR demonstrates that arginine metabolism is required for the adaptive proline response to halofuginone.

EXPRESSION AND LOCALIZATION PROFILES OF RHOPTRY PROTEINS IN *PLASMODIUM BERGHEI* SPOROZOITES

Tomoko Ishino[1], Naohito Tokunaga[1], Mamoru Nozaki[1], Takafumi Tsuboi[2], Motomi Torii[1]

[1]*Ehime University, Toon, Japan,* [2]*Ehime University, Matsuyama, Japan*

The apical structure of infective forms of apicomplexan parasites is highly conserved as containing the secretory organelles named rhoptries and micronemes. Proteins localized to the rhoptry neck region are secreted from the apical-end of infective-stage parasites to form the tight junction between parasites and target cells prior to invasion. In the *Plasmodium* lifecycle, two infective forms, merozoites and sporozoites, efficiently infect different target cells: erythrocytes, hepatocytes and mosquito salivary glands. It has been questioned whether the invasion mechanisms are conserved between merozoites and sporozoites. Recently, we demonstrated that rhoptry neck protein 2 (RON2), one of the components of RON complex mediating tight junction formation, has an important role during sporozoite invasion of mosquito salivary glands by generating sporozoite-stage *ron2* knockdown parasites (Ishino et al., 2019, *Cell Microbiol*). For further elucidation of the molecular mechanisms of sporozoite invasion, the expression and localization profiling of rhoptry proteins was investigated in *Plasmodium berghei* sporozoites. Nine of 12 genes, known as merozoite rhoptry molecules, are transcribed also in oocyst-derived sporozoites at the similar or higher level compared to those in schizonts. For the comprehensive localization analyses, transgenic parasites expressing each rhoptry protein tagged by c-Myc at the C-terminal were generated. Immuno-electron microscopy demonstrates that eight proteins localize to rhoptries in sporozoites. It is noteworthy that the neck and body compartment in rhoptries was not clearly determined in sporozoites. Most rhoptry proteins except components of the high-molecular mass rhoptry protein complex are commonly expressed in merozoites and sporozoites, suggesting that a certain part of invasion mechanisms is conserved between infective forms independently of their target cells. Combined with sporozoite-stage specific gene silencing systems, roles of rhoptry proteins during invasion will be elucidated.

PREVALENCE OF *PLASMODIUM FALCIPARUM* DRUG RESISTANT MUTATIONS IN 2012 AND 2017 COMMUNITY SURVEILLANCE IN WESTERN KENYA

Zhiyong Zhou[1], Simon Kariuki[2], Sheila B. Sergent[1], Kephas Otieno[2], Benard Abong'o[2], Ying Liu[3], Winnie Chebore[2], John E. Gimnig[1], Edward D. Walker[4], Aaron M. Samuels[1], Meghna Desai[1], Ya Ping Shi[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya,* [3]*Parasitic Diseases Control and Prevention Institute, Henan Provincial Centre for Diseases Control and Prevention, Zhengzhou, China,* [4]*Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, United States*

Scale-up of malaria control over the past decades has reduced childhood morbidity and mortality and decreased malaria transmission in Kenya. However, widespread use of anti-malarial drugs, such as artemisinin-

based combination therapies (ACTs), may select for the development of anti-malarial drug resistance, potentially impeding this progress. Community surveillance and monitoring for drug-resistant parasites in human blood and mosquitoes is important to decide when a change in antimalarial regimens is necessary. The present studies in 2012 and 2017 extend our previous analysis in 1996, 2001, 2007 for tracking markers of resistance to sulfadoxine-pyrimethamine (SP), chloroquine (CQ) and ACT in Asembo Bay. Parasites from 225 and 110 blood samples (2012 and 2017, respectively) were sequenced. Additionally, 66 oocyst-positive mosquito midguts from the same area in 2012 were genotyped for the same markers. Results indicate that SP resistance mutations remained high, with the frequency of N51I, C59R, S108N of *Pfdhfr* and A437G, K540E of *Pfdhps* approaching fixation (96-100%), while the prevalence of *Pfdhps* S436H mutations increased significantly from 0% in previous 3 surveys to 9.8% in 2012, and 33.6% in 2017. The CQ resistance marker *Pfcrt* K76T declined over time, from 81.6% in 1996, 81.8% in 2001, 94.6% in 2007 to 17.3% in 2012 and 0.9% in 2017. The multi-drug resistant marker, *Pfmdr1* N86Y dropped from 74.8% in 1996, 73.1% in 2001, 71.0% in 2007 to 9.6% in 2012 and 0% in 2017, but *Pfmdr1* Y184F prevalence increased from 17.9% in 2007 to 53.4% in 2012 and 55.9% in 2017. Importantly, no mutations in the *K13* propeller domain associated with artemisinin resistance were found. Parasites from human blood and mosquito oocysts showed similar prevalence for all markers. The increased prevalence of *Pfdhps* S436H may confer increased resistance to SP. The present study finds no evidence of artemisinin resistance in western Kenya. However, the increase in Y184F prevalence may be due to the selection by the partner drug in ACT, lumefantrine. Therefore, regular surveillance and further evaluation of resistance markers is pivotal for effective treatment of malaria.

EXTENSIVE CUTANEOUS ULCERATIONS IN A PATIENT FROM MYANMAR: AN OLD ENEMY WHICH SHOULD NOT BE FORGOTTEN

Khin R. Ko[1], Aye A. Win[1], May Zabe[1], Aye M. Win[1], Mya Paing[1], Cho C. Nwe[1], Soe A. Thu[1], Moe M. San[1], Patricia F. Walker[2]

[1]*University of Medicine [1], Yangon, Myanmar,* [2]*University of Minnesota, St. Paul, MN, United States*

A 23 year old female presented with multiple painful erythematous skin papules and nodules over the hands, forearms, lower extremities, trunk and face of eight months duration. Lesions ulcerated for 1 month before admission. High grade fever, joint pain, loss of appetite and weight loss were associated with onset of skin lesions. All biochemical parameters were within normal limits with the exception of low albumin and proteinuria. Screening tests for connective tissue diseases and infective serology tests were negative. Wound swab culture revealed growth of *Klebsiella pneumoniae*. Slit skin smear for AFB showed multiple bacilli. Skin biopsy was not done. Patient was admitted and treated as severe erythema nodosum leprosum (ENL) (type 2 lepra reaction), as her presenting symptom complex for Hansen's disease.

884

SEASONAL MALARIA CHIMIO PREVENTION 2017 IN THE HEALTH DISTRICT OF GOUDOMP SENEGAL COST-EFFECTIVENESS ANALYSIS OF TWO TREATMENT STRATEGIES FOR CHILDREN AGED 3-120 MONTHS

Malick Anne[1], Mamadou Mactar Leye[2], Doudou Sene[3], Abdel Kader Dieye[4], Ibrahima Mbamby Keita[5], Youssoupha Ndiaye[5]

[1]*Senegal Health Ministry and Social Action, Kaolack, Senegal,* [2]*Institute Health Development of Mbour Sénéngal, Mbour, Senegal,* [3]*National Malaria Control Program, Dakar, Senegal,* [4]*Senegal Health Ministry and Social Action, Sedhiou, Senegal,* [5]*Senegal Health Ministry and Social Action, Dakar, Senegal*

Despite a good coverage rate for the 2017 Seasonal Malaria Chemo-Prevention (SMC) campaign, more than 95% treatment for children aged 3 to 120 months, a major challenge persists regarding the complete treatment in three days of these children. . The pilot study conducted in the Goudomp district serves as a basis for analyzing the cost-effectiveness ratio of these two approaches. The overall objective of the study is to conduct cost-effectiveness analysis of seasonal malaria prevention strategies for children aged 3-120 months in the Goudomp health district. It was a mixed estimate: an economic evaluation of the three-day and one-day directly observed treatment (DOT) strategies at the 2017 SMC and a qualitative study for the community actors, nurses and the executive team. The quantitative study included 12-health post: six who completed the full treatment strategy under DOT and six who completed the one-day DOT strategy. The choice of posts that had led the strategy was based in a reasoned manner taking into account certain criteria: the location of health posts, the size of the population, the accessibility of structures, the motivation of providers. For the qualitative study, 240 community actors All the head nurses from the 12 health posts and 4 members of the executive team were also interviewed. The average cost in the three-day DOT treatment strategy compared to that of the one-day DOT was respectively passing from the first to the third passage of 1.69$, 1.38$ and 1.39$ against 1.41$, 1.11$ and 1.25$. Note a variation if we compare the two strategies respectively of +0.28, +0.28 and 0.14. The ratio cost effectiveness is 1052.97$ per case avoided for the full treatment strategy compared to 2223.72$ per case avoided for the one-day DOT strategy. Conferring on the most cost-effective three-day TDO strategy. The qualitative study showed a deficiency in the delivery of three doses to children and strong adherence of providers and community relays in the comprehensive treatment strategy to increase the effectiveness of drugs. Comprehensive TDO strategy strengthens child protection, reduces risk of antimalarial drug resistance

NEW INSIGHTS INTO THE MODE OF ACTION OF THE ANTIMALARIAL DRUG PROGUANIL

Kathy Andrews[1], Gillian Fisher[1], Andrews Riches[2], Oliver Hutt[2], Karen Jarvis[2], Tony Wilson[2], Mark von Itzstein[3], Pradeep Chopra[3], Yevgeniya Antonova-Koch[4], Stephan Meister[4], Elizabeth Winzeler[4], Mary Clarke[1], David Fidock[5], Jeremy Burrows[6], John Ryan[2], Tina Skinner-Adams[1]

[1]*Griffith University, Nathan, Australia,* [2]*CSIRO, Clayton, Australia,* [3]*Griffith University, Gold Coast, Australia,* [4]*University of California San Diego, La Jolla, CA, United States,* [5]*Columbia University Medical Center, New York, NY, United States,* [6]*Medicines for Malaria Venture, Geneva, Switzerland*

Malarone® is a combination of atovaquone and proguanil that is used for malaria prophylaxis and treatment. Atovaquone has potent anti-plasmodium activity as a cytochrome bc1-inhibitor while dogma is that proguanil does not have potent intrinsic activity. Proguanil can, however, potentiate atovaquone activity and its cyclization-metabolite (cycloguanil) is a dihydrofolate reductase inhibitor with potent activity. We have recently found that proguanil, and an analogue that cannot convert to cycloguanil (tBuPG), have potent slow-acting activity *in vitro* against asexual *P. falciparum* parasites. This activity is folate-metabolism and isoprenoid biosynthesis-independent. In yeast DHODH-expressing parasites, proguanil and tBuPG slow action activity remains, however bc1-inhibitor activity switches from fast to slow-acting. Proguanil and tBuPG both act synergistically with bc1-inhibitors, while cycloguanil antagonizes activity. Overall, our data suggest that proguanil has potent slow-acting activity against asexual-stage *P. falciparum*, that bc1 is essential to parasite survival independent of DHODH-activity and that Malarone® may act as a triple-drug combination (including antagonistic partners). These findings raise the possibility that a cyclization-blocked proguanil may be a better *in vivo* combination partner for antimalarial bc1-inhibitors.

GENOTYPES AND PHENOTYPES OF RESISTANCE IN ECUADORIAN *PLASMODIUM FALCIPARUM*

Gabriela Valenzuela[1], Luis E. Castro[2], Julio Valencia[3], Petra Rohrbach[4], **Fabian E. Saenz**[1]

[1]*Pontificia Universidad Católica del Ecuador, Quito, Ecuador,* [2]*Ministerio de Salud Pública del Ecuador, Guayaquil, Ecuador,* [3]*Ministerio de Salud Pública del Ecuador, Esmeraldas, Ecuador,* [4]*McGill University, Montreal, QC, Canada*

Malaria continues to be endemic in the coast and amazon regions of Ecuador. Clarifying the current situation of *P. falciparum* resistance in the country will support malaria elimination efforts. Molecular analyses of 69 samples were performed to search for mutations in known resistance markers (*pfcrt*, *pfdhfr*, *pfdhps*, *pfmdr1* and *k13*) and *Pfmdr1* copy number was determined by qPCR. PFMDR1 transporter activity was characterized in live parasites using live cell imaging in combination with the Fluo-4 transport assay. Chloroquine, quinine, lumefantrine, mefloquine, dihydroartemisinin and artemeter sensitivities were measured by *in vitro* assays. The majority of samples from this study presented the CVMNT genotype for *pfcrt* (72-26), NEDF SDFD mutations in *pfmdr1* and wild type genotypes for *pfdhfr*, *pfdhps* and *k13*. The Ecuadorian *P. falciparum* strain ESM-2013 showed *in vitro* resistance to chloroquine, but sensitivity to quinine, lumefantrine, mefloquine, dihydroartemisinin and artemeter. In addition, transport of the fluorochrome Fluo-4 from the cytosol into the digestive vacuole (DV) of the ESM-2013 strain was prevented. All analyzed samples revealed one copy of *Pfmdr1*. This study indicates that Ecuadorian parasites presented the genotype and phenotype for chloroquine resistance and were found to be sensitive to sulfadoxine-pyrimethamine, arthermeter-lumefantrine, quinine, mefloquine, and dihydroartemisinin. The results suggest that the current malaria treatment employed in the country remains effective. Our results clarify the status of antimalarial resistance in Ecuador and aide to best inform the *P. falciparum* elimination campaigns in the country.

USING AMPLICON-BASED NEXT GENERATION SEQUENCING TO DETECT DRUG RESISTANCE MARKERS IN *PLASMODIUM FALCIPARUM* FROM AFRICA

Brooke M. Clemons, Erica Lasek-Nesselquist, Susan Madison-Antenucci

New York State Department of Health Wadsworth Center, Albany, NY, United States

Each year ~1,700 malaria cases are diagnosed in the United States and are almost exclusively associated with travel. Cases identified in New York State (NYS) alone contribute ~20% of this total and are largely caused by *Plasmodium falciparum* (*Pf*). For this species, drug resistance is recognized in all currently available antimalarial classes. To investigate *Pf* drug resistance markers in NYS patients with reported travel history, we used amplicon-based next generation sequencing (NGS) to detect single nucleotide polymorphisms in six genes that are known to cause, or are strongly associated with, treatment failure. The genes targeted were *pfcrt*, *pfdhfr*, *pfdhps, pfmdr, pfcytb* and *pfk13*. All *Plasmodium* positive samples in NYS are required to be confirmed by the Wadsworth Center Parasitology Laboratory. As a result, we were able to sequence hundreds of blood samples containing *Pf* from patients who had traveled to over 30 different endemic countries. These data were compared to generate a maximum likelihood phylogeny based from a concatenated gene alignment. Antimalarial resistance markers were also detected and compared within and between countries. Data thus far show ~25% of African samples have *pfcrt* mutations associated with chloroquine resistance, ~95% have *pfdhfr* mutations linked to pyrimethamine and proguanil failure and >99% of samples have *pfdhps* mutations impacting sulfadoxine efficacy. The data indicate that ~70% of patient samples have mutations in the *pfmdr* gene, reported to cause resistance to multiple drugs including quinine, amodiaquine and artemether-lumefantrine. Less than 1% of samples contain *pfcytb* mutations, therefore overall susceptibility for atovaquone remains high. Lastly, we have not observed *pfk13* mutations that cause artemisinin resistance. Using NGS to detect *Pf* drug resistance markers in NYS's population allows for a better understanding of antimalarial efficacy. These data can assist in more accurate recommendations for prophylaxis in travelers to endemic countries and can assist clinicians in choosing treatment to lessen the risk of recrudescence once infected.

888

EFFICACY AND SAFETY OF ARTEMETHER-LUMEFANTRINE, ARTESUNATE-AMODIAQUINE AND DIHYDROARTEMISININ-PIPERAQUINE IN THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN THE DEMOCRATIC REPUBLIC OF CONGO IN 2017: AN OPEN-LABEL RANDOMIZED TRIAL

Gauthier Masia Kahunu[1], Joris Likwela Losimba[2], Eric Mukomena Sompwe[2], Junior Matangila[3], Hyppolite Muhindo Mavoko[3], Ntamabyaliro Nsengi Yumva[1], Papy Mandoko Nkoli[1], Albert Kutekemeni Kaputu[2], Aboubacar Sadou[4], Leah F. Moriarty[5], Eric Halsey[5], Pascal Ringwald[6], Jean Jaques Muyembe Tanfum[7]

[1]*Unit of Clinical Pharmacology and Pharmacovigilance University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [2]*National Malaria Control Programme, Ministry of Health DRC, Kinshasa, Democratic Republic of the Congo,* [3]*Faculty of Medicine University of Kinshasa DRC, Kinshasa, Democratic Republic of the Congo,* [4]*United States Agency for International Development, President's Malaria Initiative, Kinshasa, Democratic Republic of the Congo,* [5]*President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*World Health Organization Global Malaria Programme, Geneva, Switzerland,* [7]*Institut National des Recherches Bio-médicales (INRB) DRC, Kinshasa, Democratic Republic of the Congo*

Regular monitoring of artemisinin-based combination therapy (ACT) efficacy is important for timely detection of the emergence of antimalarial drug resistance. In a study conducted in 2012-13, artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ), the first line treatments for uncomplicated *Plasmodium falciparum* malaria in the Democratic Republic of Congo (DRC), met WHO standards for efficacy and safety. In 2017, we conducted a study of the efficacy of dihydroartemisinin-piperaquine (DP) in addition to AL and ASAQ. In a three-arm, open label randomized trial, 1613 children aged six to 59 months with uncomplicated *Plasmodium falciparum* malaria were enrolled from six sites representing the diversity of malaria epidemiologic settings in DRC (same sites as 2012-2013 study). After randomization and receiving an ACT for three days, participants were followed for 28 (AL and ASAQ arms) or 42 (DP arm) days. Clinical outcome was classified according to the standard WHO protocol published in 2009. The uncorrected adequate clinical and parasitological response (ACPR) rates for AL, ASAQ, and DP, respectively, were 79.8%, 72.0%, and 58.6% in Rutshuru, 63.0%, 76.2%, and 55.7% in Mikalayi, 85.1%, 92.7%, and 90.1% in Kimpese, 75.3%, 100%, and 64.1% in Kapolowe, and 88.0%, 100%, and 90.5% in Kabondo. Results are not available for Bolenge. The analysis to determine PCR-corrected results is ongoing. Five serious adverse events were reported, none of which were attributed to the ACT. Based on the uncorrected results, the efficacy of AL, ASAQ and DP appears to vary by site in DRC. PCR correction of the recurrent infections, which is currently pending, will offer more insight into the low uncorrected efficacy in some of the sites.

889

IDENTIFICATION OF NOVEL ANTIMALARIALS BY HIGH THROUGHPUT SCREENING OF *PLASMODIUM FALCIPARUM* PROTEASOME

Lydia Mata Cantero[1], Alvaro Cortés[1], Mercedes García[1], Stanley Xie[2], David Gillett[2], F. Javier Gamo[1], Esther Fernández[1], Leann Tilley[2], Maria G. Gómez Lorenzo[1]

[1]*GlaxoSmithKline, Tres Cantos, Madrid, Spain,* [2]*University of Melbourne, Melbourne, Australia*

The most severe form of malaria is caused by the protozoan parasite *Plasmodium falciparum*. Current first-line treatments are based on artemisinin combination therapies (ACTs). However, the malaria parasite has developed resistance against all widely used antimalarials, and ACTs are not an exception. Increasing drug resistance has led to an urgent need for developing novel therapies acting though new parasite targets. Ideally, new drugs should be effective not only on acute infection, but also on different stages of the parasite lifecycle to block transmission. Targeting proteasome fulfill these criteria, as is one of the best validated targets in malaria parasites. Human proteasome inhibitors used for cancer treatment are active on all parasite stages, liver, blood (both sexual and asexual) and mosquito. Moreover, in blood stages they show a synergistic behavior against sensitive and resistant parasites when combined with artemisinins. Although *P. falciparum* proteasome exhibits a high degree of homology with its human counterpart, significant structural divergences have been found, including an unusually open β2 active site. These divergences are being exploited to develop inhibitors with selectivity for the parasite proteasome, thus limiting the potential side effects derived from human proteasome inhibition. Here, we present a high throughput screening campaign where around 550K compounds from GSK screening collection have been tested using purified *P. falciparum* proteasome. Chymotrypsin-like activity was used as primary assay to filter the compounds, followed by secondary assays to test trypsin and caspase-like activities, as well as evaluation of selectivity using purified human proteasome. Results from the primary screening, validation in secondary and selectivity assays, as well as the progression cascade to validate both biochemically and biologically the hits will be presented.

890

QUIESCENT ARTEMISININ-RESISTANT *PLASMODIUM FALCIPARUM* PARASITES ARE ABLE TO SURVIVE MOST ANTIMALARIAL DRUGS, INCLUDING ARTEMISININ PARTNER DRUGS: WHAT CONSÉQUENCES?

Lucie Paloque[1], Thibaud Reyser[1], Manel Ouji[1], Sandie Ménard[2], Benoit Witkowski[3], Jean-Michel Augereau[1], Françoise Benoit-Vical[1]

[1]*CNRS; LCC (Laboratoire de Chimie de Coordination), Toulouse, France,* [2]*CPTP (Centre de Physiopathologie de Toulouse Purpan), INSERM U*[1043]*, CNRS UMR*[5282]*, Université de Toulouse III, Toulouse, France,* [3]*Malaria Unit, Pasteur Institute in Cambodia, Phnom Penh, Cambodia*

Quiescence phenomenon is an unconventional drug resistance mechanism of *Plasmodium falciparum* that occurs in *pfk13* mutated parasites in response to artemisinins treatment. During artemisinin-based combination therapies (ACTs), due to the respective pharmacokinetics properties of the drugs, artemisinin-resistant parasites are first exposed to artemisinins which induce the quiescence phenomenon of a parasite subpopulation. The ability of these quiescent parasites to also survive artemisinin partner drugs may lead to parasite recrudescence. We designed a novel *in vitro* phenotypic assay, named Quiescent-stage Survival Assay, to assess the efficacy of drugs on quiescent artemisinin-resistant parasites. In this assay, as it happens in patients, parasites are first exposed to a 6h-pulse of artemisinins inducing quiescence entry, then exposed, during 48h, to a combination of both artemisinins, to maintain the quiescent state, and the drug to be evaluated. In this way we investigated the efficacy of artemisinin partner drugs currently used in ACTs, but also other antiplasmodial drugs recommended by the World Health Organization for malaria treatment. These experiments were achieved on relevant quiescent artemisinin-resistant parasites from lab strains and Cambodian field isolates. Our results show for the first time that the drug activity on proliferating artemisinin-resistant parasites cannot be predictive of its efficacy level against quiescent artemisinin-resistant parasites. Indeed, we highlighted that because of their mode of action, some drugs highly active on dividing artemisinin-resistant parasites, lost their activity during the parasite quiescent state. These results are particularly interesting since artemisinin resistance was proved as a first step to multi-resistance acquisition responsible for clinical failures. This study provides a valuable tool for taking into account chemosensitivity of quiescent artemisinin-resistant parasites during drug discovery and development process of new partner drugs especially in the current context of artemisinin resistance.

891

CHANGES IN ANTIMALARIAL DRUG SENSITIVITY OVER TIME IN EASTERN UGANDA

Patrick K. Tumwebaze[1], Marvin Duvalsaint[2], Victor Asua[1], Oswald Byaruhanga[1], Thomas Katairo[1], Martin Okitwi[1], Stephen Orena[1], Jennifer Legac[2], Brett Bayles[2], Melissa Conrad[2], Samuel L. Nsobya[1], Roland A. Cooper[3], Philip J. Rosenthal[2]

[1]*Infectious Disease Research Collaboration, Kampala, Uganda,* [2]*University of California, San Francisco, CA, United States,* [3]*Dominican University, San Rafael, CA, United States*

Malaria remains a large problem in Uganda, although disease incidence varies greatly across the country, in part due to varied use of malaria control measures in different districts of the country. The first line therapy for malaria, artemether-lumefantrine, and the alternatives artesunate-amodiaquine and dihydroartemisinin-piperaquine, have all shown excellent treatment efficacy. We have monitored the ex vivo drug sensitivity and prevalence of key genetic determinants of resistance of *Plasmodium falciparum* from patients presenting with malaria in Tororo and Busia districts in eastern Uganda since late 2015. Parasite isolates have shown good sensitivities to chloroquine (CQ; median IC_{50} 20 nM), monodesethylamodiaquine (7.3 nM), piperaquine (5.3 nM), lumefantrine (4.9 nM), mefloquine (8.8 nM), pyronaridine (1.1 nM), atovaquone (0.3 nM), and dihydroartemisinin (1.5 nM). The prevalence of parasites with ex vivo IC_{50} consistent with resistance to CQ (IC_{50} >80 nM) has decreased over time (isolates with IC_{50} >80 nM 24% (24/100) in 2016 and 1.9% (3/161) in 2018 ($p < 0.0001$). Consistent with this finding, the prevalences of key mutations associated with CQ resistance have decreased over time (mixed/mutant *pfcrt* K76T 39% (37/96) in 2016 and 4.7% (8/170) in 2018; *pfmdr*1 N86Y 5% (4/99) in 2016 and 0.6% (1/177) in 2018; *pfmdr*1 D1246Y 19% (19/98) in 2016 and 8.3% (14/169) in 2018. Interestingly, comparing samples collected over the same time frame (May-June, 2018), the prevalence of the *pfcrt* 76T mutation was greater in parasites collected in Tororo District, where district-wide indoor residual spraying of insecticide (IRS) has greatly reduced malaria transmission, compared to that in parasites collected in nearby Busia District, where IRS has not been used (mixed/mutant 33.3% in Tororo; 3.6% in Busia; $p=0.0027$). In summary, sensitivity of *P. falciparum* to standard antimalarials remains excellent in eastern Uganda, but parasites have evolved over time, most likely in response to the pressure of wide use of artemether-lumefantrine, and changes in malaria epidemiology appear to impact on prevalences of resistance markers.

892

CORRELATIONS OF EX VIVO ANTIMALARIAL DRUG SENSITIVITIES BETWEEN STANDARD AND NEW ANTIMALARIAL COMPOUNDS IN TORORO, UGANDA

Thomas Katairo[1], Patrick K. Tumwebaze[1], Oswald Byaruhanga[1], Martin Okitwi[1], Sam L. Nsobya[1], Brett R. Bayles[2], Benjamin Blasco[3], Didier Leroy[3], Philip J. Rosenthal[4], Roland A. Cooper[2]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*Dominican University of California, San Rafael, CA, United States,* [3]*Medicines for Malaria Venture, Geneva, Switzerland,* [4]*University of California, San Francisco, CA, United States*

The efficacies of artemisinin-based combination therapies (ACTs) are threatened by resistance to both artemisinins and partner drugs, which has emerged in southeast Asia. Of great concern is spread of ACT resistance to Africa, where the greatest burden of falciparum malaria is present. As part of a long-term study to characterize potencies of existing antimalarials and experimental lead compounds, we have monitored the ex vivo sensitivities of *Plasmodium falciparum* collected from patients presenting with malaria in Tororo and Busia Districts, eastern Uganda, since 2015. Ex vivo sensitivities for standard antimalarial drugs and lead compounds from the Medicines for Malaria Venture portfolio were assessed with 72 h growth inhibition (IC_{50}) assays for 518 clinical isolates collected from 2015-18. In order to gain insights into shared mechanisms, we measured the strength and direction of associations between IC_{50} values of tested antimalarials using the Spearman rank-order correlation coefficient. We observed moderate to strong correlations between compounds predicted to have shared mechanisms of action. For aminoquinolines and related compounds, positive correlations were observed for chloroquine, monodesethylamodiaquine, AQ13, pyronaridine and ferroquine but, interestingly, not for the bisquinoline piperaquine. Positive correlations were also seen among drugs targeting the parasite mitochondrion (proguanil and the cytochrome B inhibitors atovaquone and ELQ300), the putative transporter PfATP4, dihydroorotate dehydrogenase, and phosphatidylinositol 4-kinase. Interestingly, activities of a number of compounds with unknown mechanisms of action correlated with those with known mechanisms, suggesting novel insights regarding mechanisms of action or resistance. Additional studies assessing correlations in activities between compounds and the genetic bases of shared mechanisms are underway.

Seasonal Malaria Chemoprevention (SMC) consists of giving preventive doses of Sulfadoxine-Amodiaquine (SP/AQ) monthly during the peak malaria season. The purpose of this study was to assess the relationship between the number of rounds of SP/AQ received and the mean parasite densities in children during and after an SMC campaign. During the 2018 SMC campaign SP/AQ was delivered door to door on designated days in August, September, October and November of 2018. During each round, the first dose (of three) was administered to children from 3 to 59 months of age during door-to-door visits. Instructions were given for the other two doses to be administered by the child's caregiver on the subsequent 2 days. The approach of this study was to screen children who presented to the health center with malaria symptoms. Between October 2018 and March 2019, 864 children from 3 to 59 months of age were screened and blood smears were prepared to identify *P. falciparum*. 428 of the 864 children screened had parasitemias ≥ 25 per μl. We examined the relationship between parasitemia and the number of rounds of SP/AQ that a child had received based on the hypothesis that children who received all 4 rounds of SP/AQ should have lower mean parasite densities than children who received less than 4 rounds of SP/AQ. Analysis of these data indicate there were no differences in mean parasite densities between children who received four rounds of SP/AQ and children who received less than four rounds of SP/AQ ($p = 0.493$). In addition, at one study site, children who reported receiving all four rounds of SP/AQ had higher mean parasite densities ($p = 0.039$) than children who received fewer rounds of SP/AQ with a marked impact on children more than 48 months of age. These results suggest there is a need to reinforce drug administration compliance by caregivers during days 2 and 3 of each round of SMC treatment.

894

FUNCTIONAL ANALYSIS OF THE ANTIMALARIAL TARGET *PLASMODIUM FALCIPARUM* PHOSPHATIDYLINOSITOL 4-KINASE

Anna R. Sternberg, Matthew R. Hassett, Paul D. Roepe

Georgetown University, Washington, DC, United States

Artemisinin-based combination therapy (ACT) is the front-line treatment recommended for uncomplicated *Plasmodium falciparum* infections by the World Health Organization (WHO). With the rise in delayed clearance phenotype (DCP) infections due to reduced ACT efficacy in Southeast Asia, much research has been focused in identifying novel, potent antimalarial agents. Recent high-throughput screening efforts have identified phosphatidylinositol 3-kinase (PI3K) and phosphatidylinositol 4-kinase (PI4K) inhibitors as very potent antimalarial drugs. The *P. falciparum* malarial parasite genome encodes a single PI3K and sequence analysis suggests that the enzyme is a "class III" or "Vps34" PI3K. Sequence analysis of the *P. falciparum* PI4K antimalarial target suggests that it is a PI4K "type III beta" isoform. Both enzymes are likely to be essential genes in *P. falciparum*, which makes them attractive antimalarial drug targets. Previously, we heterologously expressed, purified, and characterized the PfVps34 enzyme as a class III PI3K, as well as a target for artemisinin-based antimalarials. Consequently, we optimized the *pfpi4k3b* gene for heterologous expression in yeast, purified the protein to homogeneity, and adapted a recently validated quantitative assay for PIP production from PI to characterize enzyme activity and to quantify drug inhibition.

895

TARGETING PHOSPHATIDYLINOSITOL 3' KINASE TO DESIGN NOVEL COMBINATION THERAPIES AGAINST ARTEMISININ RESISTANT *PLASMODIUM FALCIPARUM*

Kalpana Iyengar, Paul Roepe

Georgetown University, Washington, DC, United States

Resistance to artemisinin (ART) combination therapies in *Plasmodium falciparum* malaria is a continuously growing problem. Previous results from our laboratory have shown that *P. falciparum* parasites encode an autophagy - like process, that this pathway is triggered in response to external stressors such as starvation or cytocidal drug treatment, and that the process is impaired in drug resistant parasites. Phosphatidylinositiol 3' kinases (PI3K) are key regulators of autophagy. Not surprisingly then, we have found that PI3K inhibitors are extremely potent antimalarial compounds that both inhibit the autophagy response and are synergistic with artemisinin (ART) - based drugs. We have also shown that the synthetic trioxolane OZ439 is equally potent against both ART resistant (ART-R) and sensitive (ART-S) *P. falciparum* strains. Taken together, these

findings led us to further investigate the autophagy pathway in both ART-S and ART-R parasites. Results from these experiments further support the conclusion that there is a distinct autophagy pathway in *P. falciparum* parasites, and that this pathway is further dysregulated in ART-R parasites relative to chloroquine resistant (CQR) parasites studied previously. Significant cytostatic and cytocidal synergy was found for drug combinations involving ART - based drugs and PI3K inhibitors. Based on these data, we suggest novel endoperoxide-based combination therapies for the treatment of ART-R parasites.

896

THE SUBSTANDARD ARTEMISININ EPIDEMIC - ACCELERATING RESISTANCE IN *PLASMODIUM FALCIPARUM* MALARIA?

Matthew R. Hassett, Paul D. Roepe

Georgetown University, Washington, DC, United States

The acceleration of antimicrobial resistance (AMR) is often hypothesized to be, in part, an unfortunate consequence of more frequent use of subtherapeutic dosages of drugs. In 2017, the World Health Organization (WHO) estimated that nearly 1 in 10 medical products tested in low- and middle-income countries failed to meet quality standards. Artemisinin-based combination therapies (ACTs) are currently the frontline treatment for malaria infections recommended by WHO, and currently our last line of defense to effectively combat malaria in the clinic. Troublingly, use of substandard ACTs has been well-documented over the last decade. Perhaps relatedly, there has been an increasing number of cases of delayed clearance of parasites in patients who were treated with ACTs, suggesting decreasing ACT efficacy. Effectively understanding any link between substandard adherence and/or dosing of drug and subsequent proliferation of ACT resistant parasites is critical for future treatment and containment of ACT resistance. We have developed a tissue culture-based approach for testing possible connections between substandard drug use and the spread of ACT resistance. Via sequencing of *Pfkelch13*, a molecular marker that is predictive for artemisinin resistance in *Plasmodium falciparum*, we are able to monitor competition of mixed populations of sensitive and resistant strains over time and under various conditions. We will present data related to subtherapeutic drug use that may promote spread of ACT resistance in *P. falciparum* malaria.

897

ANALYSIS OF PIPERAQUINE TRANSPORT BY *PLASMODIUM FALCIPARUM* CHLOROQUINE RESISTANCE TRANSPORTER ISOFORMS HETEROLOGOUSLY EXPRESSED IN *S. CEREVISIAE* YEAST

Bryce E. Riegel, Paul D. Roepe

Georgetown University, Washington, DC, United States

Emerging resistance of *Plasmodium falciparum* malaria to artemisinin derivatives and partner drugs in Southeast Asia represents a major health challenge. Piperaquine (PPQ) is a bisquinoline antimalarial drug that is used as a partner drug with dihydroartemisinin (DHA) in artemisinin combination therapy (ACT). DHA/PPQ (Artekin, Eurartesim) has been recommended by WHO and widely used since 2009. However, evolving resistance to both PPQ (PPQR) and DHA has been reported in South East Asia. Resistance to the former front-line quinoline drug chloroquine (CQ), as well as to other quinoline - based compounds, is caused by multiple mutations in the *P. falciparum* chloroquine resistance transporter (PfCRT). While multiple markers for PPQR have been reported - including amplification of plasmepsins 2 and 3, a non-synonymous SNP in Exonuclease1, and several mutations in PfCRT - a better understanding of the mechanism(s) of resistance is needed. Here we have tested whether specific PfCRT mutations recently detected in *P. falciparum* Cambodian isolates contribute to PPQR. Using a galactose inducible expression system, we monitored PPQ transport in *S. cerevisiae* yeast expressing PfCRT at the plasma membrane. Elevated levels of PPQ transport were found for yeast expressing multiple PPQR-associated PfCRT isoforms relative to wild type, suggesting these mutations in PfCRT promote altered PPQ transport and contribute to PPQR.

898

USING A SMALL FLUORESCENT PROBE TO MEASURE REDOX POTENTIAL IN THE *PLASMODIUM FALCIPARUM* DIGESTIVE VACUOLE

Andreas V. Willems, Paul D. Roepe

Georgetown University, Washington, DC, United States

The recent emergence of artemisinin (ART) resistance in *Plasmodium falciparum* malarial parasites is of major concern and has focused attention on the mechanism of action of ART - based drugs. During the intraerythrocytic stage of parasite development, copious amounts of free ferriprotoporphyrin IX (FPIX) heme is released upon hemoglobin catabolism within the parasite digestive vacuole (DV). Recently, we have shown that ART-FPIX adducts are formed within ART treated parasites, and that the abundance of these toxic adducts is altered for ART resistant *P. falciparum*. Adduct formation is dependent upon glutathione (GSH) balance within the DV. For these reasons we have synthesized novel fluorescent small molecule GSH probes and have endeavored to localize them specifically to the DV using our previously reported approach. With specific localization we are able to use these methods to compare the redox environment within the DV of ARTS vs ARTR *P. falciparum.* Data quantifying DV [GSH] will further elucidate the mechanism of ART - based drug action and ART resistance.

899

IN VIVO EFFICACY AND FREQUENCY OF MOLECULAR MARKERS OF RESISTANCE OF *P. FALCIPARUM* TO SULFADOXINE-PYRIMETHAMINE PLUS AMODIAQUINE IN BOUGOUNI, MALI AND HOUNDÉ, BURKINA FASO

Issaka Sagara[1], Issaka Zongo[2], Irene Kuepfer[3], Matthew Cairns[3], Modibo Diarra[1], Amadou Barry[1], Frederic Nikiema[2], Amadou Tapily[1], Samba Coumaré[1], Ismaila Thera[1], JeanBosco Ouedraogo[4], Paul Milligan[3], Daniel Chandrahoman[3], Abdoulaye Djimde[1], Brian Greenwood[3], Alassane Dicko[1]

[1]*Malaria Research and Training Center/University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, Bobo Dioulasso, Burkina Faso,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*Institut de Recherche en Sciences de la Santé, Bobo Dioulasso, Burkina Faso*

Seasonal malaria chemoprevention (SMC) is being implemented widely in Sahelian countries. The World Health Organization recommends continued monitoring of drug resistance in areas where SMC is being deployed. As part of the large trial of the SMC with or without Azithromycin, we assessed the frequency of the molecular markers of resistance of *P. falciparum* to Sulfadoxine-Pyrimethamine (SP) and Amodiaquine (AQ) in children after one and three years of SMC and the *in vivo* response of *P. falciparum* to SP and AQ after three years of SMC in Bougouni, Mali and Hounde in Burkina Faso. In 2016, after three years of implementation of SMC, the PCR uncorrected proportion of adequate clinical and parasitological response (ACPR) was 94.8% (95% CI 85.0 - 98.3) in Burkina and 96.1% (95% CI 91.5 - 98.2) in Mali. After PCR correction the ACPR was 99.3% (95% CI 95.4 - 99.9) in Mali and remained unchanged in Burkina. The frequency of the three mutations dhfr-59I + dhps-437G + dhps-540E associated with resistance to SP in Mali was 0.8% (1/125) in 2014 and 4.2% (5/120) in 2016, p =0.09. The corresponding figures in Burkina Faso were 0 % (0/61) in 2014 and 1.5% (2/134) in 2016 p =0.34. Similarly, the frequency of the double mutation (Pfcrt-76T + pfmdr1-86Y), associated with resistance to AQ, remained similar in both countries; 16.3% (20/123) in 2014 and 12.8% (15/117) in 2016 in Mali p =0.44, while in Burkina double mutations were detected in 6.8% (4/59) children in 2014, but not seen in 113 children in 2016. The frequency of these

markers in schoolchildren aged 6-12 years in the same villages were similar to those seen in the study children. In summary, SMC implementation was not associated with evidence of an increase in frequencies of molecular markers of resistance to SP and AQ or a reduced 28 days *in vivo* efficacy after three years of the SMC.

GUT MICROBIOME PREDICTS LUMEFANTRINE PHARMACOKINETICS IN HEALTHY MICE

Matthew M. Ippolito[1], Joshua Denny[2], Elizabeth Nenortas[1], Theresa A. Shapiro[1], Nathan Schmidt[2]

[1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [2]*University of Louisville, Louisville, KY, United States*

The antimalarial drug lumefantrine exhibits highly variable pharmacokinetics—absorption, distribution, and clearance—between individuals with up to 16-fold differences in drug exposure. Differences are due, in part, to poor absorption which is mitigated by administration with fatty food. We hypothesized that the intestinal microbiome may also play an important role in lumefantrine disposition. Four cohorts of isogenic mice from different vendors (n=24) previously shown to harbor distinctive enterotypes were administered a humanized dose of lumefantrine (150 μg/g) by gavage. Gut microbiome was characterized by 16s rRNA amplicon sequencing of fecal pellets and enterotypes were classified according to β-diversity using weighted UniFrac distance. Plasma was collected at 0, 0.5, 1.5, 10, and 24 h post dose for drug analyte quantitation by liquid chromatography tandem mass spectrometry. Drug exposure measured as maximal concentration (C_{max}) and area under the drug concentration-time curve (AUC_{0-24}) was estimated by the linear-log trapezoidal method in non-compartmental analyses. Oral clearance (Cl/F) and apparent volume of distribution (Vd/F) were estimated using covariate analysis of enterotype with stepwise selection in population-based compartmental models. Four discrete enterotypes were identified. Enterotypes 1 and 2 had significantly greater taxonomic abundance than 3 and 4, and β-diversity plots showed clustering of the same pairs. Mice with enterotypes 1 and 2 had higher lumefantrine exposure than enterotypes 3 and 4 (C_{max} = 542 and 768 vs. 392 and 380 ng/ml, $P \leq 0.04$ for pairwise comparisons; AUC_{0-24} = 511,000 and 657,000 vs. 344,000 and 333,000 ng*h/ml, $P \leq 0.02$). Results of compartmental analyses suggest that enterotype-related differences in Cl/F but not Vd/F correlated with drug exposure. The gut microbiome has previously been shown to contribute to inter-individual variation in metabolism of orally administered drugs. Here, we demonstrate that gut microbiome differences may partially account for variation in lumefantrine exposure.

EXPANSION OF CHLOROQUINE SENSITIVE HAPLOTYPES IN THE *PLASMODIUM FALCIPARUM* RESERVOIR IN BONGO DISTRICT, GHANA

Charles A. Narh[1], Kathryn E. Tiedje[1], Michael F. Duffy[1], Anita Ghansah[2], Abraham R. Oduro[3], Kwadwo A. Koram[2], Karen P. Day[1]

[1]*School of Bioscience/Bio*[21] *Institute, The University of Melbourne, Melbourne, Australia,* [2]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana,* [3]*Navrongo Health Research Centre, Navrongo, Ghana*

In the early 2000s widespread resistance to chloroquine (CQ) prompted Ghana to change its first-line treatment policy to artemisinin-based combination therapies (ACTs) for uncomplicated *P. falciparum* malaria. Following this withdrawal of CQ, ongoing surveillance of clinical infections in children has shown that sensitivity to CQ has rebounded. In Ghana, the genomic signatures suggest that ACTs, artesunate-amodiaquine and artemether-lumefantrine, exert differential selection at the two drug transporter genes, *Pfcrt* and *Pfmdr1*. What is happening to the spread of drug-resistance–associated mutations in the large reservoir of asymptomatic infections has been poorly studied. This study set out to monitor this neglected reservoir in Bongo District, Ghana at the end of the 2012 dry season by genotyping the *Pfcrt* and *Pfmdr1* mutations associated with chloroquine (CQ) resistance and the microsatellite *loci* flanking these genes. For the isolates sequenced at *Pfcrt* (N=170) and *Pfmdr1* (N=198), the majority carried CQ-sensitive haplotypes, specifically *Pfcrt* CVMNK (88.2%) and/or *Pfmdr1* NY (17.7%) or *Pfmdr1*NF (69.7%). To investigate selection of these haplotypes, isolates with single genomes were typed at 11 microsatellite *loci* flanking *Pfcrt* (N=55) and *Pfmdr1*(N=46). For *Pfcrt*, 93.8% of isolates with the CQ sensitive CVMNK haplotype (N=48) had unique multilocus microsatellite haplotypes that were diverse (*He* = 0.75). This result indicates that CVMNK has expanded in the *P. falciparum* reservoir via soft selective sweeps from genetically diverse parasites. For *Pfmdr1* NY (N=8) and NF (N=35), all isolates had unique multilocus microsatellite haplotypes, and there was no significant difference in the *He* (NY: 0.85, NF: 0.83), suggestive of equal selective advantage. We have shown that this asymptomatic *P. falciparum* reservoir, which has limited exposure to antimalarial drugs during the dry season, harboured highly diverse *Pfcrt* and *Pfmdr1* haplotypes. The change in treatment policy to ACTs has influenced this underlying diversity and as such it is important to prioritize this reservoir during monitoring programs to inform policy.

902

LABORATORY EVALUATION OF INTRODUCED PROCEDURAL ERRORS ON MALARIA RAPID DIAGNOSTIC TEST PERFORMANCE

Christina M. Carlson, Yong Ah, Scott Wilson, Jeffrey A. Glenn, Michael Aidoo

Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria rapid diagnostic tests (RDTs) account for ~75% of all malaria testing in sub-Saharan Africa and are often used by community health workers or other health workers in peripheral facilities. These workers are often trained using job aids extracted from manufacturer's instructions for use (IFU). Imperfect compliance with IFUs could lead to procedural errors during RDT administration, with unknown consequences on diagnostic result accuracy. We aimed to systematically determine the consequences of procedural errors on RDT outcome in a laboratory setting. Cultured samples containing *Plasmodium falciparum (Pf)* parasites at 1,000, 200, and 50 parasites/μL (5 μL total volume) were tested with 6 separate RDT products that met the WHO RDT procurement criteria and target either 1) *Pf*-specific HRP2 and the pan-malaria pLDH antigens or 2) *Pf*-specific HRP2 and *P. vivax*-specific pLDH antigens. Results of RDTs conducted according to IFUs were compared to results of the same products for which the following errors were deliberately introduced: higher and lower buffer volumes and extended and shortened incubation times. Common consequences of introduced errors on RDT performance across tested products included incomplete blood clearing or red background resulting from shortened incubation times or excessive buffer volume. For some tests at lower parasite density, poor blood clearing obscured weak positive test lines and could produce a false-negative test result. For 3 of 6 products tested, insufficient buffer volume resulted in failed migration of sample across the length of the test strip, producing an invalid test result. For the same 3 products, extended incubation time and/or the combination of extended incubation time and increased buffer volume improved test result reads from tests run as per IFU. Minor incubation time and buffer volume deviations from IFU can result in RDT performance anomalies that may lead to incorrect test result interpretation and reporting, with serious implications for patient care and the success of malaria control programs. Efforts should be made to communicate product and IFU changes to non-laboratory users.

903

DIAGNOSTIC PERFORMANCE OF ULTRA-SENSITIVE RAPID DIAGNOSTIC TESTS FOR MALARIA IN PREGNANT WOMEN ATTENDING ANTENATAL CLINICS IN WESTERN KENYA

Aaron M. Samuels[1], Oliver Towett[2], Brian Seda[2], Kelvin Onoka[2], Kephas Otieno[2], Winnie Chebore[2], Kammerle Schneider[3], Patrick Walker[4], Titus Kwambai[2], Meghna R. Desai[5], Laurence Slutsker[3], Simon K. Kariuki[2], Feiko ter Kuile[6]

[1]*Centers for Disease Control and Prevention, DPO, AE, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya,* [3]*PATH, Seattle, WA, United States,* [4]*Imperial College, London, United Kingdom,* [5]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

In settings with moderate to high malaria transmission, infection with *Plasmodium falciparum* can cause adverse outcomes in pregnant women and their fetuses, such as maternal anemia and low birthweight neonates. In these settings, infections during pregnancy may have a low density of parasites or associated antigens in peripheral blood; particularly amongst multi-gravid women. Such infections are more likely to be below the detection limit of blood smear microscopy (BS) and standard rapid diagnostic tests (RDTs). Diagnostic tests with increased sensitivity, and subsequent treatment, may prevent adverse pregnancy outcomes. In the high transmission setting of western Kenya, we compared the diagnostic characteristics of expert BS, First Response Malaria Ag. (pLDH/HRP2) Combo RDTs (RDT), and the ultra-sensitive Alere™ Malaria Ag P.f. RDT (uRDT), using polymerase-chain reaction (PCR) as the gold standard for detection of *P. falciparum* infections in women attending their first antenatal clinic (ANC) visit in 9 ANC clinics. From May-September, 2018, 488 individual women attended these clinics for their first ANC visits and 483 had all 4 tests performed. The median parasite density per μL determined by qPCR was 148 (Interquartile range: 11-1260); 122 (25.2%) were positive by PCR; 105 (21.7%) were positive by uRDT; 96 (19.9%) were positive by RDT; and 66 (13.7%) were positive by BS. Compared to PCR, the sensitivity and specificity for BS were 52.5% (95% Confidence Interval [CI]: 43.2-61.6) and 99.5% (CI: 98.0-100); RDT 63.1% (CI: 53.9-71.7) and 94.7% (CI: 91.9-96.8), and uRDT 69.7% (CI: 60.7-77.7) and 94.5% (CI: 91.6-96.6). When stratified by gravidity, the sensitivity of RDTs and uRDTs in pauci-gravidae (primi- and secondi-gravidae) were 69.9% (CI: 58.0-80.1) and 79.5% (CI: 68.4-88.0), respectively. In multi-gravid women, the sensitivity of RDTs and uRDTs were 53.1 (CI: 38.3-67.5) and 55.1% (CI: 40.2-69.3), respectively. In this setting, the performance of uRDTs in pregnant women at first ANC visit was marginally better than that of a standard RDT. Evaluation of other more sensitive point-of-care tests in the ANC setting should be considered.

904

INTEGRATING VERTICAL AND LATERAL FLOW ASSAYS FOR IMPROVED DIAGNOSIS OF ASYMPTOMATIC MALARIA INFECTIONS

Carson P. Moore, Nathaniel Z. Piety, David W. Wright

Vanderbilt University, Nashville, TN, United States

A major challenge for malaria control and elimination programs is sensitive and specific diagnosis of patients within the asymptomatic transmission reservoir. Because many commercially available rapid diagnostic tests (RDTs) have detection limits around 200 parasites/μL, low-level asymptomatic patients can be missed during point-of-care (POC) diagnosis. These patients have been reported as having average parasite burdens as low as 5 parasites/μL in some endemic settings. In order to detect these infections, the limit of detection of available tests must be improved. We report a method to increase the signal generated on malaria RDTs by utilizing a vertical flow sample preparation method consisting of a metal functionalized cellulose membrane in tandem with a lateral flow assay. This method allows for extraction and enrichment of both primary biomarkers of malaria: *Plasmodium falciparum* histidine-rich protein 2 (*Pf*HRP2) and *Plasmodium* lactate dehydrogenase (*P*LDH). Integration of the proposed enrichment and enhancement system allows for concentration of the antigens from large sample volumes directly onto POC-ready RDTs. This system exploits the ease of functionalization of cellulose and the innate affinity between the histidine residues of *Pf*HRP2 and immobilized divalent metal ions. The functionalization of these membranes with chelating ligands and divalent metalions was first optimized for the capture of *Pf*HRP2. More than 99% of the *Pf*HRP2 was extracted from a 250 μL blood sample in a simple flow-through assay and 89% of the captured protein was eluted from the membrane using ethylenediaminetetraacetic acid. Use of this enhancement protocol on an in-house HRP2 lateral flow assay (LFA) yielded a limit of detection of 3 parasites/μL. A histidine-rich *P*LDH-specific capture agent (*P*CA) was then developed to allow for capture of both *P*LDH and *Pf*HRP2 on the surface of the modified membrane. Using the novel *P*CA, 80% of *P*LDH was immobilized on the membrane. Future work will include optimization of *P*LDH elution from the membrane and integration with a PLDH-specific LFA for point-of-care detection of both biomarkers.

905

ATYPICAL *PLASMODIUM FALCIPARUM* SEEN IN GIEMSA-STAINED SMEAR

Mamadou Alpha Diallo, **Ndeye Anna Seck**, Khadim Diongue, Mouhamadou Ndiaye, Aida Sadikh Badiane, Mame Cheikh Seck, Daouda Ndiaye

Cheikh Anta Diop University, Dakar, Senegal

A 4-year-old boy was admitted to a health post of Kedougou, Senegal, for fever, headache and vomiting. As the patient was suspected of uncomplicated malaria he was tested using an HRP-2 based RDT which came out positive for *Plasmodium falciparum*. Giemsa-stained thick and thin smear was then performed. However, the microscopic examination showed *Plasmodium*-infected erythrocytes that have features of both *P. falciparum* and *P. ovale* - both of which are endemic in Senegal. This could lead to misdiagnosis for an inexperienced microscopist. In fact, it was observed that many of infected red blood cells (RBCs) were oval in shape with fimbriated edges which is consistent with *P. ovale*. For differential diagnostic, additional details were observed; the presence of Maurer clefts alone was indicative of *P. falciparum*. In addition, the smear was monotonous with high parasitemia. The diagnosis of *P. falciparum* malaria was confirmed by PCR; no other malarial species were associated. The patient was treated effectively with artemether/lumefantrine and he had significant clinical improvement over the next three days. The diagnosis of *P. falciparum* is usually made by microscopy, demonstrating the presence of young trophozoites in Giemsa-stained thick and thin films. Infected red blood cells (RBCs) are usually normal in size with no significant change. *P. falciparum* rings are typically small with regular small and curved cytoplasm. In well-stained thin films Maurer clefts may be observed in RBC infected with mature trophozoites. In some cases mature trophozoites of *P. falciparum* may cause red blood cell deformation which may lead to confusion with another species. Here, the unusual elongated infected RBCs resembled the ones of *P. ovale* infection. Maurer's clefts may resemble the Schüffner's dots seen in *P. vivax* and *P. ovale*, but are usually larger and more coarse. Additionally, Maurer's clefts in this case are few in number and do not cover the whole infected RBC as it should be seen in *P. ovale* and *P. vivax*. Accurate identification of the *Plasmodium* species may be difficult or uncertain due to variations in morphological characteristics within *P. falciparum* specie.

906

IMPROVEMENT OF MALARIA DIAGNOSIS THROUGH OUTREACH TRAINING AND SUPPORTIVE SUPERVISION (OTSS) IN BENIN FROM 2015 TO 2018

Augustin Kpemasse

National Malaria Control Program, Cotonou, Benin

Malaria is the leading cause of morbidity and mortality in Benin. In 2015, the National Malaria Control Program (NMCP), with the support of the

U.S. President's Malaria Initiative (PMI), launched Outreach Training and Supportive Supervision (OTSS) to improve malaria microscopy diagnostics in Benin. A total of 123 health facility laboratories were enrolled into the OTSS scheme. OTSS consisted of 1) updating national malaria microscopy guidelines to reflect World Health Organization recommendations and 2) expert microscopists performing semiannual supervision in all enrolled health facilities. Every six months, OTSS supervision teams verified the availability of laboratory equipment, supplies, and consumables in all enrolled facilities, performed quality control assessments of a random sample of stored slides from the facility through a double reading process, and made recommendations for improvement. Each supervision visit was followed with close monitoring of the implementation of recommendations. From 2015 to 2018 significant improvements in OTSS indicators occurred. The percentage of functional microscopes in enrolled laboratories increased from 64% to 70%. The percentage of health facilities with stock-outs in methanol decreased from 23% to 3%. The overall sensitivities for all participants against expert microscopists increased from 75% to 92% and the overall specificities increased from 89% to 100%. In addition, the rate of correct identification of *Plasmodium falciparum* species rose from 82% to 100%. OTSS improved the quality of malaria diagnosis by microscopy through the rigorous monitoring of adherence to protocols, standards, and guidelines. OTSS also helped enhance provider performance. OTSS should be maintained and scaled-up to maintain a high level performance of malaria microscopy in Benin.

907

A SYSTEMATIC REVIEW OF NOVEL BIOMARKERS FOR MALARIA DIAGNOSIS

Ewurama D. Owusu, Augustina Frimpong, **Seda Yerlikaya**, Xavier Ding

FIND, Geneva, Switzerland

Prompt diagnosis and treatment of malaria have consistently been shown to be the most effective way of preventing an uncomplicated case of malaria from developing into a severe one. Increasingly the most common diagnostic tests used to detect malaria among suspected patients are rapid diagnostic tests (RDT) which rely on the identification of parasite-specific biomarkers in bodily fluids like blood and urine. Plasmodial antigens histidine-rich protein 2 (HRP2), *Plasmodium* lactate dehydrogenase and aldolase are the three traditional biomarkers currently in use, but there are challenges with their clinical performance in the context of changing malaria epidemiology. Efforts to identify novel biomarkers are ongoing for diagnostic development a. We report here the results of a systematic review of published data on biomarker candidates for malaria diagnosis and provide, for the first time, a comprehensive analysis of the current landscape of biomarkers with the potential to overcome the limitations of HRP2 and pLDH. A comprehensive search term was composed and used to perform a systematic search of MEDLINE, EMBASE, Web of Science, and CENTRAL databases, as well as grey literature to identify original research, which report on biomarker candidates for malaria diagnosis. After removing duplicates, 4103 records remained for screening. Data from studies eligible for inclusion have been extracted and sorted by pre-defined variables, providing a comparative analysis of malaria biomarker candidates and identifying those well-suited for the development of novel diagnostic tests for uncomplicated malaria diagnosis based on nature and origin of biomarker, diagnostic developmental stage, and method/sample type used for detection. This study will enable a comprehensive database of malaria biomarker candidates and help synergize product development efforts globally.

EVALUATION OF THE PERFORMANCE OF SD-BIOLINE MALARIA RAPID DIAGNOSTIC TEST CARRIED OUT BY COMMUNITY MEDICINE DISTRIBUTORS AGAINST MICROSCOPY AND PCR IN THE DIAGNOSIS OF MALARIA IN SOUTHWEST NIGERIA

Catherine Olufunke Falade[1], IkeOluwapo Oyeneye Ajayi[1], Ayodele Samuel Jegede[1], Chinenye Afonne[1], Tolulope Ogunsesin[1], Roland I. Ibenipere Funwei[1], Olusola Ojurongbe[2], Jan Singlovic[3], Melba Gomes[3]

[1]*University of Ibadan, Ibadan Nigeria, Ibadan, Nigeria,* [2]*Ladoke Akintola University of Technology, Oshogbo, Nigeria,* [3]*UNICEF/UNDP/World Bank/WHO/Special Programme for Researchmand Training in Tropical Disease, World Health Organization, Geneva, Switzerland*

The WHO recommends that malaria diagnosis be parasite-based as much as possible. Malaria rapid diagnostic test (MRDT) is the preferred option for programmatic use. This study set out to evaluate the performance of SD-Bioline™, an HRP-II based MRDT performed by trained voluntary community medicine distributors (CMD) during a pilot study of parasite-based diagnosis of malaria in a rural community in south west Nigeria, where malaria transmission is intense. MRDT, thick blood smears and dried blood spots (DBS) on filter paper were performed from finger prick blood samples during a cross-sectional study of febrile children aged 3 to 59 months presenting to CMD in Ona-Ara Local Government Area, Southwest Nigeria. MRDT was read at study site by trained CMDs according to manufacturer's instructions. Blood smears and DBS were processed in the laboratory using standard procedures. More than half, (52.4%; 547) of 1043 enrollees were females. The mean age of the study participants was 17.86 ±10.6 months (range 3-59 months). Malaria parasite was detected in 821 (78.7%) by MRDT, 574 (55.0%) by microscopy and 721 (69.18%) by PCR. Over 90% of the blood smears were readable. The Geometric mean parasite density was 6,735/μL; range: 40 - 317,200/μL. The sensitivity, specificity, PPV. NPV, accuracy and κ-value for SD-Bioline MRDT using microscopy as gold standard were 92.5%, 38.2%, 64.8%, 80.6%, 68.15 and 0.322 respectively. Corresponding figures when PCR was used as the gold standard were 88.2%, 42.6%, 88.2%, 61.7% 74.0% and 0.336 respectively. When microscopy was compared to PCR, corresponding values were 93.9%, 61.6%, 79.8%, 89.4%. 79.2% and 0.567 respectively. Speciation revealed that *Plasmodium falciparum* constituted 97.8% (707/721) of detected malaria parasites while *P. malariae constituted* 4.4% (32/721) and *P. ovale,* 2.5% (18/721). *P. malariae* and *P. ovale* occurred as co-infections with *P. falciparum* in 71.9% (23/32) and 72.2% (13/18) of cases. *P. vivax* was not detected. Trained community medicine distributors successfully performed MRDT, Blood smears and DBS thus providing parasite-based diagnosis of malaria at the community level.

909

ASSESSMENT OF COMPETENCE OF PARTICIPANTS BEFORE AND AFTER 6-DAY INTENSIVE MALARIA MICROSCOPY TRAINING IN RWANDA

Noella Umulisa[1], Veneranda Umubyeyi[1], Tharcisse Munyaneza[2], Ruzindana Emmanuel[2], Aline Uwimana[3], Stephen Mutwiwa[1], Aimable Mbituyumuremyi[3]

[1]*Maternal and Child Survival Program/Jhpiego, Kigali, Rwanda,* [2]*National Reference Laboratory (NRL), Rwanda Biomedical Centre (RBC), Kigali, Rwanda,* [3]*Malaria and Other Parasitic Diseases Division (Mal & OPDD), Rwanda Biomedical Centre (RBC), Kigali, Rwanda*

Microscopic diagnosis of Giemsa stained thick and thin blood films by skilled microscopists has remained the gold-standard laboratory method for the diagnosis of malaria. Sufficient training of laboratory staff is paramount for the correct microscopic diagnosis of malaria. The aim of this assessment was to evaluate laboratory technicians' performance diagnosing malaria by microscopy at health facility level within 6 districts in Rwanda. In May 2018, the Maternal and Child Survival Program (MCSP),

in collaboration with the Rwanda Biomedical Center (RBC), conducted a 6-day malaria microscopy training for laboratory technicians from 75 health facilities located in six districts in Rwanda. The training puts emphasis on practical compared to theoretical sessions when determining parasite density and detection of malaria species. In August 2018, the MCSP with RBC conducted a follow-up assessment. Of the 75 technicians trained, 35 were randomly chosen and assessed at their respective health facilities. Assessment teams distributed standardized pre-validated slide-panels to each technician. The laboratory technicians were requested to report parasite densities using the semi-quantitative (+) method. During the training, a significant improvement was found between pre and post-tests scores, with median scores improving from 52% to 85%. The overall post-training sensitivity and specificity of laboratory technicians in detecting malaria parasites were 99.6% and 85.16% respectively while positive predictive value and negative predictive value were 98.5% and 95.8% respectively. Species identification and parasite quantification accuracy were 90% and 88% respectively. The percent agreement between laboratory professionals and expert microscopists in the detection of malaria parasites was 90.7% with a Kappa index of 0.89. This assessment demonstrates laboratory technicians' satisfactory performance concerning parasite species and density detection while illustrating the importance of continuous capacity building of laboratory technicians to ensure accurate diagnosis for the appropriate treatment of malaria.

910

PERFORMANCE OF A HIGH SENSITIVITY MUSE® MALARIA *P.F.-P.V.* DETECTION ASSAY IN A STUDY IN LAGOS, NIGERIA

Wellington Oyibo[1], Chinonye Anabike[1], Bummi Olalekan[1], Ginika Onuachwusi[1], Adeyanju Adeyinka[1], Gracemary Ndidium[1], Uche Igbasi[1], Julie Clor[2], James Mulry[3], **Kamala Tyagarajan**[2]

[1]*ANDI Centre of Excellence for Malaria Diagnosis, Lagos, Nigeria,* [2]*Luminex Corporation, Hayward, CA, United States,* [3]*Merck Global Health Institute, Germany, Germany*

Effective malaria diagnosis is critical in the implementation of current malaria case management strategies. The need for development of high sensitivity detection methods which also provide typing of malarial parasites has been amplified. While microscopy is considered a gold standard, it requires a high degree of operator expertise and training to provide reliable and sensitive results. A new method has recently emerged, which uses microcapillary cytometry on the low cost Muse® Cell Analyzer along with the Muse® Malaria *P.f.-P.v.* Detection Assay. The assay uses multiplexing to confirm the presence of malarial parasite antigens by detecting *P.f.* HRP2, *P.f.* LDH, and *P.v.* LDH antigens in parallel with high detection sensitivity down to a few parasites/μL. In this study, we evaluated the research use only Muse Malaria *P.f.-P.v.* Detection Assay with fresh EDTA-whole blood samples in our laboratory in Lagos, Nigeria. In total, 62 adult and pediatric samples with parasitemia of 19-450,000 parasites/μL were examined. Data on the samples was obtained using three methods: malaria microscopy of Giemsa-stained blood films; malaria RDT (SD Bioline P.f/Pan); and the Muse Malaria *P.f.-P.v.* Detection Assay. Comparison of results from the Muse Assay demonstrated excellent agreement with expert microscopy as well as RDTs. Clear shifts were observed from low to high parasitemia, making interpretation simple. Compared to microscopy, the sensitivity of the assay was 100% and the specificity of the assay was 95.24% for the limited sample set. It was noted that while Muse HRP2 and RDT HRP2 test results were similar to microscopy, pLDH RDT results were much less sensitive compared to microscopy. Muse *P.f.* LDH results showed correspondence to microscopy results. The assay with dual high sensitivity *P. falciparum* markers provided high confidence when analyzing *P. falciparum* samples, and also ensured that *P. vivax* LDH antigens were not being missed. The Muse Malaria *P.f.-P.v.* Detection Assay can be a valuable high sensitivity tool in research laboratories to ensure *Plasmodium* antigens are appropriately detected and classified.

911

DIAGNOSIS OF RED CELL GLUCOSE-6-PHOSPHATE DEHYDROGENASE (G6PD) DEFICIENCY IN BURKINA FASO: COMPARISON OF QUANTITATIVE AND QUALITATIVE TESTS

Edith C. Bougouma[1], Emelie Badoum[2], Sam Coulibaly[1], Samuel Serme[1], Issiaka Soulama[1], Alphonse Ouedraogo[1], Alfred B. Tiono[1], Sodiomon B. Sirima[1]

[1]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso,* [2]*Université de Ouagadougou, Ouagadougou, Burkina Faso*

G6PD deficiency is the most widespread enzyme defect that can result in red cell breakdown under oxidative stress when exposed to certain medicines including antimalarials. Development of reliable, easy-to-use, rapid diagnostic tests (RDTs) to detect G6PD deficiency at point of care is essential to deploying primaquine therapies as part of malaria elimination strategies We compared CareStart™ test kits for G6PD deficiency screening test (CSG) and G6PD BinaxNow text kits to by comparing its performance to quantitative G6PD enzyme activity using a Fluorescent spot test (FST) a quantitative G6PD enzyme activity test and colorimetric method. The study took place in Banfora, Participant with G6PD deficiency status was checked in study participants in the field conditions (capillary blood: CBS) with Diagnostic CSG Test then invited to the laboratory where venous blood samples (VBS) were collected and tested for G6PD deficiency two qualitative G6PD RDTs Tests (CSG and BinaxNow) and semi quantitative method (FST). Results were compared with the quantitative spectrophotometric analysis of G6PD activity. Comparison was also done between CBS and VBS. Sensitivity (SE) of CSG (97.14%), BinaxNow (97.06%) and FST (97.7%) tested with venous blood were comparable ($p>0.05$).The specificity (SP) scores for the three tests (CSG, BinaxNow and FST) compared to Colorimétric were 53.70%, 52.72% and 59.18% respectively. When the CSG tests were performed on capillary blood samples or on venous blood samples, SE of CSG was not comparable ($p< 0.05$). In conclusion, all the three test formats had a highest SE when performed on VBS and was comparable to the Colorimetric. The FST had the highest SP among all tests formats. The performance and operational characteristics of the CSG performed on VBS suggest the test to be a good alternative to the Semi quantitative and quantitative where basic laboratory equipment are lacking. Our observations underscore the need for improved CSG test sensitivity using CBS. Ensuring safe use of 8-aminoquinolines depends on highly sensitive and specific G6PD deficiency diagnostic tests suitable for routine use in the field.

912

PERFORMANCE OF THE PFHRP2 BASED RAPID DIAGNOSTIC TEST (CARESTART™) IN THE DETECTION OF ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTION IN BOUGOUNI, MALI

Modibo Diarra[1], Amadou Tapily[1], Issaka Sagara[1], Hama Yalcouyé[1], Amadou Barry[1], Aly Tiama[1], Seydou Goro[1], Samba Coumaré[1], Mohamed Koné[1], Ismaila Thera[1], Irene Kuepfer[2], Matthew Cairns[2], Paul Milligan[2], Daniel Chandrahoman[2], Brian Greenwood[2], Alassane Dicko[1]

[1]*Malaria Research and Trainig Center/University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Rapid Diagnostic Tests are used routinely for the diagnosis of clinical malaria by health care workers. However, their ability to detect asymptomatic *Plasmodium falciparum* infection has not been adequately studied in endemic areas. Here we assessed the performance of a PfHRP2 based Rapid Diagnostic Test (RDT) CareStarT^{M} for the detection of asymptomatic malaria infections in Bougouni, Mali. A total of 2001 children, aged 6 to 59 months enrolled in a large trial of seasonal malaria chemoprevention (SMC) with or without Azithromycin were surveyed in December 2016, 4-6 weeks after the last SMC cycle. RDT were undertaken and blood smears collected from all children. Overall, 10.1% (203/2001) of children had a positive malaria blood smear and 16.8% (337/2001) had

a positive RDT. Compared to blood smear, the sensitivity of RDT was low 69.9 % (95% CI 63.6%- 84.9%) while the specificity was high 88.9%, (95% CI: 87.4%- 94.9%). The negative predictive value was high 96.3% (95% CI: 95.3% -100.0%) while the positive predictive value was low 42.1% (95% CI: 36.8%- 50.4%). The PfHRP2 based Rapid Diagnostic Test CareStarT^{M} test has good specificity and good negative predictive value for the detection of asymptomatic malaria, but the sensitivity and the positive predictive values were low. More sensitive RDTs are needed for the detection of asymptomatic malaria to support the malaria elimination initiative in Sahelian countries.

MALARIA PRESCRIBING PRACTICES AT AN URBAN HEALTH CENTER IN KUMASI, GHANA

Mariah Owusu-Agyei[1], Ernest Adjei[2], Christian K. Addai[2], Michael K. Addei[2], Peter K. Brenya[2], Roland Abbey[2], Tsiri Agbenyega[3], Michael Cappello[4]

[1]*University of Pennsylvania, Philadelphia, PA, United States,* [2]*HopeXchange Medical Centre, Kumasi, Ghana,* [3]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [4]*Yale University, New Haven, CT, United States*

Up to 90% of patients presenting with fever to healthcare centers in sub-Saharan Africa are treated presumptively for malaria. Since overtreatment could lead to antimalarial drug resistance, the WHO launched the "Test-Treat-Track (T3)" initiative to encourage diagnostic testing for every suspected case of malaria prior to treatment. This study aimed to characterize the diagnostic features and prescribing practices for malaria at HopeXchange Medical Center, a recently established public-private facility in Kumasi, Ghana (pop. 2.06 million). We conducted a retrospective chart review of patients prescribed antimalarials between January 2017-December 2018. Records were reviewed for malaria test results, fever, and co-treatment with antibiotics. Data were analyzed using descriptive statistics and Chi-square tests, followed by logistic regression modelling to assess factors associated with diagnostic testing . Over 24 months, 5040 patients were prescribed antimalarials. Among this group, 22.7% (1145/5040) had fever at presentation and 63.7% (3208/5040) had a diagnostic test performed. Treated patients were more likely to have a malaria diagnostic test performed if they were younger, admitted to the inpatient service, febrile, and covered by insurance. Inpatient status was the strongest predictor of receiving a malaria test (Odds Ratio=4.99 [3.88,6.42]). Among patients tested for malaria, 68.9% (2209/3208) had a positive result, while the remainder were treated despite testing negative. In addition, 38.7% (1950/5040) of patients were co-treated with antibiotics. The number of patients who received treatment in the absence of a positive diagnostic test result is high (56.2%), suggesting that clinicians frequently rely on clinical signs and symptoms to guide therapeutic decisions for malaria. However, a minority of treated patients presented with fever, suggesting that other clinical features drive decision making at HopeXchange. Further study of prescribing practices is needed in order to define barriers to WHO guideline adherence in the management of malaria in high-transmission urban settings.

914

EVALUATING SEROLOGY-BASED RAPID DIAGNOSTIC TESTS AS A TOOL TO IMPROVE *PLASMODIUM FALCIPARUM* SURVEILLANCE IN LOW-TRANSMISSION SETTINGS

Monique Ambrose[1], Victoria M. Hunt[2], Christine M. Bachman[2], David Cate[3], Bernhard H. Weigl[3], David Bell[3], Chris Drakeley[4], Caitlin Bever[1], Jaline Gerardin[5]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*Global Good, Intellectual Ventures, Bellevue, WA, United States,* [3]*Intellectual Ventures, Bellevue, WA, United States,* [4]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [5]*Northwestern University, Evanston, IL, United States*

Surveillance programs in low-transmission settings may fail to accurately estimate local transmission levels due to the scarcity of active infections detectable by conventional rapid diagnostic tests (RDTs). To increase surveillance power in these settings, diagnostic tests capable of detecting antimalarial antibodies that persist for months after parasite clearance are under development. Here, we use a mechanistic model of malaria transmission (EMOD) to quantify the performance characteristics that would allow an RDT based on serological biomarkers to outperform existing HRP2-based case-management RDTs. We consider two *Plasmodium falciparum* surveillance use cases for these 'serology RDTs': stratifying villages for targeted interventions and certifying areas as free of recent local transmission. Our analyses reveal that the surveillance season and geography strongly influence the relative performance of the two types of RDTs: compared to the HRP2-based RDT, the serology RDT performs best when surveillance occurs during the low-transmission season in regions with high seasonality. For example, to outperform HRP2-based RDTs in both use cases, a serology RDT that detects infection for a mean of 240 days after parasite clearance and has 98% specificity would need ≥60% sensitivity when surveillance is conducted in the wet season but only ≥40% sensitivity when surveillance is conducted in the dry season. We also find that serology RDTs that detect infection for a mean of 240 days after parasite clearance improve surveillance power compared to those with shorter detection periods (60 or 120 days). By contrasting the performance of existing HRP2-based RDTs and hypothetical serology RDTs, this modeling analysis will inform target product profiles and guide development of high-value diagnostic tools.

915

IMPACT OF ULTRASENSITIVE MALARIA DIAGNOSTICS ON ASYMPTOMATIC PREGNANT MOTHERS IN AMHARA REGION, ETHIOPIA

Banchamlak Tegegne[1], Gizachew Yismaw[1], Ranmalee Amarasekara[2], Abu Naser Mohon[2], James Cheaveau[2], **Dylan R. Pillai**[2]

[1]*Amhara Public Health Inst, Bahir Dar, Ethiopia,* [2]*University of Calgary, Calgary, AB, Canada*

According to the WHO, in Africa, 30 million women living in malaria-endemic areas become pregnant each year. Up to 200,000 newborn deaths each year result from malaria in pregnancy. Diagnosis of malaria in pregnancy is limited by microscopy with poor sensitivity. Malaria, particularly due to *P. falciparum*, in pregnant women increases the risk of maternal death, miscarriage, stillbirth and neonatal death. Ethiopia currently requires diagnosis of malaria in pregnancy in order to treat with antimalarials and does not employ IPTP. We conducted a comparative diagnostic study with LAMP (Illumigene Malaria) compared to traditional diagnosis with microscopy in both asymptomatic and symptomatic pregnant mothers at Jawi Health Centre in Amhara Region during peak transmission season (2018). In the study population, 29 of 36 mothers (mean age 24.2 years) who presented to the antenatal clinic were asymptomatic. Of the 29 asymptomatic mothers, 23 were in the first trimester and 17 were multigravida, Malaria positivity amongst asymptomatic mothers was 2/29 (6.9%) by microscopy, 1/29 (3.4%) by RDT, 9/29 (31%) by LAMP, and 9/29 (31%) by ultrasensitive qRT-PCR. The sensitivity of microscopy in asymptomatic pregnant mothers was 25.0% (95% CI 3.19% - 65.09%), RDT 12.5% (0.32% - 52.65%), LAMP 87.50% (47.35% - 99.68%) and qRT-PCR 87.50% (47.35% - 99.68%) using a consensus gold standard. These data suggest that ultrasensitive diagnostics are able to detect malaria far more frequently than currently approved diagnostic tools. Current efforts are focused on following mothers treated with asymptomatic carriage to determine the impact on maternal and fetal outcome including anemia and birthweight of the infant.

916

PLATE-BASED ASSAY FOR TYPING AND CHARACTERIZING *PLASMODIUM* ANTIGENS USING MICROCAPILLARY CYTOMETRY

Julie Clor, Xuemei Wan, Kamala Tyagarajan

Luminex Corporation, Hayward, CA, United States

Malarial research spans a wide variety of researchers, from labs using simplified technologies that are more proximal to samples, to labs involved in large scale, complex studies that are interested in the parallel analysis of a large number of samples. We recently demonstrated the performance of the Muse® Malaria *P.f.-P.v.* Detection Assay, a research use only, bead-based immunoassay for the detection of *Plasmodium falciparum*, *Plasmodium vivax,* and mixed infection samples, on the simple, low cost Muse Cell Analyzer for simplified yes/no callouts. In this study, we explore the application of the Muse Malaria *P.f.-P.v.* Detection Assay on the Guava® easyCyte™ 12HT System, a benchtop flow cytometer based on principles of microcapillary cytometry that enables analysis in a 96-well plate format. The system allows for automated walkaway acquisition of samples in a plate after sample preparation. Further, the InCyte™ Software package associated with the platform contains a heat mapping feature that allows for rapid and easy detection of all three malarial antigens, providing an immediate view of experimental "hits". In addition, quantitative comparisons can be obtained by exporting MFI information with standards of known concentration included to predict antigen concentration in samples being studied. Dynamic range data and the application to frozen blood samples from *P. f.*, *P. v.,* and mixed infection donors using the easyCyte 12HT System will also be presented. The plate-based adaptation of the assay provides excellent performance across a wide range of parasitemia and exhibits superior detection sensitivity of a few parasites/µL for both *P.f.* and *P.v.* detection, when compared to traditional methods such as microscopy and RDTs. The availability of simple, plate-based approaches for the rapid analysis of multiple antigens in a large number of malarial samples can enhance speed and detection capability for malarial researchers spanning all kinds of labs.

917

OPERATIONAL PERFORMANCE OF A HIGHLY-SENSITIVE DIAGNOSTIC METHOD FOR DETECTION OF MALARIA INFECTIONS IN PREGNANCY IN PAPUA NEW GUINEA

Benishar Kombut[1], Pele Melepia[2], Ruth Fidelis[2], Elma Nate[3], Lina Lorry[3], Livingstone Tavul[3], Maria Ome-Kaius[4], Michelle JL Scoullar[5], Philippe Boeuf[5], Shazia Ruybal-Pesántez[4], Michaela Riddell[6], Lisa Vallely[6], Andrew Vallely[6], Chris Morgan[5], Freya JI Fowkes[5], James Beeson[5], Jack Richards[5], Benedict Mode[7], William Pomat[8], Ewurama Owusu[9], Sandra Incardona[9], Xavier C. Ding[9], Stenard Hiasihri[2], Moses Laman[3], **Leanne J. Robinson**[5]

[1]*PNG Institute of Medical Research; Burnet Institute, Kokopo, Papua New Guinea,* [2]*Burnet Institute, Kokopo, Papua New Guinea,* [3]*PNG Institute of Medical Research, Madang, Papua New Guinea,* [4]*Walter & Eliza Hall Institute of Medical Research, Melbourne, Australia,* [5]*Burnet Institute, Melbourne, Australia,* [6]*Kirby Institute, Sydney, Australia,* [7]*East New Britain Provincial Government, Kokopo, Papua New Guinea,* [8]*PNG Institute of Medical Research, Goroka, Papua New Guinea,* [9]*FIND, Geneva, Switzerland*

Plasmodium falciparum infections during pregnancy contribute to adverse outcomes, such as maternal and neonatal anaemia, as well as low birth weight. These infections are often sub-clinical and difficult to diagnose due to placental parasite sequestration giving rise to low-level peripheral parasitaemia. Studies using sensitive polymerase-chain reaction (PCR) techniques indicate that at least half of all infections in maternal venous blood are missed by light microscopy or conventional rapid diagnostic tests. The aim of this study is to assess the performance of a new highly sensitive rapid diagnostic test (HS-RDT) for the detection of *P. falciparum* infections during pregnancy in Papua New Guinea (PNG). The study is ongoing and will screen 940 pregnant women attending ante-natal care clinics in Gazelle, Kokopo and Rabaul Districts of East New Britain Province (ENB), PNG. The HS-RDT and conventional malaria HRP2/pLDH(Pf/Pan) Combo test are being performed in the clinic, with Pan/Pf/Pv loop-mediated isothermal amplification (LAMP) performed in the laboratory on the same day, and light microscopy and quantitative real-time PCR (qPCR) performed retrospectively. The performance of the HS-RDT will be compared with Pf/Pan RDT, light microscopy and LAMP in peripheral blood samples, with qPCR as reference standard. The performance of LAMP for the detection of *P. falciparum* and *P. vivax* infections in pregnancy will similarly be evaluated, using qPCR as reference test. We are also assessing health service measures of feasibility and acceptability of point-of-care options. Preliminary data indicates a moderate burden of malaria and a high burden of anaemia in pregnancy in ENB and full results will be available for presentation at the meeting. This study will provide critical evidence to guide the improved detection of malaria infections in pregnancy in PNG and other co-endemic settings.

918

FACTORS ASSOCIATED WITH SEVERE MALARIA DEATHS: LESSONS FROM A MORTALITY AUDIT CONDUCTED IN HEALTH FACILITIES IN UGANDA

Patrick Bukoma[1], David O. Salandini[1], Viola Nampera[1], JohnBaptist Bwanika[1], Ruth N. Kigozi[1], Sam S. Gudoi[1], Jane Nabakooza[2], Julius K. Kuule[2], Kassahun Belay[3], Gloria Ssebikaari[3], Mame Niang[4], Peter mukobi[5], James Tibenderana[6], Peter Thomas[4]

[1]*PMI Malaria Action Program for Districts Project, Uganda, Kampala, Uganda,* [2]*Uganda National Malaria Control Program, Kampala, Uganda,* [3]*US President's Malaria Initiative, US Agency for International Development, Kampala, Uganda,* [4]*US President's Malaria Initiative, Malaria Branch, Centers for Diseases Control and Prevention, Atlanta, GA, United States,* [5]*Ministry of Health, Kampala, Uganda,* [6]*Malaria Consortium, London, United Kingdom*

Malaria is among the leading causes of morbidity and mortality in Uganda. In 2016, Ministry of Health (MoH) adopted clinical audit guidelines to improve quality of severe malaria management in health facilities (HF), aiming to achieve 'near zero' deaths by June 2020. Between 2017 and 2019, to help strengthen severe malaria management, the US President's Malaria Initiative supported the PMI Malaria Action Program for Districts (MAPD) Project to conduct a criteria-based review—based on MoH malaria guidelines in HF, seeking to identify factors associated with malaria deaths in two hospitals and one HC, selected purposively having reported the highest numbers of malaria deaths in the national health management information system. Joint MAPD and MoH audit teams collected data on HF systems, patient satisfaction, clinical and laboratory diagnosis and, care and treatment practices. We used WHO definitions of complications to assess diagnosis, yet they were not in the national treatment guidelines. Descriptive data analysis was conducted. The overall average score of 66% on HF functionality, competency and patient satisfaction indicators was well below the 80% clinical audit target. Health worker (HW) recognition of danger signs of complications was very low—24%; notably dyspnoea—8%, convulsions—20% and altered sensorium—23%. Half—54%, the deaths were treated for malaria without laboratory confirmation. 45% of deaths had investigations for alternative diagnoses and biochemistry; no death had tests to confirm treated bacterial infections. 93% deaths had received first line treatment for severe malaria according to MoH guidelines; a third—32% concurrently received antibiotics, while 94% deaths had not received intensive care. The Systems and practices in place were inadequate to ensure quality healthcare in the three HF. Thus, inadequate recognition and treatment of complications appear to be key factors in malaria deaths, and should be addressed at both system and HW levels. Adoption of WHO definitions of malaria complications in national treatment guidelines is needed to better guide diagnosis and treatment of severe febrile illness.

919

AN ULTRA-SENSITIVE PF-HRP2 ELISA FOR THE DETECTION OF LOW-DENSITY FALCIPARUM MALARIA

Diane D. Hall, Neil C. Marshall, Anthony M. Smithyman, G. H. Rajasekariah

Cellabs, Sydney, Australia

The WHO 2015 Global Technical Strategy for Malaria 2016-2030 made significant progress through the period 2015-2018, with often dramatic declines in malaria deaths and overall incidence, resulting in an estimated 10 countries primed for malaria elimination by 2020. However effective elimination strategies may also significantly reduce malaria parasite densities in the population, below the limit of detection of the conventional rapid diagnostic tests being used in elimination campaigns. The new challenge for the elimination effort is to determine whether these lower parasite densities still allow transmission of infection, as seen in past eradication programmes, where resurgence has been observed to confound the gains in eradication. But without sufficiently sensitive diagnostic tools this will be difficult. Thus there is now an urgent need for higher sensitivity tests to study the dynamics of transmission in low-density settings. We report here the development of a next-generation, ultra-sensitive and quantitative ELISA based on the long-established WHO reference kit, the Malaria Ag CELISA. The newly developed Quantimal Ultra-sensitive Pf-HRP2 CELISA was designed to provide a limit of detection as low as 10 picogram per mL Pf-HRP2, estimated to represent 1 parasite per mL. Included is a reference positive control calibrated using a *Plasmodium falciparum (Pf)* recombinant antigen. This positive control is an essential component used to construct a standard curve, allowing the quantitative determination of PfHRP2 in samples. This ultra-sensitive assay may be useful in supporting low-density *Pf* transmission surveillance and elimination activities.

920

MALARIA RAPID DIAGNOSTIC TESTS AS DNA STORAGE TOOL TO QUANTIFY *PLASMODIUM SPP* INFECTION

Etienne A. Guirou[1], Tobias Schindler[1], Maximilian Mpina[1], Salome Hosch[1], Glenda Cosi[1], Anna Deal[1], Silvan Wehner[1], Kamaka Ramadhani[2], Jongo Said[2], Carlos Cortes[3], Wonder Phiri[3], Jose Osa Osa Nfumu[3], Charity Okoro Eribo[3], Olivier Tresor Donfack[3], Guillermo A. Garcia[4], Claudia Daubenberger[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*Ifakara Health Institute, Bagamoyo, United Republic of Tanzania,* [3]*Medical Care Development International, Malabo, Equatorial Guinea,* [4]*Medical Care Development International, Silver Spring, MD, United States*

Rapid and accurate diagnosis of malaria is essential for control and relies on Rapid Diagnostic Tests (RDTs) and microscopy. Most commercialized RDTs detect *Plasmodium falciparum* Histidine Rich Protein 2 (PfHRP2) but are limited in detecting asymptomatic, low parasitemic *P. falciparum* infections. RDTs do not discriminate between the different non-falciparum malaria species. Quantitative polymerase chain reaction (qPCR) is more sensitive and enables to distinguish the different *Plasmodium* species. We developed and evaluated a novel, cheap, high-throughput method to extract DNA from RDTs followed by qPCR assays to identify and quantify *P. falciparum* and non-falciparum infections. Our approach is supported by novel software solutions for the identification of barcoded RDTs and automated analysis pipelines to quality control qPCR data generated. We applied our new DNA extraction and qPCR data analysis pipeline in a subset of RDTs collected during the 2018 Malaria Indicator Survey conducted on the island of Bioko in Equatorial Guinea. RDTs collected from 227 pregnant and 209 non-pregnant, age matched women were included. We found that the proportion of *Plasmodium* infection was higher in non-pregnant (13.46%, 28/208) compared to pregnant women (6.61%, 15/227) (p=0.02). Nine *P. falciparum* infections were detected by qPCR that were missed by RDTs. Ten malaria positive RDTs were identified lacking qPCR amplification, indicating that circulating PfHRP2 after successful malaria treatment might be detected. Parasite density was low in both groups of women (range 1 - 2165 parasites/μL). Among the pregnant women, we detected more infections in first trimester (n=6) compared to second (n=4) and third trimester (n=4) of pregnancy. Importantly, *Plasmodium* positive pregnant women had lower mean hemoglobin levels compared to non-infected pregnant women. *P. malariae* was detected in one pregnant and in two non-pregnant women. Here, we demonstrate the feasibility of extracting DNA from used RDTs to identify and quantify *Plasmodium spp.* at high throughput facilitating unprecedented malaria surveillance at the molecular level.

921

PERFORMANCE OF A NOVEL HEMATOLOGY ANALYZER FOR MALARIA DIAGNOSIS IN AN ENDEMIC REGION OF COLOMBIA

Tatiana Maria Lopera-Mesa[1], Lina Zuluaga-Idarraga[1], Alexandra Rios[1], Veronica Sierra[1], Edwar Garzón[1], Ikki Takehara[2], Yuji Toya[2], Chiaki Takeuchi[2], Kinya Uchihashi[2], Alberto Tobón-Castaño[1]

[1]*Universidad de Antioquia, Medellin, Colombia,* [2]*Sysmex Corporation, Kobe, Japan*

Early and accurate detection of *Plasmodium* is critical to reduce malaria morbidity and mortality. Microscopic parasite identification is the diagnostic gold standard; however, it requires expert personnel and has limited sensitivity. Performance of Sysmex's analyser XN-30 for malaria diagnosis is described and compared to microscopy and real-time PCR (RT-PCR) in an endemic area of Colombia where *P. falciparum* and *P. vivax* are present. Acute febrile patients were enrolled between July 2018 and March 2019 in Quibdó city (Pacific region). Malaria diagnosis was done by microscopy / RDT in the field, and later confirmed by RT-PCR. Venous blood in EDTA was processed on the XN-30 within 4h of collection. Sensitivity, specificity, positive/negative predictive values (PPV, NPV), and likelihood ratio of positive and negative tests (LRP and LRN), were calculated. The intra-class correlation coefficient (ICC) and Bland-Altman plot were used to evaluate concordance of parasitemia. A total of 1,389 enrolled subjects were screened. The mean age was 29,2 (SD ± 19,3); 90% were black, 84% from urban areas and 1% were pregnant. *Plasmodium* was confirmed by RT-PCR in 24.8% of the subjects (345/1389). All cases were uncomplicated, attributed to *P. falciparum* (74.2%), *P. vivax* (23.2%) and mixed infections (1%). Compared with microscopy, the XN-30 showed a sensitivity of 95.4% (CI_{95} 92.9 - 97.8), specificity of 99.7% (CI_{95} 99.3 - 100), PPV of 99.0% (CI_{95} 97.8 - 100) and NPV of 98.5% (CI_{95} 97.7 - 99.3); concordance ICC 0.90 (CI_{95} 0.87 - 0.92) and average of the differences -1475 parasites/uL compared with thick smear, and ICC 0.97 (CI_{95} 0.96 - 0.97) and average of the differences -0.0021% compared with thin smear. Using RT-PCR as a reference, the XN-30 showed a sensitivity of 95.1% (CI_{95} 92.6 - 97.6), specificity of 100% (CI_{95} 99.9 - 100), PPV of 100% (CI_{95} 99.8 - 100), NPV of 98.4% (CI_{95} 97.5 - 99.2) LRN 0,05 (CI_{95} 0,03 - 0,08), and concordance ICC 0.97 (CI_{95} 0.96 - 9.70). The XN-30 analyzer offers a rapid and accurate alternative method for malaria diagnosis in areas where *P. falciparum* and *P. vivax* co-circulate, and it can eventually contribute to reducing the impact of this disease.

SYNTHESIS AND EVALUATION OF METABOLITES OF ANTIMALARIAL PYRIDO[1,2-A]BENZIMIDAZOLES

Richard Ferger[1], Kelly Chibale[2]

[1]*University of Cape Town, Cape Town, South Africa,* [2]*South African Medical Research Council Drug Discovery and Development Research Unit, Cape Town, South Africa*

Malaria constitutes one of the leading causes of deaths world-wide. Despite recent decades of strategic implementations aimed at intervening the drastic mortality and morbidity rates, malaria still heavily impacts the public health and economies of lesser developed countries. A series of novel metabolites of antimalarial pyrido[1,2-*a*]benzimidazole (PBI) compounds containing Mannich base side chains were designed, synthesized and evaluated for antiplasmodium activity, inhibition of

hemozoin formation, and tested for turbidimetric solubility. Some of the Mannich base side chains were designed to overcome the rapid bioactivation and metabolism of the currently prescribed antimalarial, amodiaquine. The most potent analogue exhibited sub-micromolar activity (IC_{50} value of 0.81 μM) against the drug-sensitive *NF*54 strain of *P. falciparum*. Meanwhile, three of the compounds showed moderate inhibition of the late stage gametocytes with >70% inhibition at 5 μM and >50% inhibition at 1 μM. All but two of the synthesized analogues were potent inhibitors of the formation of beta-hematin with IC_{50} values ranging between 6.5 and 43.9 μM.

923

EVALUATION OF ANTIOXIDANT AND ANTIMALARIAL ACTIVITY OF LEAF EXTRACTS OF *LUFFA CYLINDRICA*

Oluremi Aduke Saliu[1], Ayodeji Oluwafemi Idowu[2], Musbau Adewunmi Akanji[2], Biodun Noel Saliu[3]

Malaria still remains one of the life threatening diseases despite receiving global attention over the years. It is endemic in sub-Saharan Africa where the level of poverty is quite high. The most vulnerable population are the young children, pregnant women and non-immune travelers or immigrants. Resistance to antimalarial drugs has contributed to the prevalence of this menace. Due to the frequency of malaria infection and the current trend of resistant malaria parasites, the use of local herbs in the treatment of malaria especially in developing countries like Nigeria is becoming more acceptable. *Luffa cylindrica* is one of such medicinal plants traditionally used in the treatment of malaria by the people of Nigeria. *Luffa cylindrica* belongs to the family of *Cucurbitaceous* and it is commonly called sponge gourd vegetable. There are ethnobotanical reports on the use of the plant in treating malaria. This study therefore aimed to investigate the antimalarial potential of extracts of *L. cylindrica* leaf in *plasmodium berghei*-infected Wistar mice and the *in vitro* antioxidant activity. Fresh leaves of *Luffa cylindrica* were successively extracted with n-hexane, ethylacetate, methanol solvents and distilled water (aqueous). Preliminary phytochemical evaluation of the four extracts was carried out using standard methods. Each extract was subjected to *in vitro* antioxidant study using different assay. The antimalarial study of the extracts was assessed *in vivo* at a calculated dose of 100, 200 and 400 mg/kg b.w and were compared with chloroquine and artesunate used as the reference antimalarial drugs. Acute oral toxicity evaluation was also carried out. Saponins, flavonoids, tannins, triterpenes, phenolics, alkaloids and cardiac glycosides were present in appreciable amounts. All the extracts showed varying *in vitro* antioxidant activity. The methanolic extract among other extracts exhibited the most potent antimalarial activity and also showed significance in the mean survival time of mice comparable with chloroquine and artesunat thus justify the acclaimed use of the plant in treating malaria.

924

USE OF AN *IN VITRO PLASMODIUM CYNOMOLGI* LIVER MODEL FOR RAPID DISCOVERY OF NEXT-GENERATION ANTIMALARIAL DRUGS

Alison E. Roth[1], Samantha O. Aylor[1], Erica C. Penn[1], Ratawan Ubalee[2], Gregory A. Reichard[1], Susan E. Leed[1], Norma E. Roncal[1], Brian A. Vesely[2], Silas A. Davidson[2], Norman C. Waters[2], Mara Kreishman-Deitrick[1], Brandon S. Pybus[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Malaria eradication is critically dependent on novel anti-relapse drugs which specifically target the dormant liver-stage form (hypnozoite) in *Plasmodium vivax*. Additionally, new tools are sorely needed for military personnel and travelers going into and returning from *P. vivax* endemic areas. To date, the 8-aminoquinoline (8-AQ) drugs are the only effective anti-hypnozoite drug class. However, 8-AQs are toxic to G6PD-deficient individuals and CYP2D6 polymorphisms alter drug metabolism thus emphasizing the need for improved chemodiversity with retained clinical efficacy. Preclinical drug screening focused on malaria liver-stage parasites, especially hypnozoites, has been hampered by the inefficiencies of current models and the intrinsically difficult task of obtaining infectious *P. vivax* sporozoites. To discover new leads for anti-hypnozoite drugs, we used our validated and high-throughput standardized *in vitro P. cynomolgi* liver-stage model to screen >10,000 small molecule compounds comprised of the CIS 9000 library (an analytically filtered subset of the WRAIR drug repository), novel 8-AQs, and natural products. Compounds were initially screened in single-point concentration (3-10 μg/ml) examining both chemoprophylactic and curative (radical cure) activity against liver-stage schizonts and hypnozoites in this system. Several hits were further evaluated for hepatocyte toxicity (MTT) where nontoxic compounds were subsequently tested in dose-response studies. Further, hits were assessed for multistage activity using our SYBR Green blood-stage assay and compounds of interest were subjected to efficacy studies using an *in vivo P. berghei* mouse model. In summary, our data reveals novel chemotypes with prophylactic and curative activity against hypnozoites enabling new approaches and potential targets for development of next-generation anti-relapse drugs.

925

A NEW AND IMPROVED COLLABORATIVE SYSTEM TO EFFICIENTLY EVALUATE NATURAL PRODUCT EXTRACTS FOR ANY THERAPEUTIC AREA: PROOF-OF-CONCEPT IN MALARIA, MULTI-DRUG RESISTANT BACTERIA AND LEISHMANIASIS

Susan Leed[1], Brandon Pybus[1], Chad Black[1], Barry O'Keefe[2], Tanja Grkovic[3], Diana Caridha[1], Qigui Li[1], Robert Campbell[1], Jason Rohde[1], Mozna Khraiwesh[1], Erica Penn[1], Alison Roth[1], Norma Roncal[1], John Goulart[1], Tesfaye Teshome[1], Gustave Bonkoungou[1], Lisa Xie[1], Qiang Zeng[1], Hsiu Ling Lin[1], Jing Zhang[1], Ping Zhang[1], Malik Raynor[1], Thomas Langowski[1], Benjamin Sullivan[1], Samantha Aylor[1], Mara Kreishman-Deitrick[1], William McCalmont[1], Patricia Lee[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*National Institutes of Health, National Cancer Institute, Developmental Therapeutics Program Division of Cancer Treatment and Diagnosis, Center for Cancer Research and Natural Products Branch, Molecular Targets Program, Frederick, MD, United States,* [3]*Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Natural Products Support Group, Frederick, MD, United States*

Malaria, multi-drug resistant bacteria, and leishmaniasis are serious infectious disease threats, and there is an urgent need for new therapeutics to combat emerging resistance to currently available drugs. Given the scarcity of truly novel chemical classes that do not cause inherent toxicity, the research community is reconsidering the cost-benefit ratio of natural product interrogation. Historical obstacles, such as pure compound elucidation from crude extracts have made natural product screening problematic. The Walter Reed Army Institute of Research (WRAIR) Experimental Therapeutics Branch (ET) and the National Cancer Institute's (NCI) Program for Natural Products Discovery (NPNPD) have a unique opportunity to use established *in vitro* high-throughput screens (HTS) to assess NPNPD's diverse, >230,000 natural product extract library against malaria, multi-drug resistant bacteria, and leishmaniasis. This collection of natural products has never been systematically tested against any infectious disease targets. WRAIR/ET and NCI/NPNPD have completed a proof-of-concept of the cooperative system for each therapeutic area. During the malaria proof-of-concept, NCI/NPNPD provided 88 crude extracts and 616 primary fraction extracts for testing in the WRAIR/ET *in vitro* efficacy and toxicity assays. Secondary fractionation was conducted on the hits and sent back to WRAIR/ET for assessment. Fractions that showed potency were then purified into discrete compounds by NCI/NPNPD and confirmed by WRAIR/ET for malaria blood-stage efficacy, 3 compounds had IC50s between 1.2 – 16.6 nM in sensitive and resistant

Plasmodium falciparum strains and no cytotoxicity (NCI 60 cell-line panel). Potent compounds from this effort will be first evaluated for drug-like attributes and synthetic tractability, and promising compounds will then be considered for entry into already established *in vivo* efficacy, toxicity, and pharmacokinetics animal models at WRAIR/ET. This ground-breaking collaboration can be adapted to any therapeutic area of interest to discover and develop new natural product derived drugs for advancement to FDA approval.

926

TNRND315, A TORIN-2 DERIVATIVE TARGETS PI4K AND HAS POTENT ACTIVITY AGAINST *PLASMODIUM FALCIPARUM* ASEXUAL, SEXUAL AND MOSQUITO STAGES

Karthik Mosur Krishnan[1], Peter Ziniel[1], Hao Li[2], Wei Sun[2], Wei Zheng[2], Xiuli Huang[1], Nita Gombakomba[1], Sandra Mendoza Guerrero[1], Daniel Hupalo[1], Wenwei Huang[2], Philip Sanderson[2], Clifton Dalgard[3], Matthew Wilkerson[3], Kim C. Williamson[3]

[1]*Henry M Jackson Foundation, Bethesda, MD, United States,* [2]*National Center for Advancing Translational Sciences (NCATS, NIH), Rockville, MD, United States,* [3]*Uniformed Services University, Bethesda, MD, United States*

Recent efforts to control and ultimately eradicate malaria have stimulated interest in the development of safe and effective transmission blocking drugs. A large screen for compounds active against sexual stage parasites required for transmission, called gametocytes, identified Torin-2 as effective in both *in vitro* and *in vivo* rodent malaria models. Here we describe functional analysis of a Torin-2 derivative TRND000384315 (TRND315). Assays to determine stage specificity establish that the compound has potent activity against early *Plasmodium falciparum* schizonts as well as gametocytes. Using the *P. berghei*/mouse malaria model *in vivo*, administration of two 40 mg/kg doses was found to completely block transmission by inhibiting the development of ookinetes and oocysts in the mosquito. Whole genome sequence analysis of independently derived Torin-2 resistant *P. falciparum* lines found mutations in the region containing phosphatidylinositol 4-kinase (PfPI4K). The whole gene was duplicated in one line and the other had a single non-synonymous mutation in the enzyme active site. Interestingly, qRT-PCR indicated that both lines exhibited up-regulation of PI4K transcript. In addition, preliminary PI4P quantification by competitive ELISA suggests that treatment with TRND315 decreases cellular PI4P levels. Together the results support PI4K as a potential target for TRND315.

927

ARTESUNATE RESPONSE OF *PLASMODIUM FALCIPARUM* K13 MUTANT (C580Y) IN HUNSG MOUSE MODEL

Shulin Xu, Debora R. Casandra, Courtney Herman, Samantha J. Barnes, John H. Adams

Center for Global Health and Infectious Diseases Research, College of Public Health, University of South Florida, Tampa, FL, United States

Artemisinin-based combination therapies (ACTs) are the most effective treatment to reduce the *Plasmdium falciparum* infection burden and deaths, but point mutation C580Y in K13 propeller have been reported associations with ART resistance (ART-R). In this study we investigated K13 mutants artesunate responses in a humanized NSG mouse (HuNSG) model, using two parasite lines (76H10C580Y, 76H10C580Rev) previously characterized in *Aotus*, as an alternate *in vivo*model for studies of ART-R. For clearance studies, infected mice with parasitemia more than 0.5% were treated with artesunate (4mg/kg/day) for 3 daily injections and monitored at 0, 6, 12, 24, 36, 48, 72, 96 and 120 hours and then transfer to new HuNSG mouse "1 to 1" to monitor for parasite recrudescence weekly. Ring-stage Survival Assay (RSA) was used to evaluate in parallel the *ex-vivo*susceptibility of parasites cultivated in HuNSG mice to DHA. 76H10C580Y did not have longer half-life or more times of recrudescence than 76H10C580Rev parasite after infection of HuNSG mice and artesunate treatment. Parasites showed similar clearance times in primary infection and recrudescence. These results support the previous findings in NHP model infections, which create doubt about correlations between K13 mutations and altered parasite clearance half-life (t1/2) as markers of clinical resistance to ART. This study also indicates that the *P. falciparum*-HuNSG mouse model may provide a more accessible *in vivo*method for analyzing ARTs parasite clearance profiles. This model provides an additional tool for study of drug mechanisms of action and potential ART drug combinations.

928

IDENTIFYING COMPOUNDS THAT TARGET RESISTANT PARASITES AS A STRATEGY TO SUPPRESS THE EMERGENCE OF ANTIMALARIAL RESISTANCE

Rebecca Mandt[1], Maria Jose Lafuente-Monasterio[2], Madeline R. Luth[3], Matthew Reynolds[4], Sabine Ottilie[3], Elizabeth A. Winzeler[3], Javier Gamo[2], Dyann F. Wirth[1], Amanda K. Lukens[1]

[1]*Harvard TH Chan School of Public Health, Boston, MA, United States,* [2]*Tres Cantos Medicines Development Campus, GlaxoSmithKline, Madrid, Spain,* [3]*University of California San Diego, San Diego, CA, United States,* [4]*Harvard College, Cambridge, MA, United States*

Resistance has arisen to every therapy used in the clinical treatment of malaria, necessitating the continuous development of new drugs targeting different aspects of parasite biology. Unfortunately, even novel therapeutics can be stymied by the rapid emergence of resistance in parasite populations. For example, resistance to the *Plasmodium* dihydroorotate dehydrogenase (DHODH) inhibitor DSM265 arose during Phase 2 clinical trials. Our lab and others found that DHODH can accommodate a variety of mutations that decrease the parasites' sensitivity to DSM265, and that several of these mutations have no negative impact on parasite fitness *in vitro*, explaining why resistance to this drug arises so readily. However, we have also previously demonstrated that mutations in DHODH that give resistance to one inhibitor can cause increased sensitivity to other classes of DHODH inhibitors, a phenomenon generally termed 'collateral sensitivity'. Here, we tested several DSM265-resistant parasites against a range of compounds identified in our recently-published Tres Cantos Open Lab screen, and observed different patterns of cross-resistance and collateral sensitivity. We identify one compound, TCMDC-125334, that is active against all mutant lines tested. In particular, the DHODH C276Y mutant which arose in clinical trials with DSM265 is ~10-fold more sensitive to TCMDC-125334 than wildtype parasites. In attempts to select for resistance to TCMDC-125334 *in vitro,* we have thus far been unable to isolate parasites with high level (>2-fold) resistance. Treating the C276Y line with TCMDC-125334 selects for parasites with increased resistance, but which are still relatively sensitive compared to wildtype. We hypothesize that, because resistance to TCMDC-125334 occurs less frequently, this compound could be particularly effective in combination with DSM265, and experiments to test this are ongoing. Overall, this research demonstrates the value of screening for compounds that target resistant parasites, and more broadly of utilizing our understanding of resistance evolution in designing strategies for preventing or reducing resistance.

929

SMALL MOLECULE SCREEN OF EPIGENETIC INHIBITORS ON *PLASMODIUM FALCIPARUM* BLOOD STAGE REPLICATION AND GAMETOCYTE MATURATION

Leen Vanheer, Björn F. C. Kafsack

Department of Microbiology and Immunology, Weill Cornell Medicine, New York, NY, United States

The regulation of gene expression by histone modifications is critical for parasite survival in both asexual and sexual blood stages of *Plasmodium falciparum*, and changes substantially as parasites differentiate from one to the other. This makes inhibitors targeting these pathways intriguing in terms of their potential as multi-stage active anti-malarials. Therefore, we screened two cherry-picked libraries of small molecule epigenetic inhibitors from Selleckchem (142 compounds) and Cayman Chemicals

(139 compounds) for their effect on asexual blood stage replication and gametocyte development. These compounds include inhibitors of epigenetic writers, readers, and erasers known in mammalian systems, including histone deacetylases (HDAC), histone demethylases (HDM), histone methyl transferases (HMT) and histone acetyl transferases (HAT). We identified 74 epigenetic inhibitors with EC90s below 10 μM for inhibition of gametocyte development, of which 27 compounds retained their >90% inhibitory effect at 1 μM . Asexual stage growth was blocked >90% by 73 compounds at 10 μM , of which 30 compounds maintained their inhibitory effect at 1 μM . Dose-response curves were determined for compounds with potent activity at 1 μM, with several that had EC50 concentrations in the low nano-molar range against both asexual and sexual blood stages. These include inhibitors previously identified to be active against *P. falciparum* blood stages as well as several that had not previously been tested. Additionally, we identified multiple compounds that displayed higher activity against gametocyte maturation compared to asexual replication. The emergence of drug resistance in *P. falciparum*, the most virulent human malaria parasite, necessitates the development of novel anti-malarial drugs. These findings provide support for the development of new classes of anti-malarials that target the parasite's epigenetic regulation machinery.

930

REPURPOSING FDA APPROVED DRUGS TO TREAT MALARIA: UNDERSTANDING THE MECHANISM OF ACTION

Steven Goicoechea[1], Yash Gupta[2], Jessica Simpson[1], Whelton A. Miller III[2], Brijesh Rathi[3], Ravi Durvasula[2], Prakasha Kempaiah[2]

[1]*Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States,* [2]*Loyola University Chicago Stritch School of Medicine and Department of Medicine, Loyola University Medical Center, Maywood, IL, United States,* [3]*Department of Chemistry, Hansraj College University Enclave, University of Delhi, Delhi, India and Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States*

Emerging drug resistance in the *Plasmodium falciparum* parasite imperils malaria control and urges for the development of new antimalarial drugs. While the development of new drugs is a lengthy process that requires considerable financial investment, repurposing of FDA approved drugs that are effective against the malaria parasite can circumvent initial cost and time needed to introduce a drug to market. In the current study, we shortlisted compounds from the ChEMBL database, a manually curated database of bioactive molecules with drug-like properties. Nearly 100 compounds with possible secondary targets were tested against PfD6 and PfDd2 strains using an IC_{50} test in the erythrocyte stage of the malaria parasite. Nearly twenty compounds strongly inhibited growth of both PfD6 and PfDd2 (IC_{50} <2μM). Further, we selected those leads that have homologous targets in *P. falciparum*: Amlodipine Besylate (voltage-dependent calcium channel), Azithromycin (23S rRNA, arginine deiminase type-4, bacterial 50S ribosomal subunit), Balsalazide (peroxisome proliferator-activated receptor gamma, prostaglandin G/H synthase, arachidonate 5-lipoxygenase), Benzapril (angiotensin-converting enzyme), and Escitalopram (sodium-dependent serotonin transporter). The drugs were subjected to comparative docking analysis to assess the conservancy in the mechanism of action in parasite and host. The differences observed in target, homologue function, and interacting amino acids were further exploited to derive parasite-specific pharmacophore. We are currently performing specific assays to confirm the drug targets to understand the mechanism of action against *P. falciparum*.

931

A BIOINFORMATICS PIPELINE TO REPURPOSE APPROVED DRUGS AS ANTI-PARASITIC LEADS

Yash Gupta[1], Whelton A. Miller III[1], Samuel K. Kwofi[2], Brijesh Rathi[3], Ravi Durvasula[1], Prakasha Kempaiah[1]

[1]*Loyola University Chicago Stritch School of Medicine and Department of Medicine, Loyola University Medical Center, Maywood, IL, United States,* [2]*Department of Biomedical Engineering, School of Engineering Sciences, College of Basic and Applied Sciences, University of Ghana and Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States,* [3]*Department of Chemistry, Hansraj College University Enclave, University of Delhi, Delhi, India and Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States*

Two of the most important human diseases caused by protozoan parasites; malaria and leishmaniasis, have a combined disability adjusted life years of approximately 42 million. Many of the currently used medications are becoming less effective due to the development of drug resistant strains of parasites, necessitating the continued search for new drugs. Recently drug Lansoprazole, a proton pump inhibitor has been shown to have activity against tuberculosis through *in vitro* and animal studies. While similar compounds Omeprazole and pantoprazole have no such activity and the target of Lansoprazole is cytochrome bc1 complex (QcrB), acts through intracellular sulfoxide reduction to lansoprazole sulfide. Due to presence of similar sulfoxide reduction pathway in malaria parasite, *Plasmodium falciparum* (Pf; methionine sulfoxide reduction), which is important for amino acid uptake and redox balance. Most importantly, earlier reports of use of 'Morpholino Thiophenes' being highly active against Pf (Target; dihydroorotate dehydrogenase) also Mtb; QcrB Inhibitors. Therefore, we tested the drug against Pf and found it to be highly active against both PfD6 (sensitive, 0.8μm±0.1) and PfDD2 (resistant, 0.8μm±0.1) strains. However, the current dosage range for Lansoprazole for an adult human is 15-30mg which is far less from dosage required for successful antibiosis. Therefore, to identify the target of Lansoprazole in Pf and improve dose restrictions, we performed docking analysis with 'cytochrome bc1 complex' and 'dihydroorotate dehydrogenase' modelled proteins with Lansoprazole. Based on interacting docked posed validated by MD simulations, we deciphered pharmacophores and subjected the leads to a 'ligand based virtual screening' populating a curated library prescreened by in silico ADMEtox predictions. The retention of activity in the hits was again determined by molecular dockings and MD simulation validations. Thus, we have successfully pipelined from a novel lead to putative drug candidates while mitigating the shortcomings of the former drug.

932

DISRUPTION OF *PLASMODIUM FALCIPARUM* DIHYDROFOLATE REDUCTASE AND THYMIDYLATE SYNTHASE INTERACTIONS IS LETHAL TO MALARIA PARASITES

Devaraja G Mudeppa, Bennett Guo, SooNee Tan, Shiva Kumar, Pradipsinh K Rathod

University of Washington, Seattle, WA, United States

The target of selective antifolate drugs*, Plasmodium falciparum* dihydrofolate reductase-thymidylate synthase (*Pf*DHFR-TS), is a single 71 kDa polypeptide which forms an obligated dimer for TS function. Previously we demonstrated that folding and function of *Pf*DHFR is independent of *Pf*TS. Folding of *Pf*TS protein into a functional enzyme, however, is dependent on upstream *Pf*DHFR. We demonstrate that the activation of *Pf*TS domain requires the assistance of pre-folded *Pf*DHFR. Crystal structure of *Pf*DHFR-TS displayed several key contacts between *Pf*DHFR and *Pf*TS. Site-directed mutagenesis at the contact sites between *Pf*DHFR residues and *Pf*TS disrupted TS activity. A competing peptide derived from the contact residues disrupted *Pf*TS activity in cell-free protein synthesis reactions, was lethal to bacteria that were dependent *Pf*DHFR-TS, and to malaria parasite. This approach to attack parasite-specific protein-protein interactions opens an opportunity to design small molecule inhibitors against this previously unknown parasite vulnerability. Beyond that, this new approach may be of general interest for disrupting pathogen functions in a species-specific manner.

933

EXPLORING FUNGAL METABOLITES FOR MALARIA TRANSMISSION BLOCKING AGENTS

Manpreet Kaur, Guodong Niu, Yue Hao, Jun Li

Florida International University, Miami, FL, United States

Malaria remains one of the major concerns in public health sector, with an estimated 219 million clinical cases in 87 countries. Malaria transmission can be controlled by inhibiting *Plasmodium* development in mosquitoes, mainly by vector controls including insecticidal-treated mosquito nets or spraying insecticides. Due to increased insecticidal resistance, there is a growing need for alternate approaches for blocking malaria transmission. Fibrinogen-related protein 1 (FREP1) has been identified as one of the critical midgut proteins for *Plasmodium* invasion. Eliminating parasite infection by disrupting the FREP 1- parasite interaction using small molecules might be an effective solution for stopping malaria transmission. Although plant species have been extensively studied for novel small molecules against malaria transmission, fungi are one of the understudied natural resources. Based on the results of an earlier ELISA-based screening method developed by our group for a fungal extract library, the candidate fungal extract from our *Cladosporium Cladosporioides* isolate had been identified that inhibited the interaction between FREP1 and *P. falciparum* infected cells by 95%. The crude fungal extract was tested on mosquitoes using a standard membrane feeding assay (SFMA) at 100 μg/mL blood concentration, showing complete inhibition of the development of oocysts in mosquitoes. The crude fungal extract was then further fractionated using flash column chromatography and the collected fractions were continuously screened using the SFMA to eliminate inactive fractions. The active fractions at each stage were further fractionated and tested, leading to an active compound which shows 100% inhibition at 20 μg/mL blood concentration. The structural elucidation of the active compound was done using a combination of LCMS and NMR data analysis techniques. This fungal metabolite is an effective active lead candidate for malaria transmission blocking drugs.

934

DIFFERING RISK FACTORS FOR MALARIA AMONGST ADULTS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Molly Deutsch-Feldman[1], Nicholas F. Brazeau[1], Kyaw Thwai[1], Melchior Kashamuka[2], Antoinette Tshefu[2], Jonathan J. Juliano[1], Steven R. Meshnick[1]

[1]*University of North Carolina - Chapel Hill, Chapel Hill, NC, United States,* [2]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo*

Malaria remains a significant public health problem worldwide, and especially in sub-Saharan Africa. Adults are frequently infected and may serve as a reservoir for further transmission. Yet, we know very little about risk factors for infection in adults. In the Democratic Republic of the Congo (DRC), malaria prevalence amongst adults is approximately 30%. In this study, we assessed malaria in adults using over 17,000 samples from the nationally representative 2013-2014 Demographic and Health Survey (DHS) conducted in the DRC. *Plasmodium falciparum* infection was determined by PCR. Covariates were drawn from the DHS and used to build a multi-level model to identify both individual and community level risk factors for infection amongst adults. Additionally, we included the community level proportion of drug resistant infections, determined by genetic sequencing, as potential risk factors. All identified risk factors were then assessed for modification by urbanicity category as designated in the DHS (large cities, small cities, towns, rural areas). Individual risk factors include: younger age, male sex, lower education, and lower wealth. Community level risk factors include: decreased community bed-net use, decreased average education, and decreased average wealth. Decreased malaria prevalence was also associated with increased cluster level antifolate-resistance mutations, probably due to increased antimalarial use. The modification analysis indicates no protective effect of individual or increasing cluster level net use in cities, but highly protective effects elsewhere. Both increasing individual and community level education are highly protective in large cities and showed little effect in towns or rural areas. A similar trend is seen for wealth. Modification of risk factors by urban status may be due to differences in transmission intensity, brand of bed-nets used, and access to resources. The findings from these analyses will help the DRC identify individuals and communities at higher risk for malaria infection. They also shed light on differences in the epidemiology of malaria by different urban settings.

THE PREVALENCE OF ASYMPTOMATIC, SUBMICROSCOPIC AND UNCOMPLICATED MALARIA IN A HIGHLAND AREA OF KENYA WITH LOW TRANSMISSION

Lindsey B. Turnbull[1], George Ayodo[2], Kavitha Udumula[1], Travis Putzke[1], Tuan Tran[1], Chandy C. John[1]

[1]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya*

Continued progress towards malaria elimination requires a greater understanding of the prevalence of submicroscopic infections among healthy individuals and those with mild, non-specific symptoms to inform interventions at the local level. We have conducted longitudinal surveillance of clinical malaria in the Kenyan highland sites of Kipsamoite and Kapsisiywa, areas of unstable transmission, since 2002. Symptomatic individuals (with fever or headache) were prospectively enrolled at the site health centers and tested for malaria by microscopy. Those with microscopy confirmed malaria were treated with artemisinin combination therapy. All others were diagnosed with non-malarial illness and provided appropriate clinical care. To investigate and disentangle clinical malaria from other infections in which the patient may also have asymptomatic parasitemia, we retrospectively assessed malaria surveillance samples collected from 2015 - 2017 using quantitative PCR (qPCR) and determined the number of individuals with submicroscopic malaria. Cross-sectional blood collections from asymptomatic individuals were also conducted in August 2016, January 2017, and June 2017 to assess for asymptomatic parasitemia. Monthly prevalence of submicroscopic malaria among symptomatic individuals ranged from zero to 20.9%. In Kapsisiywa, symptomatic individuals were more likely to have submicroscopic parasitemia than asymptomatic individuals (OR= 5.44, 95%CI 1.89, 15.60, $p < 0.01$). Symptomatic *P. falciparum* qPCR positive individuals did not seek follow-up care at a higher rate than symptomatic qPCR negative individuals and only 2 of 26 symptomatic qPCR positive individuals analyzed thus far had a visit within 30 days in which they were microscopy positive, suggesting that malaria infection in most sub-microscopic individuals is controlled by the host immune response. The study data indicate that in low, unstable transmission settings, testing of febrile individuals for *P. falciparum* infection by qPCR may be a high-yield method to detect individuals sub-microscopically infected with *P. falciparum*.

936

SUBPATENT MALARIA IN PREGNANCY: A SYSTEMATIC REVIEW AND INDIVIDUAL PATIENT DATA META-ANALYSIS

Anna Maria van Eijk[1], Subpatent Malaria in Pregnancy Study Group[2]

[1]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [2]*WWARN, Oxford, United Kingdom*

Malaria in pregnancy causes adverse pregnancy outcomes. In semi-immune pregnant women, many *Plasmodium* infections are asymptomatic and below the level of detection (subpatent) by microscopy (submicroscopic) or rapid diagnostic tests (RDT). Previous studies to determine the clinical relevance of low-grade infections provided conflicting results. We conducted an individual-participant data meta-analysis to determine the impact of subpatent malaria infections on adverse pregnancy outcomes. We searched the Malaria in Pregnancy Library (updated 3 times/year from over 20 databases) to identify eligible studies using the keywords

"Polymerase Chain Reaction", "PCR", "subpatent" or "submicroscopic" published between January 1997 and January 2019. Studies involving pregnant women in malaria endemic regions were eligible if they reported diagnostic results based on PCR and either microscopy or RDT and information on birth outcome or maternal haemoglobin (prespecified endpoints). Authors of eligible studies were approached from March 2017 to March 2019. Datasets were standardized, merged and grouped by study and location. Overall, 487 records were screened, and 80 potential studies identified. By March 2019, datasets from 32 studies were received covering 66 substudies. Preliminary results using two-stage random-effects meta-analysis and microscopy/PCR showed that, compared to women without malaria at delivery, women with microscopic and submicroscopic placental malaria had lower mean haemoglobin levels (patent: mean difference [MD]=0.8g/dL, 95% CI 0.7-0.9, p<0.001, 32 substudies, *I2*=0.0%, N=9,431; submicroscopic: MD=0.2g/dL, 0.1-0.3, p=0.003, 34 study sites, *I2*=19.5%, N=10,342). Results were similar with maternal blood at delivery. The difference in mean birthweight was: microscopic, MD=150gr decrease, 97-202, p<0.001, 33 substudies, *I2*=34.6%, N=9,647; submicroscopic MD=34gr, -1-68, p=0.059, 36 substudies, *I2*=19.5%, N=10,690). Preliminary results show that submicroscopic malaria infections detected at delivery are associated with decreased maternal haemoglobin levels and possibly birthweight.

937

MALARIA AMONG INDIVIDUALS AND COMMUNITIES ACROSS SEASONS IN SITES WITH VARYING ENDEMICITIES IN KINSHASA PROVINCE, DEMOCRATIC REPUBLIC OF THE CONGO

Alpha Oumar Diallo[1], Seungwon Kim[2], Varun Goel[3], Alison Poffley[1], Kyaw Thwai[1], Mvuama M. Novo[4], Joseph A. Bala[4], Marthe Nkalani[4], Georges Kihuma[4], Joseph Atibu[4], Michael Emch[3], Jonathan B. Parr[5], Jonathan J. Juliano[6], Steven R. Meshnick[1], Melchior Kashamuka Mwandagalirwa[4], Antoinette Tshefu[4], Margaret Carrel[2]

[1]*Department of Epidemiology, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States,* [2]*Department of Geographical and Sustainability Sciences, University of Iowa, Iowa City, IA, United States,* [3]*Department of Geography, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States,* [4]*Ecole de Santé Publique, Faculté de Médecine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [5]*Division of Infectious Diseases, School of Medicine, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States,* [6]*Division of Infectious Diseases, School of Medicine, University of North Carolina-Chapel Hill, Chapel Hill, NC, Chapel Hill, NC, United States*

Globally, the Democratic Republic of the Congo (DRC) has one of the highest malaria burdens with a prevalence of over 30% in both children and adults. To better understand the individual and household factors associated with malaria, a prospective longitudinal study was conducted across seven sites (242 households and 1,565 individuals) with varying endemicities in Kinshasa Province. Participants were sampled at four separate visits from 2015-2016 (baseline and three follow-up visits) at 6-month intervals during which questionnaires were completed, participants were tested for *Plasmodium falciparum* via rapid diagnostic tests (RDT) and dried blood spots were collected for polymerase chain reaction (PCR) testing. Participants with malaria symptoms between scheduled visits attended local health centers (unscheduled visits), where their axillary temperatures and RDT results were recorded and dried blood spots were collected for PCR testing. Seventy-four percent of participants had malaria outcomes recorded across all four visits, with a further 13% having recordings for three of four visits. Malaria prevalence was highest at follow-up two (37% via RDT and 40% via PCR); malaria prevalence measured by PCR was consistently higher than RDT. The urban Kinshasa site had the lowest malaria prevalence (3-10%) in all four time periods, while sites with the highest malaria prevalence varied across visits, ranging as high as 60% via PCR in a rural village during the rainy season, 2016. Children aged 6-15 years had the highest malaria prevalence (45-50%) in most sites across time and reported consistently low bednet use. No consistent seasonal trends for malaria and bednet use were observed. There were 3,024 unscheduled visits to the local health clinics amongst 1,045 study participants during the study, with a median of 2 visits per participant per year. Of these, 43% had malaria diagnosed via RDT and 59% had PCR-positive malaria outcomes. These results and future analyses of these data that incorporate household characteristics will elucidate factors associated with malaria prevalence across varying endemicity levels in the DRC.

938

THE IMPACT OF OLYSET® NET AND DAWAPLUS® 2.0 ON THE RISK OF *PLASMODIUM* INFECTION IN GEMBE EAST, WESTERN KENYA

Noriko Tamari[1], George O. Sonye[2], Beatrice Awuor[2], James O. Kongere[3], Muneaki Hashimoto[4], Masatoshi Kataoka[4], Stephen Munga[5], Noboru Minakawa[1]

[1]*Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan,* [2]*Ability to Solve by Knowledge Project, Mbita, Homa Bay, Kenya,* [3]*Centre for research in Tropical Medicine and Community Development, Nairobi, Kenya,* [4]*National Institute of Advanced Industrial Science and Technology (AIST), Health Research Institute, Kagawa, Japan,* [5]*Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya*

Olyset® Net is a long-lasting insecticidal bed net (LLIN) incorporated with permethrin and DawaPlus® 2.0 is coated with deltamethrin. While the World Health Organization (WHO) has recommended various types of LLINs for vector control, the effectiveness of different types of LLINs are unclear in the field settings. We assessed the impact of Olyset® Net and DawaPlus® 2.0 on the risk of *Plasmodium* infection in Gembe East, western Kenya. Olyset® Net and DawaPlus® 2.0 were distributed in September and October of 2014 and June and July of 2017 respectively at the study site. Children ⩽15 years of age were tested for *P. falciparum* infection using with polymerase chain reaction (PCR). We directly observed their sleeping location, number of persons sharing a net, types of the bed net they used, material of wall and gap of eaves (open/close) in their sleeping rooms. The proportional hole index (PHI) was estimated for each net following the WHO guideline, and indoor resting female anophelines were collected from their sleeping rooms. We also characterized socioeconomic status (SES) for each household. Of 254 examined, 74 (29.1%) and 180 (70.9%) children slept under Olyset® Net and DawaPlus® 2.0, respectively. The PCR-positive prevalence was 37.8% for Olyset® Net-users and 57.8% for DawaPlus® 2.0-users. The difference was statistically significant (bivariate analysis: p<0.01). Similarly, number of persons sharing a net (sharing with none or one person/sharing with two or more), PHI on the sides, SES and material of wall (mud/others) were statistically significant between use of Olyset® Net and DawaPlus® 2.0. Multivariate Bayesian logistic regression with spatial dependency confirmed that children using Olyset® Net were at lower risk than DawaPlus® 2.0-users (OR=0.67, 95% Credible Interval: 0.45-0.97). Although the mechanism that makes the difference was not clear, the results from this study suggest that Olyset® Net after three years use was more effective for preventing from *Plasmodium* infection, compared to DawaPlus® 2.0 after a half year use.

939

MALARIA IMPORTED INTO PERU: THE ROLE OF VENEZUELAN CITIZENS

Fiorela Alvarez[1], Ana Pilar Ramos[1], Karim Pardo[2], Verónica Soto[2], Juan José Contreras[1], Dionicia Gamboa[3], Alejandro Llanos-Cuentas[1]

[1]*Unidad de Leishmaniasis and Malaria, Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima,*

Peru, [2]Ministerio de salud Perú, Lima, Peru, [3]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru

Between 2000 to 2017 there was a decrease of 14.4% of malaria cases in the Americas, mainly due to control interventions. During the last years, the increment of malaria in Venezuela has generated concern in neighboring countries. This country has showed a 365% increase of malaria between the period 2000 and 2017 and 71% in 2017 in comparison with 2016. In 2017, the American continent reported 975,700 cases of malaria of which 53% corresponded to Venezuela. Until December 2018 more than 1 million of Venezuelans arrived in Peru, with multiple health problems, including malaria. This abstract describes the situation of imported malaria cases reported in the Malaria Program of the Cayetano Heredia Hospital, a national reference center located in Lima city where 100% of the cases of malaria that have been attended at this health center came from endemic areas of malaria in Peru or from abroad. The first Venezuelan with vivax malaria at our hospital was diagnosed in March 2017, and since then the number of cases has increased steadily. In that year 10.5% (15/70) of malaria cases were registered in Venezuelan citizens and in 2018 more than half of the cases (50.46%, 50/107) were Venezuelans. 84.06% of them had vivax malaria and 15.94% mixed malaria and22.8% were recurrent episodes. Currently in Lima there is no active transmission of malaria and all of them arrived in Peru through the Pan-American highway, reason why we think that most of the recurrent cases correspond to relapses. The majority of this population lives in temporary places, works in the informal sector and does not have or refuse to give a telephone number to follow them up. For all these characteristics, malaria imported by Venezuelan citizens represents a public health problem in Peru and the MHO and other ministries must collaborate and work together to implement adequate strategies to decrease the burden of imported malaria and assuring that Peruvian malaria elimination process remain unaffected.

EXISTENCE OF MALARIA HOTSPOTS IN ZANZIBAR: POTENTIAL CONTRIBUTION TO ONGOING MALARIA TRANSMISSION

Mohamed Haji Ali

Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania

Malaria prevalence in Zanzibar has remained less than 1% since 2008; however, transmission continues, and there is a need to implement activities to continue progress toward elimination. Malaria hotspots are geographically clustered cases and potential sources of malaria infection where targeted interventions might interrupt transmission. The objectives of this analysis were to identify and characterize malaria hotspots in Zanzibar. Hotspots were defined as a village with more than 5 total cases per 1000 population per year. Malaria surveillance data between 2015 and 2018 from all 10 districts (383 Shehias) were analyzed. Overall, there were 43 malaria hotspots (39 Unguja island; 4 Pemba island). The highest incidence among all the hotspots was 56.5/1000 for 2015, 29.7/1000 for 2016, 22.5/1000 for 2017 and 44.7/1000 for 2018. In Unguja, 30 (77%) hotspots were located in three districts (16 Magharibi, 8 Mjini, and 6 Kati). In Pemba, 3 (75%) hotspots were located in Micheweni district. Among the 43 hotspots, households within 17 (40%) hotspots in 2016 and 19 (44%) hotspots in 2017 were targeted for indoor residual spraying (IRS) based on incidence and available resources to conduct IRS; 15 hotspots were targeted for repeat IRS between 2016 and 2017. The majority of malaria hotspots in Zanzibar are located in four districts and are potential sources of ongoing malaria infection where targeted interventions might interrupt transmission. Characters (with spaces): 1,456

EVALUATION OF ASYMPTOMATIC MALARIA IN DAK NONG PROVINCE IN THE HIGHLANDS OF VIETNAM FOR THE MALARIA ELIMINATION ROADMAP

Huynh H. Quang[1], Marina Chavchich[2], Nguyen T. Trinh[1], Nguyen D. Manh[3], Michael D. Edstein[2], Nicholas J. Martin[4], Kimberly A. Edgel[4]

[1]*Institute of Malariology, Parasitology and Entomology, Quy Nhon, Vietnam,* [2]*Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia,* [3]*Military Institute of Preventive Medicine, Hanoi, Vietnam,* [4]*U.S. Naval Medical Research Unit Two, Singapore, Singapore*

Malaria cases have been steadily declining in Vietnam since 2006, providing the opportunity for malaria elimination by 2030. A significant challenge for elimination is asymptomatic parasite carriers, which represent a silent reservoir for malaria transmission and contribute to the persistence of malaria. Gaining an understanding of the prevalence and distribution of asymptomatic malaria will help design intervention strategies to achieve elimination. We conducted a survey, where finger prick blood samples were collected from two cohorts of asymptomatic people each with approximately 1,415 subjects residing in three communes of Tuy Duc district, Dak Nong Province, Vietnam. The communes Dak Buk So, Dak Ngo, and Quang Truc were stratified using criteria from the National Malaria Control Program as low, moderate and high malaria endemic areas, respectively. The first and second cohorts of asymptomatic people were surveyed at the end of the wet season (November-December 2018) and at the start of the dry season (February-March 2019), respectively. All subjects were free of malaria symptoms and negative by rapid diagnostic testing and microscopy. RNA was extracted from 50 μL of blood and preserved in RNAprotect®. Malaria parasites were detected by one-step RT-qPCR targeting 18s ribosomal RNA transcripts of *Plasmodium falciparum, P. vivax, P. ovale* and *P. malariae*. Preliminary data for the first cohort showed asymptomatic parasite prevalences of 1.5%, 3.6%, and 12.8% for the low, moderate and high endemic areas, respectively. All subjects were also screened for glucose-6-phosphate dehydrogenase (G6PD) deficiency (Carestart Biosensor) revealing 1.5% and 3.8% with severe and intermediate G6PD deficiency, respectively. This information is essential for future elimination strategies using anti-hypnozontocidal drugs (primaquine or tafenoquine) for treating *P. vivax* malaria. The study is ongoing and more information on *Plasmodium* species identification and gametocyte prevalence will be presented. These data will be discussed in the context of devising targeted strategies for malaria elimination.

942

CHILDREN WITH CLINICAL *PLASMODIUM FALCIPARUM* INFECTION HAVE INCREASED SHARING OF HAPLOTYPES WITH HOUSEHOLD MEMBERS AS WELL AS TEMPORALLY-PROXIMAL, SYMPTOMATIC PEERS

Cody S. Nelson[1], Kelsey M. Sumner[2], Betsy Freedman[1], Andrew A. Obala[3], Judith N. Mangeni[3], Steve M. Taylor[1], Wendy P. O'Meara[1]

[1]*Duke University, Durham, NC, United States,* [2]*University of North Carolina, Chapel Hill, NC, United States,* [3]*Moi University, Eldoret, Kenya*

Falciparum malaria transmission has failed to decline in proportion to control efforts in certain regions such as Bungoma county, western Kenya. One proposed strategy to eradicate malaria is ring testing and treatment, however it remains unknown whether infections spread locally or if asymptomatically-infected household members are a risk factor for clinical disease. From April 2013 to June 2014, we enrolled 442 cases (RDT+ children hospitalized with malaria) and 442 matched controls; all household members of cases and controls were also enrolled and tested, of which 13.6% (n=608/4449) were RDT+. From each RDT+ participant, parasite gDNA was PCR-amplified at both Pf circumsporozoite protein (*csp*) and apical membrane antigen 1 (*ama1*) *loci*, amplicons sequenced on an Illumina Miseq, and haplotypes inferred using dada2. We identified

120 *csp* and 180 *ama1* unique haplotypes. We evaluated genetic distance between infected individuals using three novel indices: sharing of parasite haplotypes on binary and proportional scales and the L1 norm. Case children median [IQR] binary/proportional sharing of both *csp* and *ama1* haplotypes was significantly increased with members of their origin household (e.g. *csp* binary sharing: origin = 50.3 [0-87.5] vs. similar household = 0 [0-50.3]; p = 0.01; Wilcoxon Sign-Rank test), indicating that cases are more likely to share haplotype-identical parasites with members of their own household. We also computed population-level haplotype sharing indices for all pairs of case children and observed no association between genetic relatedness and geographic distance. In contrast, we identified a strong inverse relationship between haplotype sharing and temporal distance, which we exploited to identify the molecular signature of an outbreak. Overall, these findings suggest that, although haplotype sharing is more common within households, temporal rather than geographic proximity predicts parasite genetic similarity. The observation that identical haplotype combinations are found nearly simultaneously across the study area implies that ring testing approaches may not effectively reduce transmission.

943

MALARIA MORBIDITY AND MORTALITY TRENDS IN CENTRAL UGANDA

Daniella Busharizi[1], Ruth Kigozi[1], Emily Goodwin[1], Patricia Mukose[1], Gloria Ssebikaari[2], Peter Thomas[2], Paul Oboth[1], Patrick Bukoma[1], Damian Rutazaana[3], Thomson Ngabirano[1], Godfrey Magumba[4], James Tibenderana[5], Sam S. Gudoi[1]

[1]*PMI Malaria Action Program for District Project, Uganda, Kampala, Uganda,* [2]*US President's Malaria Initiative, US Agency for International Development, Kampala, Uganda,* [3]*Uganda National Malaria Control Program, Kampala, Uganda,* [4]*Malaria Consortium, Kampala, Uganda,* [5]*Malaria Consortium, London, United Kingdom*

Malaria remains a global heath challenge with 3.2 billion people at risk. In 2016, there were 216 million cases of malaria and 445,000 deaths globally. In Uganda, malaria is among the leading causes of morbidity and mortality, contributing to 30-50% of outpatient department attendance and over 20% of inpatient hospital admissions. In the last quarter of 2016, the US President's Malaria Initiative (PMI)-supported Malaria Action Program for Districts (MAPD), instituted several interventions to prevent and control malaria in nine high burden districts in Uganda: Kyotera, Sembabule, Lwengo, Rakai, Lyantonde, Bukomansimbi, Kalangala, Kalungu and Masaka. These included: distributing long lasting insecticidal nets through schools and health facilities, improving data reporting and use, and training and mentoring health workers in malaria diagnosis and case management. This study sought to assess the effect of these interventions by comparing trends in malaria morbidity and mortality at the start (October - December 2016: pre-I) and during the intervention period (October - December 2017: post-1yr and October -December 2018: post-2yr). Analysis of District Health Information System 2 data from all 400 district health facilities showed that while the proportion of malaria that was confirmed did not change from 76% in pre-intervention (pre-I), to 75% post-1yr intervention (post-1yr), it improved to 89% in post-2yr. The proportion of OPD attendance due to malaria fell from 41% in Pre-1 to 27% in post-1yr and 15% in post-2yr (p-value = 0.003). Similarly, the proportion of inpatient admissions due to malaria reduced from 31% to 21% and then to 15% (p-value = 0.001) in pre-1, post-1yr and post-2yr periods respectively. The number of reported malaria deaths per 100,000 population in the region has fallen from 4 (pre-I) to 3 (post-1yr) to 2 (post-2yr). Malaria morbidity and mortality in this region appears to have fallen significantly over the last 2 years and lessons related to implementing multi-channel vector control and reinforcing health worker capacity should be well noted to guide national control efforts.

944

AN OUTBREAK OF *PLASMODIUM FALCIPARUM* MALARIA IN AN ELIMINATION SETTING IN SABAH, MALAYSIA

Giri S. Rahajram[1], Matthew J. Grigg[2], Timothy William[3], Danshy Alaza[4], Joseph Benedict[4], Rashidah Mohammad[5], Jenarun Jelip[6], Nicholas Anstey[2], **Bridget E. Barber**[2]

[1]*Queen Elizabeth Hospital, Kota Kinabalu, Malaysia,* [2]*Menzies School of Health Research, Darwin, Australia,* [3]*Gleneagles Kota Kinabalu Hospital, Kota Kinabalu, Malaysia,* [4]*Infectious Diseases Society Sabah, Kota Kinabalu, Malaysia,* [5]*Sabah Department of Health, Kota Kinabalu, Malaysia,* [6]*Ministry of Health Malaysia, Putrajaya, Malaysia*

Malaysia aims to eliminate human malaria by 2020, and in the eastern state of Sabah, incidence of *Plasmodium falciparum* malaria has fallen substantially in recent years. In Kudat District, there has been no case of *P. falciparum* reported since 2015. However, an outbreak of *P. falciparum* has occurred on Banggi Island, Kudat District, in 2019, with a total of 111 cases reported during January to March. To evaluate the effect of waning immunity on the clinical and epidemiological features of falciparum malaria, we compared patients with falciparum malaria in 2019, to patients presenting in the same region with falciparum malaria during 2012 – 2015 (n=96). During 2012 – 2015 median age was 16 years (IQR 10 – 31 years), and 31 (32%) were children ≤ 12 years. In contrast, in the 2019 outbreak to-date the median age of falciparum malaria patients is 11 years (IQR 8 - 24 years), and 58% of all cases are children (chi2: p<0.0001). Median parasite densities were also lower, with a median parasitemia among adults of 1,372/μL (IQR 519 – 3,600/μL) in 2019 compared to 9,924/μL (IQR 2,522 – 22,860/μL) in 2012 – 2015, and 2,740/μL in children in 2019 compared to 7,392/μL (IQR 1,462 – 36,546/μL) during 2012 – 2015. These data are consistent with previous reports demonstrating clinical disease at lower parasite densities in low-transmission settings, with this finding particularly marked in adults. Genomic analysis of *P. falciparum* isolates from 2012 – 2015, and from the 2019 outbreak, will be conducted to investigate the changing *P. falciparum* population structure in the elimination setting.

945

PROACTIVE COMMUNITY CASE MANAGEMENT OF MALARIA IN CHILDREN AGED 6-59 MONTHS: RESULTS OF A PILOT PROJECT IN NORTHERN BENIN, WEST AFRICA, 2018

Happy Hezouwe Awide

Peace Corps Benin, Cotonou, Benin

Malaria is the leading cause of mortality in children <5 years old in Benin. WHO estimates that the average Beninese family spends 25% of their annual income on malaria-related costs. To address this burden, the National Malaria Control Program implemented a community case management strategy in 2011 that involved provision of free malaria testing with rapid diagnostic tests (RDTs) and treatment with artemisinin-based combination therapies (ACTs) to children aged 6-59 months who are brought to Community Health Workers' (CHW) homes by their parents (passive case detection). Despite these efforts, early malaria care seeking remained low in rural communities. To address barriers to care seeking, Benin Peace Corps Volunteers piloted a ProActive Community Treatment (ProACT) model in 2018 in eight villages in the northern districts of Cobly and Natitingou (Nati). CHWs were trained to conduct weekly household visits to test and treat symptomatic children aged 6-59 months for malaria. Villages in Cobly and Nati were on average 8 and 16 km away from the nearest health centers, respectively. Between June-August 2018, 26 (Cobly: 14, Nati: 12) participating CHWs made 12 weekly visits to all households in their communities. They tested 1,077 (96%) of 1,126 symptomatic children aged 6-59 months with RDTs; 1,002 (89%) tested positive for malaria and were treated with ACTs. Most children (759, 80%) who tested positive were 12-59 months old. CHWs referred 135 (12%) symptomatic children to health centers for concerning symptoms or negative RDTs. During the same time period, CHWs passively (in their own homes) treated 642 children who tested positive for malaria with

ACTs. Cobly CHWs treated more children through ProACT (658) than with the passive approach (307); Nati CHWs treated similar numbers of children through the ProACT (296) and passive (335) approaches. This pilot demonstrated that ProACT can increase the number of children who are tested and treated for malaria by CHWs when compared to standard passive malaria case detection.

946

SIMPLE CALCULATION TO IMPROVE ROUTINE HEALTH FACILITY MALARIA INCIDENCE ESTIMATES

Julie I. Thwing[1], Alioune Camara[2], Baltazar Candrinho[3], Rose Zulliger[4], James Colborn[5], John Painter[1], Mateusz Plucinski[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*National Malaria Control Program, Conakry, Guinea,* [3]*National Malaria Control Program, Maputo, Mozambique,* [4]*Centers for Disease Control and Prevention, Maputo, Mozambique,* [5]*Clinton Health Access Initiative, Maputo, Mozambique*

With the increased emphasis on malaria surveillance as an intervention, malaria incidence as reported through health information systems is increasingly used to understand trends in malaria burden and to target and monitor interventions. However, incidence data are sensitive to changes in rates of testing of suspected cases, care-seeking rates, and reporting completeness, and must be interpreted with care. Burden estimates have historically relied on community-based prevalence surveys or modeling, which are neither available frequently nor practical for programmatic decision making. We derived an algebraic formula to convert crude incidence rates to a corrected estimate of incidence. It applies a correction factor to adjust for differential testing of febrile illness by care providers, and uses the ratio of community incidence of non-malaria fever to health facility-reported incidence of non-malaria fever to account for care-seeking rates and data completeness. This formula was applied to district level data from Guinea and Mozambique from 2016-2018, and to aggregate data from sub-Saharan African countries for 2015 to estimate corrected incidence and continent-wide needs for malaria tests and treatments, assuming universal testing of febrile illness and current care-seeking rates. Maps of corrected incidence were more consistent with maps of survey prevalence than was crude incidence in Guinea and Mozambique. In areas prioritized for case management support, crude incidence showed increases from 2016-2018 (+11% annual increase in Guinea and +16% in Mozambique), while the corrected incidence showed the opposite trend (-7.2% in Guinea, -2.5% in Mozambique). Countries in southern and eastern Africa reporting recent increases in malaria incidence generally had lower corrected incidence than countries in central and west Africa. The unmet need for malaria tests was 160 M (IQR: 139-188) and for malaria treatments was 37 M (IQR: 29-51 M). Malaria incidence should be interpreted in the context of biases in testing and care-seeking rates. Adjusting for these biases provides insight into true spatiotemporal trends of malaria burden.

947

LONGITUDINAL OBSERVATIONAL STUDY EXAMINING COMMUNITY DYNAMICS OF MALARIA TRANSMISSION IN MALI

Jen C. Hume[1], Issaka Sagara[2], Daman Sylla[2], Jennifer Kwan[1], Mahamadou A. Maiga[2], Abdoulaye Katile[2], Emily Higbee[1], Amatigue Zeguime[2], Mamadou Coulibaly[2], Patrick E. Duffy[1]

[1]*National Institutes of Health/National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [2]*MRTC/USTTB, Bamako, Mali*

In 2018 a three-year longitudinal cohort study was initiated in the villages of Bancoumana and Doneguebougou in Mali to assess transmission dynamics. Approximately 1500 individuals aged 6 months to 65 years of age across the two communities were enrolled into two distinct cohorts: Direct Skin Feeding (DSF) cohort and Parasite Surveillance (PS) cohort. All individuals are seen monthly for malaria smears in conjunction with live and spray mosquito collections in/around residencies while DSF participants also undergo a single direct skin feeding assay at each visit using insectary-raised mosquitoes. In the first year of the study valuable parasitemia data through the dry and rainy seasons was generated indicating that children aged 11-17 years old carry the highest burden of infection throughout the year with parasitemia levels over 10% even in the dry season. This preponderance of infection is borne out in DSF data where positive skin feeding assays were observed most frequently in children aged 11-17 years old. To date, almost 7000 DSF have been completed and 73% of the positive skin feeds have been observed in 9-18 year olds, 13% in 5-8 year old children and 13% in adults. Over 7000 mosquito collections have been conducted with >4000 live bloodfed mosquitoes collected and dissected for infection. In this presentation we will examine dynamics of natural malaria infection and transmission over time in different age groups, the relationship between transmission measured by DSF assays of laboratory-raised mosquitoes, and by speciation assessment of live wild-caught mosquitoes.

G6PD deficiency (G6PDd) is the most common enzyme abnormality of humans (prevalences across the malaria endemic world as high as 35%). G6PDd is X-linked so males are either normal or deficient while women can be normal, fully deficient (homozygotes) or partially deficient (heterozygotes). The high prevalence in tropical areas suggests protection against malaria but this is controversial. Claims have been made that there is protection in female heterozygotes only, in hemizygotes only, in both or in neither! We conducted a retrospective analysis of data from clinical studies on vivax malaria and epidemiological studies of G6PDd conducted over the past ten years in Afghanistan where G6PD "Mediterranean" variant is the main cause of G6PDd. We conducted a meta-analysis using all previously published data on G6PDd in people of Pashtun ethnicity living in malaria endemic areas mainly in the eastern Afghanistan, where the clinical malaria studies were conducted. Samples were tested on site by the fluorescent spot tests, stored and transferred to MORU Thailand for genotyping of G6PD Mediterranean variant (563C>T) by PCR-RFLP. The proportions of G6PD Mediterranean male hemizygotes and female homozygotes and heterozygotes were significantly lower in vivax malaria patients than in controls (people visiting clinics or vaccination centers who did not have vivax malaria). In patients with *P. vivax* malaria 2.9% (95% CI 1.3-4.7) were male hemizygotes compared with 7.3% (5.3-9.9) in controls. For the female heterozygotes the respective proportions were 7.4% (5.1-10.2) vs. 13.6% (10.1-17.8). Thus there was a gene dose related protective effect of G6PD "Mediterranean" variant against vivax malaria; in male hemizygotes and female homozygotes 60.4% (28.7-82.2) versus 45.2% (15.6-65.2) for heterozygotes.

949

LOW INCIDENCE OF CLINICAL MALARIA IN UNDER-FIVES IN BANCOUMANA, MALI, A MALARIA VACCINE TESTING SITE

[1]*National Institutes of Health/National Institute of Allergy and Infectious Diseases, Rockville, MD, United States,* [2]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [3]*Laboratory of Malaria, Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

Despite an estimated 20 million fewer malaria cases worldwide in 2017 than in 2010, no significant progress occurred between 2015-2017 (WHO 2018). An efficacious vaccine remains an urgent priority to bolster malaria reduction. Here, clinical malaria incidence in a general population living in a malaria-endemic area was characterized to inform future evaluations of vaccine candidates. A total of 875 volunteers aged 6 months to 65 years old were enrolled in this study of community dynamics of malaria transmission and mosquito feeding in Bancoumana, Mali, a village located 60 km southwest of Bamako (population ~10,000 people). From Feb 2018 to Jan 2019, malaria blood smears and/or rapid diagnostic tests (RDTs) were performed monthly or upon observation of clinical symptoms to confirm clinical malaria prior to treatment. Incidence rate was calculated as the number of confirmed malaria episodes divided by the number of participants for each age group followed. The overall incidence rate of clinical malaria was 0.62 (546/875)/person/year. The incidence rate of clinical malaria by age group was 0.31 (50/160)/child/year for ages 6 months - 4 years, 0.77 (186/239)/child/year for ages 5-10 years, 0.87 (184/210)/child/year for ages 11-17 years, and 0.47 (126/266)/adult/year for ages ≥ 18 years. The seasonality of malaria incidence by age group in the dry (from Jan to Jun) and wet (from Jul to Dec) seasons was respectively 0.01 (3/160) vs 0.29 (47/160)/child/season for ages 6 months - 4 years, 0.07 (17/239) vs 0.70 (169/239)/child/season for ages 5-10 years, 0.05 (12/210) vs 0.81 (12/210)/child/season for ages 11-17 years, and 0.03 (8/266) vs 0.44 (118/266)/adult/season for ages ≥ 18 years. Malaria incidence in Bancoumana is highly seasonal with the greatest burden in children aged 11-17 and 5-10 years. The disproportionately low incidence in under-fives could be explained by seasonal malaria chemoprevention distributed during the high malaria transmission season (Jul/Aug to Oct/Nov). The seasonal and age patterns of the malaria burden should be considered when developing new malaria control strategies and evaluating new interventions in a community.

Robust tools to evaluate *Plasmodium* exposure on both a population and individual level are needed to guide malaria control efforts and accelerate progress towards elimination. Antibody responses have been used to assess exposure on a population level but serological surveillance could be greatly improved by reliable markers that can detect recent exposure on an individual level. Identification of such markers requires detailed knowledge of the kinetics of the antigen-specific response. We examined antibody kinetics in 65 adult travellers with different levels of prior malaria exposure who were followed longitudinally in Sweden, a malaria free country, for 1 year after a natural *P. falciparum* infection. First we quantified antibody responses to 8 blood-stage antigens using a bead-based assay and applied a mathematical model that captures the boosting and biphasic decay in antibody levels to characterise the kinetics of the response. We found that prior malaria exposure was associated with a greater longevity of the response to vaccine-candidate antigens MSP1, MSP2, MSP3, AMA1 and RH5. For these antigens, the half-life of the long-lived component of the response ranged from 1.8–3.7 years and individuals with prior exposure maintained 2–9-fold greater antibody levels throughout follow-up. We then proceeded to evaluate a larger set of 111 blood-stage antigens using a protein microarray (KILchip V1.0) developed in Kenya. We applied the same antibody kinetics model and performed classification analysis to identify responses predictive of recent exposure. Antibody responses to GAMA, PTEX150, PF3D7_1136200 and PfSEA1 were most informative in predicting if an individual had been infected within the last three months and exhibited shorter half-lives and more consistent boosting and decay independent of the degree of prior exposure. Using a state-of-the-art assay developed in a southern endemic country, we characterised the antibody kinetics after a successfully treated *P. falciparum* infection in travellers and identified serological markers of both cumulative and recent exposure that can improve current tools for malaria surveillance.

The long-term goal of these studies is to identify and resolve obstacles to the control and ultimate elimination of malaria. Its specific aims are to test for spatial, temporal and spatio-temporal clustering of plasmodial infection and to examine the relationship between clustering of infection and the epidemiology of *P. falciparum*. This study was performed at four sites: two rural sites in Mali, one rural site in The Gambia and a peri-urban site in Senegal. Active detection of *P. falciparum* infection was based on twice-yearly blood smear surveys at the start and end of the transmission season. A total of 834 households participated in this study (n=239 in Dangassa, n=308 in Dioro, n=141 in The Gambia and n=146 in Senegal). Thick smears were used to identify infected individuals and to estimate the household prevalence of infection. Moran's I was used to quantitate spatial correlations. The Local Moran's I and SaTScans were used to identify spatial, temporal and spatio-temporal clusters of individuals with *P. falciparum* infection. Spatial cluster analyses yielded insignificant Moran's I results for both Mali sites, consistent with random spatial patterns for *P. falciparum* infection in rural Mali. There was spatio-temporal clustering

at the rural sites in Mali and The Gambia but not at the Senegal site. Although spatio-temporal clustering of *P. falciparum* infection was observed at all study sites, larger spatio-temporal clusters (≥ 3 households) were observed only at the Mali sites in 2014 and 2015. In contrast, smaller clusters of *P. falciparum* infection (≤ 3 households) were observed in The Gambia and Senegal and there was a cluster of households with a higher prevalence of infection in Senegal adjacent to a forested area in the peri-urban community of Madina Fall. These studies provide evidence for spatial clustering of infection in The Gambia, temporal clustering in Dioro and spatio-temporal clustering at the Dangassa and Dioro sites in Mali. In contrast, there was no evidence for spatial clustering in Madina Fall (Senegal).

SEROLOGICAL ASSESSMENT OF MALARIA AND LYMPHATIC FILARIASIS IN THE DOMINICAN REPUBLIC

Justin Willingham[1], Eric Griggs[1], Hunter Keys[2], Manuel Gonzales[3], Gregory S. Noland[4]

[1]*Emory, Atlanta, GA, United States,* [2]*University of Amsterdam, Amsterdam, Netherlands,* [3]*Centro de Prevención y Control de Enfermedades transmitidas por Vectores y Zoonosis, Ministerio de Salud Pública, Santo Domingo, Dominican Republic,* [4]*The Carter Center, Atlanta, GA, United States*

The island of Hispaniola, comprised of the Dominican Republic and Haiti, is the only island in the Caribbean with active malaria transmission and accounts for 95% of the lymphatic filariasis (LF) burden in the Americas. A cross-sectional, household cluster survey was conducted in *bateyes*—agricultural settlement villages home to Haitian migrant workers, their descendants, and ethnic Dominicans—in the Dominican Republic from March to April 2016 to determine the prevalence of malaria and LF by rapid antigen test and microscopy. The study also included collection of dried blood spots from one adult and one other randomly selected household resident of any age to determine the seroprevalence of malaria and LF antibodies using a multiplex bead assay. This study reports serology results from 1,331 samples with matched diagnostic results (median age: 34 years; range: 2—96). Although no (0%) person was *Plasmodium*-positive by RDT or microscopy, overall seroprevalence to *P. falciparum* antigens MSP-1, AMA-1, CSP, and LSA-1 was 16.9%, 10.0%, 1.5%, and 1.2%, respectively. Seroprevalence of long-lived antibodies MSP-1 and AMA-1 increased with age from 2.5% and 1.3%, respectively, in those < 10 years of age to 23.8% and 19.1% in those ≥60 years of age. Seroprevalence of short-lived antibodies CSP and LSA-1 was uniformly low across age groups. For LF, six individuals were FTS-positive (0.5%), but none (0%) were microfilariae-positive. Overall seroprevalence to Wb123, Bm14, and Bm33 antibodies was 1.3%, 16.2%, and 7.7%, respectively. Seroprevalence to Bm14, but not Bm33 or Wb123, increased with age. Univariate analysis for malaria seropositivity (PfMSP-1) revealed significantly higher odds of infection in the Southwest region and among those without access to a bednet, but no significant difference by country of birth or ethnicity. Age was the only significant predictor for LF seropositivity identified. These results indicate very low recent exposure to malaria and LF in the Dominican Republic and provide important data to prospectively monitor transmission elimination in Hispaniola.

UNDER THE RADAR: EPIDEMIOLOGY OF *PLASMODIUM OVALE* INFECTIONS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Cedar Mitchell[1], Nicholas F. Brazeau[1], Kashamuka Mwandagalirwa[2], Antoinette K. Tshefu[2], Kyaw Thwai[1], Jonathan B. Parr[1], Jonathan J. Juliano[1], Steven R. Meshnick[1]

[1]*University of North Carolina Chapel Hill, Chapel Hill, NC, United States,* [2]*University of Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo*

There are six species of the malaria parasite known to infect humans, two of which, *Plasmodium ovale wallikeri* and *{. ovale curtisi*, form a species complex known as *Plasmodium ovale.* While *P. ovale* has been shown to be prevalent throughout sub-Saharan Africa, little is known about the true burden of disease or the epidemiological factors associated with infection. Knowledge of the distribution of all malaria species is critical to malaria elimination efforts. Understanding the impact of *Plasmodium falciparum*-targeted interventions on non-falciparum species is particularly important. We conducted a risk factor analysis to characterize the epidemiology of *P. ovale* infections in the Democratic Republic of the Congo (DRC) using the nationally representative, cross-sectional 2013 DRC Demographic and Health Survey. Of 18,149 Congolese adults tested in our study sample, 143 prevalent *P. ovale* infections were detected, yielding a point prevalence estimate of 0.8% (95% CI: 0.59, 0.98). Using log-binomial regression models with generalized estimating equations to account for correlation among sampling clusters, we detected risk factors positively associated with increased ovale prevalence. These included male sex (prevalence ratio [PR] 2.12, 95% CI: 1.38, 3.26), co-prevalent *P. falciparum* infection (PR:3.52, 95% CI: 2.06, 5.99), and rural residence (PR: 2.19, 95% CI:1.31, 3.66). We found insufficient evidence for an effect of long lasting insecticidal net use on *P. ovale* prevalence (PR: 1.02, 95% CI:0.63, 1.62). Preliminary molecular analyses of our study sample identified both *P. ovale spp.* circulating in DRC. Further analyses will fully characterize the prevalence of *P. ovale curtisi* and *P. ovale wallikeri* among our full study sample size and elucidate risk factors associated with each species to build on our understanding of this neglected malaria species in one of the most malarious countries in the world. To our knowledge, this is the largest nationally representative survey of *P. ovale* conducted to date. Findings will provide insight into its epidemiology in the DRC and elsewhere in sub-Saharan Africa.

954

SEVERITY OF MALARIA IN A BIRTH COHORT OF INFANTS LIVING IN A HIGHLY ENDEMIC AREA OF UGANDA

Nicholas August Zehner[1], Teddy Andra[2], Richard Kajubi[2], Isaac Ssewanyana[2], Melissa Conrad[3], Felistas Nankya[2], Harriet Adrama[2], Tamara D. Clark[4], Moses Kamya[4], Grant Dorsey[3], Prasanna Jagannathan[1]

[1]*Stanford School of Medicine, Stanford, CA, United States,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*University of California San Francisco, San Francisco, CA, United States,* [4]*Makerere University, Kampala, Uganda*

Progress towards controlling *Plasmodium falciparum* malaria has stalled in high transmission settings, where the burden of severe malaria and death falls largely on infants and young children. A better understanding of the natural history of malaria in the setting of insecticide treated bednets (ITNs) and artemisinin-based therapy (ACT) will assist in deployment of prevention efforts. We enrolled a birth cohort of children from Busia, Uganda, an area with very high and perennial malaria transmission, and followed them through one year of age. Mothers were enrolled during pregnancy, given an ITN, and both mothers and children received all care at a study clinic, including ACT for smear-positive cases of symptomatic malaria. Routine assessments were performed every 4 weeks, including evaluation for parasitemia by microscopy. Of 678 live births, 6.5% were preterm, 8.9% low birth weight, and sickle cell trait prevalence was 17%.

Overall, there were 1,131 incident episodes of malaria (1.8 episodes ppy, range 0-10), increasing from 0.66 episodes ppy from 0-3 months to 2.9 episodes ppy from >9-12 months of age. Parasite prevalence at monthly visits increased from 5% from 0-3 months to 26% from >9-12 months of age. There were 8 episodes of severe malaria in 8 children (0.01 episodes ppy) - 1 severe anemia and 7 episodes of respiratory distress, including one death in a 9 month-old girl who had experienced 2 prior uncomplicated episodes. Episodes of severe malaria were accompanied by higher objective temperatures (P=0.04) and a trend towards longer duration of reported fever (P=0.08) and higher parasite densities (P=0.08) than uncomplicated cases, and 4 of 8 children had >=2 episodes of uncomplicated malaria before having severe malaria. Of 581 children followed through one year of age, 26% had no evidence of malaria parasitemia, 39% had only symptomatic malaria when infected, and 35% had at least one episode of asymptomatic parasitemia. Together, these data suggest that, in a high transmission setting where children are given ITNs and ACT, although the risk of malaria is high, severe malaria is preventable with prompt access to antimalarial therapy.

955

IS MALARIA ELIMINATION POSSIBLE IN UGANDA: EVIDENCE FROM POPULATION-BASED SURVEYS AND HEALTH FACILITY DATA 2014 AND 2019

Bosco B. Agaba[1], Damian Rutazaana[1], Paul Mbaka Mbaka[2], Jimmy Opigo Opigo[1], Monica Nabatanzi[1], Daniel Kyabayinze[1], Catherine Maiteki[1], Henry Katamba[1], Belay Kassahum[3]

[1]*Department of Disease Control, Ministry of Health, Kampala, Uganda,* [2]*World Health Organization, Uganda Country Office, Kampala, Uganda,* [3]*US President Malaria Initiative, PMI Uganda, Kampala, Uganda*

Malaria remains a major public health problem in Uganda despite increased intervention coverage. However malaria indicator surveys and health facility data have shown consistent decline in parasite prevalence, incidence, and deaths. In this study, we show evidence of declining malaria burden and increasing heterogeneity of malaria transmission pattern in Uganda. Using population-based survey data, we compared estimates of parasitemia for 2009, 2014 and 2018 using a sample of children aged 0-59 months at comparable time points coinciding with second peak transmission season. We determined differences in proportions of parasitemia between three time points of 2009, 2014 and 2018. Next we used multiple data sources to measure changes in malaria mortality and morbidity over time and constructed malaria incidence, risk and stratification maps to identify high and low transmission zones. Based on survey data, there was a reduction in malaria parasitemia from 42%, 19% and 16% (RDT) in 2009, 2014 and 2018 respectively. Based on Risk stratification, malaria transmission was highly heterogeneous across the country ranging from <5%, 5%-50% and >50% for low, medium and high transmission respectively. Health facility data showed reduction in malaria cases from 393 cases per 1,000, 396 cases per 1,000 and 241 per 1,000 populations in 2009, 2014 and 2018 respectively. There was also a reduction in malaria deaths from 21 deaths per 100,000 in 2009, to 17 deaths per 100,000 in 2014 and 8 deaths per 100,000 in 2018 respectively. Malaria morbidity and mortality is declining in Uganda. Transmission pattern is highly heterogenous ranging from very high to extremely low transmission areas. Low transmission areas could be targeted for malaria elimination.

956

DETECTION OF THE ASYMPTOMATIC *PLASMODIUM FALCIPARUM* INFECTIOUS RESERVOIR AMONG SCHOOLCHILDREN IN TANZANIA USING MOSQUITO SKIN FEEDING ASSAYS

Billy Ngasala[1], Vincent O. Nyasembe[2], Christopher Basham[3], Mwajabu Loya[1], Zackary Park[3], Brian Tarimo[4], Feng-Chang Lin[3], Andreas Mårtensson[5], Jonathan Juliano[3], Rhoel R. Dinglasan[2], Derrick K. Mathias[2], **Jessica T. Lin**[3]

[1]*Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania,* [2]*University of Florida, Gainesville, FL, United States,* [3]*University of North Carolina, Chapel Hill, NC, United States,* [4]*Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania,* [5]*Uppsala University, Uppsala, Sweden*

We are conducting a three-year field study to characterize the asymptomatic infectious reservoir in an area of declining malaria endemicity in Bagamoyo district, Tanzania. In October-November 2018, we screened 530 schoolchildren ages 8-16 for *Plasmodium falciparum*, finding that 21% were positive by RDT, 15% were positive by microscopy, and 33% were positive by an 18s rRNA real-time PCR (qPCR) assay with a limit of detection of ~1 parasite/l blood. Fifty-five RDT-positive children (median parasite density = 227 parasites/l) were enrolled for mosquito feeding assays. Of these, 69% (38/55) had gametocytes detectable by Pfs25 qRT-PCR. We used direct skin feeding assays (DFAs), which more closely mimic Anopheline sampling of gametocytes within capillaries, to evaluate the infectiousness of these individuals to mosquitoes and observed that 60% (28/47) were infectious to insectary-reared *Anopheles gambiae IFAKARA strain*. Mosquito infection was sporadic, with a low median infection rate of 7% (IQR 4-10%), yet infected midguts often harbored many oocysts. In 17 DFAs where only 1-2 mosquitoes were infected, 40% of positive midguts (10/25) harbored >100 oocysts. It is unclear if this "jackpotting effect" is due to gametocyte clustering in capillary blood. Gametocyte densities in capillary and venous blood as determined by Pfs25 RT-qPCR were closely correlated (r=0.92, p<0.001); however, gametocytes detected in 6 capillary blood samples were not detected in the corresponding venous samples, without the converse scenario. Of the 28 subjects who were infectious to mosquitoes, 21% were gametocytemic by microscopy, 68% were gametocytemic by RT-qPCR, 61% were slide-positive, and 86% were positive by 18s qPCR at the time of mosquito feeding. Thus, molecular tests appeared incompletely sensitive to detecting the entirety of the infectious reservoir in this school-age survey. By July 2019, we plan to recruit ~100 schoolchildren with submicroscopic malaria to measure transmission from lower parasite densities. Results will inform models of malaria transmission and shape strategies for interrupting transmission in areas moving towards malaria elimination.

957

CARRIAGE OF *PLASMODIUM FALCIPARUM* AND NON-*P. FALCIPARUM* INFECTIONS AND GAMETOCYTES IN ASYMPTOMATIC POPULATION IN WESTERN KENYA

Carolyne M. Kifude[1], Deborah Stiffler[2], Stephen Ocholla[3], John Waitumbi[1], Janet Oyieko[1], Shirley Luckhart[4], V.Ann Stewart[2]

[1]*US Army Medical Research Directorate-Africa, Kisumu, Kenya,* [2]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [3]*US Army Medical Research Directorate, USAMRD-Africa, Kisumu, Kenya,* [4]*University of Idaho, Moscow, ID, United States*

Accurate identification of malaria species is important in malaria control efforts. However, in asymptomatic malaria, diagnosis of *non*-falciparum submicroscopic malaria species can be difficult. This is due to mixed infections with other *Plasmodium* species and low parasitemia levels. Lowland western Kenya in particular is holoendemic for malaria transmission and has high rates of asymptomatic malaria infections. However, the true burden of submicroscopic non-*P. falciparum* infections has not been determined in this population. Using panels of highly sensitive and specific qPCR assays, we report the prevalence of malaria

species including *P. falciparum, P.malariae, P.ovale* and *P.vivax* either as single or mixed infection. In addition, we determined the magnitude of gametocyte carriage in this asymptomatic population. Using 1762 dried blood spots (DBS) samples collected in a HIV/malaria co-infection study in a malaria endemic region in western Kenya, the presence of any species of malaria was first determined using an improved assay based on genus-conserved sequences of the *Plasmodium* 18S ribosomal gene. If positive for malaria, panels of highly species-specific qPCR assays were developed to determine the presence and quantity the four malaria species. In addition, we used three stage- gametocyte specific RNA transcripts to quantify gametocyte carriage. Preliminary analysis shows malaria prevalence of about 69.5% as detected by sensitive molecular techniques. Of these, *P.falciparum* was the most prevalent species (59.1%), followed by *P.malariae* (4.7%) and *P. ovale* (2.6%). We have so far not detected any *P.vivax* in our population. Of the 18S positive samples by genus assay, only 66.4 % could be speciated suggesting that there is need for even more sensitive species assays for detection of sub-microscopic malaria. We will report on the magnitude of sexual malaria parasitemia using our gametocyte panel. The relevance of this study is that asymptomatic malaria carriage of both *falciparum* and non-*falciparum* species is an efficient reservoir of malaria hence the need for higher public health priority.

958

THE POTENTIAL IMPACT OF MATERNAL DEPRESSION ON PARENT-CHILD INTERACTIONS AND PARASITIC INFECTION IN BENINESE INFANTS

Post partum maternal depression occurs in an estimated 13-19% of women following childbirth, with women from developing countries particularly at risk. Numerous studies in low-income settings have found links between maternal depression and neonatal and child health outcomes such as stunting, underweight, inhibited neurodevelopment, and diarrheal disease. However, few studies further investigated the potential consequences in terms of offspring morbidity. Our objective was to explore the relationship between maternal depression one year after birth and parent-child interactions, risk of *Plasmodium falciparum* malaria, and risk of soil-transmitted helminth infection in infants 1-2 years of age in Benin. Our population included mothers and their children enrolled in a clinical trial during the second trimester of pregnancy (MiPPAD). Maternal depression was assessed using the Edinburgh Postnatal Depression Scale (EPDS) in mothers of children one year post-partum. Parent-child interactions were assessed through the HOME subscales at one year post-partum. Blood, urine, and stool samples were taken from children to diagnose malaria and helminth infection prospectively from 1-2 years of age. Crude and adjusted linear and negative binomial regression models tested associations. Of the 303 children in analyses, 39 (12.87%) had mothers with depressive symptoms according to a cut-off of >=13 points. Mean HOME score was 27 (SD=2.4). From 1-2 years of age, median number of malaria episodes per child was 3 (0-14) and 82/240 (34.17%) children had at least one helminth infection. Adjusted linear regression analyses revealed post partum maternal depression to be significantly correlated to a reduced HOME score (Coefficient=-0.12 95% CI: -0.19--0.05). Adjusted negative binomial models did not reveal significant associations between post-partum maternal depression and increased risk of malaria episodes (IRR=1.00, 95% CI: 0.97-1.02) and increased risk of helminth infection (IRR=0.99 95% CI: 0.93-1.05). As expected, parent-child interactions were affected by post-partum depression, but this did not seem to affect offspring morbidity.

959

SHIFT OF DEMOGRAPHIC BURDEN OF MALARIA CASE OF RWANDA USING HMIS

Michee Kabera Semugunzu[1], Jean Louis Mangala[1], Monique Mulindahabi[2], Noella Umulisa[3], Aimable Mbituyumuremyi[1], Jeanine U. Condo[1]

[1]*Rwanda Biomedical Center, Kigali, Rwanda,* [2]*CDC President's Malaria Initiative, Kigali, Rwanda,* [3]*Maternal and Child Survival Program (MCSP), Kigali, Rwanda*

Malaria is a major cause of out patients' consultation in Sub Saharan African country and particularly in Rwanda where malaria constituted more than 30% of outpatient's consultation in year 2017-2018. The Rwanda National Malaria Program Annual Report 2017-18 shows that the number of malaria deaths reduced from 529 cases in 2016-2017 to 382 cases in 2017-2018 (28% reduction), and in the same period, severe malaria cases reduced from 14,033 cases in 2016-2017 to 10,894 cases in 2017-2018 (22.4% reduction). We analyzed demographic characteristic of all 2018 malaria cases and deaths captured through the Rwanda Health Management Information System (HMIS) by age group and gender. All inpatients malaria cases were 16,501: 8, 040 (49%) males and 8,461 (51%) females. A total of 7,688 severe malaria cases were reported, with 4,056 (53%) male and 3,632 (47%) female (p value<0.0001). From Jan to Dec 2018, 331 malaria deaths were notified with171 (52%) male and 160 (48%) female. The proportion of malaria deaths among inpatients male (2.1%) was not different to the proportion of malaria deaths among female (1.9%), p value>0.05. Inpatients malaria cases were 6,662 (40.4%) in under5; 4,663 (28.3%) aged 5 to 19 years and 5, 176 (31.4%) 20 years and above. A total of 3,496 (45%) severe malaria cases were found in children under5; 2,502 (33%) aged between 5 to 19 years and 1,690 (22%) 20 years and above. Malaria deaths were 86 (26%) for under5; 74 (22%) aged between 5-19 years and 171(52%) for 20 years and above. The proportion of malaria deaths to total malaria inpatients was respectively 1.3% for under5; 1.6% for 5 to 19 years and 3.3% for patients of 20 years and above (p-value<0.0001). The Routine malaria data shows that male are most likely to develop severe malaria and adults of 20 years and above have higher mortality risk.

960

DEMOGRAPHIC SURVEILLANCE TO MONITOR PREGNANCY OUTCOMES IN MALARIA ENDEMIC AREA IN OUELESSEBOUGOU, MALI

Gaoussou Santara[1], Naissem Andemel[2], Amadou Barry[1], **Almahamoudou Mahamar**[1], Moussa Traore[1], Seydou Traore[1], Mamoudou Samassekou[1], Ibrahim H. Soumbounou[1], Oumar Attaher[1], Djibrilla Issiaka[1], Halimatou Diawara[1], Patrick E. Duffy[2], Michal Fried[2], Alassane Dicko[1]

[1]*Malaria Research and Training Center (MRTC), Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology (LMIV), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Rockville, MD, United States*

Placental malaria is associated with poor outcomes for both women and their babies. To reduce poor pregnancy outcomes associated with malaria infection, WHO recommends monthly anti-malarial treatment with sulfadoxine pyrimethamine (SP) during the second and third trimester and the use of insecticide-treated bed nets. However, due to the spread of SP-resistant parasites in some parts of Africa, new interventions such as a vaccine to prevent placental malaria is needed. Prior to testing a

vaccine that may be given as a primary vaccine series or as a boosting dose during early pregnancy baseline information on pregnancy outcomes in the target population is needed. We assessed the frequency of poor pregnancy outcomes and their relation to malaria in pregnant in women in Ouelessebougou Mali from February 2017 to March 2019. Pregnant women were recruited during the antenatal consultations at the community health centers and information on malaria and pregnancy outcomes were collected four weeks post pregnancy termination (delivery, miscarriage or stillbirth). The proportion of pregnancy loss (defined as miscarriage, stillbirth and early neonatal death) and preterm delivery (PTD) were 3.9% (70/1777 and 4.7% (73/1777) respectively. The proportion of low birth weight deliveries was 6.5%. In multivariate logistic regression model adjusted for age, SP-IPTp, and bed net use, young age (<18), was associated with increased odds of pregnancy loss (OR 1.86 (95%CI 1.01-3.43, p=0.04); SP-IPTp, and bed net use were associated with reduced odds of pregnancy loss: 0.34 (0.14-0.83), p=0.02 and 0.48 (0.22-1.03) p=0.06 respectively. Women aged <18 and >35 years had increased odds of PTD, 2.98 (1.77-5.02) p<0.0001 and 2.26 (1.04-4.90) p=0.04 respectively. SP-IPTp and bed net use did not reduced the odds of PTD. The rates of pregnancy loss and preterm birth were high in area with high malaria transmission. Younger age is associated with pregnancy loss, and both young age and age >35 years are associated with increased odd of PTD.

961

PREVALENCE OF MALARIA INFECTION IN PREGNANT WOMEN IN OUELESSEBOUGOU, MALI

Moussa Traore[1], **Almahamoudou Mahamar**[1], Gaoussou Santara[1], Seydou Traore[1], Mamoudou Samassekou[1], Ibrahim H. Soumbounou[1], Seydina O. Maguiraga[1], Oumar Attaher[1], Adama Sissoko[1], Sekouba Keita[1], Bacary S. Diarra[1], Djibrilla Issiaka[1], Halimatou Diawara[1], Patrick E. Duffy[2], Michal Fried[2], Alassane Dicko[1]

[1]*Malaria Research and Training Center (MRTC), Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology (LMIV), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Rockville, MD, United States*

Malaria during pregnancy is associated with low birth weight, preterm delivery, severe maternal anemia, and maternal and perinatal death. Despite ongoing control efforts, the burden of pregnancy malaria remains high in endemic countries in sub-Saharan Africa such as Mali. We assessed the frequency of malaria infection among women appearing for antenatal consultations by rapid diagnostic test (RDT) in community health centers in Ouelessebougou health district during the malaria transmission season. Information collected included gestational age, gravidity, residence area as well as the use of intermittent preventive treatment of malaria in pregnancy with sulfadoxine–pyrimethamine (IPTp-SP) and insecticide treated nets (ITN). Among 496 pregnant women (PW) screened from August 2018 to January 2019, 39.2% were infected. The prevalence of malaria infection was higher in the rural versus semi-urban health center (57.9% (92/159) vs. 30.4% (102/336) respectively (p = 0.0002)). The frequency of positive RDT decreased from 49.4% (84/170) in primigravidae to 40.7% (59/145) in secundigravidae to 28.3% (51/180) in multigravidae women (p = 0.0003). Based on the women's report and review of antenatal clinic cards, only 38.4% (164/428) of women in their second or third trimester had received IPTp-SP. In multivariate analysis malaria infection was significantly higher in primigravidae women (OR: 2.54, 95% CI: 1.28-5.04, p=0.008), in secundigravidae women (OR: 2.67, 95% CI: 1.35-5.25, p=0.004). The odds of malaria infection was lower in pregnant women living in urban area (OR: 0.30, 95% CI: 0.17-0.53, p<0.001), who received IPTp-SP (OR: 0.30, 95% CI: 0.14-0.54, p<0.001) and always sleep under ITN (OR: 0.21, 95% CI: 0.08-0.53, p=0.001). Malaria infection is pervasive among pregnant women in Mali. Efforts are needed to improve the coverage of the preventive measures such as IPTp-SP. An effective strategy such as an easily administered malaria vaccine would be an important addition to reduce this huge burden of malaria in pregnancy.

962

IMPROVING THE SPATIAL GRANULARITY FOR TARGETING INDOOR RESIDUAL SPRAYING ON BIOKO ISLAND

Olivier Tresor Donfack[1], Guillermo A. Garcia[2], Jordan M. Smith[1], David L. Smith[3], Carlos A. Guerra[2]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Medical Care Development International, Silver Spring, MD, United States,* [3]*Institute for Health Metrics and Evaluation, Seattle, WA, United States*

Since the launch of the Bioko Island Malaria Control Project 16 years ago, 26 rounds of indoor residual spraying (IRS) have been completed on the island. Between 2015 and 2018 IRS was targeted based on risk stratification at the community level (fourth administrative division). Communities, however, vary in area and population and malaria transmission within them is highly heterogeneous. This has raised concerns regarding the efficiency of allocating a costly intervention such as IRS. For round 26, conducted in 2019, we adopted a new approach using a grid of 100x100 m sectors as the units for targeting. The aim was to target ~15,000 households considering 80-85% spray coverage. First, we identified transmission hotspots using kernel smoothing of individual *Plasmodium falciparum* parasite rate (*Pf*PR) data from the 2018 malaria indicator survey after excluding individuals with a history of travel. This allowed us to estimate sector-level *Pf*PR assumed to represent locally acquired malaria. We chose an arbitrary threshold of *Pf*PR>10% for targeting. There were 1443 such sectors containing 24,402 households. Further selection of target sectors was needed to keep within the preset number of households to spray. To do so, we ranked sectors based on a combination of *Pf*PR, population, sample size, and an urban/rural divide. The latter was used such that 80% of households would be selected from urban and 20% from rural areas. The highest ranked sectors were selected until the ~15,000 household mark was reached. Higher population sectors were preferred because the total spray area would be smaller. Higher sample size sectors were preferred because *Pf*PR estimates would have narrower confidence intervals. A total of 692 sectors were selected for spraying, most of which were clustered. Coverage will be estimated at the sector level to achieve the desired 80-85% mark. This new approach allowed IRS to be more focalized by increasing the spatial granularity of the target units, improving the efficiency and, hopefully, the effectiveness of this costly intervention.

SELECTIVE WHOLE GENOME AMPLIFICATION OF DNA IN LOW PARASITEMIA SAMPLES OF *PLASMODIUM VIVAX* FROM PERU

Mac Pholo Aguirre Huamaní[1], Paulo César Manrique Valverde[1], Christopher Delgado Ratto[2], Jean-Pierre Van geertruyden[2], Dionicia Gamboa Vilela[1], Dionicia Gamboa Vilela[3], Dionicia Gamboa Vilela[4]

[1]*Laboratorio de Malaria, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Global Health Institute, University of Antwerp, Antwerp, Belgium,* [3]*Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru,* [4]*Instituto de Medicina Tropical "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru*

The low recovery of parasite DNA in low parasite density *Plasmodium vivax* infections (=sub-microscopic infections) restricts the inclusion of sub-microscopic infections in population genetics and population genomic studies. The under-estimation of the genetic diversity biases the understanding of *P. vivax* transmission especially in low endemic settings where submicroscopic infections are predominant. Different methods have been developed to overcome this problem, being the Selective Whole Genome Amplification (SWGA) one of the most promissory tools. However, its effectiveness in low parasite density *P. vivax* infections has not been reported yet. This work aims to evaluate the performance of SWGA in *P. vivax* sub-microscopic infections. The protocol reported by Cowell *et al.* 2017 was adapted to improve the yield of the method while assessing

the minimum amount of DNA sample required for amplification (LOD) and its application on 20 field samples. Changes in different components and parameters of the SWGA reaction were tested. Parasite and human DNA quantity were measured by real-time PCR before and after the SWGA to determine the parasite DNA enrichment. The best performance of the method SWGA occurred at 24 hours of incubation, with 1 μL of Phi29 enzyme from illustra GenomiPhi V2 DNA amplification kit, 1.25 mM of dNTPs as final concentration, 6.4 μM of the pvset1920 primer set, and 3.4 μM of the pvset1 primer set. When two rounds of SWGA were applied, the method generated lower parasite DNA concentrations (~0.6 times) but the percentage of parasite DNA was greater (~3.5 times) than using one round. The minimum amount of parasite DNA required to produce at least 1200 parasite DNA molecules/μL was between 0.75 - 1 parasite DNA molecules/μL and 17 out of the 20 field samples amplified correctly. Our results showed that SWGA could be used to enrich *P. vivax* DNA in low parasitemia samples allowing larger coverage of samples to be included in genetic studies and also we provide a protocol to determine the fidelity of SWGA.

964

AMPLICON DEEP SEQUENCING VERSUS TRADITIONAL GENOTYPING OF MSP1 AND MSP2

Daniel Castaneda-Mogollon, Ranmalee Amarasekara, Conrad Izydorczyk, Dylan R. Pillai

University of Calgary, Calgary, AB, Canada

Malaria infection is thought to be polyclonal in nature. Microscopic or polymerase chain reaction methods are only able to detect the predominant clone due to inherent limitations. Detection of the predominant clone may not reveal the true complexity of infection which may include minority variants that are more virulent or resistant to anti-malarials. We sought to compare traditional PCR methodology with amplicon deep sequencing based on next generation sequencing. We analyzed data from 15 PCR-confirmed *Plasmodium falciparum*-infected patients and 5 control samples using the merozoite surface protein 1 and 2 (msp1 and msp2) genes as markers. Amplification of the MAD20, RO33, and K1 msp1 and FC27 and 3D7 msp2 alleles was performed using nested PCR, followed by an agarose gel electrophoresis to determine the presence and number of alleles per locus in each sample. Deep sequencing of both msp genes was performed using an Illumina MiSeq platform, followed by determination of the number of alleles present per locus per sample using SRST2 (Short Read Sequence Typing), a reference-based DNA read mapping and SNP calling bioinformatics software. Multiplicity of infection was determined by estimating the number of alleles per locus and compared against a bioinformatics haplotype-based approach. Deep sequencing found 11 K1 alleles across the 15 patient samples, 9 for MAD20, 5 for RO33, 9 for FC27, and 13 for 3D7, whereas nested PCR followed by gel electrophoresis found 9 for K1, 6 for MAD20, 3 for RO33, 3 for FC27, and 10 for 3D7. Deep sequencing found 3 K1 alleles across the 5 control samples, 2 for MAD20, 3 for RO33, 4 for FC27, and 5 for 3D7, whereas nested PCR found 3 K1 alleles, 2 for MAD20, 3 for RO33, 2 for FC27 and 4 for 3D7. Additionally, the agarose gel confirmed a MOI average and standard error of the mean (SE) of 1.4 ± 0.18 across the 20 samples by employing conventional methods, whereas deep sequencing yielded a value of 1.85 ± 0.19 (p value of 0.03). Our findings suggest deep sequencing yields significantly higher number of alleles per locus, and thus, MOI per sample which may have implications for drug treatment and diagnostics.

EVOLUTION OF *PLASMODIUM FALCIPARUM* AFTER AN OUTBREAK FACILITATES LOW ENDEMICITY MALARIA TRANSMISSION IN ECUADOR

Shazia Ruybal-Pesántez[1], Fabián E. Sáenz[2], Claudia A. Vera-Arias[2], Kathryn E. Tiedje[1], Karen P. Day[1]

[1]*School of BioSciences/Bio*[21] *Institute, University of Melbourne, Melbourne, Australia,* [2]*Centro de Investigación para la Salud en América Latina, Escuela de Ciencias Biológicas, Pontificia Universidad Católica del Ecuador, Quito, Ecuador*

In Latin America, *Plasmodium falciparum* outbreaks are common. In the coast of Ecuador, an outbreak in 2012-2013 documented 150 *P. falciparum* clinical cases after less than 10 annual cases in previous years, pointing to the risk of "epidemics". Following the outbreak, the number of reported *P. falciparum* cases in Ecuador increased by 38% in 2014 and 78% in 2015. We aimed to understand how malaria could be sustained by characterizing *P. falciparum* transmission dynamics using the "*var*code", a genotyping tool based on the *var* multigene family encoding the major variant surface antigen. The *var* genes encoding this antigen are highly polymorphic and *var* repertoires or haplotypes are rapidly evolving, enabling high discriminatory resolution to define transmission networks in real-time. We apply this tool to characterize *P. falciparum* during and after the outbreak from 2013-2015 to detect parasite genetic *var*codes circulating locally. We then reconstructed transmission networks to identify clusters of genetically-related parasites in space and/or time. Our findings reveal the "real-time" evolution of *P. falciparum* after an outbreak, consistent with an endemoepidemic population structure whereby low but sufficient levels of recombination among parasites can generate new *var*codes and sustain transmission in a local population. Comparisons to other South American parasite populations elucidate possible origins of *var*codes circulating in Ecuador. This study confirms that the *varcode* provides a useful surveillance tool to characterize a rapidly evolving *P. falciparum* parasite population.

966

VARIED PREVALENCE OF MARKERS OF ANTIMALARIAL DRUG SENSITIVITY ACROSS UGANDA

Victor Asua[1], Marvin Duvalsaint[2], Ozkan Aydemir[3], Jennifer Legac[2], Samuel L. Nsobya[1], Melissa D. Conrad[2], Jeffrey Bailey[3], Philip J. Rosenthal[2]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*University of California San Francisco, San Francisco, CA, United States,* [3]*Brown University, Providence, RI, United States*

Antimalarial drug resistance, mediated in part by known *P. falciparum* genetic polymorphisms, is of concern. Chloroquine/sulfadoxine-pyrimethamine (SP) was replaced as the Ugandan treatment regimen by artemether/lumefantrine in 2006. SP is used to prevent malaria in pregnant women. Recent reports showed changing prevalence of key parasite polymorphisms. To continue surveillance, 50 samples were collected in 2018 from children (6 mo-10 yr) diagnosed with malaria by microscopy or rapid test at each of 13 sites across Uganda. Polymorphisms associated with resistance were characterized by ligase detection reaction fluorescent microsphere (LDR) and molecular inversion probe (MIP) assays, copy number (CN) variations were assessed by qPCR, and the K13 propeller domain was sequenced. Agreement between LDR and MIPs assays was excellent. Preliminary analysis shows that prevalences of polymorphisms varied across the country. For transporter mutations, prevalences (by MIPs analysis) were 0-42% for *pfcrt* 76T, 0-3% for *pfmdr1* 86Y, 38-86% for *pfmdr1* 184F, and 3-46% for *pfmdr1* 1246Y; the highest prevalences of 76T were at sites near international boundaries. For antifolate mutations, 5 mutations (*pfdhfr* 51I, 59R, 108N;*pfdhps* 437G, 540E) were at nearly 100% prevalence, as seen previously, and the prevalence of mutations mediating higher-level resistance was high at multiple sites (*pfdhfr* 164I 15-75% at 7 sites; *pfdhps* 581G 15-65% at 6 sites), with the highest prevalences in western Uganda. Polymorphisms associated elsewhere

with altered sensitivity to lumefantrine (increased *pfmdr1*CN), piperaquine (increased *plasmepsin-2* CN), and artemisinins (K13 mutations) were uncommon. Comparing our results to older data, prior increases in the prevalence of *pfcrt* K76 wild type parasites appear to have stalled, especially in border areas. Overall, although genetic evidence suggesting ACT resistance is lacking, recent data suggest incomplete loss of resistance to chloroquine and increasing high-level resistance to antifolates, with varied patterns across the country. Continued surveillance for drug resistance markers is an important priority.

967

SEEKING GENES AND THEIR EXPRESSION PROFILES THAT CONTROL SEXUAL ASSIGNMENT IN *PLASMODIUM FALCIPARUM*

Margaret R. Smith, Kazutoyo Miura, Ababacar Diouf, Bingbing Deng, Luwen Zhou, Carole A. Long

National Institute of Allergy and Infectious Diseases, Rockville, MD, United States

The sexual stage of *Plasmodium* parasites is a bottleneck in the malaria life cycle, and blocking the development process could potentially stop disease transmission. Although AP2-g transcription factor is known to be important for sexual stage commitment, what is not known is what genes or gene expression profiles control the sexual assignment of gametocytes (i.e., either developing to male or female gametocytes). We are addressing this question using two lines of *P. falciparum* NF54, SA and N1. N1 is a female gametocyte dominated strain with a female to male ratio of ~20 while SA has a ratio of ~2. In turn, due to the female dominancy, N1 gives fewer oocysts than SA when doing standard membrane-feed assay. Whole genomic sequencing and RNA-sequencing were performed to determine the factors which contribute to the different sex ratios. DNA-Sequencing was performed using PacBio. N1 and SA were compared with the reference strain 3D7 individually. N1 had 3847 variants from 3D7 and SA had 4030 variants from 3D7. This came down to 112 variants that were recognized as high or moderate impact of N1 and SA based on the definition from the ensembl.org glossary. For the RNA-sequencing, RNA samples were collected at 0, 8, 16, 24, 32, 40 and 48 hours after induction of synchronized gametocyte cultures. Data from DNA-sequencing and RNA transcriptomics will be presented. This study will help better understand the sexual assignment in gametocytes in *Plasmodium falciparum.*

968

MAPPING COMPETITIVE GROWTH OF MALARIA PARASITES TO ASSESS THE FITNESS IMPACT OF ARTEMISININ RESISTANCE

Katelyn M. Vendrely[1], Lisa A. Checkley[1], Marina McDew-White[2], Ian H. Cheeseman[2], Ashley M. Vaughan[3], François H. Nosten[4], Timothy J. Anderson[2], Michael T. Ferdig[1]

[1]*Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States,* [2]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [3]*Seattle Children's Research Institute, Seattle, WA, United States,* [4]*Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Mae Sot, Thailand*

In vitro competitive growth assays measure the relative growth between co-infecting *Plasmodium falciparum* parasites during the blood stage and can serve as an index of fitness, revealing fitness disparities between the co-infecting parasites. Differences in blood stage fitness costs often result from drug resistance mutations which may be mitigated by compensatory mutations. Drug resistance can be conferred by a single point mutation or after a complex series of mutations that either enhance resistance or compensate for fitness costs. With the recent independent emergences of artemisinin resistance and the number of mutations associated with resistance, it is important to understand the relative competitive fitness of the blood stage parasites with different sets of mutations. Genetically distinct drug resistant parasites with different sets of mutations are likely to vary in blood stage proliferation rate, contributing to their chance of transmission to the mosquito vector. Quantitative trait locus (QTL) mapping has long been used as a way to identify genetic *loci* alone or in combination that correlate with a specific phenotype. Using QTL mapping, we can determine what mutations allow drug resistant parasites to be fit in the blood stage, as measured by *in vitro* competitive growth assays. By genetically crossing two parasites that differ in their drug resistance and fitness phenotypes, we can use the recombinant progeny to map *loci* using QTL. Using our optimized competitive growth assays, we can generate a quantitative phenotype for a full progeny set to infer mechanisms that alleviate fitness costs associated with drug resistance. Improved understanding of the fitness costs of different parasites proliferating in human blood and the role different resistance mutations play will contribute to an understanding of the potential for specific mutations to spread in populations.

969

ATG10 GENETIC VARIANTS ARE NOVEL PREDICTORS OF LONGITUDINAL SUSCEPTIBILITY TO SEVERE MALARIAL ANEMIA AND ALL-CAUSE MORTALITY IN KENYAN CHILDREN

Caroline Ndege[1], Samuel B. Anyona[2], Elly Munde[2], Nick Hengartner[3], Benjamin H. McMahon[3], Paul Fenimore[4], Qiuying Cheng[5], Christophe G. Lambert[5], Collins Ouma[6], Douglas J. Perkins[5]

[1]*University of New Mexico-Kenya Global Health Programs, Albuquerque, NM, United States,* [2]*University of New Mexico-Kenya Global Health Programs, Kisumu, Kenya,* [3]*Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States,* [4]*University of New Mexico, Albuquerque, NM, United States,* [5]*University of New Mexico Center for Global Health, Albuquerque, NM, United States,* [6]*Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Kisumu, Kenya*

Plasmodium falciparum severe malarial anemia [(SMA, hemoglobin (Hb) <5.0 gdL^{-1}] is a leading cause of morbidity and mortality among children under 5 years residing in *P. falciparum* holoendemic areas. The pathogenesis of SMA is multifactorial and polygenic. To identify novel molecular pathways that influence development of SMA, whole genome and transcriptome profiling were performed in a subset of Kenyan children (n=144, 3-36 months) with discrete non-SMA and SMA phenotypes. Although not previously investigated in malaria, autophagy related gene-10 (*ATG10*) emerged as a significant predictor of enhanced susceptibility to SMA (2.126-fold increase, *P*=0.024). To validate these findings, the relationship between *ATG10* polymorphisms [-7723T/G (rs2406905), -4322T/A (rs4391141), and -2442G/C (rs1023969)] and malarial outcomes were investigated in children (n=1,512, aged<5 years) at enrollment and over a 36-month follow-up. Inheritance of the -7723 recessive genotype (GG) increased susceptibility to SMA at enrollment (OR=1.690, *P*=0.037), and longitudinally (RR=1.630, *P*=0.049). At enrollment, carriage of the -4322 TA genotype protected against SMA (OR=0.59, *P*=0.014), while the -2442 GC genotype enhanced development of SMA (OR=1.550, *P*=0.009). Cross-sectionally, haplotypes (-T7723G/-T4322A/-G2442C) enhanced susceptibility to SMA in carriers of GTC (OR=1.37, *P*=0.056), GTG (OR=2.34, *P*=0.003), and TTC (OR=1.641, *P*=0.005), whereas protection was present in carriers of TAG (OR=0.570, 95%CI: 0.35-0.94, *P*=0.027). Longitudinally, the GTG (RR=1.63, *P*=0.013) and TTC (RR=1.87, *P*=0.012) haplotypes predicted increased risk of SMA. Transcriptional analyses revealed that variants which protected against SMA had lower *ATG10* expression, while those associated with enhanced risk had elevated expression. Inheritance of -7723 TG and GG genotypes increased all-cause mortality by 78% (*P*=0.050) and 117% (*P*=0.056) respectively, while GTC haplotype carriage increased susceptibility by 89% (*P*=0.018). Collectively, these novel findings show that variation in *ATG10* predicts susceptibility to SMA and all-cause mortality.

Severe malarial anemia (SMA) is a leading cause of childhood morbidity and mortality in holoendemic *Plasmodium falciparum* transmission regions such as Siaya, Kenya. To enhance the molecular understanding of factors that predispose children to SMA, we explored the relationship between non-synonymous point mutations in C3 [rs2230199 (2307C>G, Arg^{102}→Gly) and rs11569534 (34420G>A, Gly^{1224}→Asp)] and malaria disease outcomes in children (n=1,597, <3 years) at enrollment and during a 3-year longitudinal follow-up. At enrollment, there was a reduced risk of malaria in carriers of the 2307CG genotype (OR=0.714, 95%CI: 0.523-0.974, *P*=0.033) and GG haplotype (OR=0.633, 95%CI: 0.467-0.857, *P*=0.003), while inheritance of the CG haplotype reduced the risk of SMA (OR=0.623, 95%CI: 0.394-0.985, *P*=0.043). Longitudinal analyses revealed an increased risk of malaria in carriers of the AA genotype at locus 34420 (RR=1.124, 95%CI: 1.021-1.237, *P*=0.017) and carriers of the GA haplotype (RR=1.063, 95%CI: 1.018-1.110, *P*=0.006). Conversely, there was a reduced risk of malaria over the follow-up period in children who inherited the CG (RR=0.884, 95%CI: 0.817-0.958, *P*=0.002) and GG (RR=0.945, 95%CI: 0.982-1.001, *P*=0.054) haplotypes. Longitudinal susceptibility to the development of SMA in children with malaria was enhanced in carriers of the 2307GG genotype (RR=2.095, 95%CI: 1.175-3.734, *P*=0.012), and reduced in children who inherited the CG haplotype (RR=0.628, 95%CI: 0.451-0.875, *P*=0.006). Taken together, the novel results presented here show that non-synonymous point mutations in C3 at Arg^{102} and Gly^{1224} alter the risk of contracting malaria, and the development of SMA once an individual becomes infected with *P. falciparum*.

Juliano[1]

[1]*Institute for Global Health and Infectious Diseases, University of North Carolina Chapel Hill, Chapel Hill, NC, United States,* [2]*National Institute for Medical Research, Tanga, United Republic of Tanzania,* [3]*Department of Pathology and Laboratory Medicine, Brown University, Providence, RI, United States,* [4]*National Institute for Medical Research Headquarters, Dar es Salaam, United Republic of Tanzania,* [5]*National Malaria Control Programme, Ministry of Health, Community Development, Gender, Elderly and Children, Dar es Salaam, United Republic of Tanzania,* [6]*Swiss Tropical and Public Health Institute, Basal, Switzerland,* [7]*World Health Organization Country Office, Dar es Salaam, United Republic of Tanzania*

Genetic and genomic information is increasingly useful in assessing prevalence of clinically important mutations, parasite transmission patterns, and the impact of interventions. In order to leverage these analyses, a current understanding of local and regional parasite diversity and population structure is needed. However, many genotyping methods, such as whole genome sequencing, can be cost-prohibitive for large surveys needed for such discrimination. Here, we use two molecular inversion probe (MIP) panels (one designed around 1,800 variable single nucleotide polymorphism positions across the genome; the other on SNPs associated with drug resistance in 14 genes) to investigate *P. falciparum* population structure in Tanzania. We used over 1,000 clinical isolates collected as dried blood spots in 13 councils across the country. After removing markers and samples with high missingness (greater than 90% missing genotypes), preliminary principal component analysis (PCA) and Admixture analyses using 1,617 markers and 744 samples revealed segregation between samples collected from north/north-west and south/south-east. At the region level, average multiplicity of infection estimates ranged from 1.28 to 1.65 and tracked with increasing estimates of malaria prevalence, suggesting the ability of MIPs to inform estimates of transmission. Population structure appears to be driven by both non-drug resistance and drug-resistance associated mutations. Allele frequencies for certain *pfdhps* and *pfcrt* mutations segregated between geographic regions, and mutations on chromosome 2 and 11 (not previously shown to be related to drug resistance) contributed to the structure seen by PCAs. Further analyses with this data will attempt to discriminate parasite populations on the council-level using different subsets of variants (based on genomic position, snps verses indels, and allele frequencies). These analyses will provide an understanding of the genetic diversity and population structure of Tanzanian parasites to the National Malaria Control Program, on which assessments of the impact of control interventions can be made.

972

MLMOI - AN R-PACKAGE TO ESTIMATE MULTIPLICITY OF INFECTION

Kristan A. Schneider, Meraj Hashemi Eshkiki

University of Applied Sciences Mittweida, Mittweida, Germany

The co-occurrence of multiple genetically distinct parasite lineages within one infection, referred to multiplicity of infection (MOI), is recognized as an important quantity in malaria. Still MOI is often estimated by biased ad-hoc methods. Furthermore, accurate estimates of lineage frequencies are hampered by MOI. Here, an easy-to-use R package is introduced that allows to accurately estimate MOI and lineage frequencies from parasite molecular data by maximum likelihood. In particular, maximum-likelihood estimates for the distribution of MOI, lineage frequencies and prevalence are provided. To facilitate its usability, the package provides a flexible import function that allows in various entry formats to be imported and converted into one standard format appropriate for estimating MOI, lineage frequencies and prevalence. These formats include microsatellite, SNP or codon data, entered in various ways, e.g., one- or three-letter amino acid code. In particular, users do not need to provide their data in a particular pre-defined format. Rather, users can choose from a large variety of formats that will require only little adjustments by hand. During data import, potential issues and data entry errors are detected in an additional step to check data quality.

973

ASSOCIATION OF ALPHA GLOBIN VARIANTS WITH *PLASMODIUM KNOWLESI* MALARIA DISEASE SEVERITY AND INFECTION SUSCEPTIBILITY

Matthew J. Grigg[1], Jessica Nino De Rivera[2], Bridget E. Barber[1], Timothy William[3], Tsin W. Yeo[4], Christopher J. Drakeley[5], Nicholas M. Anstey[1], Hans Ackerman[2]

Medicine, Nanyang Technological University, Singapore, Singapore, Singapore, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

Plasmodium knowlesi is a monkey parasite that is increasingly reported to infect humans across Southeast Asia. Importantly, *P. knowlesi* causes severe disease in around 6-9% of clinical cases in areas of Malaysia, and can result in case fatalities. Previously highly endemic malaria species such as *P. falciparum* and *P. vivax* in this region have exerted considerable selection pressure on the human genome, resulting in well established red blood cell (RBC) polymorphisms known to mediate disease severity, such as seen with alpha globin variants for *P. falciparum*. For *P. knowlesi*, phenotypic G6PD deficiency has also been associated with protection against susceptibility to symptomatic infection; however to date other RBC polymorphisms have not been evaluated in this context. This study aimed to evaluate the association between common alpha globin variants in Southeast Asia and infection susceptibility and disease severity in clinical cases of *P. knowlesi* malaria. Samples were utilised from a population based case-control study was conducted from 2012-15 in Sabah, Malaysia, enrolling PCR confirmed *P. knowlesi* cases and village matched health controls. Additional *P. knowlesi* malaria patients enrolled in an ongoing Sabah prospective study were also included. In total 1,176 patients with confirmed *P. knowlesi* infection, including >120 meeting WHO severe malaria criteria, and 860 malaria negative controls are expected to be included in the final analysis. High throughput digital droplet PCR technology will evaluate the 5 most common Southeast Asian alpha globin variants: -3.7 deletion, -4.2 deletion, Constant Spring mutation, Cd59 (Adana) mutation, and --FIL deletion, in addition to the inferred --SEA deletion. Results will be presented at the ASTMH meeting and include the number and proportion for each alpha globin variant, including subsets of copy number variant, and relationship with; a) disease severity, and b) disease acquisition, using descriptive statistics and logistic regression models. The final outcome will assess whether relevant alpha globin variants alter disease susceptibility and severity to zoonotic *P. knowlesi* malaria.

974

MULTIPLEXED AMPLICON SEQUENCING OF *PLASMODIUM FALCIPARUM* FOR DRUG RESISTANCE GENOTYPING AND BARCODING

Christopher Jacob[1], Naomi Park[1], Eleanor Drury[1], Kirk Rockett[2], Scott Goodwin[1], Carol Scott[1], Victoria Simpson[3], Sonia Goncalves[1], Olivo Miotto[1], Dominic Kwiatkowski[1]

Every malaria endemic country requires systems to monitor and survey the state of disease in their respective nation. While the goals of surveillance may be different, key metrics like proportions of drug resistant parasites and transmission intensity are valuable pieces of information that can inform policy and help make decisions related to the control of disease. Specific assays can detect resistance to a single drug based on a molecular marker(s), but the time and cost increase is high when information about multiple drugs is needed, as in areas with high proportions of multi-drug resistant parasites. Estimates of transmission intensity using genetics can be done by looking at the proportion of mixed infections in a subset of parasites from a given location, either through model-based methods using multi-locus "barcodes" or from deep sequencing of single highly polymorphic *loci*. Our method uses multiplex PCR to generate a panel of amplicons for detection of resistance to first line treatments including artemisinin, piperaquine, chloroquine, sulfadoxine, and pyrimethamine. We also genotype a 101 SNP barcode which can be used to estimate multiplicity of infection using multi-locus model-based programs. In addition to drug resistance and barcode genotyping, a set of assays can also detect the presence of other *Plasmodium* parasites including *P. vivax*, *P. knowlesi*, P. Ovale, and P. malariae. Using ~140 amplicons across 3 PCRs we reliably genotype 384 samples in a single sequencing reaction, generating an average of >100x coverage per amplicon. This method is optimized for use on DNA extracted from either whole blood or filter paper blood spots. So far more than 10,000 *P. falciparum* parasites have been genotyped from South America, Asia, Africa, and Oceania.

975

MOLECULAR AND IMMUNOLOGICAL CHARACTERIZATION OF *PLASMODIUM FALCIPARUM* GAMETOCYTE-SPECIFIC GENES

Jonas A. Kengne-Ouafo[1], Yaw Aniweh[1], Saikou Y. Bah[1], Collins M. Morang'a[1], Lucas Amenga-Etego[1], Britta C. Urban[2], Gordon A. Awandare[1], Bismarck Dinko[3]

Plasmodium falciparum has an inherent ability to rapidly evolve resistance to drugs/vaccines. Therefore, the need for increased efforts towards drug/vaccine development. However, much of the parasite genome remains uncharacterized. This study sought to identify and characterize gametocyte-specific genes and determine their immunogenicity in malaria endemic regions. Genes were prioritized based on gametocyte specific expression or uniform expression pattern across different erythrocytic stages using available published and unpublished *P. falciparum* laboratory strain transcriptomics and proteomics data. Genomes from the Pf3k (https://www.malariagen.net/projects/pf3k) database were used to assess the genetic diversity of selected genes while differential gene expression in Ghanaian field isolates was determined by q-PCR. Prioritization led to the identification of 2 genes: gametocyte-specific PF3D7_051300 and PF3D7_115800 with expression across all erythrocytic stages. Moreover, peptides corresponding to predicted B-cell epitopes of the corresponding protein sequences of the prioritized genes were commercially synthesized to study the naturally acquired humoral immune response in malaria-infected children in Ghana. Genomic sequence analysis revealed the genes were relatively conserved (FsT values of 0.08 and 0.115 respectively) across continents and were found to be under directional selection based on the negative Tajima's D values obtained, -2.35 and -2.33 respectively. These values were higher in South East Asia (SEA) than in Africa. Further RT-qPCR of field isolates using asexual (rings, trophozoites and schizonts) and gametocyte (gametocytes III, IV & V) stages showed that, PF3D7_051300 had a gametocyte-biased expression while PF3D7_115800 was expressed across stages. These expression patterns were consistent with observations in laboratory strains that were used for prioritization. Ongoing immunological investigations will describe the natural immunity to these candidates and determine their potential as vaccine candidates for transmission blocking interventions.

976

POPULATION GENETICS, SEQUENCE DIVERSITY, SELECTION AND COMPLEXITY OF INFECTION OF *PLASMODIUM FALCIPARUM* APICAL MEMBRANE ANTIGEN 1 GENE IN TWO ECOLOGICAL ZONES IN GHANA

Benedicta Ayiedu Mensah[1], Benjamin Abuaku[1], James Myers Hansen[1], ozkan Aydemir[2], Patrick Marsh[2], Francis Anto[3], Jeffrey Bailey[2], Anita Ghansah[1]

[1]*Noguchi Memorial Institute for Medical Research, Accra, Ghana,* [2]*Brown University, Providence, MA, United States,* [3]*University of Ghana School of Public Health, Accra, Ghana*

One major challenge to the global agenda for malaria elimination is the extensive genetic diversity of the parasite population, resulting in the development of drug resistance and variation in antigens targeted for vaccine development. The aim of this study was to determine how much the increased use of artemisinin-based combination therapies (ACTs) and other control interventions are shaping the genetic diversity of the *Plasmodium falciparum* population in two ecologically distinct populations

in Ghana. A total of 803 dried blood spots (DBS) on filter paper were collected from symptomatic children, aged 6 months to 14 years, with *P. falciparum* mono-infection in the coastal savanna (Cape-Coast) and the forest (Begoro) zones of Ghana from 2014 to 2017. The study leveraged the high specificity and relatively low-cost of targeted next generation sequencing using molecular inversion probes for targeting and sequencing on the illumina MISEQ platform for sequencing of *Plasmodium falciparum* Apical Membrane Antigen 1 (*PfAMA1*) gene. The result showed high genetic diversity in *PfAMA1* in Ghanaian sequences with a total of 164 *PfAMA1* haplotypes and a haplotype diversity of 0.993. The overall nucleotide diversity of the *PfAMA1* sequences was 0.015. There was no significant genetic differentiation between the two study populations in Ghana. Parasite isolates from the two ecological zones in Ghana showed a moderate level of genetic differentiation with sequences from Thailand (Fst=0.054) and low differentiation with sequences from Kenya (Fst=0.004). The results also showed balancing selection which might have contributed to the high diversity in *PfAMA1*. Seventy three percent of the infections were monoclonal with an overall complexity of infection of 1.30. This study provides new data on genetic diversity of *PfAMA1* gene in Ghana and gives valuable information or the development of an effective *PfAMA1*-based malaria vaccine, thus strengthening the importance of investigating genetic diversity of *P. falciparum* and evolutionary history of parasite populations in the field of malaria vaccine development.

977

RELATEDNESS BETWEEN MALARIA PARASITES: PORTABLE INSIGHTS ACROSS SETTINGS

Aimee R. Taylor[1], Pierre E. Jacob[2], Daniel E. Neafsey[1], Caroline O. Buckee[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Harvard University, Cambridge, MA, United States*

Increasingly, genetic surveillance of malaria parasites is being used in near-elimination settings to describe patterns of importation and monitor drug resistance. Studies of parasite relatedness based on identity-by-descent (IBD) have generated demographic insight on a temporal-spatial scale relevant for disease control. However, questions remain about what data should be collected and the requirements for reliable inference of relatedness, with most efforts to date being relatively ad hoc. Using a globally diverse set of published data sets of single-genotype *Plasmodium falciparum*and *Plasmodium vivax* parasite samples, we demonstrate the superior portability of IBD-based relatedness estimates relative to those based on allele sharing (i.e. identity-by-state). Under a hidden Markov model framework, we characterize the number and type of genetic markers required for specified error around relatedness estimates, demonstrating that reliable inference can be made using genetic markers without requiring whole genome sequences. Using the parametric bootstrap, we demonstrate how confidence intervals around estimates can aid interpretation across results based on vastly different data types. Finally, we show how concepts from transport theory can be adopted for a more generalized approach to demographic inference. These results provide a basis for statistically informed prospective study design and surveillance strategies. Given a robust foundation, analyses of genetic data from the surveillance of malaria parasites can achieve portability across different data types, accommodating the diversity of different experimental approaches extant in the field and allowing insights from meta-analyses to move the field forward.

978

PROTECTION AGAINST MALARIA IN HETEROZYGOUS GIRLS FOR G6PD DEFICIENCY IN ANGOLA

Miguel Brito, Chissengo Tchonhi

CISA - Health Research Centre in Angola, caxito, Angola

G6PD deficiency has become more prevalent in malaria endemic regions because genetic variants can confer protection against *Plasmodium*. However, these conclusions are still in debate. The aim of this work is to evaluate the prevalence of G6PD deficiency in an African holoendemic region for *Plasmodium falciparum*, estimating the genotype and phenotype of the enzyme, and evaluating the risk of malaria associated with the G6PD genotype. A prospective longitudinal cohort study, involving 1692 children selected in the maternity ward and monitored over quarterly medical consultations for two years. The G202A and A376G genotypes were determined through Real Time PCR methods. For enzyme activity, we applied the NeoLISA kit for Neonatal G6PD deficiency screening to measure the NADPH produced calorimetrically in the kinetic mode. The prevalence of the A-allele was 19.4%, with 19% hemizygous boys and 4.5% A-homozygous girls. Enzyme deficiency, measured by enzyme activity, was highly prevalent (32.7% in males and 30.5% in females). The average enzymatic activity was also low for A-hemizygous boys (1.66U/ gHb) and for homozygous girls (0. 97U/gHb). Heterozygous girls would seem to hold some protection against malaria, when compared to the other genotypes, mainly A-/A- (X^2=14.35, p=0.014). The prevalence of G6PD deficiency among children in Bengo is high. Heterozygous girls, as proposed elsewhere, may be the driving force for positive selection. This data may serve for the ministry of health in taking safe and appropriate decisions regarding the usage of potentially unsafe drugs for G6PD deficient individuals.

979

HUMAN ANTIBODIES TO AN EPITOPE IN PVDBP BLOCK ADHESION OF *PLASMODIUM FALCIPARUM* PLACENTAL PARASITES VIA CRYPTIC EPITOPES IN VAR2CSA

Catherine J. Mitran[1], Angie Mena[1], Hazel Lugo[1], Ali Salanti[2], Francis B. Ntumngia[3], John H. Adams[3], Eliana M. Arango[4], Amanda Maestre[4], Michael F. Good[5], Stephanie K. Yanow[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*University of South Florida, Tampa, FL, United States,* [4]*University of Antioquia, Medellín, Colombia,* [5]*Institute for Glycomics, Griffith University, Gold Coast, Australia*

During Plasmodium falciparum infection in pregnancy, parasites express the PfEMP[1] surface antigen VAR^{2}CSA that mediates sequestration of infected red blood cells (iRBCs) to the placenta. Vaccines that target the DBL domains within VAR^{2}CSA are currently in clinical trials and the goal is to elicit antibodies that will block sequestration by interfering with the interaction of VAR^{2}CSA and chondroitin sulphate A (CSA) in the placenta. We are pursuing a novel strategy to develop a vaccine against P. falciparum placental malaria that is based on cross-reactivity between PvDBP from P. vivax and cryptic epitopes within VAR^{2}CSA. This approach is based on our previous findings that a monoclonal antibody (mAb) raised against PvDBP cross-reacts with VAR^{2}CSA and blocks P. falciparum adhesion to CSA in vitro. Also, we discovered that human antibodies to VAR^{2}CSA can be acquired outside of pregnancy and arise from exposure to PvDBP. Here, we identified an epitope within PvDBP that is the target of the mAb and showed that a peptide of this epitope completely blocks antibody recognition of VAR^{2}CSA. To determine whether this same epitope is involved in cross-reactivity of human antibodies to VAR^{2}CSA, we affinity-purified antibodies specific to this epitope from pools of sera from Colombian men and children. These purified antibodies recognized VAR^{2}CSA by ELISA, and strongly blocked adhesion of P. falciparum iRBCs to CSA in vitro. Furthermore, sera from multigravid African women or from rabbits immunized with VAR^{2}CSA do not recognize the epitope from PvDBP, demonstrating that the epitope in VAR^{2}CSA is cryptic. Together, these findings identify key epitopes in PvDBP elicited by natural exposure to P. vivax and mouse immunization that cross-react with cryptic epitopes in VAR^{2}CSA.

980

MEASUREMENT OF *PLASMODIUM FALCIPARUM*- AND *P. VIVAX*-SPECIFIC ANTIBODY PROFILES ON PROTEIN MICROARRAYS FROM DRIED BLOOD SPOTS

Christine F. Markwalter[1], Myat Htut Nyunt[2], Zay Yar Han[2], Aarti Jain[3], Omid Taghavian[3], Philip L. Felgner[3], Christopher V. Plowe[1], Kay Thwe Han[2], Myaing M. Nyunt[1]

Sensitive and field-deployable detection tools are needed for malaria surveillance and elimination in low-prevalence settings. An ideal such tool would not only measure parasite prevalence, but also estimate recent aggregate malaria exposure, providing a more robust characterization of malaria transmission in a population. Serological biomarkers are promising targets for malaria surveillance because they can indicate cumulative recent exposure and are easily integrated into existing point-of-care platforms. Serological responses to *Plasmodium falciparum* and *P. vivax* antigens, identified and measured using protein microarrays, may serve as useful tools for identifying antibody biomarkers of exposure. Typically, serum samples are probed on protein microarrays to measure antibody responses to malaria antigens. The complexity of sample processing and requirement of cold-chain limit the usefulness of this method, particularly in remote hard-to-reach places where malaria is prevalent. Dried blood spots are potentially useful alternatives to serum; they are easy to collect, durable, easy to transport, and present little biohazard risk. In this study, protein microarrays were used to measure antibody profiles against 250 *P. falciparum* and 250 *P. vivax* antigens or fragments in matched serum and DBS from 100 individuals from Ingapu Township, Myanmar and found good correlation between serological responses derived from the two sample matrices. We applied the same DBS elution methodology and protein microarrays to measure antibody responses of individuals with low-density malaria infections and matched uninfected individuals from Injangyang and Ann Townships in Myanmar. Thus, using dried blood spots can extend protein microarray sero-surveillance to remote areas where cold chains required to collect and transport frozen samples do not exist.

ANTIBODY LEVELS TO *PLASMODIUM FALCIPARUM* INFECTED ERYTHROCYTES INCREASE OVER SUCCESSIVE PREGNANCIES

Oumar Attaher[1], Ahamadou Youssouf[1], Bacary Soumana Diarra[1], Sekouba Keita[1], Almahamoudou Mahamar[1], Moussa Traore[1], Gaoussou Santara[1], Alassane Dicko[1], Patrick Duffy[2], Michal Fried[2]

[1]*Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Sciences Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology; National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States*

During pregnancy, *Plasmodium falciparum* parasites sequester in the placenta & adhere to the receptor chondroitin sulfate A (CSA). Infected erythrocyte (IE) adhesion to CSA is mediated by VAR2CSA, a member of the *P. falciparum* erythrocyte membrane protein family (PfEMP1) that is preferentially expressed by placental parasites. Here we examined the levels & breadth of antibodies reacting with surface IE proteins of heterologous parasite isolates collected from malaria-infected pregnant women in Ouelessebougou, Mali. Antibody levels to IE surface proteins were measured by flow cytometry & included samples collected from 177 women between 2012 to 2015 at delivery. IE surface recognition was defined as the ratio of the proportion of IE recognized by the women's plasma to the proportion of IE recognized by plasma from naïve donors (negative control). Antibody levels to surface IE were significantly higher in multigravidae compare to primigravidae & secundigravidae ($p < 0.0001$), & similar between primigravidae & secundigravidae. In addition to comparison by gravidity groups, we compared antibody reactivity with IE surface proteins by gravid number. Antibody levels were similar between women in their 3rd pregnancy (G3) & secundigravidae & significantly lower than women with >=3 pregnancies (G4 and higher). The breadth of reactivity with IE surface proteins positively increased with the number of pregnancies ($\beta=0.43$, $p<0.0001$). The associations between plasma IE surface reactivity, malaria infection during pregnancy & pregnancy outcomes are currently under investigation & will be presented.

982

ANTIBODY PROFILES INDUCED BY IMMUNIZATION WITH RADIATION ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITES (PFSPZ VACCINE) IN MALARIA NAIVE VOLUNTEERS

Freia-Raphaella Lorenz[1], Rolf Fendel[1], Philip L. Felgner[2], B. Kim Lee Sim[3], Stephen L. Hoffman[3], Peter G. Kremsner[1], Benjamin Mordmüller[1]

[1]*Institute of Tropical Medicine, University of Tübingen, Tübingen, Germany,* [2]*Vaccine R&D Center, University of California Irvine, Irvine, CA, United States,* [3]*Sanaria Inc., Rockville, MD, United States*

Immunization with attenuated, live sporozoites has been shown to evoke sterile protection against *P. falciparum* malaria in multiple clinical trials. Yet, the mechanism of protection and the contribution of the humoral immune response remain unclear. In a recent study (MAVACHE) conducted at the Institute of Tropical Medicine, University of Tübingen, healthy malaria naive volunteers were vaccinated by direct venous inoculation of three doses of $9x10^5$ irradiated, live *P. falciparum* sporozoites (PfSPZ Vaccine) each. Vaccination efficacy was assessed by two controlled human malaria infections (CHMI) of both homologous (NF54) and heterologous (7G8) *P. falciparum* strains. Significant sterile immunity was seen in both CHMIs. IgG and IgM antibody profiles of the study participants were assessed by probing serum samples on a protein microarray representing 228 unique antigens selected from previous full proteome microarray analyses. Levels of specific IgG and IgM antibodies directed against differentially recognized antigens were determined throughout the study by ELISA. On the microarray, sera of fully protected vaccinees recognized a higher number of different plasmodial antigens and displayed elevated levels of specific IgG compared to incompletely protected vaccinees. Sterile immunity was furthermore associated with a subset of specific IgG and IgM antibodies, including various surface, transport and export proteins of the sporozoite and liver stage parasite. Strong immunogenicity of the predominant sporozoite surface protein CSP (circumsporozoite protein) was observed in all vaccinees but anti-CSP antibody titers did not correlate with the outcome of protection in CHMI. In general, the antibody repertoire predicting exposure to the vaccine substantially differed from the identified markers of protection. Profiles of IgG responses are likewise distinct from those of IgM reactions. However, recurring patterns are observed between individual samples. Thus, breadth and composition of the humoral immune response may serve as predictors for sterile protection from malaria following immunization with PfSPZ Vaccine.

983

GUT MICROBIOTA MODULATION OF GERMINAL CENTER REACTIONS IMPACTS SEVERITY OF *PLASMODIUM* INFECTIONS

Morgan Duff[1], Whitney Powell[1], Joshua Denny[1], Nathan Schmidt[2]

[1]*Department of Microbiology and Immunology, University of Louisville, Louisville, KY, United States,* [2]*Ryan White Center for Pediatric Infectious Diseases and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States*

Infections by the parasite *Plasmodium* result in approximately 200 million cases of malaria and 400,000 deaths each year. Though over 40 percent of the world population live in areas affected by malaria, there is currently no effective vaccine and resistance to antimalarial drugs is continuing spread. Our lab has previously identified that the composition of the gut microbiota in mice can modulate the severity of malaria, leading to

differences in blood stage parasite burden and the duration of infection. Humoral immunity is known to be critical in mediating clearance of *Plasmodium* blood stage infections, prompting the hypothesis that mice with enhanced control of *Plasmodium* will exhibit better germinal center responses. In support of this hypothesis, mice with decreased parasite burdens show an increase in numbers of germinal center B cells, T follicular helper cells, and parasite-specific antibody titers compared to mice with high parasite burdens. Additionally, germ-free mice colonized with cecal contents from mice that display low or high parasitemia and that were subsequently infected with *Plasmodium* phenocopy differential germinal center responses. These data demonstrate that the gut microbiota is sufficient to shape the magnitude of germinal center reactions. Mechanistically, when mice that develop low parasite burdens were treated with antibodies that disrupt germinal center reactions, they had similarly high parasite burdens as control mice. These findings suggest that microbiome-mediated modulation of germinal center reactions may be a mechanism by which the gut microbiota impacts the development of severe malaria. Enhanced germinal center reactions in mice with low parasitemia during the acute infection also impacted memory, as these mice were protected against challenge with a heterologous, lethal *Plasmodium* species. This research provides mechanistic insight into both how the microbiota interacts with the adaptive immune system as well as how the immune system interacts with *Plasmodium* in order to clear infections, providing knowledge that can be used in efforts to provide optimal treatments for malaria.

984

VACCINE OPTIMIZATION BY IDENTIFICATION, CHARACTERIZATION, AND DOWNSELECTION OF HUMAN T CELL EPITOPES FROM *PLASMODIUM FALCIPARUM* CIRCUMSPOROZOITE PROTEIN

Amy R. Noe[1], Frances E. Terry[2], Brian C. Schanen[3], Pooja Hindocha[2], Leonard Moise[2], Jayne M. Christen[1], Kenneth D. Tucker[1], Timothy W. Phares[4], William D. Martin[2], Anne S. DeGroot[2], Donald R. Drake III[3], Lorraine Soisson[5], Carter Diggs[5], Robin Miller[5], Susan Youll[5], David R. Milich[6], David C. Whitacre[6]

[1]*Leidos Life Sciences, Leidos Inc., Fredrick, MD, United States,* [2]*EpiVax Inc., Providence, RI, United States,* [3]*Sanofi Pasteur, VaxDesign Campus, Orlando, FL, United States,* [4]*ExGloH, Leidos Inc., Fredrick, MD, United States,* [5]*Malaria Vaccine Development Program, United States Agency for International Development (USAID), Washington, DC, United States,* [6]*VLP Biotech Inc., San Diego, CA, United States*

An effective malaria vaccine must prevent disease in a wide range of populations living in regions with vastly different transmission rates and protect against genetically diverse *Plasmodium falciparum* strains. Helper CD4+ T cells, in particular those of the Th1 lineage, are central to development of protective immune responses to *P. falciparum*, playing roles in B cell activation and maturation processes as well as in cytokine production. Therefore, we took advantage of recent in silico modeling advances to predict and analyze the HLA-restricted CD4 (class II) epitopes (peptide sequences that bind HLA-DR) relevant to achieving broad human population coverage in a Pf circumsporozoite protein (CSP) vaccine, utilizing cognate T cell help. Based on in silico analysis, several class II epitope clusters are predicted in the N- and C-terminal regions of PfCSP. Further, one predicted class II cluster overlaps with the highly-variable region 2 (R2) in the C-terminus of PfCSP (3D7 strain). To identify additional predicted class II epitopes, 478 PfCSP R2 peptide sequence variants were analyzed for HLA-DR binding. Of these, nine predicted R2 variant class II clusters were identified through the silico analysis. The resulting peptide sequences were synthesized and assessed for HLA-DR binding *in vitro* as well as for the ability to prime/activate lymphocytes resulting in generation of cytokine responses using human PBMCs. The latter was conducted using MIMIC® technology (Modular IMmune In vitro Construct), a surrogate human immune system enabling researchers to test human immune responses to antigen. We found sufficient differential cellular activation and cytokine profiles among HLA-DR-matched PBMC donors to downselect class II epitope clusters for inclusion in a vaccine targeting PfCSP.

MALARIA-SPECIFIC B CELL RESPONSES IN CHILDREN AND ADULTS FROM UGANDA

Jake Gonzales[1], Isaac Ssewanyana[2], John Rek[2], Sebastiaan Bol[1], Bryan Greenhouse[3], **Evelien M. Bunnik**[1]

[1]*The University of Texas Health Science Center, San Antonio, TX, United States,* [2]*Infectious Disease Research Collaboration, Kampala, Uganda,* [3]*University of California San Francisco, San Francisco, CA, United States*

Individuals living in malaria-endemic regions over the years develop an immune response that protects against disease. This naturally acquired immunity targets the blood stage of the parasite's life cycle and is at least in part dependent on antibody-mediated inhibition. Protective antibodies are likely to be a small part of the total antibody repertoire. By studying immune responses at the single B cell level, we aim to understand how protective immunity develops and which antibody characteristics are important for protection. We have used B cell tetramers to isolate memory B cells specific for two blood stage malaria antigens (MSP1 and AMA1) in non-immune children and immune adults living in Tororo, Uganda, a region of high malaria transmission. Children harbored both antigen-specific IgM+ and IgG+ memory B cells, while around 80% of the antigen-specific memory B cells in adults were IgG+. The antibody variable regions of these memory B cells were amplified and analyzed by Sanger sequencing. In parallel, we performed B cell receptor sequencing to study the broader B cell receptor landscape. In comparison to the full repertoire of IgG+ memory B cells, MSP1 and AMA1-specific memory B cell receptors in adults contained high levels of somatic hypermutations (on average 27 amino acid changes in the V_H segment). We observed clonal expansion of antigen-specific B cell lineages and found evidence of convergent antibody evolution within an individual. Collectively, these results highlight the strong selection pressure of malaria exposure on antibody responses and suggest that extensive affinity maturation may be required for strong parasite inhibition. Ongoing experiments are aimed at testing antibody reactivity in various functional assays. The results of this project will contribute to our understanding of the development of anti-malaria antibody responses and the antibody features that are necessary to achieve protection.

PLASMODIUM-DERIVED HEMOZOIN IMPAIRS ANTIBACTERIAL INNATE IMMUNITY TO SYSTEMIC INFECTIONS

Chris Harding[1], Nicolas Villarino[2], Evelin Schwarzer[3], **Nathan W. Schmidt**[4]

[1]*University of Louisville, Louisville, KY, United States,* [2]*Washington State University, Pullman, WA, United States,* [3]*University of Torino, Torino, Italy,* [4]*Indiana University, Indianapolis, IN, United States*

Plasmodium species cause nearly 200 million episodes of malaria annually. One complication of malaria is increased susceptibility to invasive bacterial infections. Prior studies have shown that *Plasmodium* infections impair host immunity to non-Typhoid *Salmonella* (NTS) through both activation of heme-oxygenase I and the subsequent release of immature granulocytes from the bone marrow and myeloid cell-derived IL-10. Yet, it is not known if these mechanisms are specific to NTS or if they represent general defects to systemic bacterial infections. Moreover, it is not known if a parasite-derived factor is responsible for *Plasmodium*-induced immunosuppression. We show here, that *Plasmodium yoelii* 17XNL infected mice had impaired clearance of systemic *Listeria monocytogenes* during both acute parasitemia and up to 2-months after resolution of *P. yoelii* infection that was independent of heme-oxygenase I and IL-10. *P. yoelii*-infected mice were also susceptible to *Streptococcus pneumoniae* bacteremia, a common malaria-bacteria co-infection, with higher blood and spleen

bacterial burdens and decreased survival compared to naïve mice. Mechanistically, splenic phagocytes from *P. yoelii* infected mice exhibit an impaired ability to kill intracellular *L. monocytogenes*, and neutrophils from *P. yoelii*-infected mice produce less reactive oxygen species in response to *L. monocytogenes* or *S. pneumoniae*. Finally, treating splenic phagocytes with *Plasmodium*-derived Hz (*P. yoelii* or *P. falciparum*) impaired killing of intracellular *L. monocytogenes*. Moreover, treating naïve mice with *Plasmodium*-derived Hz was sufficient to impair bacterial clearance. Collectively, we have demonstrated *P. yoelii* infections impair host immunity to diverse bacterial pathogens by Hz-dependent suppression of innate immunity.

PEDIATRIC PARTICIPATION RATES IN A LONGITUDINAL MALARIA IMMUNOLOGY STUDY

Anushay Mistry[1], Nelly Koskei[2], Jonathan Kurtis[3], John Michael Ong'echa[2], Ann Moormann[1]

[1]*University of Massachusetts Medical School, Worcester, MA, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya,* [3]*Brown University Warren Alpert Medical School, Providence, RI, United States*

The resurgence of drug resistant *Plasmodium falciparum* parasites continues to motivate work toward developing a safe and efficacious malaria vaccine. Immuno-epidemiologic studies of naturally acquired immunity (NAI) have been a useful strategy to identify new malaria vaccine targets. However, retention of pediatric participants throughout longitudinal studies is essential for gathering comprehensive exposure and outcome data. Within the context of a 3-year, 400-patient pediatric cohort study involving monthly finger pricks and bi-annual venous blood sample collections, we are conducting qualitative surveys to assess factors impacting participant retention. Phase One was conducted in July 2018, 3 months after study initiation; 236 parents/guardians participated in focus groups, 3 withdrawn participants in key informant interviews and 10 community health volunteers (CHVs) in individualized interviews. Qualitative analysis indicates overall satisfaction with the study, with 136 guardians (57%) reporting no concerns. Focus group discussants associated attendance with benefits including improved access to comprehensive healthcare services and perceived reputation of healthcare quality. Participants also expressed appreciation for the thorough and extensive consent process. CHVs reported that uninvolved community members perpetuated rumors of inappropriate use of study samples, dangers associated with venous blood draws, and complaints of insufficient incentives provided in return for study participation. Another concern expressed was the volume of blood drawn, expressed by 13 (5%) guardians over 3 focus group meetings. Phase Two will be conducted in July 2019 utilizing the aforementioned procedures to monitor participant satisfaction and determine the source of community-based concerns. Distance and other logistical barriers that could impede compliance with monthly research visits at the clinic have been mapped and will be used to evaluate attrition. Decreased satisfaction over the course of the study may warrant proactive community education to alleviate study-related concerns.

988

THE EFFECT OF ADDING AZITHROMYCIN TO THE ANTIMALARIALS (SULPHADOXINE/PYRIMETHAMINE AND AMODIAQUINE) USED FOR SEASONAL MALARIA CHEMOPREVENTION ON THE IMMUNE RESPONSE TO *PLASMODIUM FALCIPARUM*

Joshua M. Obiero[1], Matthew Cairns[2], Aarti Jain[1], Omid Taghavian[1], Andrew Sy[1], Rie Nakajima[1], Algis Jasinskas[1], Issaka Zongo[3], Issaka Sagara[4], Jean-Bosco Ouedraogo[3], Alassane Dicko[4], Daniel Chandramohan[2], Brian Greenwood[2], Philip L. Felgner[1]

[1]*University of California, Irvine, CA, United States,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso,* [4]*University of Science, Techniques and Technologies of Bamako, Bamako, Mali*

Seasonal malaria chemoprevention (SMC) provides a high level of protection against non-severe and severe malaria in young children. However, it is unclear to what extent the immune system of children protected by SMC is affected by a diminished exposure to malaria infection, and how this might be affected by improving the efficacy of SMC regimens. A proteome micro-array study was conducted to determine differences in the naturally acquired anti-malaria antibody responses among children who received SMC with azithromycin (AZ) or with a placebo, and children who did not receive SMC treatment. A household randomized trial was conducted in Mali and Burkina Faso from 2014 to 2016, starting in August each year, during which approximately 20,000 children aged 3-59 months at the beginning of each malaria transmission season received four, monthly cycles of SMC with sulfadoxine-pyrimethamine plus amodiaquine (SP+AQ), together with either AZ or a matching placebo. Serum samples from 101 study children aged between 36 and 48 months who had received SMC with placebo or AZ for three transmission seasons were collected together with samples from 100 children who did not receive SMC, and 35 adults. Samples were probed on protein micro-arrays containing 228 unique *P. falciparum* 3D7 proteins to determine differences in antigen specific antibody levels between the groups. We identified 128 and 175 antigens recognized by more than 10% of the children and adults respectively. Children who did not receive SMC had significantly higher immune responses to 84 antigens compared to children who received SMC. These results show no demonstrable difference in the antibody response against malaria following the addition of AZ to SMC. In contrast, children who received SMC had significantly lower antibody levels and a narrower range of responses compared to children who did not receive SMC. This lower antibody response is an expected consequence of the lower parasite burden experienced by children in the SMC group. Whether these lower anti-parasite immune responses in the SMC group increases future susceptibility to malaria infection is not yet clear.

RECEPTOR TRANSPORTER PROTEIN 4 (RTP4) NEGATIVELY REGULATES IFN-I RESPONSE AND ANTI-MALARIAL IMMUNITY

Xiao He, Xinzhuan Su

National Institutes of Health, North Bethesda, MD, United States

Malaria infection stimulates complex and delicately regulated host immune responses. Recognition of pathogen-associated molecular patterns (PAMPs) by pattern recognition receptors (PRRs) activates a series of signaling cascades, leading to production of cytokines including type-I and type II interferons (IFN-I and IFN-II) and chemokines that mediate migration of immune cells to affected tissues. Previously, we performed a trans-species expression quantitative *loci* analysis (Ts-eQTL) using progeny from a genetic cross involving parasite strains that stimulate differential IFN-I responses and identified many putative interferon-stimulated genes (ISGs). We have focused on an ISG gene called RTP4 (Receptor Transporter Protein 4) that is known as a probable chaperone protein playing a role in trafficking and cell surface expression of some G-protein coupled receptors (GPCRs). Here we show that RTP4 is also a negative regulator of malaria induced IFN-I response. RTP4's protein level is upregulated after malaria infection *in vivo* or malaria RNA/DNA transfection *in vitro*. Over expression of RTP4 *in vitro* can significantly reduce IFN-I production. Disruption of RTP4 *in vivo* enhances IFN-I production and slightly improves host survival after *Plasmodium* yoelii infection. RTP4 binds to many molecules in IFN-I signaling pathways including STING, TRAFs, TBK1, IRF3 and S6k1. RPT4 also interferes with TBK1 binding to STING, reduces phosphorylation of TBK1 and IRF3, and decreases ubiquitin levels of many adaptor proteins in the IFN-I signaling pathways. These results demonstrate that RTP4 can function as a negative regulator of IFN-I signaling in addition to its reported function in protein transport.

990

FUNCTIONAL CHARACTERIZATION OF ANTI-RH5 ANTIBODIES FROM A MALARIA ENDEMIC AREA FOR FUTURE VACCINE DEVELOPMENT

Alexandra C. Willcox[1], Kazutoyo Miura[1], Ababacar Diouf[1], Daniel G. Alanine[2], Rebecca A. Dabbs[2], Jing Jin[2], David J. Pattinson[2], Mahamadou Diakite[3], Simon J. Draper[2], Carole A. Long[1]

The reticulocyte-binding protein homologue 5 (RH5) is a conserved protein on *Plasmodium falciparum* merozoites that is essential for parasite invasion of host erythrocytes. RH5 is currently the most promising *P. falciparum* blood-stage vaccine candidate, and a recent Phase I/IIa clinical trial demonstrated that vaccination with RH5 could reduce parasite growth rate in malaria-naïve volunteers in a blood-stage controlled human malaria infection (CHMI) model. Characterization of pre-existing anti-malarial immunity in endemic populations will support future RH5 vaccine development. Our group previously reported anti-RH5 IgG titers to be ~100-fold lower in RH5-immune Malians than the peak titers in RH5-vaccinated malaria-naïve UK volunteers. In this study, we affinity-purify RH5-specific IgGs from naïve, RH5-vaccinated UK volunteers and from naturally infected Malians in order to functionally characterize these antibodies *in vitro*. Using the growth inhibition assay (GIA), we find that some RH5-specific IgGs from Mali inhibit parasite growth at the same antibody titer as IgGs from the vaccinees, while others fail to inhibit parasite growth. Further experiments are underway to explain these differences. We also combine human anti-RH5 mAbs, which were generated from the vaccinees, with total IgGs from Malians. We identify a subset of Malian IgGs that work synergistically with the mAbs to inhibit parasite growth in GIA. Experiments will be performed to determine what distinguishes this subset of Malian IgGs from others. Our results will demonstrate how naturally-acquired anti-malarial immunity may interact with vaccine-induced anti-RH5 immunity.

991

SEROLOGIC MARKERS OF PREVIOUS MALARIA EXPOSURE AND FUNCTIONAL ANTIBODIES INHIBITING PARASITE GROWTH ARE ASSOCIATED WITH PARASITE KINETICS FOLLOWING A *PLASMODIUM FALCIPARUM* CONTROLLED HUMAN INFECTION

Isaie J. Reuling[1], Jane Achan[2], Zen Yap[1], Edgar Dabira[2], Abdullahi Ahmad[2], Momodou Cox[2], Davis Nwakanma[2], Kevin Tetteh[3], Lindsey Wu[3], Guido Bastiaens[1], Yonas Abebe[4], Anita Manoj[4], Kazutoyo Miura[5], Carole Long[5], Peter F. We assessed the impact of exposure to *P. falciparum* on parasite kinetics, clinical symptoms, and functional immunity after controlled human malaria infection (CHMI) in two cohorts with different levels of previous malarial exposure. Nine adult males with high (sero-high) and ten with low (sero-low) previous exposure received 3200 controlled human malaria infection by direct venous inoculation and were followed for 35 days for parasitemia by thick blood smear (TBS) and quantitative polymerase chain reaction (qPCR). End points were time to parasitemia, adverse events and immune responses. Ten of Ten (100%) volunteers in the sero-low and 7 of 9 (77.8%) in the sero-high group (89%) developed parasitemia detected by TBS in the first 28 days (p = 0.125). The median time to parasitemia was significantly shorter in the sero-low group [9 days (7.5-11.0) vs.11.3 days (7.5-18.0), log rank test, p=0.005]. Antibody recognition of sporozoites was significantly higher in the sero-high (median 17.93 AU, IQR 12.95-24) than the sero-low volunteers (median 10.54 AU, IQR 8.36-12.12); p=0.006. Presence of blood-stage antibodies was also significantly higher (p=0.0003) in the sero-high group (median 50.98 AU, IQR 22.46-65.07) than in the sero-low group (median 3.16 AU, IQR 2.43-8.71). Growth inhibitory activity (GIA) was significantly higher in the sero-high (median 21.8%, IQR 8.15-29.65) than in the sero low (median 8.3%, IQR 5.6-10.23) (p=0.025). CHMI was safe and well tolerated in this population. Individuals with serological evidence of higher malaria exposure were able to better control infection and had higher parasite growth inhibitory activity.

992

PROLONGED *PLASMODIUM FALCIPARUM* EXPOSURE LEADS TO THE DEVELOPMENT OF ABERRANT $CD56^{NEG}CD16^{POS}$ NATURAL KILLER CELLS

Catherine S. Forconi[1], Cliff Oduor[2], John M. Ong'echa[3], Jeff A. Bailey[2], Ann M. Moormann[1]

[1]*Department of Medicine, Division of Infectious Diseases, University of Massachusetts Medical School, Worcester, MA, United States,* [2]*Department of Pathology and Laboratory Medicine, Warren Alpert Medical School, Brown University, Providence, RI, United States,* [3]*Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya*

Natural Killer (NK) cells are essential in the clearance of red blood cells infected with *Plasmodium falciparum*, however previous studies have been limited to investigations of $CD56^{dim}CD16^{pos}$ NK cells. Chronic viral infections have been found to promote the expansion of a CD56 (negative) NK cell subset with impaired effector function. In our study of otherwise healthy Kenyan children, we found they had significantly more $CD56^{neg}CD16^{pos}$ NK cells after prolonged exposure to malaria compared to age-matched children from a low malaria transmission area (13.5% versus 6%, respectively, p=0.006). Moreover, elevated levels of $CD56^{neg}CD16^{pos}$ NK cells appear to persist into adulthood (median 10.6% [3.6 to 17.2%]). We characterized this $CD56^{neg}CD16^{pos}$ NK subset using histology staining, multicolor flow cytometry and RNA-sequencing. We found $CD56^{neg}CD16^{pos}$ NK cells to be morphologically similar to $CD56^{dim}CD16^{pos}$ NK cells but had higher expression of FCGR3B (CD16b) (p=0.000008) and MPEG1 (Perforin 2) (p=0.0000007), and lower expression of KLRF1 (NKp80), IL18RAP and IL18R1 (IL18 receptor) (p=0.000003, p=0.000003 and p=0.00005, respectively). Phenotypically, $CD56^{neg}CD16^{pos}$ NK cells share characteristics of adaptive NK cells, however, they differ from "memory-like" NK cells, with consistent expression of NKG2C/CD57, lower expression of NKp46 and CD160, and higher expression of KIR3DL1 compared to $CD56^{dim}CD16^{pos}$ NK cells. Finally, higher plasma levels of IL-12p70 and IL-2 (known to help NK cell activation and proliferation) and IL-6 and MIP1a were found in *P. falciparum* un-exposed compared to exposed children. Together, these findings suggest that the expansion of $CD56^{neg}CD16^{pos}$ NK cells could help explain diminished cytotoxicity capacity against blood-stage infections and is a mechanism by which malaria evades NK-cell mediated immunity.

993

ALTERED EXPRESSION OF METABOLIC SIGNALING PATHWAYS IN MONOCYTES DURING ACUTE MALARIA IN CHILDREN

Katherine R. Dobbs[1], Paula Embury[1], David Midem[2], Peter Sumba Odada[2], John Vulule[2], James W. Kazura[1], Arlene E. Dent[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Kenya Medical Research Institute, Kisian, Kenya*

Monocytes are innate immune cells that play a key role in host protection and pathogenesis during malaria. As immune cells respond to infection, metabolic pathways are regulated to support or direct functional changes. We sought to determine whether metabolic signaling pathways

were altered in monocytes during acute malaria in children. Negatively selected monocytes were obtained from cryopreserved peripheral blood mononuclear cell (PBMC) samples from 6 children in western Kenya at presentation with acute uncomplicated malaria and 6 weeks following treatment. RNA and protein were purified from monocyte cell lysates and hybridized to a NanoString CodeSet of genes and proteins important to regulation of several cellular processes such as differentiation, apoptosis, and metabolism (mRNA PanCancer Pathways Panel of 730 target genes and protein Solid Tumor Panel of 25 total and phospho-proteins). Of the 730 target genes, 100 were differentially expressed, including 69 decreased and 31 increased during acute malaria compared to recovery. The protein panel revealed significantly decreased levels of phospho-Akt (log_2 fold change -0.93, p=0.02) during acute malaria compared to recovery. Several genes up- and down-stream in the phosphoinositide 3-kinase (PI3K)/Akt pathway were differentially expressed, including increased expression of the Akt inhibitors *PTEN* (log_2 fold change 0.67, p=0.002) and *PPP2CB* (log_2 fold change 0.67, p=0.02) and increased expression of *CCND3* (log_2 fold change 1.62, p=0.0004), which encodes the protein cyclin D3 and is important for cell cycle regulation and glucose metabolism. In addition, protein levels of phospho-c-Raf were decreased during acute malaria (log_2 fold change -0.41, p=0.03) along with altered expression of several genes in the MAPK/ERK pathway (including *CSF1R, PRKCA, RASA4, RASGRP1, MAP2K1*, and the ERK1/2 inhibitors *DUSP2, DUSP5,* and *DUSP6*). Data analysis is ongoing and will be correlated with cellular metabolic and functional assays. These data show that acute uncomplicated malaria is associated with altered expression of pathways important to monocyte metabolism.

994

ENHANCING MALARIA ELIMINATION AND CONTROL EFFORTS IN HIGH AND LOW BURDEN AREAS OF ZAMBIA USING SPATIO-TEMPORAL MODELLING OF TRENDS IN INCIDENCE AND RISK

Jailos Lubinda[1], Yaxin Bi[2], Busiku Hamainza[3], Adrian J. Moore[1]

[1]*Ulster University, Coleraine, United Kingdom,* [2]*Ulster University, Newtown Abbey, United Kingdom,* [3]*National Malaria Elimination Center, Lusaka, Zambia*

Consistent progress and a decade of optimism has shaped the emphasis of many malaria programs, inspiring a shift from control to elimination. Zambia has made significant strides in reducing national malaria mortality and has seen declining incidence rates in several districts. This enthused the agenda to eliminate malaria by 2021. Tailored approaches target elimination in low-burden areas, while intensified control efforts will lead up to elimination in high-burden areas. In order to achieve this strategic approach to control and elimination, a co-ordinated, accurate method for the identification of priority high-burden and low-burden areas is required. However, no such method currently exists to accurately identify, map and help guide the deployment of appropriate intervention resources to such areas. We developed a multi-criterion spatio-temporal approach to map malaria risk, rates and trends at district level based on data from 2000 to 2015. Spatiotemporal concentration and variation of malaria burden was calculated using risk, rate, and trend indices, then ranked and mapped across a spectrum from high to low-burden. Low burden areas are suitable for elimination while high-burden areas, characterised by high incidence rates, elevated risk and increasing trend compared with their geographical neighbours are suited for intensified control leading to elimination. Our results confirmed that malaria morbidity increased in most areas since 2010, but mortality continued declining. Over 3 million people live in high mortality/incidence burden areas with increasing temporal trends, while 1.6 million are in high-incidence burden districts. Under 5 children carry the highest incidence and mortality burden. Identifying high-burden areas is fundamental to targeting intervention programmes for maximum impact. Our robust method provides a practical means to prioritize clusters of both high and low-burden malaria that can inform and support tailored programmes and tools for control or elimination. The incorporation of relevant age categories within such methods is highlighted as being important for control and elimination efforts.

995

MAPPING FOR MALARIA CONTROL IN GRAND ANSE, HAITI USING A MULTI-METRIC BAYESIAN APPROACH

Punam Amratia[1], Ewan Cameron[1], Alyssa Young[2], Katherine Twohig[1], Andre Python[1], Darlene Bhavnani[2], Emilie Pothin[3], Arnaud Le Menach[2], Justin Cohen[2], Samson Marseille[4], Jean-Frantz Lemoine[4], Ambre Dismer[5], Jean-Baptiste Mérilien[4], Karen Hamre[5], Eric Rogier[5], Michelle Chang[5], Peter Gething[1], Katherine Battle[1]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*Clinton Health Access Initiative, Boston, MA, United States,* [3]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [4]*Programme National de Contrôle de la Malaria/MSPP, Port-au-Prince, Haiti,* [5]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

The island of Hispaniola is determined to eliminate malaria. Multiple metrics have been collected through surveillance programs in relatively high-risk areas such as Grand'Anse, Haiti. However, it becomes challenging to interpret transmission intensity when using multiple metrics, yet if we use a single metric, we may fail to capture aspects of the transmission landscape. Here we present an integrated multi-metric approach that jointly models serological prevalence, incidence and health facility catchments such that each metric can be leveraged to produce fine-scale spatio-temporal outputs for the Grand'Anse Department in Haiti. Data used for this model comes from monthly reported incidence for 2017, case tracing from health facilities done by the National Malaria Control Program for 2017 and serological markers from transmission assessment surveys (TAS) from 2012 to 2016. A Gibbs sampler containing a joint gaussian process model for serology and monthly incidence was designed with spatial and spatio-temporal structure respectively. The catchment modelling was done using travel time distances in a simplified gravity model. Non traced cases per health facility were predicted using the incidence and catchment surfaces for the most likely pixel location. Weakly informative priors were chosen for all parameters in the model. Fit and accuracy of the model was checked by spatial cross-validation and Bayesian probability integral transform test. A sensitivity analysis for incidence was done by removing serology, then catchments from the Gibbs sampler.The final outcomes produced an annual seroprevalence and monthly predicted case incidence surfaces for 2017. Incidence had a biphasic seasonal trend, with most cases concentrating closer to the coastal region. The use of travel times in the catchment model was able to capture the likeliest movement pathways for treatment seeking and predict most likely pixels for non-traced cases. These outcomes are intended to optimise the placement of community health workers in Grand'Anse department as well as focussed application of control interventions.

996

UTILIZING HIGH RESOLUTION MALARIA MAPS AND FUTURE FORECASTS TO OPTIMIZE SITE SELECTION FOR CLINICAL TRIALS IN MALARIA

Daniel J. Weiss[1], Samir Bhatt[2], Ivan Demin[3], David Hughes[3], Peter W. Gething[1]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*Imperial College, London, United Kingdom,* [3]*Novartis Pharma AG, Basel, Switzerland*

To support site selection for future phase 2 and 3 clinical trials in malaria, the Malaria Atlas Project (MAP) created annual *Plasmodium falciparum* prevalence and incidence maps for Africa. This work extends the existing MAP approach by applying autoregressive integrated moving average (ARIMA) forecasting to predict the potential range of burden to 2023. Model uncertainty is propagated from both the geostatistical and the ARIMA models, and uncertainty expands through time in years following the most recently collected response data. The resulting burden estimates were used to derive the expected incidence and absolute number of malaria cases for a set of 54 candidate sites in 23 endemic countries in sub-Saharan Africa. The approach will help in identifying sites with higher likelihood of greater patient numbers for future clinical trials. Additionally, model predictions were derived for 8 sites currently involved

in an ongoing phase 2b clinical trial in malaria using maps for year 2018. The model predictions were compared to the observed recruitment rates, which indicated a positive correlation between both. This provides further confidence in using the malaria maps forecasts for site selection.

997

TRACKING PROGRESS TOWARDS MALARIA IN ELIMINATION IN CHINA: A MODELLING STUDY

Isobel Routledge[1], Shengjie Lai[2], Katherine E. Battle[3], Kyle Gustafson[4], Azra C. Ghani[1], Manuel Gomez-Rodriguez[5], Joshua Proctor[6], Swapnil Mishra[1], Zhongjie Li[7], Samir Bhatt[1]

[1]*Imperial College London, London, United Kingdom,* [2]*University of Southampton, Southampton, United Kingdom,* [3]*University of Oxford, Oxford, United Kingdom,* [4]*U.S. Navy, Washington, DC, United States,* [5]*Max Planck Institute for Software Systems, Saarbrücken, Germany,* [6]*Institute for Disease Modelling, Bellevue, WA, United States,* [7]*Chinese Centre for Disease Control, Beijing, China*

The People's Republic of China has achieved major reductions in malaria incidence in recent years and is on track to elimination, having reported zero locally acquired cases in 2017 and 2018. Understanding the spatio-temporal pattern underlying this decline, in particular the relationship between locally acquired and imported cases, can help inform efforts to maintain elimination and prevent re-introduction. This is particularly pertinent in Yunnan province in the Greater Mekong Subregion, where the potential for local transmission remains a concern. Using an individual level dataset of all confirmed and probable cases of *P. vivax* and *P. falciparum* malaria in Yunnan province recorded between 2011 and 2016 (N = 4287), we jointly estimate the case reproduction number, *Rc* and the number of unobserved source infections (caused by either missed cases or asymptomatic infections generating secondary case). We use these estimates within spatio-temporal geostatistical models to map how transmission varied over space and time and to provide estimates of the timeline to elimination and the risk of resurgence. We estimate the mean *Rc* between 2011 and 2016 to be 0.171 (95% CI = 0.165, 0.178) for *P. vivax* cases and 0.089 (95% CI = 0.076, 0.103) for *P. falciparum* cases. From 2014 onwards, no cases were estimated to have *Rc>1* . The proportion of cases with *Rc>0* also declined during this period, with this decline occurring earliest in the more accessible areas of the province. An unobserved source of infection was estimated to be moderately likely ($p<0.5$) for 19/ 611 cases and high ($p<0.8$) for 2 cases, suggesting high levels of case ascertainment. Our estimates suggest that, if current intervention efforts are sustained, Yunnan is unlikely to experience sustained local transmission up to 2020. However, even with a posterior mean *Rc* of 0.02 (95% CI: 0 - 0.32) projected for the year 2020, sporadic locally-acquired cases could occur due to the large number of imported cases. The declines in *Rc* estimated here coincide with the implementation and improved adherence to China's elimination policy and support China being on track to eliminate malaria by 2020.

998

PROSPECTIVELY ESTIMATING THE HEALTH IMPACT OF UPCOMING PRESIDENT'S MALARIA INITIATIVE IMPACT MALARIA PROJECT-SUPPORTED SEASONAL MALARIA CHEMOPREVENTION CAMPAIGNS IN 70 DISTRICTS ACROSS NIGER, MALI AND CAMEROON IN 2019

Keith Esch[1], Matt Hamilton[2], Eline Korenromp[2], Elizabeth Lacroix[3], Gladys Tetteh[1], Moussa Thior[1]

[1]*PMI Impact Malaria Project, Washington, DC, United States,* [2]*Avenir Health, Glastonbury, CT, United States,* [3]*Population Services International, Washington, DC, United States*

In 2019, the U.S. President's Malaria Initiative's Impact Malaria (IM) project supported National Malaria Control Programs to conduct seasonal malaria chemoprevention (SMC) campaigns in 70 high burden districts across 6 sub-national regions in Niger, Mali and Cameroon. There are 3,704,842 targeted children ages 3-59 months in these districts, representing 37% of eligible children in the 3 countries. IM prospectively estimated the deaths, episodes and disability-adjusted life years (DALYs) averted by these campaigns using epidemiological models. Avenir Health's Spectrum-Malaria (Sp-MA) impact model projected the number of children under 5 (CU5) deaths and episodes avertable by scaling up SMC to reach 90% of children ages 3-59 months with at least 3 treatment cycles during the SMC campaign in sub-national regions receiving IM-support. The model assumes constant coverage of other malaria interventions at 2016 levels, with SMC scale up from 2019 to 2020 and impact from scale up occurring in 2020. Each cycle consists of 1 SP tablets and 3 amodiaquine tablets. Results were then converted into CU5 deaths and episodes averted per targeted child. Finally, DALYs averted per targeted child were calculated by applying 2017 Global Burden of Disease disability weights to CU5 malaria deaths. An estimated 4,694 deaths; 1,153,118 cases; and 405,631 DALYs will be averted during the three IM-supported campaigns. These include: In Niger's 17 districts across 2 regions, an estimated 1,747 deaths; 456,364 cases; and 151,051 DALYs. In 9 districts in Mali, across 2 regions, 1,561 deaths; 292,864 cases; and 134,593 DALYs, and 1,386 deaths; 403,890 cases and 119,998 DALYs across 45 districts in 2 regions of Cameroon. Results show the significant health impact expected from ongoing scale-up of SMC across the Sahel. There are differences across countries and between their regions in the relative benefit of SMC per beneficiary. This modeling can be applied non-IM supported SMC campaigns as well. These results can be used by governments and other implementers to plan and target SMC campaigns geographically to maximize impact and may be useful in advocacy efforts.

999

DEVELOPING OPEN SOURCE SOFTWARE TO SUPPORT CLIMATE DATA INTEGRATION FOR OPERATIONAL MALARIA FORECASTS IN ETHIOPIA

Dawn M. Nekorchuk[1], Worku Awoke[2], Mastewal Worku[3], Zelalem Mehari Nigussie[2], Abere Mihretie[4], Aklilu Getinet[4], Justin K. Davis[1], Michael C. Wimberly[1]

[1]*University of Oklahoma, Norman, OK, United States,* [2]*Bahir Dar University, Bahir Dar, Ethiopia,* [3]*Amhara Public Health Institute, Bahir Dar, Ethiopia,* [4]*Health, Development, and Anti-Malaria Association, Addis Ababa, Ethiopia*

The goal of the Epidemic Prognosis Incorporating Disease and Environmental Monitoring for Integrated Assessment (EPIDEMIA) is to develop and implement malaria early warning systems that integrate public health surveillance with environmental monitoring of climate variations. Through a co-development process including research partners from the U.S. and Ethiopia, we identified the following major requirements for malaria forecasting software. The system must 1) automate the major steps required for operational data processing, modeling, and report generating, 2) work in concert with, but not replicate, existing surveillance programs and health information system, and 3) be implementable in LMICs with existing computational resources and personnel for long-term sustainability. To meet these requirements, we developed the R package epidemiar to provide a generalized set of functions for disease forecasting. R is a free software environment for statistical computing. In addition, we designed workflows and wrote customized code for disease forecasting, including a Google Earth Engine script to capture the necessary summaries of the environmental variables and formatting scripts to create distributable reports with maps and graphs of the results. Since the beginning of 2019, a local team based at Bahir Dar University in Ethiopia has been using EPIDEMIA to produce weekly malaria forecasting reports. The epidemiar package was written to be flexible for implementation in other locations and across a wide range of infectious diseases that are affected by environmental conditions. A companion R project epidemiar-demo contains a fully functional demonstration of the epidemiar forecasting workflow. Both projects are available publically on Github. These software tools facilitate the integration of earth science data with epidemiological data to support early detection and early warning of transmission events for infectious diseases with environmental drivers. The

results complement operational public health surveillance and can help to target interventions at the times and locations where outbreaks are most likely.

MACHINE LEARNING APPROACHES TO BETTER UNDERSTANDING DRIVERS OF *PLASMODIUM FALCIPARUM* MALARIA AND ANEMIA CO-INCIDENCE IN SOUTHWESTERN MADAGASCAR

Akshaya V. Annapragada[1], Benjamin L. Rice[2], Hervet J. Randriamady[3], Christopher D. Golden[4]

[1]*Harvard John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, United States,* [2]*Department of Organismic and Evolutionary Biology, Harvard University, Cambridge, MA, United States,* [3]*Madagascar Health and Environmental Research (MAHERY), Maroantsetra, Madagascar,* [4]*Department of Nutrition, Harvard TH Chan School of Public Health, Boston, MA, United States*

In Madagascar, there is geographic overlap of regions with high prevalence of malaria and anemia, and recently malaria incidence has been increasing in some regions of the country. This motivates study of the local drivers of malaria infection and co-incidence with anemia. Anemia prevalence is determined by a combination of factors, including nutritional and infectious disease status, but is biologically linked to malaria, as malaria parasites lyse red blood cells as a part of the infection cycle. For vulnerable, rural communities in Madagascar, such as those in the semi-arid southwest, a lack of health monitoring infrastructure and paired data on demographics and disease status has limited previous studies. Therefore, we analyzed newly available data from cross-sectional surveys performed in 2017 (n = 2690 individuals, all ages, both sexes) in Atsimo Andrefana province that recorded malaria infection status, anemia status, and over 200 socio-demographic variables. We present preliminary estimates of malaria and anemia prevalence, and their co-incidence. We observed an overall 16.9% malaria prevalence and 34.3% anemia prevalence among individuals sampled. Of those with anemia, 52.3%, 44.8% and 2.9% had mild, moderate and severe anemia, respectively. Among individuals testing positive for malaria, 50.7% also had anemia and 8.6% of all individuals had both malaria and anemia; a significant association (chi-squared test of independence, p < 1e-15). Further, we aimed to develop machine learning methods to determine key drivers of malaria, anemia, and co-incidence from the dataset, and predict individuals and communities susceptible to disproportionate disease burden. We employ matrix factorization methods for dimensionality reduction, such as Principle Component Analysis and k-means clustering, to identify the subset of survey questions significantly contributing to variation. In the future, we aim to train a Convolutional Neural Network to predict malaria, anemia, and co-incidence using the key socio-demographic variables we identify with the methods above.

1001

MODELLING HYPOTHESIZED INTERACTIONS OF *PLASMODIUM FALCIPARUM* AND *P. VIVAX*

Roslyn Hickson[1], Ricardo Aguas[2], Angela Devine[3], James McCaw[1], Lisa White[4]

[1]*University of Melbourne, Parkville, Australia,* [2]*University of Oxford, Nuffield Department of Medicine, United Kingdom,* [3]*Menzies School of Health Research, Darwin, Australia,* [4]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand*

Half of the global population are at risk of malaria, and there are over 200 million cases and 400,000 malaria deaths annually. The greatest threat is posed by two of the parasite species that infect humans, with 1.98 billion people at risk of both *Plasmodium falciparum* and *P. vivax*. *P. vivax* is posing a challenge to the elimination of malaria with the relative and absolute prevalence increasing in several countries, such as Papua New Guinea and India. There are several hypotheses about both the biological mechanisms for the interactions of these two species, and about the best intervention approach for *P. vivax* to enable elimination efforts to align with those for *P. falciparum*. We are developing mathematical models of population level transmission of *P. falciparum* and *P. vivax* to identify which of the hypothesised species interactions are supported by available data.

1002

THE INFLUENCE OF CHOICE OF METHOD, SEASONALITY AND MOVEMENT ON THE DETECTION OF MALARIA HOTSPOTS

Josephine K. Malinga, Yeromin P. Mlacha, Amanda Ross

Swiss Tropical and Public Health Institute, Basel, Switzerland

There has been increasing interest in variation in the risk of malaria at local scales such as within and between villages. As transmission has declined in many settings, targeted interventions for pockets of higher transmission have been trialled and the impact of hotspots of transmission on the surrounding areas debated. Methods to detect hotspots frequently rely on statistical significance and do not consider underlying processes such as the geographical distance between parent and offspring infections, season, the relationship between the malariological outcome and underlying transmission intensity, or the shape and gradient of the hotspot. We use an individual-based spatial simulation model to assess the influence of these features on the performance of measures of heterogeneity to identify underlying pockets of higher transmission intensity from a commonly used outcome, malaria prevalence. We calculate the sensitivity and specificity for households lying inside the pockets of higher transmission. The sensitivity, the proportion of households correctly identified as lying inside the pockets of higher transmission, was lower when there was a gentle decay in risk from the hotspot boundary, the hotspot was irregularly shaped or with a greater mean distance between parent and offspring infections. Both the gradient in risk and greater infection spread increased the size of the detected hotspot. The size of the detected hotspots also depended on the season. The Kulldorff's scan statistic with elliptical or circular windows and the Bayesian model both had greater sensitivity and specificity than Tango's flexible scan statistic in our tests. Only the Bayesian model gave estimates of how much higher the prevalence was in the pocket of higher transmission. The choice of outcome, method of detection and features affected the sensitivity and specificity of the measures and should be taken into account when interpreting analyses of heterogeneity. The characteristics of a pocket of higher transmission may partly determine how well it can be detected as a hotspot, and are also likely to affect the impact of the hotspot on the surrounding areas.

1003

MODELLING THE ROLE OF *ANOPHELES FUNESTUS* IN AN EAST-AFRICAN SETTING WHERE INSECTICIDE-TREATED NETS ARE ALREADY WIDELY USED BUT MALARIA TRANSMISSION PERSISTS

Manuela Runge[1], Halfan Ngowo[2], Tomas A. Smith[1], Nakul Chitnis[1], Fredros Okumu[2], Emilie Pothin[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*Ifakara Health Institute, Ifakara, United Republic of Tanzania*

Major malaria vectors contributing to malaria transmission in Sub-Saharan Africa are members of the *Anopheles funestus* and *An.gambiae* complex. Effective use of long-lasting insecticidal nets has substantially reduced transmission by *An. gambiae s.s.* Continued effective control might contribute to diminishing the role of the highly anthropophilic *An. funestus*. In Kilombero, Tanzania, *An. funestus* and *An. arabiensis* are dominant malaria vectors with *An. funestus* now being the main contributor to transmission despite low abundance. We considered whether malaria elimination was possible if *An. funestus* were eliminated locally and if so, determined the required reduction of *An. funestus* mosquitoes to interrupt transmission, using the dynamic transmission model 'OpenMalaria'. Data from Kilombero informed the effective treatment coverage, the vector composition and the biting behaviour of mosquitoes. The impacts of reducing adult mosquitoes, larvae or both on vector abundance, entomological inoculation rates (EIR), and

malaria prevalence in humans were simulated using generic intervention deployments for ten years for settings with varying pre-intervention EIR values. In all settings, preventing emergence of *An. funestus* reduced malaria prevalence by 50% within six months, but prevalence decreased more slowly after that in higher transmission settings (mediated by *An. arabiensis*). Reducing *An. funestus* emergence by 10% to 50% was sufficient to achieve malaria prevalence of <1% within 5 years in low EIR settings, and by 80% to 100% in moderate EIR settings. Such reductions in prevalence were not possible in high EIR settings. Elimination was only achieved at very low EIR and >75% *An. funestus* emergence reduction. Targeting adults only could also lead to local elimination if outdoor biting mosquitoes could be targeted. In conclusion, the model suggested that the local elimination (or a substantial reduction in emergence) of *An. funestus* would interrupt malaria transmission at low EIR settings, but not in higher EIR settings. Additional larval control may be crucial in settings with a high proportion of outdoor biting.

1004

EFFECTIVE TREATMENT WITH ANTIMALARIALS AGAINST *PLASMODIUM FALCIPARUM* MALARIA 1992 - 2016

Susan F. Rumisha, Giulia Rathmes, Tim C. Lucas, Andre Python, Michele Nguyen, Anita Nandi, Peter W. Gething, Daniel J. Weiss

Malaria Atlas Project, Big Data Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Malaria incidence, prevalence and mortality are influenced by variations in treatment efficacy, treatment seeking behaviour, and the proportional use of available antimalarials. The combination of these factors is crucial for enumerated ineffectively (or untreated) cases, which constitute the cases at risk of resulting in severe disease and even death. As such, effective treatment with an antimalarial is a key input into our malarial mortality models, and high-resolution maps of this metric provide a guide to malaria elimination programs for improving antimalarial coverage. This project utilized data generated from therapeutic efficacy studies (TES), demographic health surveys and malaria indicator surveys (DHS-MIS), and ACTWatch project to estimate effective treatment in all MEC globally between 1992 - 2016. Data on 232 TES comprising 756 treatment arms, 89,713 individuals across 50 countries on Artemisinin Combination Therapies (ACTs), Sulfadoxine-Pyrimethamine (SP) and Chloroquine (CQ) covering a period between 1992 - 2016, were analysed using Bayesian geostatistical models, fitted separate for ACTs and non-ACTs to predict spatiotemporal patterns of efficacy for individual antimalarials in malaria endemic countries (MEC). Models were fitted using integrated nested Laplace approximations validated on predictive ability and accuracy. Efficacy level was set to over 90% treatment success. We summarized proportional usage for specific-antimalarials from DHS-MIS (2,365,905 children) and ACTWatch (2,153,507 cases) for the same period for each country. Treatment seeking patterns were estimated using DHS survey data. Synthesizing the three components, we calculated the population-adjusted proportion of individuals who received effective treatment in 110 MEC for the 25-year period.

1005

USING PREDICTIVE MODELING FOR THE PROACTIVE IDENTIFICATION OF MALARIA HOTSPOTS IN SENEGAL

Maya Fraser[1], Jean-Louis Lankia[2], Michael Betancourt[3], Michael Hainsworth[1], Yakou Dieye[2], Kammerle Schneider[1], Hana Bilak[1], Laurence Slutsker[1], Hannah Slater[1]

[1]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States,* [2]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Dakar, Senegal,* [3]*Freelance, New York, NY, United States*

Malaria continues as a major public health problem in Senegal. However, recent progress in program scale-up has resulted in substantial burden reductions and a national commitment to malaria elimination. As malaria incidence declines, transmission becomes more spatially heterogeneous, meaning that a large proportion of cases occur in fewer locations particularly in the north region. Currently, these localized clusters of malaria cases (outbreaks) are targeted reactively—when five cases occur within 15 days around 100m, a team is deployed to treat all individuals in the index case household and neighboring houses. However, this approach relies on the occurrence of an outbreak to trigger a response and likely is too late to prevent additional infections in individuals near the targeted neighborhood, or potentially even visitors to the area. We have developed a novel predictive statistical modeling framework to proactively identify "hotspots"—areas at high risk of experiencing outbreaks—for proactive targeting of measures (e.g., IRS, focal drug administration) to prevent outbreaks before they occur. Geolocated routine surveillance data (via the DHIS 2 national malaria reporting platform) from individual health facility catchment areas were regressed against a range of predictive covariates selected based on our understanding of malaria epidemiology and the drivers of transmission, including access to treatment, rainfall, temperature, and vector control coverage. A Bayesian generalized linear spatial model was used and implemented in Stan. Maps were developed identifying health facility catchment areas most at risk of outbreaks in the forthcoming transmission season and were integrated within a malaria visualization platform used in-country to inform intervention planning. The next step is to design a pilot study to evaluate the effectiveness of this approach to proactive malaria surveillance.

1006

SHARING THE KNOWLEDGE: THE PRESIDENT'S MALARIA INITIATIVE (PMI) HOSTS A SCIENTIFIC CONFERENCE IN HONOR OF WORLD MALARIA DAY, ANTANANARIVO, MADAGASCAR, 2018

Catherine M. Dentinger[1], Jocelyn Razafindrakoto[1], Laurent Kapesa[1], Jemima Andriamihamina[1], Andritiana Tsarafihavy[2], Eliane Razafimandimby[3], Henintsoa Rabarijaona[4], Sedera Mioramalala[5]

[1]*US President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Antananarivo, Madagascar,* [2]*USAID Mikolo Project, Antananarivo, Madagascar,* [3]*USAID Maternal Child Survival Program, Antananarivo, Madagascar,* [4]*Malaria Program, World Health Organization, Antananarivo, Madagascar,* [5]*National Malaria Control Program, Antananarivo, Madagascar*

Madagascar malaria researchers attend international meetings, but their presentations are rarely shared in-country in a forum that permits discussing implications, identifying applications, and refining research agendas. In honor of World Malaria Day 2018, PMI and the Roll Back Malaria Partnership to End Malaria held a conference to share findings. PMI and the *Institut Pasteur de Madagascar* hosted a half-day abstract writing workshop; PMI implementing partners leveraged resources to cover conference costs, an estimated $3,000. PMI and a medical faculty professor served as moderators; students registered participants and distributed evaluations. Evaluation data were entered into an Epi-Info database and analyzed using Microsoft Excel 2016. Fifteen researchers attended the abstract-writing workshop, 4 (27%) of whom submitted evaluations, which indicated that the workshop was beneficial but too short. For the conference, 19 submissions were chosen for 8 oral and 11 poster presentations. Topics included new approaches to prevention; findings from surveillance, parasitology and entomology studies; and improving community-based services. Of 194 attendees, 94 (48%) completed evaluations. Participants included clinicians, laboratorians, epidemiologists, program managers, public health practitioners, and faculty and students from medical and nursing schools; 92% indicated the event met their expectations and 97% stated they would like to attend again. One presenter noted that the conference allowed for feedback that enabled them to refine their work in advance of the ASTMH conference. Suggestions for future conferences included hosting a full-day event, finding a means to include regional and district public health personnel, including participants from other sectors such as education and environment, and sharing copies of posters and presentations with participants. This first PMI-supported conference in Madagascar to share

results of malaria prevention projects and studies was well-received. Plans to host a one-day event in 2019, using technologies to include field-based practitioners, are underway.

1007

ZAMBIA MALARIA INDICATOR SURVEY 2018: CONTINUED PROGRESS TOWARD NATIONAL COVERAGE AND BURDEN REDUCTION TARGETS

Busiku Hamainza[1], Maya Fraser[2], Elizabeth Chizema-Kawesha[1], Kafula Silumbe[3], Mercy Mwanza-Ingwe[1], Hawela Moonga[1], Anthony Yeta[1], Mutinta Mudenda[1], Fred Masaninga[4], John M Miller[3]

[1]*National Malaria Elimination Centre, Lusaka, Zambia,* [2]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States,* [3]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia,* [4]*World Health Organization, Lusaka, Zambia*

The Zambia National Malaria Indicator Survey (MIS) 2018 was conducted by the Ministry of Health through the National Malaria Elimination Centre in April and May 2018 with the support of its partners. The MIS is a national household survey designed to assess the coverage of key malaria interventions and malaria prevalence in children under five years of age. The 2018 MIS was based on a nationally representative two-stage cluster sample of 4,475 households selected from 179 standard enumeration areas. A total of 4,177 households were interviewed in the survey, along with 3,680 women of reproductive age. A total of 2,883 children under the age of five provided finger prick blood samples for malaria testing. Consenting households and household members were asked about their household dwelling as well as standardized questions about insecticide-treated mosquito net (ITN) coverage and use, indoor residual spraying (IRS), prevention of malaria during recent pregnancies, and management of fever among children. Overall, national malaria parasite prevalence by microscopy was 9% among children under five years of age in 2018, a reduction compared to the previous MIS in 2015 (19%). Zambia achieved high coverage (80%) of at least one ITN per household, while 45% of households reported having at least one ITN for every two household members. Thirty-five percent of Zambian households reported IRS within the previous 12 months. Among women of reproductive age, 81% reported receiving at least two monthly doses of intermittent preventive treatment (IPTp) with sulfadoxine-pyrimethamine (SP) during their most recent pregnancy, and 67% reported receiving three doses of SP. Additional results from key coverage indicators will be presented. The 2018 MIS represents significant progress across nearly all key indicators compared with previous similar surveys. This success is based on a foundation of solid programming and implementation efforts by a range of partners supporting the National Malaria Elimination Programme.

1008

TRAINING OUTCOME FOR MALARIA MICROSCOPY DURING AN ANTIMALARIAL THERAPEUTIC EFFICACY STUDY 2017

Safia M. Ali

Zanzibar Malaria Elimination Program, Zanzibar, United Republic of Tanzania

Antimalarial therapeutic efficacy studies (TES) should be linked with accurate malaria microscopy in order to monitor patient response to prescribed antimalarial medications based on WHO protocol. Our objectives were to conduct malaria microscopy training and assess laboratory technician improvements in microscopy. A 5-day malaria microscopy theory and practical training course was conducted in May 2017 to precede the biannual TES in Zanzibar. Eleven hospital laboratory technicians from the three TES recruitment health facilities received training on parasite detection, species identification, and parasite counting. Technicians completed pre-course and post-course written and practical tests including microscopy examination of blood slides with known *Plasmodium falciparum*, *P. malariae, P.* ovale, and mixed infections with densities ranging from 100 to 30,000 parasites/μL, as well as negative slides. We calculated sensitivity and specificity of the trainees microscopy readings of 128 samples collected during the TES using the readings by senior microscopists as the gold standard. The average test score before the training was 48.6%, while the average score after the training increased to 85.3% ($p<0.01$). Compared to the microscopy readings by the senior microscopists, the sensitivity and specificity of the trainee readings were 95% and 100%, respectively. Malaria microscopy training for hospital technicians is essential before starting antimalarial TES, and training improved performance in Zanzibar. Similar training might also improve the quality of microscopy for routine diagnosis.

1009

INFECTING HEALTHY VOLUNTEERS WITH MALARIA: CAN THIS BE DONE IN THE GAMBIA? A QUALITATIVE STUDY

Edgard Diniba Dabira, Jane Achan, Umberto D' Alessandro

MRCG at London School of Hygiene & Tropical Medicine, Banjul, Gambia

Controlled human malaria infection (CHMI) model, in which healthy volunteers are infected with *Plasmodium falciparum* to assess the efficacy of novel malaria vaccine and drugs has become a valuable tool to accelerate the development of vaccines and drugs. Perceptions and acceptability of the community is key for participation and retention of study participant in such studies and this is vital for the success of the trial. However, until now, little is known about communities' perceptions and acceptability regarding the CHMI model. As an ancillary study of the recently conducted CHMI study in The Gambia, we assess communities' perceptions and acceptability. We conducted an exit interview with the 19 CHMI trial participants and selected five participants for an in-depth interview; ten semi-structured interviews and three focus groups discussions were conducted at the community level. Respondents included students, ethic committees' members, researchers and civil servants and key local leaders. Participants acknowledged the risk involved in the CHMI model and appreciated the fact that the study is carried out in the country. Financial compensation was a major motivation for participation, but a fair compensation is required. Parents are key for decision-making process. Although the CHMI model presents a perceived risk, respondents acknowledged the importance and the necessity to conduct the CHMI study in The Gambia as it would ultimately benefit to the country.

1010

LESSONS LEARNED IN ENSURING EFFECTIVE IMPLEMENTATION OF INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM): UGANDA'S EXPERIENCE

Maureen Amutuhaire, Damian Rutazaana, Allen Nabanooba, Jimmy Opigo, Jesca Nsungwa Sabiiti, Denis Rubahiika

Ministry of Health, Kampala, Uganda

The Ministry of Health (MoH) and development partners introduced the integrated community case management (ICCM) program due to the high under-five mortality rate attributed to malaria, diarrhea and Pneumonia. In 2016, the National Malaria control program scaled up efforts to optimize the implementation of iCCM. To evaluate the effect of the interventions, we reviewed data from January 2017 to December 2018. The data was analyzed from Health information records of village health teams and facilities, supervision reports from the district health team, partners and MoH and minutes of iCCM meetings held at national level, district and at facility level. The majority of the sick children (55%) were seen by Village Health Teams compared to 45% by the facility health workers. There was a threefold increase in the number of sick children seen by the VHTs from 675,982 cases seen in 2017 to 1,973,335 cases in 2018. 474,193 children diagnosed with pneumonia in 2017 compared with 188,698 children in 2018. 1,069,292 children diagnosed with Malaria seen by the VHTs in 2017 compared to 394,266 in 2018. Community reporting increased from 17.8% to 31.9% and stock out of iCCM commodities reduced by 45%. District MoH engagements, harmonization of program implementation

and reporting, stock management innovations, regular VHT support supervision , home visits and continuous sensitization of communities enabled these achievements in iCCM implementation

1011

IMPROVED PERFORMANCE OF THE MALARIA SURVEILLANCE, MONITORING AND EVALUATION SYSTEM FROM 2015 TO 2018 IN MADAGASCAR

Jean-Marie NGbichi[1], Maurice Ye[1], Alain Rakotoarisoa[2], Léa Bricette Andriamampionona[2], Solo Harimalala[3], Mauricette Andriamananjara[3], Laurent Kapesa[4], Yazoume Ye[1]

[1]*MEASURE Evaluation, ICF, Rockville, MD, United States,* [2]*Direction de la Veille Sanitaire, de la Surveillance Epidémiologique et Riposte, Ministry of Public Health, Antananarivo, Madagascar,* [3]*National Malaria Control Program, Ministry of Public Health, Antananarivo, Madagascar,* [4]*USAID PMI, Antananarivo, Madagascar*

MEASURE Evaluation has worked with the National Malaria Control Program (NMCP) since 2015 to strengthen malaria surveillance in Madagascar with support from the U.S. President's Malaria Initiative and partners. After a 2015 baseline survey of key malaria surveillance indicators in the national integrated disease surveillance and response (IDSR) system including completeness, timeliness of reporting and data accuracy we conducted a follow-up survey in 2018 and compared the results of the two surveys. *T-test* for means from independent samples were estimated and *p-values* calculated. Differences were considered significant if p<0.05. Completeness of routine malaria reporting by health facilities (*Centres de Santé de Base:* CSB) was 73.0% in 2018 compared with 65.3% in 2015 (*p=0.214*). Timeliness of CSB reporting was 68.4% in 2018 compared with 45.5% in 2015 (*p=0.0005*). Completeness of community-based reporting was 94.3% in 2018 compared to 8.6% in 2015 *(p<0.00001*) while timeliness was 55.0% in 2018 compared to 5.2% in 2015 *(p<0.00001).* Regarding data accuracy, the comparison of data from weekly reporting forms to weekly malaria data in registries showed 87.0 % accuracy in a randomized sample of CSB in 2018 compared to 73.3% in 2015 *(p<0.00001).* MEASURE Evaluation's support in strengthening malaria SME in Madagascar has likely contributed to these significant improvements in malaria and overall IDSR data reporting both at facility and community levels. These trends need to be maintained and improved, especially because Madagascar is considering malaria elimination in the coming years.

1012

EXPLORING BARRIERS AND FACILITATORS OF ACCESS AND ADHERENCE TO PEDIATRIC ARTEMISININ-BASED COMBINATION THERAPIES IN FREETOWN, SIERRA LEONE

Kristin Banek[1], Deborah D. DiLiberto[2], Emily L. Webb[1], Samuel Juana Smith[3], Daniel Chandramohan[1], Sarah G. Staedke[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*McMaster University, Hamilton, ON, Canada,* [3]*National Malaria Control Program, National Malaria Control Programme, Ministry of Health and Sanitation, Freetown, Sierra Leone*

Medication adherence is an important step in the treatment effectiveness pathway. However, medicine-taking behaviors do not occur in isolation, but are influenced by the environment in which the medicine is taken or administered. This qualitative study was embedded within a randomized controlled trial comparing adherence to artemether-lumefantrine and co-formulated amodiaquine-artesunate for the treatment of uncomplicated malaria in children under-five. The aim of the study was to explore contextual factors and identify barriers to and facilitators of access and adherence to malaria treatment at two public health facilities in Freetown, Sierra Leone. Caregivers of enrolled children were purposively selected based on their study arm and their primary adherence outcome, and were invited to participate in an in-depth interview. All interviews were conducted in Krio or English and were electronically recorded, transcribed, and translated. Interview transcripts were coded and aggregated into themes, applying a thematic content approach. Interviews with 49 caregivers were analyzed. Caregivers' responses highlighted three key aspects of the treatment effectiveness pathway that influenced access to medications and adherence to treatment: 1) health system related factors; 2) characteristics of the medications; and 3) caregivers' previous experience with malaria treatment. Caregivers reported confidence in the public health system and trust the health workers, which may have translated into better health behaviors. Ease of administration of the medication and perceived risk of side effects (namely weakness and vomiting) coupled with caregivers' prior experience with treating malaria influenced the way medications were administered to their children and whether they adhered to the prescribed treatment. In order to improve antimalarial adherence, the contextual factors in which medication-taking behaviors occur, such as must be considered. Moreover, further development and deployment of antimalarials that are easier to administer (i.e. dispersible or chewable formulations) may improve treatment adherence in children.

1013

SERVICE AVAILABILITY AND READINESS ASSESSMENT OF MALARIA CASE MANAGEMENT CAPACITIES IN HEALTH FACILITIES OF COMMUNES TARGETED FOR MALARIA ELIMINATION IN GRAND'ANSE, HAITI

Matt Worges[1], Vena Joseph[1], Thom Druetz[1], Jean Frantz Lemoine[2], Bernadette Fouche[3], Michelle Change[3], Prabhjot Singh[4], Eric Ndofor[4], Rainier Escalada[4], Joshua Yukich[1], Thomas Eisele[1]

[1]*Tulane University, New Orleans, LA, United States,* [2]*Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti,* [3]*Malaria Branch, Division for Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Pan American Health Organization, Washington, DC, United States*

Haiti and the Dominican Republic are the only 2 countries in the Caribbean with endemic malaria transmission. Haiti accounts for over 95% of all documented malaria cases among the two nations. The Haiti Malaria National Strategic Plan calls for malaria elimination by 2025. Access to quality-assured malaria case management and diagnostics, as well as a high-quality surveillance and response system, are prerequisites for malaria elimination. In Haiti, chloroquine (CQ) plus single-dose primaquine (PQ) is the first-line treatment for uncomplicated malaria, which is predominantly due to *Plasmodium falciparum*. The Haiti national policy stipulates malaria diagnosis and case management are free. To assess malaria case management and diagnostic capacities and practices, a modified service availability and readiness assessment was conducted from November-December 2017 in 5 communes of Grand'Anse - the Department targeted for aggressive elimination strategies as part of the Malaria Zero Alliance. All 16 functioning health facilities were surveyed. Preliminary results show all facilities had malaria treatment guidelines available, but only 3 of 16 had the required fever case management algorithms. All facilities reported use of rapid diagnostic tests as the primary test for malaria with 4 also reporting use of malaria microscopy. 15 of 16 facilities had CQ tablets in stock on the day of the survey and 1 had CQ tablets expired by one month. Unexpired PQ tablets were observed in all facilities. 14 of 16 facilities reported charging general user fees to outpatients, which averaged 27.5 GDES (USD 0.33). However, 5 of 16 facilities reported user fees were either not charged or refunded to malaria test positive patients. No facilities reported charging clients specifically for malaria testing/ treatment. These results are encouraging and show that the majority of surveyed facilities have the basic capacities to perform malaria case management and diagnostic practices.

1014

SCALE UP OF INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM) OF MALARIA FOR CHILDREN UNDER FIVE YEARS OLD IN LIBERIA, 2017-2018

Jannie M. Horace[1], Isaac Mwase[2], Eric Gaye[2], Barbara Jones[2], Jessica M. Kafuko[1], Mamadou O. Diallo[3]

[1]*U.S. President's Malaria Initiative, U.S. Agency for International Development (USAID), Monrovia, Liberia,* [2]*Partnership for Advancing Community-Based Services (PACS), Monrovia, Liberia,* [3]*U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States*

Liberia's health care delivery system is organized into three tiers. The first level, primary health care, consists of clinics and the community health program. National malaria case management guidelines recommend that, as part of the Integrated Community Case Management (iCCM) program, Community health Assistants (CHA) should identify suspected malaria cases through routine household visits and confirm cases using malaria rapid diagnostic tests (RDT) prior to treatment. The overall goal is to rapidly manage malaria in children under-five and provide treatment within 24 hours of symptoms onset to prevent complications. Since 2015, the Partnership for Advancing Community-based Services (PACS) has collaborated with the Ministry of Health (MOH) and recruited, trained and supported over 640 CHAs to implement iCCM in communities at least 5 km away from clinics in Bong, Lofa and Nimba counties. PACS supported the MOH to develop and disseminate health communication strategy to promote health-seeking behavior and increase iCCM uptake in the community. Malaria awareness activities, including local radio call-in shows, have exposed hard-to-reach communities to information on malaria services. PACS iCCM maintains a database to monitor program implementation and generate reports. From October 2017 to September 2018, the CHAs provided malaria treatment with the first line artemisinin-based combination therapy (ACT) to 32,910 malaria cases in children under-five. Before initiating treatment, 76.9% (CI: 76.4% -77.3%) of malaria cases were confirmed with RDTs. Sixty-eight percent (CI: 67.5% - 68.5%) of these cases were treated within 24 hours. On average, the CHAs treated 2,743 malaria cases per month. The proportion of children treated within 24 hours has steadily increased, from 54.4% (CI: 51.2% - 57.6%) in October 2017 to 75.7% (CI: 74.3% - 77.1%) in September 2018 ($p<0.001$). Challenges for iCCM implementation include frequent RDT and ACTs stock outs. PACS successfully implemented iCCM to scale up early access to malaria treatment, but the success of this approach rests on a reliable stock of malaria commodities to test and treat cases.

1015

PRIORITIZING HEALTH FACILITIES FOR MALARIA CASE MANAGEMENT TRAINING IN GHANA IN THE ERA OF LIMITED RESOURCES

James Sarkodie[1], Amos Asiedu[1], Eric LaFary[1], Richard Dogoli[1], Raphael Ntumy[1], Lolade Oseni[2], Gladys Tetteh[2]

[1]*Impact Malaria Ghana, East Legon, Accra, Ghana,* [2]*Jhpiego Baltimore, Baltimore, MD, United States*

Ghana has made significant recent improvements in malaria control, reducing malaria deaths by 70% (1565 in 2015 to 468 in 2018) with a corresponding decline in under-5 malaria case fatality rate (CFR) from 0.51% to 0.19%. However, significant geographical variations in malaria morbidity and mortality persist. To achieve greater impact, a one-size fits all training approach may no longer be the most effective option. To prioritize facilities for refresher malaria case management training, the U.S. President's Malaria Initiative-funded Impact Malaria Project in collaboration with Ghana Health Service established systematic evidence-based criteria informed by quantitative and qualitative data. Using routine HMIS data from October 2017 to September 2018, total malaria admissions, malaria deaths, malaria case fatality rates were determined for all districts in respective regions. Districts with high burden malaria mortality and morbidity were ranked using a Pareto chart; districts with CFRs above the regional average were also identified. Stakeholder meetings discussed the findings using additional qualitative information including referral patterns, access and facility ownership to explain the findings. Regional health management teams triangulated the information to generate district lists prioritized for additional training focusing on assessment for complications, treatment, managing complications, monitoring and using quality improvement methods to identify change ideas to test to improve malaria management. The percentage of districts with an under-5 malaria CFR above the regional average was 31% Ashanti (AR), 28% Brong Ahafo (BAR), 31% Eastern (ER), 15% Upper East (UER) and 27% Upper West (UWR). In AR, 30% of districts accounted for 80% of all malaria deaths; in BAR, 34% of districts for 99% deaths; in ER, 38% of districts for 80% deaths; 23% of districts reported 99% deaths in UER; and 36% districts reporting 90% of deaths in UWR. Using routine HMIS data backed by qualitative information, a rational replicable basis for the prioritization of districts for intervention can be created based on evidence.

1016

ECONOMIC BURDEN OF MALARIA IN PREGNANT WOMEN IN RIVERS STATE, NIGERIA

Ifeyinwa N. Chijioke-Nwauche, Terhemen Kasso, Omosivie Maduka, Abimbola T. Awopeju, Ibinabo L. Oboro, Paul I. Nsirimobu, Lucy E. Yaguo Ide, Mark Ogoro, Godly Otto, Chijioke A. Nwauche

University of Port Harcourt, Port Harcourt, Nigeria

Malaria remains a public health concern among pregnant women and accounts for about 11% of maternal death in Nigeria. Treatment of malaria illnesses places a great financial burden on households. The study examined the economic burden of malaria among pregnant women in 12 communities in Rivers State, Nigeria. A pretested interviewer administered questionnaire was used to harvest relevant information from a sample population of 1008 participants. Obtained data was analysed using SPSS version 22 and results are presented in frequencies, percentages and tables. The socio-demographic characteristics showed a mean age of 30.56±4.93 years; with married and single constituting 988 (98.0%) and 17 (1.7%), others 3 (0.3) respectively. Educational attainment for the respondents were tertiary 656 (65.1); secondary 348 (34.5), primary 4 (0.4). Participants included traders/business women, teachers, civil servants, unemployed persons, artisans and others with average family income of 93,504.77 Naira (260 USD) per month. Out of 413 (41%) diagnosed with malaria, 382 (92.5%) were treated with an average cost of 3,241.42 Naira (9 USD) for one episode of malaria inclusive of laboratory test. The mean cost of treatment for hospitalised persons was 19,642.86 (54.6 USD) with a loss of 6.37 days of man hours and these costs were paid through out of pocket expenses by the spouses. 26 participants reported having negative effect of hospitalization on their finances. The association between malaria diagnosis and the socio-economic status of participants were all statistically significant with p-values <0.05 at 95% confidence interval. There was also a statistical significant relationship between malaria diagnosis and treatment, however the relationship between malaria diagnosis and preventive methods was insignificant (p-value >0.05). Cost of malaria treatment constitutes a great financial burden on households since this burden is completely born by the families. We recommend that the public health systems provide free treatment for pregnant mothers or reduce the cost of treatment in order to decrease the economic burden on the households.

1017

IMPROVEMENT IN DATA QUALITY USING FRONTLINE DATA VALIDATION OFFICERS IN SEVEN STATES IN NIGERIA

Chinedu Chukwu[1], Daniel Ofem[1], Isaac Adejo[1], Victoria Erinle[1], Faith Benebo[1], Thomas Hall[2], Mariah Boyd-Boffa[3], Bala Mohammed Audu[4], Perpetua Uhomoibhi[4], Ibrahim Maikore[4], Issa Kawu[4], Sonachi Ezeiru[5], Nnaemeka Onugu[5]

[1]*Management Sciences for Health (MSH), Abuja, Nigeria,* [2]*Management Sciences for Health (MSH), Arlington, VA, United States,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*National Malaria Elimination Program, Abuja, Nigeria,* [5]*Catholic Relief Services, Abuja, Nigeria*

In Nigeria, inconsistencies between District Health Information System 2 (DHIS2) data, National Health Management Information System registers, and monthly summary forms are common. During the first quarter of 2018, a baseline assessment identified that 62% of 5,416 facilities in seven states (Adamawa, Delta, Kwara, Katsina, Ogun, Osun and Taraba) had incomplete data in the DHIS2 related to seven key malaria indicators. Without complete data, program performance is difficult to assess and planning to address gaps becomes a major challenge. Management Sciences for Health in collaboration with the Global Fund and in partnership with Catholic Relief Services and the National Malaria Elimination Program, developed a Data Validation Template, identified and trained 1,134 Validation Officers, and supported mentoring of health facility staff in 5,416 health facilities. Data Validation Officers download the data from the DHIS2 into the template and then take the data with them to health facilities to mentor staffs on any issues related to their respective data. Data validation meetings at the local government authority level were used to reinforce improvements. One year after implementation of this approach another assessment in the seven states determined that incomplete data in the DHIS2, in relation to the seven key malaria indicators, had reduced to only 13% of the 5,416 health facilities. Coaching and mentoring of health facility staffs responsible for data entry using Data Validation Templates by Validation Officers and reinforced during Data Validation Meetings improved the completeness of data in health facilities across seven states. Continuous mentoring, and identifying data issues, is necessary to ensure improvements are maintained.

1018

RETENTION OF MALARIA KNOWLEDGE AND SKILLS AND ADHERENCE TO NATIONAL TREATMENT GUIDELINES BY INTEGRATED COMMUNITY MALARIA VOLUNTEERS IN THREE STATES/REGIONS IN MYANMAR

Ni Ni Aye

Jhpiego, Yangon, Myanmar

The PMI-supported Defeat Malaria project aims to enhance technical and operational capacity of the National Malaria Control Program and providers at all levels of the health system in 3 States/Regions (S/R). In 2017, Myanmar introduced a new type of cadre, Integrated Community Malaria Volunteers (ICMV), as a foundation for integrated malaria control activities at village level. Defeat Malaria is developing their capacity to ensure malaria case management (MCM) according to National Treatment Guidelines (NTG). To date, Defeat Malaria has prepared 71 national and S/R level trainers to train and supervise 776 ICMVs caring for a population of nearly 600,000 people. The trainers offer a 5-day modular course to ICMVs, 2 days focusing on community-based prevention and MCM, including use of RDTs, ACTs, chloroquine and primaquine. ICMVs are coached using checklists as they diagnose and treat clients until they master the skills. From February-September 2018, 776 ICMVs were trained. On the pre-course test, 54% of 741 ICVMs achieved a passing score (≥80%) on the knowledge test, while 80% achieved a passing score on the post-course knowledge test. One-hundred percent achieved a passing score on use of RDTs using a standardized skills checklist during a simulation session. To date, 36 ICMVs have undergone post-training assessment of retention of malaria knowledge and RDT skills at one month after training. Ninety-four percent achieved passing scores on knowledge tests, and 83% conducted RDTs according to the skills checklist. During case simulations and per review of registers, 100% of the 36 ICMVs adhered to NTGs. ICMVs will receive regular supervision and will be followed up at 6 months after training to determine longer-term retention of knowledge and skills (data available by October 2019). While ICMVs demonstrate retention of knowledge and skills at one month after training, assessment at 6 - 12 months is necessary to ascertain long-term retention and persistent ability to care effectively. In the interim, we recommend that ICMVs receive regular supervision to ensure knowledge and skills retention associated with appropriate use of RDTs and NTGs.

1019

THE IMPACT OF IMPROVED AND COORDINATED BI-MONTHLY FACILITY REPORT ON UN-INTERRUPTED SUPPLY OF MALARIA HEALTH PRODUCTS FOR PATIENTS UNDER THE GLOBAL FUND MALARIA GRANT, (2018-2020) IN PUBLIC HEALTH FACILITIES IN ADAMAWA STATE: A CASE STUDY OF FEDERAL COLLEGE OF EDUCATION (FCE) STUDENTS' CLINIC, YOLA, ADAMAWA STATE, NORTHEASTERN NIGERIA

Melis Esi[1], James Audu[1], Thomas Hall[2], Isaac Adejo[1], Mariah Boyd-Boffa[3], Emmanuel Nfor[2], Olumide Elegbe[1], Bala Mohammed Audu[4], Kenji Goyit[4], Olukayode John[4], Sonachi Ezeiru[5], Chukwudi Uche[5]

[1]*Management Sciences for Health (MSH), Abuja, Nigeria,* [2]*Management Sciences for Health (MSH), Arlington, VA, United States,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*National Malaria Elimination Program, Abuja, Nigeria,* [5]*Catholic Relief Services, Abuja, Nigeria*

The purpose of the study is to assess the impact of improved quality of national bimonthly facility stock reports (BFSR) on malaria health product management at a students' clinic, Federal College of Education (FCE), Yola, Adamawa State. In March 2018 the stock out rates of artemisinin-based combination therapy (ACT), rapid diagnostic tests (RDT) and long-lasting insecticidal nets (LLIN) were 50%, 16.9% and 3.9% respectively, due to poor quality BFSR and weak governance contributing to missed treatment and prevention opportunities of malaria infection in the clinic. Management Sciences for Health (MSH) in partnership with Catholic Relief Services, the National Malaria Elimination Program, and the Global Fund, is responsible for strengthening Supply Chain Management Systems in 13 states in Nigeria, to ensure continuous availability of RDTs, ACTs, and LLINs. MSH provided technical assistance to three health care workers at the FCE clinic, and five members of the state logistic management coordinating unit on quality BFSR generation, LLIN inventory management and timely requisition practices, including last mile distribution (LMD) planning from March 2018 to March 2019. MSH conducted analysis using LMD improvement tools to determine the variance between malaria products available for distribution and quantities ordered by the facility. After the intervention, stock outs of malaria health products declined at FCE clinic by March 2019, with ACTs down to 17.9%, and to 0% for RDTs and LLINs. The number of students and staff treated for uncomplicated malaria with ACTs after undergoing RDT and testing positive increased from 149 in March 2018 to 346 in March 2019. Generation of accurate BFSR improves supplies of malaria health commodities, reduces stock-out rates and improves service uptake among students and faculty in this tertiary, institutional health clinic. The Federal and State Ministries of Health should use these methods to improve BFSR accuracy and timeliness, which would reduce stock outs and facilitate malaria services delivery to those in need.

1020

EFFECTIVENESS OF SEASONAL MALARIA CHEMOPREVENTION IN AREAS OF INTENSE, SEASONAL MALARIA TRANSMISSION: SECONDARY ANALYSIS OF DATA FROM A HOUSEHOLD-RANDOMIZED CLINICAL TRIAL IN BURKINA FASO AND MALI

Matt Cairns[1], Issaka Sagara[2], Issaka Zongo[3], Irene Kuepfer[1], Frederic Nikiema[3], Serge Yerbanga[3], Modibo Diarra[2], Amadou Barry[2], Amadou Tapily[2], Ismaila Thera[2], Halidou Tinto[3], Paul Milligan[1], Jean Bosco Ouédraogo[3], Daniel Chandramohan[1], Adoulaye Djimde[2], Brian Greenwood[1], Alassane Dicko[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Malaria Research and Training Center, University of Science, Techniques, and Technologies of Bamako, Bamako, Mali,* [3]*Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso*

Seasonal malaria chemoprevention is now widely used to prevent malaria in young children in the Sahel sub-region of Africa, including in areas of extremely high malaria transmission. Such areas are a particular concern given their important contribution to the global malaria mortality burden. We explored the effectiveness of SMC in two areas of intense, seasonal malaria transmission in Burkina Faso and Mali. Between August 2014 and December 2016, approximately 20,000 children aged 3-59 months at the start of each rainy season received four monthly cycles of SMC with sulfadoxine-pyrimethamine plus amodiaquine (SP-AQ), along with either azithromycin or placebo; this analysis focuses on the placebo group, who received the standard SMC regimen. Despite high coverage of SMC and provision of new long-lasting insecticidal nets to study children, approximately two-thirds of hospital admissions were caused by malaria. The overall incidence of hospitalisations for malaria was 12.5 per 1000 child-years at risk, with a clear peak each year in July, before SMC delivery began in August. Among children who had received SMC in the past 28 days, malaria incidence was approximately five-fold lower than among children without recent SMC (incidence rate ratio, 0.21 (95% CI 0.19, 0.22)). In all three years of the study, and in both countries, prevalence at the end of the rainy season exceeded 50% in school-age children who did not receive SMC, and was below 10% in study children. The effectiveness of SMC with SP-AQ remains very high in this setting, but malaria is far from being brought under control. Our results emphasise the need for additional monthly cycles of SMC to adequately cover the entire transmission season, and new interventions to further reduce the malaria burden.

1021

WHAT CAN DESCRIPTIVE NORMS TELL US ABOUT CARE-SEEKING FOR CHILDREN WITH FEVER IN AFRICA?: A MULTI-COUNTRY STUDY

Stella Babalola[1], **Angela Acosta**[1], Grace Awantang[1], Olamide Oyenubi[1], Mathew Okoh[2], Bolanle Olapeju[1], Ian Tweedie[1], Anna McCartney-Melstad[1], Michael Toso[1], Gabrielle Hunter[1], Abdul Dosso[3], Blaise Kouadio[4], Danielle Naugle[1], Mieko McKay[5]

[1]*Johns Hopkins Center for Communication Programs, Baltimore, MD, United States,* [2]*Breakthrough ACTION-Nigeria, Abuja, Nigeria,* [3]*Johns Hopkins Center for Communication Programs, Abdijan, Côte D'Ivoire,* [4]*United States Agency for International Development - United States Agency for International Development, Abidjan, Côte D'Ivoire,* [5]*Johns Hopkins Center for Communication Programs, Abidjan, Côte D'Ivoire*

There is abundant evidence of the positive links between social norms and various health behaviors, including contraceptive use, antenatal care attendance, HIV care and support, immunization, and adolescent sexual behaviors. However, studies that focus on the role of social norms for malaria-related outcomes are rare. Using cross-sectional household survey data collected between 2015 and 2018 from four African countries, this study assesses the association of descriptive norms with care-seeking in a health facility for children aged less than five years with fever. The study countries include Côte d'Ivoire (n=723 children with fever), Liberia (n=726), Madagascar (n=769) and Nigeria (n=1174). Prior studies have shown that people who perceive specific behaviors to be the norm in their community are more likely to adopt the behavior. In this study, descriptive norm is defined as the perception that at least half of the people in one's community take the action of interest. According to survey respondents, the proportion of under-five children with fever that were taken to a health facility for care was 76.7% in Côte d'Ivoire, 78.8% in Liberia, 55.4% in Madagascar, and 42.6% in Nigeria. After controlling for socio-demographic, psychosocial, household and community variables in a logistic regression model, descriptive norm was a significant correlate of care-seeking for children with fever in a health facility in three of the four countries: Côte d'Ivoire, Madagascar and Nigeria. The odds ratio associated with descriptive norm was 2.73 (CI: 1.65-4.52) in Côte d'Ivoire, 1.38 (CI: 1.01-1.89) in Madagascar, and 1.72 (CI: 1.32-2.42) in Nigeria. Social and behavior change programs designed to promote facility-based treatment of fever in children may use social norm-modeling approaches to position the care-seeking behavior as a community norm. In addition, community mobilization approaches designed to foster positive community norms about care-seeking for children with fever are recommended.

1022

FACTORS ASSOCIATED WITH SEEKING CARE FOR FEVER IN CHILDREN UNDER FIVE YEARS OF AGE IN CÔTE D'IVOIRE

Diarra Kamara[1], Abdul Dosso[1], Monne Therese Bleu[2], Amadou Diabaté[3], Grace Awantang[4], Antoine Kouame[5], Mieko McKay[1], Antoine Mea Tanoh[2], Blaise Kouadio[6], Colette Yah Kokrasset[2], Stella Babalola[4]

[1]*Johns Hopkins Center for Communication Programs, Abidjan, Côte D'Ivoire,* [2]*Ministry of Health and Hygiene, Cote d'Ivoire National Malaria Prevention and Control Program, Abidjan, Côte D'Ivoire,* [3]*Johns Hopkins Center for Communication Programs Cote d'Ivoire, Abidjan, Côte D'Ivoire,* [4]*Johns Hopkins Center for Communication Programs, Baltimore, MD, United States,* [5]*Save the Children Cote d'Ivoire, Abidjan, Côte D'Ivoire,* [6]*United States Agency for International Development, Abidjan, Côte D'Ivoire*

In Côte d'Ivoire, malaria is a major cause of child mortality and morbidity, with an estimated incidence of 286.9 per 1000 in children under 5 years of age, leading to a high proportion of school absenteeism. The national policy recommends seeking care at a health facility for a child with fever within 24 hours. According to the country's 2016 Multiple Indicator Cluster Survey, advice or treatment was sought from a facility or health provider for 45% of children under 5 years of age with fever in the past two weeks. Using data from a 2018 national survey on behavioral determinants of malaria, we conducted logistic regression to examine the association of contextual, household and individual variables on facility-based care seeking for a child under five with fever. The study sample included 723 women with a child with fever in the two weeks before the survey. Whereas the majority of the children (90%) were taken for care during their sickness, appropriate care (taking the child for care within 24 hours and in a health facility as a first recourse) was sought for only 63%. The caregiver's perception that prompt care seeking for fever is the norm (odds ratio = 1.90), that community health workers are good at treating malaria in children (1.85), and positive attitude towards prompt care seeking (1.80) were the strongest factors positively associated with seeking appropriate care for a child with fever. Other supporting factors included: if the caregiver and their partner discussed malaria; exposure to malaria messages; and the perception that malaria drugs are consistently available at the facility. Malaria programs would be advised to increase exposure to malaria messages by using a multimedia platform and community approaches. Social and behavior change activities would benefit from promoting 24-hour fever care-seeking for children as the norm, positive attitudes, dialogue between family members regarding care seeking within 24 hours for children with fever and creating platforms to foster trust in community health worker abilities to treat children. Programs should also consider ensuring consistent availability of antimalarial drugs in health centers.

1023

IMPROVING INTERMITTENT PREVENTIVE TREATMENT FOR PREGNANT WOMEN (IPTP) COVERAGE USING COMMUNITY-BASED OUTREACH STRATEGY (CBOS) IN 2 HEALTH ZONES IN BENIN: ADD (APLAHOUE-DOGBO -DJAKOTOMEY) AND DAGLA (DASSA GLAZOUE)

William Houndjo

National Malaria Control Program, Cotonou, Benin

Malaria is the leading cause of morbidity and mortality in Benin and accounts for >40% of hospital admissions. Malaria infection in pregnancy is a major public health problem; it was the main cause of death among pregnant women in 2017. To reduce malaria morbidity, the World Health Organization recommends that all pregnant women receive at least three doses of intermittent preventive treatment of malaria in pregnancy (IPTp1, 2, and 3) during routine antenatal care (ANC). IPTp has been available in Benin since 2013 but uptake is low; 28% of pregnant women nationwide receive IPTp3. To improve IPTp uptake in Aplahoue-Dogbo-Djakotomey (ADD) and Dassa Glazoue (DAGLA) health zones, the National Malaria Control Program adopted a community-based outreach strategy (CBOS) in 2018 where community health workers conducted community-based educational sessions on malaria in pregnancy and collaborated with health providers to identify pregnant women in the community who never had an ANC visit or who initiated IPTp but were lost-to-follow up, provide a dose of IPTp to all eligible pregnant women, and refer all pregnant women to the closest ANC provider. Proportions of pregnant women attending ANC who received IPTp1, 2, and 3 in each health zone were assessed before and after the CBOS intervention. During CBOS in DAGLA and ADD, 298 and 554 pregnant women who were lost-to-follow-up were identified and received subsequent IPTp doses, and 92 and 376 pregnant women who had never had ANC were enrolled, respectively. After CBOS implementation, the proportion of pregnant women attending ANC who received IPTp increased when compared to before CBOS. In DAGLA, the overall proportion of pregnant women attending ANC who received IPTp1 increased from 60% to 68%, IPTp2 from 29% to 49%, and IPTp3 from 21% to 31%. Similarly, in ADD, the overall proportion of pregnant women attending ANC who received IPTp1 increased from 67% to 78%, IPTp2 from 29% to 41%, and IPTp3 from 8% to 17%. IPTp uptake among women attending routine ANC increased after CBOS, likely because CBOS led to increased ANC attendance. CBOS should be scaled up in other health districts in Benin to improve IPTp uptake nationwide.

1024

THE RESULTS OF THE ROO*PF*S STUDY: RANDOMIZED CONTROLLED TRIAL TO ASSESS WHETHER IMPROVED HOUSING PROVIDES ADDITIONAL PROTECTION AGAINST CLINICAL MALARIA OVER CURRENT BEST PRACTICE IN THE GAMBIA

John Bradley[1], Margaret Pinder[2], David Jeffries[2], Jakob Knudson[3], Balla Kandeh[4], Musa Jawara[2], Umberto D'Alessandro[2], Steve W. Lindsay[5]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Medical Research Council Unit, Fajara, Gambia,* [3]*Schools of Architecture, Design and Conservation, Copenhagen, Denmark,* [4]*National Malaria Control Programme, Banjul, Gambia,* [5]*University of Durham, Durham, United Kingdom*

Is housing protective against malaria? Most sub-Saharan African malaria transmission occurs indoors at night, suggesting housing that impedes entry of mosquitoes may reduce the malaria burden. Observationally, those living in modern housing have a lower prevalence of malaria, but it is difficult to separate housing quality from other socio-economic factors associated with a lower malaria burden. Unfortunately, there is little high-quality evidence on the question and there have been no randomized trials showing an impact of housing on clinical malaria episodes. In the Roopfs trial, 800 traditional thatched-roofed houses in rural villages in the Gambia were randomized to either no intervention or to be fitted with metal roofs, closed eaves, screened windows, a metal-louvered screened door at the front and a metal-screened door at the back. A cohort of children living in study houses aged 6 months to 13 years was followed biweekly for two years. Those with fever were tested for clinical malaria with a rapid diagnostic test. In total 859 children were followed, and 393 malaria cases were recorded in 69,319 visits. Unexpectedly, incidence of clinical malaria was higher in the modified houses than in the traditional houses (rate ratio = 1.23 [0.99, 1.52] p=0.07) but this was not significant. CDC light traps were used to measure indoor mosquito density, which was also slightly higher in the modified houses (rate ratio = 1.28 [0.87,1.89] p=0.21). There are several plausible explanations for this result. Firstly, it is possible the screened doors and windows were insufficiently robust to prevent vector entry. Secondly, doors may have been left open since the modified houses led to higher indoor temperature and humidity. Thirdly, the higher temperature and humidity may have led to less bed net use. Fourthly, metal roofs may lead to higher concentration carbon dioxide, a mosquito attractant. While the failure of this particular intervention to reduce malaria transmission does not mean that other housing modifications will not be effective, it shows that reducing malaria through housing improvements will not be straightforward.

1025

EVALUATION OF MALARIA PARASITAEMIA AND ASSESSING THE KNOWLEDGE, ATTITUDE AND PRACTICE OF PREGNANT WOMEN ATTENDING HEALTH FACILITIES IN OWERRI METROPOLIS TOWARDS MALARIA PREVENTION AND TREATMENT

Ikechukwu Vincent Ejiogu[1], Chinyere I. Okoro[1], Chidimma M. Iyke-Ejiogu[2], Francis Ihenetu[3], Oluchi I. Okoro[4]

[1]*Federal Medical Center Owerri, Owerri, Nigeria,* [2]*Federal University of Technology, Owerri, Nigeria,* [3]*Department of Microbiology, Federal University of Technology, Owerri, Nigeria,* [4]*Beulah Medical Diagnostic Laboratory and Research, Owerri, Nigeria*

There are several studies on malaria in pregnancy but studies focusing on the perception and current practices of malaria prevention and treatment among pregnant women in the study area are sparse. This study was aimed at assessing the knowledge, perceptions about malaria prevention with emphasis on knowledge about placental malaria as well compliance to use of LLIN and IPTP among pregnant women in Owerri, South Eastern Nigeria. A hospital based cross sectional study. Data was obtained from 200 randomly selected consenting pregnant women using a pretested structured questionnaire. Recognition of malaria symptoms during pregnancy, knowledge about IPTP and placenta malaria were items used to assess the level of knowledge about malaria in pregnancy. Their blood samples were also examined for malaria parasitaemia. Malaria prevalence in the study population by microscopy was 13.5%. Also 62% of the respondents were knowledgeable about the possible detrimental effects of the presences of malaria during pregnancy. About 79.5% of the respondent positively associated mosquitoes to malaria infection while 31% and 14% associated cause of malaria infection to dirty surrounding and stagnant water respectively. Malaria Prevention attitude and Practice in this study was good (60%) while 18.5% had fair practice. More so and 15.5% of the respondents had been involved in poor practice. About 34% of the pregnant women slept under a mosquito net often .study observed statistical significance between age, occupation and malaria prevention practices (P=0.014, 0.0089).There was also statistically significant association between respondent's practice and respondent attitude (p=0.0034). Knowledge regarding the use of Sulphodaxine primethamine (SP) as drug of choice during pregnancy was limited (12.0%) as use of chloroquine was ranked highest (48%) The study demonstrated low peripheral malaria prevalence and also demonstrated that pregnant women's Knowledge, attitude and practice towards malaria prevention was considerably on the average. However, there was poor knowledge about intermittent preventive treatment of malaria (IPTP) as recommended

KEY LEARNINGS OF INTERMITTENT PREVENTIVE TREATMENT IN PREGNANT WOMEN ATTENDING ANTENATAL CARE SERVICES IN SEGOU AND MOPTI REGIONS IN MALI

Idrissa Cisse[1], Boubacar Guindo[2], Noella Umulisa[2], Sanogo Vincent[1], Assitan Dembele Coulibaly[1], Saidou Kanambaye[2], Mariam Diatty Diallo[2], Moussa Thior[3], Pharath Lim[3], Renion Saye[2], Oumar Yattara[2], Moussa Sacko[4], Adboulaye Ouologuem[4], Kathryn Malhotra[3], Tabitha Kibuka[3], Jules Mihigo[5]

[1]*Mali PNLP, Bamako, Mali,* [2]*PMI Impact Malaria Project, Bamako, Mali,* [3]*PMI Impact Malaria Project, Washington, DC, United States,* [4]*INRSP, Bamako, Mali,* [5]*USAID/PMI, Bamako, Mali*

Malaria is the primary cause of morbidity and mortality in Mali. Use of intermittent preventive treatment (IPTp) is a proven cost-effective intervention for preventing malaria in pregnancy (MiP). Mali's MiP strategy is based on WHO's recommended three-prong approach, which includes the promotion and delivery of at least three doses of sulfadoxine pyrimethamine (SP) for IPTp as early as possible in the second trimester of pregnancy. In December 2018, the U.S. President's Malaria Initiative Impact Malaria project, together with the NMCP, conducted an assessment in 12 health facilities (HF) in Segou and Mopti Regions. One objective was to assess the uptake of IPTp-SP and the barriers to its use in pregnant women attending ANC services. Quantitative and qualitative methods were used for the assessment. Data from ANC registers, district reports, and in-depth interviews with MoH stakeholders at central and regional were collected and analyzed. A systematic sample of pregnant women's ANC register records for the three months prior to the assessment were collected and reviewed from the 12 HFs (N= 204). Overall, 5.4% (n=11), 59.8% (n=122), and 34.8% (n=71) received their first dose of IPTp at 13 weeks, 14-27 weeks, and 28-40 weeks of pregnancy, respectively. Although IPTp-SP has been provided since 2006, the indicators for three or more doses of IPTp during the last two years still remain low at only 21% (MIS 2015-2016). The sample of quantitative records reviewed indicated that many pregnant women are starting IPTp-1 much later than recommended by the MoH. A workshop is planned in April 2019 to discuss current barriers to IPTp and to identify solutions to increase the utilization and early attendance of ANC. In addition, a new outreach training and supportive supervision (OTSS) MiP module will be added to routine supervision visits starting later this year. This data will provide additional information on quality of IPTp services by health providers to supplement earlier findings.

1027

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION AMONG CHILDREN FIVE TO TEN YEARS OF AGE IN KITA AND BAFOULABE DISTRICTS, MALI

Sory I. Diawara[1], Erin Eckert[2], Jules Mihigo[3], **Beh Kamate**[4], Drissa Ouattara[4], Diakalia Kone[5], Mariam Tall[5], Eric Swedberg[6], Samba Coumaré[4], Drissa Konate[1], Moctar Tounkara[1], Mahamadou Diakité[1], Seydou Doumbia[1], Nathalie Gamache[4], Protais Ndabamenye[4]

[1]*Malaria Research Training Center, Bamako, Mali,* [2]*USAID/US President's Malaria Initiative, Washington, DC, United States,* [3]*USAID/US President's Malaria Initiative, Bamako, Mali,* [4]*Save the Children, Bamako, Mali,* [5]*National Malaria Control Program, Bamako, Mali,* [6]*Save the Children, Fairfield, CT, United States*

Seasonal malaria chemoprevention (SMC) is the administration of complete therapeutic courses of antimalarial to all children 3–59 months old during the malaria transmission season. This study measured coverage, impact and cost of adding SMC in children aged 5-10 years. A non-randomized, pre-post design, with an intervention (Kita) and control (Bafoulabe) district implemented SMC for children 5-10 years old through the health system in 2017 and 2018. SMC implementation consisted of the administration of SP + AQ at monthly intervals in children 5-10 years in July, August, September and October each year. Baseline and endline household surveys were conducted in both districts. Separate surveys to measure adherence and tolerance to treatment occurred annually in the intervention district (200 households) following each of the four treatment rounds. Routine data on malaria cases tested and treated and information on SMC campaign and treatment costs were collected. SMC coverage was over 90% in both years. In four rounds, 89% and 81% of children received all three doses in 2017 and 2018 respectively. The most reported side effect by parents was weakness in 15% of cases. Parents reported positive opinions (96%) of SMC treatment. At baseline, malaria infection prevalence was similar in the two districts (23% in Kita vs. 27% in Bafoulabe p=0.28). At study end, the prevalence of malaria infection was 22% in the comparison district compared to 17% (p=0.01) in the intervention district with a 40% reduction in malaria infection prevalence. Routine data showed a 21% and 62% reduction of simple malaria and severe malaria prevalence in the intervention district versus the control district. Mild anemia and severe anemia were comparable in the two districts. The level of malaria molecular resistance rate remains below the threshold. Quintuple mutation (dhfr triple +dhps437+dhps540) remained <5% after intervention in both districts. The additional cost of prevention treatment of children 5-10 years old was US$1.22 per child in Kita. The SMC strategy contributed to malaria prevention in 5-10 year old children and should be integrated to SMC for children 3-59 months.

1028

AVAILABILITY AND COST OF ANTIMALARIAL CHEMOPROPHYLAXIS AND TREATMENT IN THE UNITED STATES FOR TRAVELERS AT HIGH RISK OF ACQUIRING MALARIA

Beth K. Thielen[1], Emily Walz[1], Hannah R. Volkman[1], Jonathan D. Alpern[2], William M. Stauffer[3], Danushka Wanduragala[4], Mackenzie L. Smith[5], Wilhelmina V. Tolbert Holder[6], Anne Frosch[7]

[1]*University of Minnesota, Minneapolis, MN, United States,* [2]*HealthPartners, St. Paul, MN, United States,* [3]*University of Minnesota and HealthPartners, Minneapolis, MN, United States,* [4]*Minnesota Department of Health, St. Paul, MN, United States,* [5]*Carleton College, Northfield, MN, United States,* [6]*New Americans Alliance for Development, St. Paul, MN, United States,* [7]*HennepinHealthcare, Minneapolis, MN, United States*

Reported cases of imported malaria to the U.S. continue to increase and disproportionately occur among individuals traveling to endemic areas to visit friends and relatives (VFR). Among VFR travelers, use of malaria chemoprophylaxis is less common than among non-VFR travelers, and a recent study suggests that cost and availability of medications can be barriers. To quantify the availability and affordability of antimalarial drugs in the United States for both chemoprophylaxis and treatment, we conducted a survey of pharmacies in two cities with large populations of VFR travelers--New York City, NY and Minneapolis/Saint Paul, MN. Surveys were conducted in areas with either high and low likelihood of having VFR travelers to Sub-Saharan Africa. Pharmacies provided data on anti-malarial medication availability (in stock at time of call) and the cash price (price if no insurance billed). To estimate cost, we calculated cost per 30-day trip to account for differences for dosing intervals and required number of pre- and post-travel doses. 138 pharmacies were surveyed, 70 in Minnesota (40 high and 38 low likelihood areas) and 70 in New York (32 high and 38 low). Inter-pharmacy variability in pricing was high, with prices varying >10-fold for medications such as atovoquone-proguanil. We noted significant geographic differences in availability of drugs, with lower availability of atovoquone-proguanil and chloroquine in New York compared to Minnesota. There was significantly decreased availability of atovoquone-proguanil in communities with a high burden of malaria cases. In summary, there were marked differences in both price and availability across cities and neighborhoods, most notably for atovoquone-proguanil, a favored drug for prevention of malaria among African travelers. These findings reinforce observations that cost and availability are barriers to VFR travelers and that the market for antimalarial is not equitable and suggest that interventions to increase access to affordable prophylaxis, particularly in locations with high concentrations of VFR travelers, could be a useful strategy to decrease imported malaria cases.

MALARIA PREVENTIVE PRACTICES AMONG UNDER-FIVES IN DELTA STATE, NIGERIA

Nsirimobu Ichendu Paul[1], NDDC Professional chair on malaria elimination[2]

[1]*University of Port Harcourt, Port Harcourt, Nigeria*

Malaria is a leading cause of morbidity and mortality in under 5 children. A holistic malaria preventive practice in endemic areas is key to reducing the mortality associated with malaria. The study assessed malaria preventive practices among under-five children in Delta State, Nigeria. This was a cross sectional study carried out in public and private health facilities in Delta state. A multi staged stratified sampling method was used to select the health facilities and to recruit the subjects for the study. Data was collected using a pretested interviewer administered questionnaire and analysed by descriptive statistics. A total of 1008 children participated in the study constituting of 542 (53.8%) male and 466(46.2%) female. Mean age of participants was 1.78±1.08 years. The modal informant in the study were the mothers, accounting for 964 (95.6%) of the total participants. Most of the participants had obtained secondary education; among fathers, there were 559 (56.6%) and 572 (57.1%) among mothers. Most of the informants had tertiary degree; 605 (53.4%) and 697 (61.8%) among mothers and fathers respectively. Among the occupations of fathers; trader/business man, self-employed, and public servants were more represented, constituting 332 (33.4%), 224 (22.5%) and 115 (11.6%) respectively. Traders/business women, the self-employed and teacher were most represented among other occupations of mothers in the study, these accounted for 500 (50.2%), 157 (15.8%) and 80 (8.0%) respectively. Malaria preventive practices included, protective window nets, use of bed net, indoor residual spraying, use of drugs, no method used and use of mosquito repellants which constituted 707 (70.1%), 569 (56.4%), 359 (35.6%), 205 (20.3%), 134 (13.3%) and 7 (0.7%) respectively. The study shows a low bed net use rate and this is worrisome considering efforts being made by the Nigerian and State Governments. It is also surprising that intentional bush clearing and disposal of cans that encourage breeding places for malaria vector, use of long protective wears in the evenings and larviciding are not yet being practiced. This calls for health education intervention.

1030

MALARIA PREVENTIVE PRACTICES AMONG PREGNANT WOMEN IN AKWA IBOM STATE, SOUTHERN NIGERIA

Terhemen Kasso, Ibinabo L. Oboro, Omosivie Maduka, Abimbola T. Awopeju, Ichendu P. Nsirimobu, Lucy E. Yaguo-Ide, Ifeyinwa Chijioke-Nwauche, Godly Otto, Carol Iyalla, Chijioke A. Nwauche

University of Port Harcourt, Port Harcourt, Nigeria

Malaria is a serious public health problem in developing countries with Africa bearing most of its burden. Pregnant women are more susceptible to malaria and it is one of the leading causes of maternal and perinatal mortality/morbidity. Use of effective malaria preventive methods during pregnancy reduces the disease burden with its complications. The aim of the study was to assess malaria preventive practices among pregnant women in Akwa Ibom state. It was a cross sectional study of pregnant women attending public and private health facilities in Akwa Ibom state. Ethical approval was obtained from the Research and Ethics Committees of Universities of Uyo and Port Harcourt Teaching Hospitals and the state ministry of Health. An informed written consent was obtained from the participants. Stratified sampling method was used in selecting the health facilities and the study participants. Information was obtained with pretested questionnaires by trained personnel with the aid of Open Data Kit (ODK) on android phones. Data was managed with SPSS 22.0 and P-value of <0.05 was considered statistically significant. There were 935 participants in the study. Their mean age was 28.52 ± 5.09 years with 879 (94.0%) being married. Most had secondary and tertiary degrees: 451(48.2%) and 440(47.1%). Majority of them were traders/business women and self-employed (58.2%) while 7% were unemployed. Most of the women 471(50.4%) were primigravidae. The mean gestational age of participants was 27.57 ± 7.40 weeks. Malaria preventive practices were use of window net, bed net and insecticides accounting for 659(71%), 447(48.2%) and 207(22.3%). There were 612 (65.5%) participants that received malaria drugs for prevention with 452(73.9%) receiving Intermittent Preventive Treatment in Pregnancy (IPTp) with Sufadoxine-Pyrimethamine (SP). Only 296 (31.7%) of them slept under bed nets the night before. There was statistically significant association between frequency of malaria diagnosis, treatment and non-usage of bed nets. Efforts should be intensified in creating awareness about the various preventive measures in order to curtail this menace.

1031

EFFECT OF MALARIA BEHAVIOR CHANGE COMMUNICATION PACKAGING ON ITN USE AND INCIDENCE OF MALARIA IN RURAL WESTERN KENYA: A RANDOMIZED THREE ARM CONTROLLED TRIAL

Judith Mangeni[1], Jane Namae[1], Lucy Abel[1], Stephen Karuru[1], Wendy Prudhomme O'Meara[2]

[1]*Moi University College of Health Sciences, Eldoret, Kenya,* [2]*Duke University, Durham, NC, United States*

Behavior change communication has been shown to improve utilization of ITNs. Appropriate utilization of ITNs remains low in Bungoma County despite high distribution of the same. In addition, a high prevalence of malaria has been reported in the same region. We sought to identify the best packaging of "ITN use" behavior change communication among pregnant mothers and their households at the Webuye Health and Demographic Surveillance Site located in Bungoma East Sub-County. The primary endpoint was "correct ITN use" measured at baseline, one month, three months and six months follow up. The secondary endpoint was the incidence of malaria infections. We conducted a three-arm randomized control trial. *Intervention A was a* standardized verbal health message delivered by a health worker at the clinic plus a poster with health information on ITN use and care. *Intervention B was* a standardized verbal health message that is delivered by the health workers at the clinic plus one 'hang up' visit and the control was the usual standard practice at the Ante-Natal Clinic. Pregnant mothers who met the eligibility criteria were individually randomized in equal proportions to either of the intervention arms or the control. ITN use information was collected as well as RDT testing done for the pregnant mother and her household members. A total of 303 pregnant mothers were recruited for this study (101 in each arm). The study is currently ongoing and we will be able to report the actual results in early September after completion of the study. This study will improve our understanding of how to maximize the return on investment of public health commodities like nets. The long follow up rather than just a few weeks post-exposure to the BCC is also a major strength for this study. Finally, another strength of the study is the fact that we used a biomarker of correct ITN use such as infection which can be compared between arms.

1032

BED NET USE AND KNOWLEDGE OF MALARIA PREVENTION IN SIERRA LEONE

Beah Joe Lebby[1], Haja Abie Manasaray[2], Ivan Macauley-Black[1], Julian Mattia[1]

[1]*Njala University, Bo, Sierra Leone,* [2]*Eastern Polytechnic (Njala University), Kenema, Sierra Leone*

Malaria is one of the most common diseases in Sierra Leone and is believed to be responsible for about 50% and 38% of outpatient visits and admissions respectively. It is the leading cause of premature death and overall death in Sierra Leone. Anopheles is the primary vector with *Plasmodium falciparum* being responsible for 100% of cases. The government introduced free distribution of bed net in 2002 as a primary means of prevention which was later expanded to all age groups in 2010. In June 2017, the Ministry of Health and Sanitation implemented universal

distribution of bed nets to households. The current report assesses the coverage of the distribution and knowledge of the importance of the use of bed net. A total of 59 chiefdoms in 7 districts were selected and questionnaires administered to a total of 383 individuals in the rural communities. Key questions included whether they had received bed nets during the campaigns, quantity of bed nets, previous use of bed nets, knowledge of causes and prevention of malaria. A total of 383 persons were interviewed with an average 6 persons per chiefdom. Overall, 98% of persons interviewed recalled receiving bed net for their household. However, 40% said it was not enough for the beds they had in the household. Also, 21% of those interviewed said they had never used bed net. On the knowledge of the primary cause of malaria, 98% knew mosquito was responsible for the transmission of malaria while 99% knew that the use of bed net can prevent malaria transmission. Also, 91% of the households received more than 1 bed net. Compared to a 2010 assessment which indicated that 87.6% of those interviewed recalled receiving bed nets during the campaign, the results show an increment in the coverage in 2017. Also, the proportion of households that received more than 1 bed net (91%) is a significant increment compared to 67% in 2010. The results show that there has been significant increase in bed net coverage but below the countries target of 100% coverage of households. It also shows that knowledge of the cause and prevention of malaria is high among individuals in the country.

1033

DETERMINANTS OF MALARIA TESTING AT HEALTH FACILITIES: THE CASE OF UGANDA

Ruth N. Kigozi[1], John Baptist Bwanika[1], Emily Goodwin[1], Peter E. Thomas[2], Patrick Bukoma[1], Persis Nabyonga[1], Fred Isabirye[1], Paul Oboth[1], Carol Kyozira[3], Mame Niang[4], Kassahun Belay[5], Gloria Ssebikaari[5], James K. Tibenderana[6], Sam S. Gudoi[1]

[1]*PMI Malaria Action Program for District Project, Uganda, Kampala, Uganda,* [2]*US President's Malaria Initiative, Malaria Branch, Centers for Diseases Control and Prevention, Atlanta, GA, United States,* [3]*Health Information Division, Ministry of Health, Uganda, Kampala, Uganda,* [4]*US President's Malaria Initiative, Malaria Branch, Centers for Diseases Control and Prevention, Kampala, Uganda,* [5]*US President's Malaria Initiative, US Agency for International Development, Kampala, Uganda,* [6]*Malaria Consortium, London, United Kingdom*

The World Health Organization (WHO) recommends prompt malaria diagnosis with either microscopy or malaria rapid diagnostic tests (mRDTs) and treatment with an effective antimalarial, as key interventions to control malaria. However, in sub-Saharan Africa, malaria diagnosis remains influenced by clinical symptoms, with patients and care providers often interpreting all fevers as malaria. The Ministry of Health in Uganda defines malaria suspects as those with a fever of history of fever. A target of conducting testing for at least 75% of malaria suspects was established by the National Malaria Reduction Strategic Plan. We investigated factors that affect malaria testing at health facilities in Uganda using data collected in a cross sectional survey of health facilities from the 43 districts of Uganda that are supported by the US President's Malaria Initiative (PMI). We assessed health facility capacity to provide quality malaria care and treatment. Data were collected from all 1085 public and private health facilities in the 43 districts. Factors assessed included support supervision, availability of malaria management guidelines, laboratory infrastructure, and RDT training to health workers. Survey data were matched with routinely collected health facility malaria data obtained from District Health Information System (DHIS2). Associations between testing at least 75% of malaria suspects and various factors were examined using multivariate logistic regression. Key malaria commodities were widely available; 92% and 85% of the health facilities reporting availability of mRDTs and artemether-lumefantrine, respectively. Overall, 933 (86%) of the facilities tested over 75% of patients suspected to have malaria. Predictors of meeting the testing target were: supervision in the last six months (OR 1.72, 95% CI (1.04-2.85)) and a health facility having at least one health worker trained in the use of mRDTs (OR 1.62, 95% CI (1.04-2.55). Our findings underscore the need for malaria control programs to ensure that all facilities have trained health workers, have a reliable supply of commodities and importantly receive regular supervision.

1034

EFFECTIVENESS OF MALARIA BOOTCAMP TRAINING: EQUIPPING PEACE CORPS VOLUNTEERS AND THEIR COUNTERPARTS TO IMPLEMENT MALARIA PREVENTION ACTIVITIES IN RURAL MADAGASCAR, 2018

Belen Godinez-Santana[1], Jocelyn Razafindrakoto[2], Mamina Herizo[1]

[1]*Peace Corps, Antananarivo, Madagascar,* [2]*President's Malaria Initiative, Antananarivo, Madagascar*

Malaria causes substantial morbidity and mortality in Madagascar, particularly in rural areas where most Peace Corps Volunteers (PCV) serve. To train PCVs to support malaria prevention activities, Peace Corps Madagascar adapted the Senegal-based Malaria Boot Camp (MBC). All 150 Madagascar PCVs were welcome to apply to the five-day training along with their community counterparts. We describe the first Madagascar-based MBC in which PCVs and their community counterparts were included, including a follow-up survey, and discuss implications. Participants were selected based on their malaria prevention work, counterpart collaboration, willingness to train neighboring PCVs, and time left in service. Sessions on malaria biology, diagnosis, treatment and prevention, and information on evidence-based behavior change techniques were led by malaria specialists. Participants learned about project design and proposed a project for their communities. PCV participants completed telephone surveys immediately following training, and three months afterward. Of 20 (13%) PCVs who applied, 16 PCVs and their respective counterparts were selected and participated. Nine (56%) PCV participants responded to either the immediate or the three-month post-MBC survey; 100% had initiated their proposed project. Participants reported they used MBC tools to conduct focus group, one-on-one, and door-to-door surveys to identify community needs. PCVs and their counterparts implemented activities including: malaria committees; bike rides to promote insecticide-treated bed net (ITN) use; surveys to determine if families needed help with ITN hang-up, use or care after a mass distribution campaign; and analysis of malaria data at their local health clinic. At least 56% of PCV participants initiated prevention activities in their communities within five months of completing MBC training; a six-month follow-up is planned. These trainings may be an effective approach to promote evidence-based malaria prevention practices in rural Madagascar.

1035

QUANTIFYING THE POTENTIAL IMPACT OF MASS DRUG ADMINISTRATION ON THE PARASITE RESERVOIR IN AN AREA OF DECLINING MALARIA TRANSMISSION IN UGANDA

Joaniter I. Nankabirwa[1], Jessica Briggs[2], John Rek[3], Emmanuel Arinaitwe[3], Sarah G. Staedke[4], Philip J. Rosenthal[2], Moses R. Kamya[1], Grant Dorsey[2], Isabel Rodriguez-Barraquer[2], Bryan Greenhouse[2]

[1]*Makarere University Kampala, Kampala, Uganda,* [2]*Division of HIV, ID, and Global Medicine, University of California San Francisco, San Francisco, CA, United States,* [3]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [4]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Significant reduction in malaria burden has been achieved in areas where indoor residual spraying (IRS) has been rolled out in Uganda. However, a large proportion of the population in some of these regions remains parasitemic, providing a potential reservoir for onward transmission. Using detailed data from an intensely followed cohort study in Uganda, we quantified the potential effect of adding mass drug administration to IRS on the parasite reservoir in a formerly high endemic setting with declining malaria transmission following sustained IRS. Between October

2017 and October 2018, we followed 492 participants enrolled in a cohort in Tororo, Uganda. One round IRS with actellic was rolled out in June/July 2018. Parasitemia was identified by active surveillance every four weeks and continuous passive surveillance using qPCR. We used this detailed longitudinal dataset to quantify the potential impact of mass drug administration (MDA), by simulating a single round of MDA administered on October 30th 2017. We assumed that the drug used for MDA would be 100% effective and clear all active infections present on the day of its administration, as well as provide protection against new infections for the subsequent 28 days. The outcomes of interest were parasite prevalence at six months and one year of follow up, and the total number of parasitemic days over the same time periods. We used linear interpolation of parasite densities to fill in the data for the days between study visits. A single round of MDA was associated with a significant decline in parasite prevalence in participants aged 5 -15 years (from 17.8% to 2.9% at 6 months; p<0.001 and from 14.4% to 4.7% at one year; p=0.001) and in participants >15 years (from 14.2% to 2.6% at 6 months; p<0.001 and from 10.8% to 3.2% at one year; p=0.008) but not in children < 5 years. MDA also reduced the total number of parasitemic days irrespective of age-group and duration of follow-up (P<0.001). MDA may provide an effective strategy for targeting the residual reservoir of malaria parasites, especially in school age children and adults, in areas with declining malaria transmission following effective vector control.

1036

ROLLOUT OF SINGLE LOW-DOSE PRIMAQUINE IN TWO SOUTH AFRICAN DISTRICTS TARGETING MALARIA ELIMINATION: ASSESSING PROGRESS AND CHALLENGES

Jaishree Raman[1], Elizabeth Allen[2], Theresa Mwesigwa[1], Aaron Mabuza[2], Bheki Qwabe[3], Gillian Malatje[4], Frank M. Kagoro[2], Karen I. Barnes[2]

[1]*South African National Institute for Communicable Diseases, Johannesburg, South Africa,* [2]*Division of Clinical Pharmacology, Department of Medicine, University of Cape Town, Cape Town, South Africa,* [3]*KwaZulu-Natal Provincial Malaria Control Programme, Jozini, KwaZulu-Natal, South Africa,* [4]*Mpumalanga Provincial Malaria Elimination Programme, Nelspruit, Mpumalanga, South Africa*

The addition of single low-dose (SLD) primaquine, a gametocytocide, to an artemisinin-based combination treatment of malaria is recommended to accelerate low transmission regions towards malaria elimination. South Africa included SLD primaquine among its suite of elimination strategies during the 2018/2019 malaria season. As primaquine is not currently registered in South Africa, its use required special approval from South African Health Products Regulatory Authority (SAHPRA), and is subject to regulatory requirements being met. Health facilities in Nkomazi District, Mpumalanga Province and uMkhanyakude District, KwaZulu-Natal Province who reported >10 malaria cases during the previous two malaria seasons, together with border malaria surveillance units were prioritised for SLD primaquine rollout. Beforehand, stakeholder meetings were held with all the relevant personnel and feedback received was used to streamline training materials and work aids. Each selected facility received on-site training on dosing with SLD primaquine and collecting SAHPRA-required information. Stock levels were monitored, with facilities replenished as needed. Patient demographic information was obtained from the provincial District Health Information System (DHIS), with response to treatment extracted from malaria case investigation forms. Over the first three months 486 tablets were dispensed, 337 in Mpumalanga and 149 in KwaZulu-Natal. The border surveillance units dispensed most tablets (300/486) during their active malaria case detection activities. The additional information required by SAHPRA was initially poorly documented at clinics and in the DHIS system, but improvements were seen over time after refresher training. Initial challenges identified were corrected with close supervision and regular refresher training session. However, to be sustainable it is imperative that primaquine is registered as soon as possible in South Africa. In addition, a cost-effective supply of primaquine is essential for achieving the high coverage rates required to impact on malaria transmission.

1037

FACTORS ASSOCIATED WITH ADHERENCE TO PRIMAQUINE 8 WEEK REGIMEN AMONG *PLASMDIUM VIVAX* CASES IN KAYIN STATE, MYANMAR

Myint Oo

ARC, Yangon, Myanmar

Treatment adherence to primaquine is crucial for radical cure and interruption of *Plasmodium vivax* transmission while progressing toward the goal of malaria elimination in Myanmar by 2030. *P. vivax* has become the dominant species in Kayin State, where 9,816 (65%) of the total 15,080 malaria cases reported in 2017 were *P.vivax* infections. A cross-sectional descriptive study was carried out in 4 Townships of Kayin State to assess the adherence to primaquine 8-week regimen (0.75mg/kg once weekly for 8 weeks), which, together with a 3-day course of chloroquine, is the regimen recommended by the national malaria treatment guidelines for uncomplicated *P.vivax* cases when treated by community-based village malaria workers (VMWs). Out of the total 342 *P.vivax* cases detected and reported in the 4 Townships from October 2017 to September 2018 by the 71 VMWs supported by the Defeat Malaria project, 140 could be interviewed by the study team with a semi-structured questionnaire in November-December 2018. The results of the interviews showed that 100 (71%) of them were male, 100 (71%) migrant, 89 (64%) forest workers, and 110 (79%) of Kayin ethnicity. Of the 140 cases who received primaquine treatment from VMWs, 84 (60%) were considered as probably adherent (full course of 8-week completed at the right dose and right interval) based on their self-reported behavior. Among the 56 cases (40%) considered as non-adherents, the non-adherence to primaquine treatment was found to be associated with being migrant vs non-migrant OR 3.84 (95% CI, 1.61-9.15) and being forest worker vs non-forest worker OR 2.14 (95% CI, 1.03-4.46), whereas no significant association was found with male vs female OR 0.52 (95% CI, 0.23-1.14) and Kayin vs non-Kayin ethnicity OR 1.76 (95% CI, 0.77-4.00). The main reasons reported for non-adherence were forgetfulness (29%), travelling (11%), busy work (13%), long treatment course (2%), and dizziness (1%). Migrant and forest-related work were the main factors associated with non-adherence to the primaquine 8-week regimen.

The 'High Burden High Impact' initiative was launched in Mozambique in 2018 coupled with AFRO operationalization meeting January 2019 at Mauritania as response to limited performance, slow progress of high burden countries that contribute over 70% of global burden. It is a call for action by Member States through WHO and RBM Partnership. HBHI aims are 1) to galvanize political attention to reduce malaria deaths, 2) to drive impact through the strategic use of information to identify the locally appropriate mix of interventions and best means of delivery, 3) to establish guidance, policies and strategies, 4) to coordinate response, demonstrating success in accelerating burden reduction. Uganda is the first country to launch and operationalize the High burden to high impact" a country-led response - catalysed by WHO and the RBM Partnership to reignite the pace of progress in the global malaria fight. WHO, US PMI, UK DFID, Action Against Malaria Foundation, TASO, UNICEF, ALMA, The Global Fund, Malaria Consortium, CHAI and others from international, national and sub-national levels supported the Malaria Programme in

designing and are supporting the operationalization of the approach. Current actions to support strategic use of information have so far included 1) strong commitment to enhance data sharing and analysis and use for action by partners and stakeholders, allowing real time decision making and action. These data will feed into national planning processes and allow the country to target resources to those most in need. 2) Setting up an analytical team of all partners led by NMCP and WHO. The team has 1) developed incidence maps by district and by sup-county, 2) developed a National Malaria Data Repository with work schedules assigned, 3) Identifying the locally appropriate mix of Interventions through mapping vectors, insecticide resistance and intervention, 4) engaging with Districts and Sub-counties for coordinated response 5) sharing information and 6) plans to conduct a malaria program review in 2019 that will result in subsequent updating of the National strategic plan, and eventually leading to 5-year implementation of a new strategy.

SENEGAL CHARTERING THE PATH TO MALARIA ELIMINATION: A PROCESS DESCRIPTION

Moustapha Cisse

NMCP Senegal, Dakar, Senegal

Senegal's progress against malaria is a public health success story, and a source of potential lessons for other countries on the path to elimination. Malaria has historically been one of Senegal's major health challenges. Less than 20 years ago, it accounted for 1/3 of outpatient visits nationwide. However, strong political leadership, community engagement, sustained support from technical and financial partners, and a proactive approach to policy adoption and intervention scale-up have had a major impact on malaria disease burden. There are now several northern districts where elimination appears to be an achievable short-term goal. With a goal of nationwide elimination by 2030, numerous milestones have been set: - Strong advocacy and sensitization towards authorities and the population - SOP development for malaria case investigations and response SOP development for accelerated transmission reduction strategies in borderline areas - Realization of the joint Elimination Scenario Planning (ESP) in Senegal and Gambia - Launch of a nationwide weekly malaria reporting system - Introduction of single-low dose primaquine in pre-elimination areas - Updating of the national guidelines for malaria surveillance to address the needs for a pre/elimination context - Assessing the performance of national malaria SME Systems in the context of malaria elimination - Decentralization and updating of the national malariology and malaria SME training courses - Development of a national manual for malaria elimination - Introduction of genomics for parasite surveillance - Development of a guide for insecticide resistance management - Development and implementation of a joint action plan for cross-border management of malaria with The Gambia - Development of a roadmap for decentralizing malaria activities With the organizational reforms recommended in the national elimination manual, the continued support of current and new partners and a strong advocacy for the engagement of national authorities in mobilizing the necessary financial resources, Senegal can be at the rendezvous for malaria elimination by 2030

1040

COMBINED SEMI-FIELD STUDIES AND A VILLAGE-BASED TRIAL TO ASSESS THE IMPACT ON *ANOPHELINE* POPULATIONS OF ZOOPROPHYLAXIS-AIDED IVERMECTIN-BASED VECTOR ELIMINATION (ZAIVE) USING PERI-DOMESTIC CATTLE TREATMENT IN THE HIGHLANDS OF VIETNAM

Andrew Lover[1], Ian Mendenhall[2], Jeffrey Hertz[3], Nguyen X. Quang[4], Huỳnh H. Quang[4]

[1]*University of Massachusetts Amherst, Amherst, MA, United States,* [2]*Programme in Emerging Infectious Diseases, Duke-NUS Medical School, Singapore, Singapore,* [3]*U.S. Naval Medical Research Unit Two, Singapore, Singapore,* [4]*Institute of Malariology, Parasitology, and Entomology (IMPE), Ministry of Health, Quy Nhon, Vietnam*

In line with regional goals in the Greater Mekong Subregion (GMS), Vietnam is committed to national malaria elimination by 2030. However, interventions targeting vulnerable populations in forested areas are lacking. Ivermectin, an endectocidal drug, has recently emerged as a potential new tool towards malaria elimination, as humans and animals retain blood concentrations that impact feeding anophelines (decreased fecundity, shortened lifespan, and lethality). Zooprophylaxis is a strategy that uses herd animals as bait to attract vectors; these alternative feedings provide passive protection to human populations. High cattle ownership in many rural communities suggests combining these strategies in an 'attract-and-kill' approach. This study utilizes semi-field testing and a community-scale randomized experimental design to assess if sufficient densities of ivermectin-treated cattle can drastically decrease vector populations and alter mosquito composition in village-based settings. In Quy Nhon, Vietnam, colonies of *Anopheles dirus* ss and *An. epiroticus* will be allowed to feed on ivermectin-treated and control cattle in a semi-field study to ensure adequate drug dosing, and to quantify impacts of ivermectin in local vectors. Thereafter, six villages in Krong Pa district (Gia Lai) are to be randomized as either control or intervention areas. In intervention villages, full herds of all consenting households will be treated with a standard veterinary dosing of 1% ivermectin by injection. At all village study sites (intervention and control), CDC light traps, cattle-baited trapping, and human-landing catches will be used to survey anopheline populations before and after the ivermectin dosing of cattle. The primary endpoint will be reduction in captures from cattle-baited traps; secondary endpoints will be changes in vector population composition. Data collection was initiated in April 2019 and will be completed in mid-2019. Trial results will be presented that quantify impacts of ivermectin-treated cattle on vector populations for development of a novel strategy targeting residual malaria transmission in the GMS.

INITIATING CASE NOTIFICATION AND CASE INVESTIGATION FOR *PLASMODIUM FALCIPARUM* CASES IN CAMBODIA

Dr. Siv Sovannaroth[1], Peng By Ngor[1], Abishek Thiagaraj[2], Bunmeng Chhun[2], Pedro Pagalday-Olivares[2]

[1]*National Center for Parasitology, Entomology and Malaria Control in Cambodia, Phnom Penh, Cambodia,* [2]*Clinton Health Access Initiative, Phnom Penh, Cambodia*

In order to achieve the elimination of *Plasmodium falciparum* (Pf) in 21 endemic provinces in Cambodia, a strong malaria information system is needed to identify local cases/*foci*, improve timeliness of response, and determine origins of transmission. The Cambodia National Center for Parasitology, Entomology and Malaria Control (CNM) developed a phased approach to introduce surveillance for elimination activities. CNM designed a pilot project in two HCs and 21 VMWs in Kampong Chhnang province to introduce case notification and case investigation and observe operational feasibility. CNM, the Clinton Health Access Initiative (CHAI) and the University of Oslo (UiO), developed a customized, DHIS2-based Android Capture App to facilitate real-time reporting with tablets located at every Health Center (HC) and with smartphones at every Village Malaria Worker (VMW). Once the initial version of a DHIS2-based malaria information system (MIS) module was released, 3 phases of testing were conducted from May-November 2018. A web platform with dashboards was also developed that could be tailored to end users. With 360 cases reported from the 2 HCs and their 21 VMWs during the pilot period, CNM demonstrated operational feasibility. High rates of completeness (86%), timeliness (95%), and case investigation (100%) were achieved. Case investigation was also conducted for all reported Pf and mixed infection cases (n=34), with 100% of them being classified as local. Operational Districts (ODs) and CNM analysed key indicators through the visual dashboard each month to enable timely response. For the first time, case classification and investigation activities were conducted independently

by the public health facilities without NGO support. Results indicated that with targeted subnational support, it is feasible to operationalize surveillance for elimination in Cambodia. These activities were transitioned from DHIS2 to the CNM MIS in December 2018, and CNM continues to improve case investigation completeness and timeliness of data in the MIS. These activities will be expanded to 9 additional provinces in 2019.

1042

THE IMPACT OF MORBIDITY AND MORTALITY RATE REDUCTION CONTRIBUTED BY VILLAGE MALARIA WORKERS AND MOBILE MALARIA WORKERS IN CAMBODIA 2004 - 2018

Po Ly[1], Siv Sovannaroth[1], Huy Rekol[1], Khengthavrin Bou[1], Kimhong Gove[2], Josh Christenson[2]

[1]*National Center for Parasitology, Entomology and Malaria Control in Cambodia, Phnom Penh, Cambodia,* [2]*Clinton Health Access Initiative, Phnom Penh, Cambodia*

The goal in the Cambodia National Strategic Plan for Malaria Elimination is to eliminate *Plasmodium falciparum* and reach and sustain zero malaria deaths by 2020. In order to reach these targets the Cambodia National Center for Parasitology, Entomology and Malaria Control (CNM) invested in a Village Malaria Workers (VMWs) Program. The VMWs scheme was established in 2004 with 235 VMWs villages and has grown to 3,025 VMWs villages (6,050 VMWs) including Mobile Malaria Workers (MMWs) in 2019, providing both preventive and curative interventions to approximately 2 million at-risk populations in hard to reach communities. CNM conducted a retrospective analysis of malaria cases and deaths reported through the health information system (HIS) between 2004 and 2018 to assess the impact of VMWs on annual morbidity and mortality trends. VMWs' performance included an examination of core activities of case management, vector control, surveillance, and community education. Between 2004 and 2018, deaths declined from 396 to 0, and cases declined from 11,398 to 5,041. VMWs consistently reported an average of 50% of total malaria cases found in the public health sector. Of the top seven highest burden provinces, tests done by VMWs were on average triple the tests done in health facilities. Health facilities organizing regular monthly meetings (with 95% of VMWs in attendance), paid monthly VMW incentives in a timely manner through electronic payments, completed training on treatment guideline updates to 3025 VMWs villages, and equipped VMWs with sufficient RDTs and ACTs. Malaria case management services provided by VMWs/MMWs to high risk populations in Cambodia has been associated with a significant reduction in the mortality rate through a chain of linkages of increasing early diagnosis and prompt treatment, care quality, targeted behavior change communication and health outcomes. CNM is exploring the additional roles to existing VMWs/MMWs such as conducting surveillance for elimination activities (investigation, classification and reactive case detection) and outreach activities to provide testing and treatment services in the forested areas.

1043

ADHERENCE TO RADICAL CURE FOR *PLASMODIUM VIVAX* MALARIA IN PAPUA, INDONESIA

Annisa Rahmalia[1], Jeanne R. Poespoprodjo[1], Chandra U. Landuwulang[1], Maya Ronse[2], Enny Kenangalem[1], Faustina H. Burdam[1], Benedikt Ley[3], Ric N. Price[3], Kamala Thriemer[3], Koen Peeters Grietens[2], Charlotte Gryseels[2]

[1]*Papuan Health and Community Development Foundation, Timika, Indonesia,* [2]*Department of Public Health, Institute of Tropical Medicine, Antwerp, Belgium,* [3]*Global and Tropical Health Division, Menzies School of Health Research and Charles Darwin University, Darwin, Australia*

Adherence to radical cure for *Plasmodium vivax* is critical for achieving the timely elimination of malaria in endemic areas. The only widely available drug for killing the dormant liver stages of *P. vivax* is primaquine (PQ) which is usually administered as a 14-day regimen. The prolonged treatment course results in poor adherence and effectiveness. To develop suitable strategies to improve patient adherence, a mixed methods study was undertaken to explore people's perceptions and understanding of malaria and malaria treatment in southern Papua, Indonesia. For the qualitative strand, qualitative interviews (n=46) and observations (n=12) were done with purposively selected informants. The quantitative component consisted of a structured questionnaire with all trial participants (n=619). Results showed that the socially accepted and commonly known malaria medication dihydroartemisinin-piperaquine - "the blue pills" - evoked confidence in the relation between the type of malaria it targeted, its perceived side effects and efficacy, and optimal adherence to the 3-day regimen. The different colour and size of the PQ tablets - "the brown pills" - and the long treatment duration, however, prompted a re-interpretation of the perceived side effects and treatment effectiveness which aligned more to perceptions of vitamin supplements. Although 84% of trial participants reported that they had finished "all drugs", only 60% reported to have taken both "the blue" and "the brown" pills needed for radical cure. In conclusion, patients continually evaluate the characteristics of their medicines, in relation to the illness and the perceived benefits and risks of the treatment. These (re-)interpretations underpin patients' decisions to adhere to or to abandon PQ treatment. Even with partial supervision patients' adherence to a 14-day PQ regimen is suboptimal.

1044

MALARIA SURVEILLANCE IN ZANZIBAR PATTERNS OF CASE NOTIFICATION AND INVESTIGATION IN LINE WITH WHO'S 1-3-7 DAYS APPROACH

Shabbir Lalji[1], Humphrey Mkali[1], Abdul-wahid Al-mafazy[1], Ssanyu Nyinondi[1], Joseph Joseph[1], Mike McKay[2], Abdallah Ali[3], Wahida Hassan[3], Mohamed Kitwasi[3], Chonge Kitojo[4], Naomi Kaspar[4], George Greer[4], Eric Reaves[5], Richard Reithinger[2], Jeremiah Ngondi[2]

[1]*RTI International, Dar es Salaam, United Republic of Tanzania,* [2]*RTI International, Washington, DC, United States,* [3]*Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania,* [4]*US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania,* [5]*US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania*

The World Health Organization (WHO) recommends a "1-3-7 days" approach for case notification, investigation, and focus investigation in areas of malaria elimination. The Zanzibar Malaria Elimination Programme's (ZAMEP) guidelines recommend case notification within one day of diagnosis, case investigation within two days, and focus investigation within 7 days. ZAMEP's Malaria Case Notification (MCN) system notifies district malaria surveillance officers (DMSOs) of confirmed cases by health workers from all the 243 health facilities in Zanzibar. We examined timeliness of case notification and investigation by all 20 DMSOs from 2013 to 2018. Overall, 21,386 (97%) confirmed cases were notified by all health facilities. Of these, 10,100 (47%) were notified in line with WHO's recommendation, i.e. within one day (24 hours) of diagnosis. During this period, 16,342 (76%) of the notified index cases were investigated further by DMSOs. Of these, 7,924 (37%) were investigated within two days following ZAMEP's current guidelines, 4,006 (19%) within 7 days, and 3,487 (44%) after 7 days. In Unguja, where the number of malaria cases was four times higher than in Pemba, only 35% of notified cases were investigated within two days by DMSOs, compared to 48% in Pemba. Overall, 42% of case investigations were done within the WHO-recommended 3 days (Unguja: 40%; Pemba: 53%). While overall case investigation rates were high, DMSOs were unable to reach all index cases within ZAMEP's or WHO's recommended timeframe of two and three days, respectively. This might reflect limitations in the number of DMSOs, especially during high transmission season. It will be important to support improvements in timeliness of both notification and case investigation if Zanzibar is to progress further on the path of malaria elimination.

DO MALARIA INFECTIONS CLUSTER AT THE HOUSEHOLD LEVEL? A REVIEW OF THE EVIDENCE TO INFORM ACTIVE INFECTION DETECTION STRATEGIES FOR MALARIA CONTROL PROGRAMS

Gillian H. Stresman[1], Charlie Whittaker[2], Teun Bousema[3], Hannah Slater[4], Jackie Cook[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Imperial College London, London, United Kingdom,* [3]*Radboud University Medical Centre, Nijmegen, Netherlands,* [4]*PATH, Seattle, WA, United States*

As transmission reduces to pre-elimination levels, many malaria programmes engage in active detection to target asymptomatic infections. Three approaches have been considered: 1) re-active case detection (RACD), where the household (and in some settings, neighbouring households) of each passively detected case are tested and/or treated, 2) mass screening and treatment (MSAT) where symptomatic individuals in the community are tested and 3) mass testing and treatment (MTAT) where all individuals are tested regardless of symptoms, with treatment in the latter two approaches either targeted at individuals testing positive or all those residing in the same household. RACD is by far the most widely adopted by malaria control programs. However, formal evidence of the effectiveness of this intervention to target the parasite reservoir is lacking. Here we collate evidence from published studies on the degree of clustering of asymptomatic infections to estimate the odds ratio of infections detected by molecular methods in households with an infection detected following the RACD, MSAT, or MTAT models compared to households with no programmatically detectable infection. Results were categorized according to the three approaches. A pooled OR was calculated and a linear trend between magnitude of effect and malaria prevalence was tested. We obtained 36 data points from 30 of 44 eligible studies. The pooled odds of infections clustering in index households from RACD, MSAT and MTAT models was 4.08 (95% CI: 2.55-6.52), 3.22 (95% CI: 2.04-5.08) and 6.68 (95% CI: 4.04-11.04), respectively. There was a significant linear trend whereby the magnitude of clustering increased with decreasing transmission. A similar trend was observed when analysing data from demographic health surveys. Preliminary analysis suggests that infections cluster around programmatically detectable infections, and this clustering is greatest in low transmission settings. These results provide the first evidence of the effectiveness of active detection strategies to identify asymptomatic infections in a population.

1046

IMPLEMENTING 24-HOUR MALARIA CASE NOTIFICATION SYSTEMS FOR THE PRIVATE SECTOR IN ELIMINATION SETTINGS: LESSONS LEARNED FROM MYANMAR AND VIETNAM

Rebecca Potter[1], Ngo Thi Thuy Nga[2], Nguyen N. Loan[2], Pham Van Chau[2], Khaing Wai Wai Phyo[3], Phone Si Hein[3]

[1]*Population Services International, Washington, DC, United States,* [2]*PSI Vietnam, Hanoi, Vietnam,* [3]*PSI Myanmar, Yangon, Myanmar*

NMCPs in Myanmar and Vietnam are rolling out elimination surveillance guidelines with a focus on the public sector, with 24-hour case notification in targeted geographies designed to trigger timely case investigations. In Myanmar and Vietnam in 2018, private sector providers diagnosed and reported 14% and 13% of the national reported case load respectively. PSI's Greater Mekong Sub-region Elimination of Malaria through Surveillance (GEMS) program is partnering with the Myanmar and Vietnam NMCPs to ensure that private sector malaria cases are notified according to standard elimination surveillance protocols. Routine surveillance data were analyzed post-intervention and supported by key informant insights. In Myanmar, 614 private general practitioners were trained to notify confirmed cases via SMS to PSI and NMCP focal points beginning in June 2018. Between July 2018 and Jan. 2019, 73% (n=275) of confirmed cases were notified to focal points by SMS within 24 hours. In Vietnam, 175 clinics in four provinces were trained to complete a shorter version of the national case notification form and submit via e-mail or Zalo (a popular social media app) to the district focal point within 24 hours. Between Sept. 2018 and Feb. 2019, 82% (n=373) of positive cases detected by private providers were reported on time to the district. Most national malaria surveillance systems do not systematically capture data from the private sector. These results demonstrate that elimination surveillance systems can and should extend to the private sector, where increasingly focal high-risk populations in the GMS continue to seek fever care. In Vietnam, modifying the lengthy case notification forms to capture the most critical data points for private sector case notification was helpful to ensuring compliance. Both settings show that mobile devices and social media apps can be used as an effective tool for submitting malaria case notification data within 24 hours. These successes may be partly attributed to providers' engagement in an existing malaria program, where PSI supports private providers on case management, reporting, and stocking commodities.

1047

ASSESSING IMPACTS OF GOVERNMENTAL CONTROLS OF ILLEGAL LOGGING ON MALARIA TRANSMISSION IN SOUTHERN LAO PDR

Emily Dantzer[1], Andrew A. Lover[2], Bouasy Hongvanthong[3], Francois Rerolle[1], Sophia Hocini[4], Rattanaxay Phetsouvanh[5], Adam Bennett[1]

[1]*University of California San Francisco, Malaria Elimination Initiative, San Francisco, CA, United States,* [2]*Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts, Amherst, MA, United States,* [3]*Lao PDR Centre for Malariology, Parasitology, and Entomology (CMPE), Vientiane, Lao People's Democratic Republic,* [4]*University of California Los Angeles, Los Angeles, CA, United States,* [5]*Department of Communicable Disease Control (DCDC), Ministry of Health, Lao PDR, Vientiane, Lao People's Democratic Republic*

Lao PDR has made significant progress in the fight against malaria in recent years with reported cases falling from 23,047 in 2010 to 8,907 in 2018. Malaria transmission is highly heterogenous with 98% of reported cases occurring in the five southernmost provinces, which are characterized by hilly, forested terrain and a workforce engaged primarily in forest-based and agricultural activities. Aligned with the regional targets of the Greater Mekong Subregion, Lao PDR aims to eliminate *Plasmodium falciparum* nationally by 2025 and all human malaria species including *P. vivax* by 2030. In countries approaching malaria elimination including Lao PDR, populations at higher risk for infection generally share similar occupational, behavioral, and social characteristics that increase their exposure to outdoor-biting and/or forest-dwelling mosquitoes. In May 2016, the Lao government enacted a decree implementing stringent regulations on the sale and export of timber to curtail illegal logging operations and consequent deforestation. To document and assess any potential changes in forest-based activities stemming from this legislation, a series of formative studies and population-based surveys were conducted between mid-2015 and November 2018. After triangulating data, these studies found that both local residents and key malaria stakeholders attributed the recent decline in cases to the logging ban. Other findings suggest that enforcement of the decree has nearly eliminated large-scale logging efforts by both foreign workers and Lao nationals, resulting in the closure of local sawmills and other businesses catering to mobile and migrant clientele. This case study highlights the potential implications of national and international policy-level interventions on malaria transmission, and underscores the potential synergies arising from strong and coordinated intersectoral government initiatives.

1048

A TWO DOSE SPOROZOITE CHALLENGE MODEL IN MICE HIGHLIGHTS LIVER STAGE DURATION AS ONE OF THE MOST IMPORTANT DIFFERENCES BETWEEN MURINE AND HUMAN *PLASMODIUM* FOR VACCINE DEVELOPMENT

Chaitra Parthiban, Zachary P. Billman, Tayla M. Olsen, Brad C. Stone, Melanie J. Shears, Sean C. Murphy

University of Washington, Center for Emerging and Re-Emerging Infectious Diseases, Seattle, WA, United States

Pre-clinical malaria vaccine studies to evaluate protective antigens rely on *Plasmodium yoelii* (*Py*) and *P. berghei* (*Pb*) rodent models. However, *Py* and *Pb* complete their liver stage in two days compared to six days for the *P. falciparum* liver stage in humans. We hypothesized that the difference in duration of the liver stage has critical but overlooked implications for how protective outcomes of $CD8^+$ T cell-based vaccine research are considered. When a vaccinated mouse is challenged, cytotoxic T lymphocyte (CTL) activation occurs within 48 hours, but T cell clonal expansion does not occur until later. Sterile protection in rodent models therefore relies on antibodies and CTLs but derives no benefit from expanding T cells. This may lead us to dismiss protective antigens as non-protective. To evaluate this possibility, we developed a novel two-dose challenge model wherein vaccinated or naïve mice are challenged first with a low dose of genetically-attenuated sporozoites to initiate T cell activation (Dose 1). This is followed by a wild-type sporozoite challenge after 48 hours (Dose 2), just as activated T cells begin to rapidly expand. This extends the window of mouse liver stage challenge to four days, closer to that in humans from an immunological perspective. By *in vivo* imaging, we saw no difference in wild-type liver burden between one- and two-dose challenge in naïve mice, indicating that Dose 1 does not reduce uptake of Dose 2. Dose 1 does not induce a significant type I interferon response at 48 hours. However, the role of expanding T cells was apparent since 80-100% of BALB/cJ mice immunized with *Py* radiation-attenuated sporozoites were protected against a two-dose challenge whereas one-dose challenge protection was 0-40%. C57BL/6 mice have been reported to be difficult to protect against *Py* challenge, but our data showed that 1-2 doses of irradiated *Py* sporozoites protect such mice against a two-dose but not one-dose challenge. Thus, by allowing both activated and expanding CTLs to contribute, the two-dose challenge model is more sensitive for determining the maximum degree of protection that can be derived from pre-clinical vaccine candidates.

1049

SAFETY AND PROTECTIVE EFFICACY AGAINST CONTROLLED HUMAN MALARIA INFECTION OF MULTI-DOSE PRIMING REGIMENS OF PFSPZ VACCINE WITH AND WITHOUT BOOST IN EQUATORIAL GUINEAN ADULTS

Said A. Jongo[1], Thomas Richie[2], Kamaka Kassimu[1], Raul Chuquiyauri[3], Peter F. Billingsley[2], Elizabeth Nyakarungu[1], Maxmillian Mpina[4], Ali Mtoro[1], Ali Hamad[1], Jose Raso[3], Anna Deal[4], Tobias Schindler[4], Vicente Urbano[3], Maria Silvia A. Lopez[3], Beltran Pasialo[5], Marta Alene Owono Eyang[3], Escolastica Raquel Mansogo Maye[3], Gertrudis Owono Bidjimi[3], Martin Eka Ondo[3], Matilde Riloha Rivas[6], Gabriel Mba Abegue[3], Yolanda Rimoy Veri[3], Carlos Cortes Falla[3], Federico Comsil Chochi[3], Dolores Mbang Ondo Mandumbi[3], Guillermo Garcia[3], Manuel Francisco Nfumi Machimbo[3], Ines Toichoa Bela[3], Juan Carlos Momo[3], Carl Maas[7], B. Kim Lee Sim[2], Bonifacio Manguire[7], Preston Church[2], Marcel Tanner[4], Claudia A. Daubenberger[4], Salim Abdula[1], Stephen L. Hoffman[2]

[1]*Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania,* [2]*Sanaria Inc., Rockville, MD, United States,* [3]*Medical Care Development International, Malabo, Equatorial Guinea,* [4]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [5]*Swiss Tropical and Public Health Institute, Malabo, Equatorial Guinea,* [6]*Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea,* [7]*Marathon Oil Corporation, Malabo, Equatorial Guinea*

PfSPZ Vaccine, composed of radiation-attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ), has been well tolerated and safe when administered as single and multi-dose priming regimens in 5 month to 65 year olds in the US, Europe, and 6 African countries, including in HIV+ adults (NCT03420053). In a previous trial we reported that increasing the dose of PfSPZ in PfSPZ Vaccine from $9.0x10^5$ to $1.8x10^6$ (3 doses at 8 week intervals) in Tanzanian adults significantly reduced vaccine efficacy (VE) against controlled human malaria infection (CHMI) from 100% to 33% (NCT02613520). When $9.0x10^5$ PfSPZ were administered on days 1, 3, 5, 7 (priming) with a 16-week boost, VE against heterologous CHMI in U.S. adults at 12 weeks was higher than with any previous regimens. We administered the same priming regimen (1,3,5,7) following by a 4-week boost to healthy Tanzanian adults and showed 80% VE against CHMI (NCT03420053). A condensed administration schedule of PfSPZ Vaccine with high VE would facilitate its deployment. To identify a regimen for a Phase 3 clinical trial, we conducted a double-blind, placebo-controlled trial in 104 Equato guinean adults that assessed the safety, immunogenicity, and VE against CHMI at ~6 weeks after last dose of one 16-week and three condensed (<28 days) vaccination regimens. In three regimens, $9.0x10^5$ PfSPZ were administered four times on days 1, 3, 5 and 7 followed by a boost on day 113 (regimen 1), a boost on day 29 (regimen 2) or no boost (regimen 3). In regimen 4, $9.0x10^5$ PfSPZ were administered on days 1 and 8 with a boost on day 29, to see if a 2-dose multi-dose prime was as effective as a 4-dose multi-dose prime. The complete unblinded results of tolerability, safety, immunogenicity and VE of this spectrum of vaccination regimens will be presented.

1050

IMMUNE ACTIVATION AND MAGNITUDE AND BREADTH OF *PLASMODIUM FALCIPARUM* HUMORAL IMMUNITY IN MALARIA PRE-EXPOSED VOLUNTEERS WITH OR WITHOUT HIV INFECTION DURING PFSPZ VACCINATION AND CONTROLLED HUMAN MALARIA INFECTION

Anneth-Mwasi N. Tumbo[1], Freia-Raphaella Lorenz[2], Jean-Pierre Dangy[3], Maximillian Mpina[1], Tobias Schindler[3], Florence A. Milando[1], Gloria Nyaulingo[1], Matthieu Perreau[4], Kamaka Ramadhani[1], Said Jongo[1], Philip L. Felgner[5], Benjamin Mordmueller[2], Thomas Richie[6], B.Kim Lee Sim[6], Marcel Tanner[3], Salim Abdulla[1], Stephen L. Hoffman[6], Rolf Fendel[2], Claudia Daubenberger[3]

[1]*Ifakara Health Institute, Bagamoyo, United Republic of Tanzania,* [2]*Institute of Tropical Medicine, University of Tubiengen, Tubiengen, Germany,* [3]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [4]*Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland,* [5]*University of California, Irvine, CA, United States,* [6]*Sanaria Inc., Rockville, MD, United States*

In 2018, we evaluated the safety, immunogenicity and efficacy of metabolically active, radiation attenuated, purified *Plasmodium falciparum* sporozoites in HIV negative and HIV positive Tanzanian adults (ClinicalTrials.gov Identifier: NCT03420053). Marked differences in protection against homologous controlled human malaria infection (CHMI) were observed between HIV positive and HIV negative volunteers that were under anti-retroviral treatment during the study. For licensed vaccines, it has been described that systemic inflammation and ongoing co-infections at time of vaccination can potentially contribute to reduced magnitude and duration of vaccine-induced immune responses. We investigated the impact of HIV infection status on systemic immune activation before PfSPZ Vaccination and after CHMI. Serum cytokine and chemokine concentrations before and during vaccination were quantified *ex vivo* using a validated 45 plex human bead array platform . HIV positive volunteers had significantly higher concentrations of Eotaxin, while in HIV negatives Tumor necrosis factor alpha (TNF-α), Growth regulated oncogene-alpha (GRO-alpha), Interleukin-8 (IL-8), Macrophage inflammatory protein-1beta (MIP-1beta), Brain derived neutrophic factor (BDNF) and Vascular endothelial growth

factor-alpha (VEGF-alpha) were elevated when compared to HIV positives at baseline. During the vaccination, most of these cytokines/chemokines remained elevated in the HIV negative cohort. In the HIV positive volunteers, Interleukin 12, p70 (IL-12p70) , Interleukin-2 (IL-2) and Eotaxin were increased 28 days post CHMI while the HIV negatives showed higher levels of BDNF and MIP1-beta only. IgG and IgM antibody profiles in both cohorts before and after vaccination, and after CHMI were investigated using a novel proteome microarray encompassing 262 *P. falciparum* (3D7) antigen data points. Collectively, we will present for the first time data on immune activation and antibody profiles in malaria pre-exposed HIV positive volunteers undergoing PfSPZ Vaccination and CHMI and correlate these to vaccine induced protection.

CHEMOPROPHYLAXIS VACCINATION (PFSPZ-CVAC) WITH HIGH DOSE OF SANARIA® PFSPZ CHALLENGE NF54 UNDER PYRIMETHAMINE OR CHLOROQUINE LEADS TO PROTECTIVE EFFICACY AGAINST HETEROLOGOUS CONTROLLED HUMAN MALARIA INFECTION IN MALARIA NAÏVE ADULTS

Agnes Mwakingwe-Omari[1], Jacquelyn Lane[1], David M. Cook[1], Sara A. Healy[1], Susan Pfeiffer[1], Sahand Kalhori[1], Charles Wyatt[1], Omely Marte-Salcedo[1], Alemush Imeru[1], Martha Nason[2], Irfan Zaidi[1], Junhui Duan[1], Jillian Neal[1], Jake Raiten[1], Jen C.C. Hume[1], Esther J. Jeon[3], Gary Fahle[4], Tooba Murshedkar[5], Adam J. Ruben[5], Sumana Chakravarty[5], Anita Manoj[5], Anusha Gunasekera[5], B. Kim Lee Sim[5], Peter F. Billingsley[5], Eric R. James[5], Thomas L. Richie[5], Stephen L. Hoffman[5], Patrick E. Duffy[1]

[1]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [2]*Biostatistical Research Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Clinical Center Pharmacy Department, National Institutes of Health, Bethesda, MD, United States,* [4]*Department of Laboratory Medicine, Molecular Microbiology, National Institutes of Health, Bethesda, MD, United States,* [5]*Sanaria, Inc., Rockville, MD, United States*

Administration of 3 doses of $5.12x10^4$ *Plasmodium falciparum* (Pf) sporozoites (SPZ) (Sanaria® PfSPZ Challenge NF54) by direct venous inoculation (DVI) to subjects taking chemoprophylaxis (Sanaria® PfSPZ-CVac) with pyrimethamine (PYR) did not lead to significant vaccine efficacy (VE) against homologous (NF54) controlled human malaria infection (CHMI) 12 weeks post 3rd vaccination (1/8 protected). Therefore, we assessed a 4-fold higher dose of PfSPZ Challenge NF54 with either PYR or chloroquine (CQ) against homologous (NF54) and heterologous (7G8) CHMI. All participants received 3 doses of $2x10^5$ PfSPZ by DVI at 4 week intervals with either PYR (PfSPZ-CVac-PYR [n=19]) or CQ (PfSPZ-CVac-CQ [n=10]). Vaccinations were safe and well tolerated: 2 serious adverse events occurred, including one possibly related and one unrelated to study procedures. By qPCR assays, we confirmed that 50 mg of PYR given 2 and 3 days post injection with $2x10^5$ PfSPZ prevented development of asexual Pf parasitemia. CHMI with $3.2 x10^3$ PfSPZ Challenge (NF54 or 7G8) was performed in unvaccinated controls (NF54 controls; n=4 and 7G8 controls; n=8) and in vaccinated groups approximately 12 weeks post 3rd vaccination. All 12 unvaccinated controls were infected. In PfSPZ-CVac-PYR groups, 7/8 (87.5%) participants were protected from homologous and 7/9 (78%) from heterologous CHMI. In the PfSPZ-CVac-CQ group, 6/6 (100%) were protected from heterologous CHMI. Immunological assays to determine immune factors and parasite antigens contributing to this remarkable response are ongoing. With these unprecedented results we are initiating a field study to explore the effectiveness of these regimens in malaria-experienced populations.

COMPLETE *PLASMODIUM FALCIPARUM* LIFE CYCLE USING FRG HUHEP MICE AS A MODEL FOR SPOROZOITE INFECTIVITY

Tao Li[1], Christiane Urgena[1], Sumana Chakravarty[1], Abraham G. Eappen[1], Asha Patil[1], Yonas Abebe[1], Adam Frock[1], Minglin Li[2], BKL Sim[2], Stephen L. Hoffman[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Protein Potential LLC, Rockville, MD, United States*

The immunocompromised and fumarylacetoacetate hydrolase-deficient mouse (Fah-/-, Rag2-/-, Il2rg-/-, termed the FRG mouse) engrafted with human hepatocytes (FRG huHep) has been shown to be an excellent model for *Plasmodium falciparum* (Pf) liver stage development. FRG huHep mice supports vigorous, quantifiable Pf liver stage development that culminates in complete maturation of liver stage at approximately 7 days after infection, providing a relevant model for liver stage development in humans. We report the complete Pf full life cycle using FRG huHep mice. FRG huHep mice were injected with either fresh PfSPZ or cryopreserved PfSPZ on day 0. Six and 7 days later the FRG mice received two consecutive transfusions of processed packed human erythrocytes, and 6 hours after the last transfusion, blood was drawn from the mice and put into continuous culture for further development of Pf human erythrocytic stage parasites. Full development and maturation of gametocytes were observed. In all experiments, Pf human erythrocytic stage parasites, both asexual and sexual stages, developed in the cultures from the FRG mice blood post either fresh PfSPZ or cryopreserved PfSPZ immunization. The mature Pf sexual stage parasites were then harvested from the cultures and used to prepare artificial infectious blood meals to infect non-aseptic mosquitoes and developed to PfSPZ in mosquitoes. The method is reproducible and can be used as a model for the infectivity of PfSPZ and other potentially novel antimalarial candidates against *Plasmodium falciparum*.

1053

COMPARATIVE REGULATORY PATHWAYS FOR CLINICAL DEVELOPMENT AND COMMERCIALIZATION OF PFSPZ VACCINE IN THE US, EUROPE AND AFRICA

Asqual Getachew, Anusha Gunasekera, Shachi Shah, BKL Sim, Thomas L. Richie, Stephen L. Hoffman, Tooba Murshedkar

Sanaria Inc., Rockville, MD, United States

PfSPZ Vaccine is Sanaria's leading malaria vaccine candidate and is currently in Phase 1 and Phase 2 clinical trials. The goal is to develop and commercialize this highly effective malaria vaccine such that it can be used to immunize entire populations to confer high-level protection against *Plasmodium falciparum* (Pf) (responsible for more than 95% of malaria associated severe illness and death world-wide). PfSPZ Vaccine is a whole sporozoite malaria vaccine that is radiation-attenuated, live, metabolically active, non-replicating, aseptic, purified, and cryopreserved in liquid nitrogen vapor phase (LNVP). With this goal of licensure in mind, a regulatory process was initiated in 2005 that commenced with a pre-IND meeting with the U.S. FDA, followed by a successful IND submission. Sanaria has progressed from conducting pre-clinical, IND-enabling studies to Phase 1 and subsequently Phase 2 clinical trials. We now anticipate initiating end-of-phase 2 discussions with FDA. In collaboration with various partners, Sanaria has conducted 18 clinical trials of PfSPZ Vaccine in the US, Europe and Africa. All Sanaria trials are conducted under U.S. FDA oversight (under an IND), with additional ethical and regulatory oversight from the host European (Germany) and African (Tanzania, Kenya, Mali, Gabon, and Equatorial Guinea) countries. The goal is to initiate a Phase 3 program next year (2020) for PfSPZ Vaccine. The regulatory pathways for clinical trials in the U.S., Europe and Africa will be compared and licensure / marketing approval processes for a malaria vaccine within the US, European and some African markets will be presented.

1054

THE REGULATORY PRODUCT DEVELOPMENT EXPECTATIONS AND REQUIREMENTS FOR INVESTIGATIONAL USE AND COMMERCIALIZATION OF A MALARIA VACCINE IN THE US, EUROPE AND AFRICA

Shachi Shah, Asqual Getachew, Anusha Gunasekera, Anita Manoj, BKL Sim, Stephen L. Hoffman, Tooba Murshedkar

Sanaria Inc., Rockville, MD, United States

Sanaria's most promising malaria vaccine candidate, PfSPZ Vaccine, is currently an investigational product with the eventual goal of licensure through the US FDA, EMA and other international regulatory bodies and subsequent commercialization. The regulatory expectations of the product through its development process (chemistry, manufacture and controls (CMC) information) evolve from the time of conducting the first pre-clinical studies to filing the first Investigational New Drug (IND) application to conducting Phase 1 and 2 studies, to conducting Phase 3 studies and subsequent licensure and commercialization. CGMPs are an integral part of the vaccine product development program at every stage. For Sanaria's investigational vaccine, ensuring its sterility, potency and stability have been key to ensuring product quality. We will review regulatory expectations for the CMC information at various stages of the development process. For example, at the pre-IND stage, safety of an investigational product is the primary concern. CMC information submitted to FDA in either an IND, Master File (MF) or Biologics License Application (BLA) fall under Module 3 (with summaries provided under Module 2) of the International Conference on Harmonisation (ICH) Common Technical Document (CTD) structure. We will concurrently review the submission components and phase-specific regulatory expectations of the product development process for our malaria vaccine within US FDA's, EMA's and certain African nations' regulatory framework.

QUALIFICATION OF THE MICROBIAL GROWTH TEST FOR IN-PROCESS SAMPLES FOR PRODUCTION OF SANARIA® PFSPZ VACCINE

Minglin Li[1], Anita Manoj[1], Bing Jing[1], Lixin Gao[1], Abraham G. Eappen[2], Tao Li[2], BKL Sim[1], Stephen L. Hoffman[2]

[1]*Protein Potential LLC, Rockville, MD, United States,* [2]*Sanaria Inc., Rockville, MD, United States*

Title: Qualification of the microbial growth test for in-process samples for production of Sanaria® PfSPZ Vaccine Sanaria® PfSPZ Vaccine is composed of aseptic, purified, cryopreserved, radiation attenuated *Plasmodium falciparum* (Pf) sporozoites (SPZ). Subsequent to the promising vaccine efficacy results, Phase 3 clinical trials are planned for 2020 to support a Biologics License Application to the FDA in 2021. Other PfSPZ products are PfSPZ Challenge and PfSPZ GA (genetically attenuated) parasites that are also aseptically manufactured. The common challenge faced for all live organism products is the absence of terminal sterilization prior to or post-vialing. As such strict and clear methods have been established to ensure aseptic processing throughout manufacture. The manufacturing process involves the use of aseptic mosquitoes to produce PfSPZ. The entire life cycle of aseptic mosquitoes occurs in aseptically maintained vessels. Each stage is assessed including eggs, pupae, adult mosquitoes and infected blood meals, as well as other in process step materials. We report here the development and qualification of the microbiological test methods used to asses our aseptic processing.

1056

STATUS OF BIOLOGICAL CONDITIONS AND PATHOLOGIES EXCLUDING VOLUNTEERS FROM MALARIA VACCINE CLINICAL TRIALS (PFSPZ) IN 2014 AND 2016 IN DONEGUEBOUGOU, MALI

Amatigue Zeguime[1], M'Bouye Doucoure[1], Sidiki Perou[1], Boucary Ouologuem[1], Souleymane Traore[1], Abdoulaye Katile[1], Allaye Tolo[1], Baba Djiguiba[1], Mahamadou S. Sissoko[1], Boubacar Traore[1], Jordyn Manucci[2], Jen C.C. Hume[3], Patrick E. Duffy[3], Ogobara Doumbo[1]

[1]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Division of Intramural Research, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

In general, a clinical trial for the development of a new product requires healthy volunteers who do not suffer from acute and chronic pathology with normal biological parameters. Sufficient recruitment of such volunteers entails many tests (biological and other), and a majority of volunteers are excluded during screening. The MRTC, LMIV/NIAID/NIH, and Sanaria, Inc conducted PfSPZ vaccine clinical trials in 2014 and 2016, recruiting male and female volunteers aged 18 to 50. Eligibility for enrollment was determined by screening tests including EKG, biochemistry, as well as hematological, serological, urine, and pregnancy tests. The eligibility rate was 40% in 2014 and 29% in 2016. EKG abnormalities excluded 21% in 2014 versus 4% in 2016. Biochemistry abnormalities were represented by high serum creatinine levels in 30% of volunteers in 2014 and 32% in 2016, and elevations of ALT in 6% of volunteers in 2014 compared to 4% in 2016. Abnormal low hematological parameters included the following: WBC 3%; PNN 5%; PLT 2%; HGB 8% in 2014 vs. WBC 5%; PNN 9%; PLT 1%; HGB 13% in 2016. Serological tests were positive for hepatitis B (23% vs. 16%), hepatitis C (2% vs. 12%), HIV (3% vs. 1%) in 2014 and 2016, respectively. Urine tests such as proteinuria and hematuria were abnormal in 2% and 4% of volunteers in 2014 and 7% vs. 18% in 2016, respectively. Pregnancy tests were positive in 0% of volunteers in 2014 and 2% in 2016. The non-inclusion of 21% vs. 4% due to EKG abnormalities in 2014 and 2016, respectively, is probably related to interpretation criteria. For hepatitis B, the drop from 23% in 2014 to 16% in 2016 is likely due to spontaneous healing. For hepatitis C, the higher rate in 2016 can attributed to the fact that the same volunteers from 2014 returned in 2016 for re-screening. Differences in hematuria between 2014 and 2016 may be related to the fact that 2016 screening was done in December, a period of schistosomiasis transmission in Doneguebougou and intensive agricultural activities. These results present a trend regarding the frequency of some pathologies in our populations, and can serve not only as a warning system, but may also contribute to the design of future studies.

1057

THE EFFECT OF IMMUNIZATION WITH PFSPZ VACCINE ON EPSTEIN-BARR ANTIBODY LEVELS AS A MARKER OF VIRAL REACTIVATION AND AS A SURROGATE RISK MARKER OF ENDEMIC BURKITT LYMPHOMA

Ann Moormann[1], **LW Preston Church**[2], Catherine Forconi[1], Said Jongo[3], Ali Mtoro[3], Maximillian Mpina[3], Claudia Daubenberger[4], Thomas Richie[2], B. Kim Lee Sim[2], Salim Abdulla[3], Stephen L. Hoffman[2]

[1]*Division of Infectious Diseases and Immunology, Department of Medicine, University of Massachusetts Medical School, Worcester, MA, United States,* [2]*Sanaria Inc., Rockville, MD, United States,* [3]*Ifakara Health Institute, Bagamoyo, United Republic of Tanzania,* [4]*Swiss Tropical and Public Health Institute, Basel, Switzerland*

Epstein-Barr virus (EBV) is a commonly occurring, asymptomatic infection of children. However, prolonged interactions between EBV and *Plasmodium falciparum* (Pf) asexual erythrocytic stages during childhood

is associated with an increased risk of endemic Burkitt lymphoma (eBL). The radiation attenuated Pf sporozoites (SPZ) in PfSPZ Vaccine never develop to the asexual erythrocytic stage. Nonetheless, in our first trial involving pediatric subjects in Africa (Tanzania), we measured EBV viral capsid antigen (VCA) IgG and IgM at baseline, 2 and 8 weeks after the last dose in subjects < 18, or 28 days after controlled human malaria infection (CHMI) in adults to look for evidence of increased viral expression as has been seen during acute Pf infection. IgG and IgM antibodies to EBV VCA (a marker for eBL risk) and EBNA1 (not associated with eBL risk) were measured in 89 subjects. Sera from EBV seronegative Kenyan infants were negative controls. Sixty of 68 subjects >12 months of age were EBV infected prior to enrollment. 14 of 21infants aged 6 to 12 months were not infected at study start. Over the study period of 24 weeks, 5 subjects (3 infants) seroconverted. In volunteers who were EBV seropositive at enrollment, there was no trend towards increased EBV-VCA IgG levels in vaccinees and no difference between vaccinees and controls. In the 5 volunteers who seroconverted during immunization, the final antibody levels were similar to the chronically EBV-infected population. Immunization with PfSPZ Vaccine was not associated with an increase in serum levels of EBV-VCA IgG in persistently EBV-infected volunteers and did not contribute to higher than expected antibody levels in recently infected volunteers. In this study of 89 subjects there was no indication that vaccination with PfSPZ Vaccine increased risk of progression to eBL.

SAFETY OF TWO *PLASMODIUM FALCIPARUM* SPOROZOITE VACCINE (PFSPZ) SCHEDULES IN HEALTHY ADULTS IN OUELESSEBOUGOU, MALI

Halimatou Diawara[1], Agnes Mwakingwe-Omari[2], **Djibrilla Issiaka**[1], Jacquelyn Lane[2], Seydou Traore[1], Ibrahim Soumbounou[1], Mahamoudou Samassekou[1], Gaoussou Santara[1], Oumar Attaher[1], Almahamoudou Mahamar[1], Kailfa Diarra[1], Amadou Konate[1], Adama Dembele[1], Amatigue Zeguime[1], Zonghui Hu[3], Michal Fried[2], Amagana Dolo[1], Peter Billingsley[4], B. Kim Lee Sim[4], Thomas L. Richie[4], Stephen L. Hoffman[4], Alassane Dicko[1], Patrick E. Duffy[2]

[1]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Biostatistical Research Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [4]*Sanaria, Inc., Rockville, MD, United States*

In a previous study of Sanaria® *Plasmodium falciparum* (Pf) sporozoite (PfSPZ) Vaccine [NF54] ($1.8x10^6$ PfSPZ/dose) given at 0, 8 and 16 weeks in malaria experienced adults was safe and had a vaccine efficacy (VE) against Pf infection of 52% by time to 1st event during 24 weeks of follow up. More condensed regimens have resulted in increased VE in malaria naïve adults. In an ongoing double-blinded study, we are evaluating the safety and VE of two regimens of $9x10^5$ PfSPZ Vaccine. 210 participants were randomized into 4 arms between June and August 2018 to receive injections with PfSPZ Vaccine or normal saline. Arms 1 (vaccine, n=70) and 3a (control, n=35) received injections at 0, 8 and 16 weeks. Arms 2 (vaccine, n=70) and 3b (control, n=35) received injections at 0, 1 and 4 weeks. Participants received artemether/lumefantrine 2 weeks prior to 3rd vaccination. All participants received the 3rd vaccination at the same time and were followed for Pf infection every 2 weeks and/or at time of illness starting immediately after 3rd vaccination. Follow-up will be completed in April 2019.Vaccinations have been safe and well tolerated with no serious adverse events reported. Of 831 total adverse events (AEs), 16 (1.9%) were grade 3 (one, a decrease in platelets was possibly related). The other grade 3 AEs, clinical malaria and hypertension, were not related to the study. 8.5% of total AEs were grade 2, most were laboratory abnormalities that were unrelated to the study. Headache and injection site pain were the most frequent grade 1 AEs. A total of 164 episodes of Pf infection were documented by microscopy, 53% in Arm 1/3a and 47% in Arm 2/3b. PfSPZ Vaccine given at 0, 8, 16 weeks and 0, 1, 4 weeks appears to be safe and well-tolerated. The study is still blinded, with plans to evaluate the safety and protective efficacy of a booster dose during a second malaria transmission season.

1059

PREVALENCE OF HEPATITIS B AND HIV INFECTIONS AMONG HEALTHY VOLUNTEERS TO PARTICIPATE IN A PFSPZ VACCINE CLINICAL TRIAL IN EQUATORIAL GUINEA

Maria Silvia A. Lopez[1], Ali Hamad[2], Kamaka Ramadhani[2], Vicente Urbano[1], Gertrudis Owono[1], Fortunata Lobede[1], Ali Mtoro[2], Said Jongo[2], Jose Raso[1], Maximilian Mpina[2], Elizabeth Nyakarungu[2], Matilde Riloha Rivas[1], Carlos Cortes[3], Guillermo A. Garcia[4], Raul Chuquiyauri[5], L.W. Preston Church[6], Peter Billingsley[6], Claudia Daubenberger[7], Thomas Richie[6], Salim Abdulla[8], Stephen L. Hoffman[6]

Hepatitis B and HIV are infections that are commonly spread through sexual contact and usually do not show symptoms in the early phase of infection. This results in a greater risk of passing the infection from one individual to others. Globally 1.34 million deaths were caused by viral hepatitis in 2015, and 940 000 deaths by HIV in 2017. The first strategic direction of the WHO Global Health Sector Strategy on Sexually Transmitted Infections 2016 - 2021 is to collect information on STI prevalence and incidence to help focused action for planning and implementation. Specifically the strategy on viral hepatitis set target to test 90% and treat 80% of people with HBV by 2030. However, at present very limited information is available on the prevalence of Hepatitis B and some information for HIV infections in Equatorial Guinea. This study primarily aimed to screen out healthy volunteers with Hepatitis B and HIV infections not to participate in the PfSPZ vaccine clinical trial in Equatorial Guinea for safety considerations. The trial's objective was to evaluate the safety, tolerability, immunogenicity, and protection that indicate the best regimen(s) of PfSPZ vaccine in Equatorial Guinea (ClinicalTrials.gov Identifier: NCT03590340). The PfSPZ vaccine study screened a total of 176 healthy adults male and female volunteers between the age of 18-45 years. Out of these 176, 16 were found to have hepatitis B infection (9.1%), 1 had hepatitis C infection (0.6%), and 4 were found to have HIV infection (2.3%). Among the volunteers excluded (72 volunteers) due to different reason, Hepatitis B &C and HIV constitute about 24% and 5.6% respectively. These infections were found in volunteers who deemed themselves to be healthy. The SDG set target to end the epidemics of AIDS ad combat hepatitis by 2030. In order to accomplish this target more effort need to be done in the improvement of the Hepatitis B vaccination coverage, prevention of HIV, diagnosis and treatment of these infections and increase the awareness of the community of these diseases in Equatorial Guinea.

The Bioko Island Malaria Control Program (BIMCP) conducts annual malaria infection surveys using rapid diagnostic tests (RDTs). However malaria incidence for *Plasmodium falciparum (Pf)* infections in selected areas for phase 3 trial remains unknown. In addition, if a substantial number of residents harbor low parasite densities, these infections are likely not detected in these surveys, missing an important population that is believed to contribute on sustained malaria transmission. In prepraration for a phase 3 trial with PfSPZ Vaccine in Bioko island, EG , we conducted a baseline assessment of the incidence of *Pf* infections to guide selection of an appropriate sample size to measure the vaccine efficacy of PfSPZ vaccine against natural infection for this upcoming phase 3 trial. Our primary objective is to determine the incidence of Pf infection by RDTs and thick blood smear slides (TBS) over a 6-month period in 240 individuals equally categorized in 3 age groups (G1: 6-59 months, G2: 5-17 years, and G3: 18-45 years) and reside in selected areas of Bioko Island in close proximity to the research center where the estimated parasite prevalence by RDT has been consistently higher than 10% for surveys conducted from 2016 to 2018. After pre-treatment with 6 doses of artmether-lumefantrine, volunteers were actively followed every two weeks for 6 months. Infections were assessed by RDT, highly sensitive RDT, and TBS prepared in accordance with a WHO standard procedure and by qPCR. The malaria incidence data will be presented.

1061

SPZ VACCINE: FOUR BILLION+ ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITES INJECTED WITH NO BREAKTHROUGH INFECTIONS

Eric Robert James, Steve Matheney, James Overby, B Kim Lee Sim, Abraham G. Eappen, Tao Li, Ming Lin Li, Anita Manoj, Peter F. Billingsley, Thomas L. Richie, LW Preston Church, Sumana Chakravarty, Anusha Gunasekera, Tooba Murshedkar, Stephen L. Hoffman

Sanaria, Rockville, MD, United States

Sanaria®PfSPZ Vaccine comprises aseptic radiation-attenuated sporozoites (SPZ) of *Plasmodium falciparum* (Pf). PfSPZ are irradiated in the mosquitoes' salivary glands using a ^{60}Co source and then are recovered by dissection and gland dissociation, purified, vialed, and cryopreserved. Mosquitoes are transferred for irradiation into infected mosquito transport containers (IMTC) and then irradiated. IMTCs were mapped using radiochromic film and alanine transfer dosimeters and the minimum and maximum dose locations determined. A reference dosimeter on the outside wall of the IMTC monitored each irradiation event. PfSPZ Vaccine production between 2010 and 2019 generated multiple lots released for use in phase 1 and 2 clinical trials and involved 458 separate irradiation events. Dosimeters were processed by the National Institute of Standards and Technology (NIST). A target minimum dose of 150 Gy was adopted as the attenuating PfSPZ Vaccine dose based on early studies using PfSPZ administered by bite of infected mosquitoes and our 6-day hepatocyte assay, in which breakthroughs occurred using 120 Gy, but not 150 Gy. Dosimeters exposed to doses of 120-170 Gy were used to calibrate the time required for a dose of 150 Gy including the lower 95% confidence interval at the minimum dose location inside the IMTC by regression analysis and the corresponding dose at the reference location was determined. A formula incorporating the half-life of ^{60}Co was used to construct tables of the irradiation times required to deliver 150 Gy on all days for each calendar year from 2010 to 2019. Analysis of the 458 reference dosimeters indicated a normal distribution with a mean of 153.4 Gy (range 150.0 to 157.8 Gy) delivered to the minimum dose location inside the IMTC. A plot of the trending data for all irradiation events recorded over this period was completely flat. As of April 2019, 18 clinical trials of PfSPZ Vaccine have been conducted, with 1,526 volunteers receiving 4,893 doses of vaccine for a total of 4.36 billion PfSPZ administered: there have been no breakthrough infections, confirming the consistency and robustness of the radiation attenuation process.

1062

CONTROLLED HUMAN MALARIA INFECTION PRODUCT TO PROBE HETEROLOGOUS PROTECTIVE EFFICACY, INFECTIONS AND STRAIN DIFFERENCES IN *PLASMODIUM FALCIPARUM*

B. Kim Lee Sim[1], Eric R. James[1], Yonas Abebe[1], Anita Manoj[1], Henry Huang[1], Peter F. Billingsley[1], Benjamin Mordmueller[2], Peter Kremsner[2], Patrick Duffy[3], Agnes Mwakingwe[3], Kirsten Lyke[4], Matthew B. Laurens[4], Thomas L. Richie[1], Stephen L. Hoffman[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Institute of Tropical Medicine, University of Tübingen, Tübingen, Germany,* [3]*Laboratory of Malaria Immunology and Vaccinology, National Institutes of Health, Rockville, MD, United States,* [4]*Division of Malaria Research, Institute for Global Health, University of Maryland School of Medicine, Baltimore, MD, United States*

Sanaria® PfSPZ Challenge (Pf7G8) is composed of aseptic, purified, cryopreserved infectious *Plasmodium falciparum* (Pf) sporozoites (SPZ) that are used to conduct controlled human malaria infection (CHMI) studies to assess anti-malarial vaccines and drugs, and innate and acquired resistance to malaria. Pf7G8 was isolated in Brazil and has sinced been shown to possess unique and various genetic (SNPs) and predicted proteomic (T cell epitopes) diversity as compared to PfNF54 the strain used until recently for nearly all CHMIs. Thus far volunteers in 2 studies in the U.S., and 2 studies in Germany, have undergone CHMI with PfSPZ Challenge (Pf7G8). PfSPZ Challenge (Pf7G8) is stored in liquid nitrogen vapor phase (LNVP) at less than -150 degrees C, and the stability of PfSPZ Challenge is assessed at Sanaria by a sporozoite membrane integrity assay (viability assay) and *in vitro* growth and development in hepatocytes (potency assay). However, the most powerful indicator of the stability of PfSPZ Challenge over time has been the infectivity of PfSPZ Challenge in humans of product held in LNVP over time. For PfSPZ Challenge (NF54), 78/78 control subjects from the U.S. or Europe who received 3,200 PfSPZ up to 33 months after manufacture became infected. PfSPZ Challenge (7G8) was assessed in two dose escalation CHMIs in the U.S. and Germany ~25 months after manufacture (N=25 volunteers), and in two vaccine trials, one ~ 3 years and one more than four years after manufacture (N=14 non-immunized control volunteers). In these studies, 25/26 subjects who received 3,200 PfSPZ of PfSPZ Challenge (7G8) became infected, including 14/14 at 3 and 4 years. CHMI has been an enormously important tool to establish the lot to lot consistency and stability of infectivity of PfSPZ Challenge and by analogy of all of Sanaria's PfSPZ-based products.

1063

A HIGH CONTENT SCREENING PLATFORM FOR ABSOLUTE QUANTITATION OF *PLASMODIUM* SPOROZOITES

Urvashi Rai[1], Timothy Hackett[2], Richard Fan[1], Anita Manoj[1], B. Kim Lee Sim[1], Stephen L. Hoffman[1], Sumana Chakravarty[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*University of Nebraska, Omaha, NE, United States*

Plasmodium falciparum (Pf) sporozoite (SPZ) quantitation is one of the quality control (QC) assays used for characterizing Sanaria's multiple PfSPZ-based clinical products. The majority of quantitation is done during stability testing. More than 4,600 individual quantitation events (an operator adding a PfSPZ sample to a disposable hemocytometer and determining the absolute PfSPZ quantities by microscopy) of PfSPZ products have been done to generate stability profiles of released lots of PfSPZ products, including Sanaria® PfSPZ Vaccine, PfSPZ Challenge, and PfSPZ-GA1. In addition, quantitation is an integral part of the QC release of these PfSPZ products. Here we report on development of a robust automated quantitation protocol for PfSPZ, based on a high content image cytometry system, the CeLLInsight CX5 (ThermoFisher Scientific™). Using this platform, we have developed a highly specific PfSPZ quantitation procedure relying on a fluorescent antibody-based detection method. It features at least a 10-fold increase in the number of PfSPZ detected in the samples used to estimate the population counts as compared to microscopy The large sampling size reduces the potential for variability between samples from the same source. It also allows accurate quantitation of low PfSPZ concentrations. Following an initial staining step, the instrument scans a total area of 25.6 mm^2 with 100-4000 PfSPZ in about 3.5 minutes, while it takes an operator (microscopist) about 7 minutes to enumerate 360-400 total PfSPZ over an area of 4 mm^2. Both operations are performed on disposable hemocytometers and the images and data captured by CeLLInsight CX5 can be digitally archived for future reference. Moreover, we can accurately detect and enumerate PfSPZ concentrations in unpurified preparations containing mosquito salivary gland components.

TRANSLATING A SEMI-AUTOMATED MOSQUITO MICRODISSECTION SYSTEM FOR MANUFACTURING PFSPZ VACCINES UNDER CGMPS

Hajar Hazime[1], Urvashi Rai[1], Mariah Schrum[2], B. Kim Lee Sim[1], Stephen L. Hoffman[1], Russell H. Taylor[2], Sumana Chakravarty[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Johns Hopkins University, Baltimore, MD, United States*

Plasmodium falciparum (Pf) Sporozoite (SPZ)-based vaccines are the only intervention in humans to have demonstrated >90% protective efficacy against controlled human malaria infection. They form the basis of Sanaria's unique technology platform of aseptic, purified, cryopreserved live *Plasmodium falciparum* sporozoites (PfSPZ). Manufacture of all PfSPZ-based products at Sanaria requires microdissection of mosquito salivary glands. Our goal was to semi-automate the key step of isolating PfSPZ from mosquito salivary glands based on integrating various biological, physical, chemical and engineering principles. Repeated sequential decapitation of mosquitoes and extrusion of glands over stereo-microscopic dimensions induces fatigue and requires extensive training. In a phased approach to automate mosquito microdissection we focused on converting the decapitation and gland extrusion steps from a sequential to a batch process. Prototypes were developed for mosquito alignment, decapitation and gland extraction, and integrated into a semi-automated mosquito microdissection system termed sAMMS. This system allows batch-processing of 30 to potentially hundreds of mosquitoes at once. Mosquito processing capacity using one unit of sAMMS compared to a single operator performing manual dissection has tripled per unit time, since inception of this project in 2014. The time to fully train and qualify individual operators for mosquito processing using sAMMS, is 15-20-fold less than manual dissection training time. We will report progress on all aspects of instituting sAMMS in cGMP operations that not only requires stringent materials compliance for clinical use, but also demands performance consistency with regard to PfSPZ yields and relative purity compared to manual dissection.

1065

INSECTICIDES SUSCEPTIBILITY AND PREVALENCE OF KDR AND ACE1 MUTATIONS AMONG WILD *ANOPHELES ARABIENSIS* AND *AN. MELAS* POPULATIONS IN THE COASTAL ZONE OF LOW MALARIA TRANSMISSION IN SENEGAL

Ousmane Sy[1], Elhadji Amadou Niang[1], Abdoulaye Kane Dia[1], Kevin Ochieng Opondo[2], Benoit S Assogba[2], Magatt Ndiaye[1], Mouhamed A Nourdine[1], Pape Cheikh Sarr[1], Lassana Konaté[1], Oumar Gaye[1], David Weetman[3], Martin Donnely[3], Ousmane Faye[1]

[1]*UCAD, Dakar, Senegal,* [2]*Medical Research Council unit the Gambia at the London School of Hygiene & Tropical Medicine, Fajara, Gambia,* [3]*Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Great progress has been made against malaria in the central western Senegal thanks to the successful implementation of IRS and SMC interventions. Nevertheless, the residual transmission maintained by *An. arabiensis* and *An. melas* in some hotspots may hamper the achievement of the elimination goal. This study was conducted to better characterize the vectors populations of this area by updating data on the two vectors susceptibility to insecticides and the prevalence of Kdr and Ace-1 mutations. Larvae were collected from different breeding sites of different level of salinity. Insecticide susceptibility tests were conducted on 3-5 days old unfed adult females. Aggressive and endophilic mosquitoes were caught respectively by human landing catches and pyrethrum spray catches. Overall, 667 specimens of *An. gambiae* s.l. were tested to 5 mains insecticides. Anopheles from the low salinity breeding sites consisting of 97.7% *An. arabiensis*, were susceptible to Deltamethrin but suspected to be resistant to Permethrin. While population collected from highly salty breeding sites, exclusively represented by *An. melas*, were susceptible to Bendiocarb, Pirimiphos-methyl and DDT. Molecular identification revealed that the host-seeking and resting populations in the study area consisted mainly of *An. arabiensis* which was found with significantly higher proportions (57.4%) than the *An. melas* (42.2%). *An. coluzzii* was very poorly represented (0.4%) and no *An. gambiae* was found. A very large distribution of the Kdr mutation was noted in the study area with a preponderance of Kdr-East over the Kdr-West in both endophilic and aggressive populations. The Kdr gene was mainly carried by the species *An. arabiensis* and less frequent in *An. melas* while the Ace-1 gene was only found in two individuals of *An. arabiensis*. This study demonstrated the susceptibility of *An. melas* to Bendiocarb, Pirimiphos-methyl and DDT and provided an update of the prevalences of the Kdr and Ace-1 mutations among the natural population of the two main malaria vectors in central-western Senegal.

1066

NEXT GENERATION VECTOR SURVEILLANCE TECHNIQUES TO GUIDE NATIONAL MALARIA CONTROL PROGRAMS

Robert Farlow[1], Thomas R. Burkot[2], Tanya L. Russell[3]

[1]*R Farlow Consulting LLC, Burkeville, TX, United States,* [2]*Australian Institute of Tropical Health and Medicine, Stratford, Australia,* [3]*Australian Institute of Tropical Health and Medicine, Cairns, Australia*

Malaria vector surveillance is being increasingly recognized as critical to the success of national malaria control programs. The World Health Organization recently published the objectives for malaria vector surveillance and provided guidance on core vector surveillance activities by transmission scenarios and vector control interventions deployed. Effective programmatic vector surveillance is limited in part by the methods used to quantify vector parameters critical to monitoring the effectiveness of interventions. This presentation is a follow-up to a survey of 35 national

malaria control programs that identified programmatic limitations to vector surveillance. In this study, 40 vector control experts were interviewed to gather expert assessments of the limitations of current vector control techniques and to clarify new ideas to improve vector control. This data was used to define target product profiles of next generation vector surveillance tools to address technical limitations of the presently deployed tools, as well as research requirements to develop and optimize NextGen surveillance tools including algorithms for representative sampling, translation of trap catches to population and epidemiologically relevant parameters and data requirements to improve sampling.

1067

ONE YEAR OF MONITORING PHYSICAL DURABILITY OF LONG LASTING INSECTICIDAL NETS IN MALI

Moussa Bm Cisse[1], Ibrahim Traore[1], Lansana Sangare[1], Abdourhamane Dicko[2], Yacouba Dansoko[1], Alice Dembele[1], Jean Marie Sanou[1], Jean Bedel Evi[3], Jules Mihigo[4], Aliou Diallo[4], Erin Eckert[5], Ousmane Koita[1]

[1]*Laboratoire de Biologie Moléculaire Appliquée/ Université des Sciences Techniques et des Technologies de Bamako, Bamako, Mali,* [2]*Programme National de Lutte contre le Paludisme, Bamako, Mali,* [3]*US Agency for International Development Global Health Supply Chain Program Procurement and Supply Management, Bamako, Mali,* [4]*President's Malaria Initiative US Agency for International Development, Bamako, Mali,* [5]*President's Malaria Initiative US Agency for International Development, Washington, DC, United States*

In 2018, 85% of households owned at least one long lasting insecticide nets (LLIN). In Mali, LLIN are distributed through mass distribution campaigns and through routine health services to pregnant women and infants. Both net durability and the "average useful life" of a net are critical factors for determining the frequency at which nets need to be replaced and the types of nets to be procured. The objectives were to 1) assess the physical durability of polyester LLINs in 2 sites; 2) compare their durability and 3) identify major determinants of field performance after one year of use. The study was carried out after the mass LLIN distribution campaign held in December 2017 in southern Mali. The study was conducted in Kenieba (Site 1) and Kita (Site 2) districts which have similar malaria epidemiology, climatic and socio-ecological profiles. Cohorts of 471 LLINs (75 denier polyester) in Site 1 and 514 (100 denier polyester) in Site 2 were identified for monitoring during the study. Physical durability monitoring was performed by taking into account the net loss rate and the physical condition of surviving nets which was measured by the proportionate hole index (pHI) after one year. After 12 months, 53% (245/465) of the LLIN in Site 1 and 60% (305/511) in Site 2 were present. In Site 1, 17% (77/465) nets were being used elsewhere and 2% (8/511) had been discarded. In Site 2, only 9% (48/514) nets were being used elsewhere. Approximately one quarter of the LLIN had unknown status (nets present but owner absent) 27% (124/461) in Site 1 and 31% (158/511) in Site 2. The all causes attrition rate was approximatively 30% in both sites. Attrition due to wear and tear was less than 2% in Site 1 and was 0% in Site 2 (100% of all the nets were intact). Similarly, the proportion of nets with pHI <64 was lower in Site 1 (66%) than in Site 2 (93%). Tears were the main type of damage, 73% in Site 1 and 34% in Site 2. The proportion of nets surviving in serviceable condition was lower in Site 1 (85%) than in Site 2 (95%; $p = 0.004$). Further analyses are being conducted to identify the reasons for the apparent lower performance of the LLINs in Site 1.

CITIZEN SCIENCE FOR MOSQUITO MONITORING AND MALARIA VECTOR CONTROL IN RUHUHA, RWANDA

Marilyn Milumbu Murindahabi[1], Constantianus J. Koenraadt[2], Willem Takken[2], Leon Mutesa[3], Emmanuel Hakizimana[4], P. Marijn Poortvliet[5], Arnold J.H. van Vliet[6]

[1]*College of Science and Technology, University of Rwanda, Kigali, Rwanda,* [2]*Wageningen University and Research, Wageningen, Netherlands,* [3]*College of Medicine and Health Sciences, University of Rwanda, Kigali, Rwanda,* [4]*Malaria and other Parasitic Diseases Division, Rwanda Biomedical Center, Kigali, Rwanda,* [5]*Strategic Communication Group, Wageningen University & Research, Wageningen, Netherlands,* [6]*Environmental Systems Analysis Group, Wageningen University & Research, Wageningen, Netherlands*

To support the Rwandese mosquito monitoring system, a citizen science approach for mosquito monitoring was implemented in five selected villages from Ruhuha sector in Bugesera district, the eastern province of Rwanda. Ruhuha is known as an agro-ecosystem, in which water irrigation schemes create potential areas for mosquito breeding, and the residents have elevated high risk of contracting malaria infection. In Ruhuha, regular mosquito monitoring programs are established due to limited budgets for mosquito surveillance. The 108 recruited volunteers in this citizen science study were asked to report experienced mosquito nuisance and confirmed malaria cases in their domestic environment. Additionally, the selected volunteers were asked to collect and submit mosquito specimens using passive traps. More than 2,000 mosquitoes were collected in a period of six months, from 2018. The main mosquito specimens submitted were *Culex* species (90%), while the remaining species were *Anopheles* species (10%). From the total *Anopheles* species collected, *Anopheles gambiae* sensu lato (43%) and *Anopheles ziemanni* (45%) specimens were the highest malaria vectors identified in the study area. Both the mosquito nuisance as the numbers of mosquitoes caught varied in space and time. The highest and lowest mosquito nuisance were reported in Kibaza and Kagasera respectively. The highest and the lowest *Anopheles gambiae* s.l. species collected were collected in Kibaza and Kagasera respectively. Ongoing work is validating the citizen science collections with traditional trap collections and aims to assess the links with the numbers of malaria cases reported in the area.

IS FLUDORA FUSION A VIABLE ALTERNATIVE TO DDT?

Rajendra Maharaj[1], Bheki Qwabe[2], Moses Mkhabela[2], Nomfundo Mfeka[3], Melanie Holder[3], Vishan Lakan[1]

[1]*South African Medical Research Council, Durban, South Africa,* [2]*KwaZulu-Natal Department of Health, Jozini, South Africa,* [3]*Bayer, Johannesburg, South Africa*

Indoor residual spraying and insecticide impregnated nets are the main methods of preventing malaria transmission. Considering increasing insecticide resistance, new chemicals that are cost-effective are needed for elimination. Currently the gold standard is DDT, an insecticide that has a long residuality and is affordable to malaria control programmes in Africa. A new insecticide mixture Fludora Fusion, a combination of clothianidin and deltamethrin, has been registered for use in malaria vector control programmes. This combination of active ingredients, with unrelated modes of action, is intended to address the challenge of insecticide resistance in malaria-transmitting mosquitoes. The study was conducted in Othobothini in KwaZulu-Natal on houses with mud, cement and painted walls to determine the suitability of using this new insecticide compared to DDT. For each of the three wall types, the insecticides were evaluated in ten different structures. WHO Cone bioassays were carried out monthly following insecticide application using 3-5-day old, non-blood fed female *Anopheles arabiensis* mosquitoes. On mud surfaces, 100% mortality was achieved after 144 hours post exposure for Fludora Fusion for all months. DDT also produced 100% mortality at the 4-day post exposure evaluation. On cement surfaces, Fludora achieved an average of 97% at 48 hours evaluation for the 12 months of evaluation. An average of 100% mortality

was attained at 120 hours from months 10. DDT also produced 100% mortality at the 72-hour evaluation for all months. On painted surfaces, 100% mortality was reached by the insecticide combination by 120 hours post-exposure. DDT produced 100% mortality at the 96 hours evaluation for all months. Compared to DDT, the mortality achieved with the use of this combination insecticide is excellent. DDT resulted in 100% mortality within 96 hours on mud and 72 hours on cement and paint surfaces. Fludora Fusion also achieved 100 % mortality within 96 hours on mud but required 72 hours to achieve 100% mortality on cement and painted surfaces. Fludora Fusion is a viable alternative to DDT.

1070

VECTOR SURVEILLANCE FOR EVIDENCE-BASED DECISION MAKING IN MALARIA VECTOR CONTROL IN BURUNDI

Virgile Gnanguenon[1], Anatolie Ndashiyimiye[2], Jeanne d'Arc[2], Denis Sinzinkayo[2], Lievin Nsabiyumva[3], Jenny Carlson[4], Aklilu Seyoum[5]

[1]*Abt Associates/PMI AIRS, Bujumbura, Benin,* [2]*NMCP, Bujumbura, Burundi,* [3]*United States Agency for International Development, Bujumbura, Burundi,* [4]*United States Agency for International Development, Washington, DC, United States,* [5]*Abt Associates/PMI VectorLink, Washington, DC, United States*

Malaria is a major public health problem in Burundi with 23 districts experiencing high incidence of the disease. Since 2017, Cankuzo, Gihofi and Kiremba districts were selected for indoor residual spraying (IRS) due to the high malaria incidence. From December 2017 through September 2018, monthly entomological surveys were conducted in eight sentinel sites using human landing catches. Overall, the average human biting rate of *Anopheles gambiae* s.l. was similar indoors (6.61 bites/person/night) and outdoors (9.27 bites/person/night) (p=0.250). For *An. funestus* s.l., the biting activity was also similar indoors (1.88 bites/person/night) and outdoors (1.02 bites/person/night). The lowest indoor biting rate was observed from January to August 2018 in Kiremba, where IRS was implemented in December. The lowest parous rates of *An. gambiae* s.l. were observed at Mabayi (69.12%) and the IRS site of Gihofi (70.54%) while the lowest parous rate of *An. funestus* s.l. was observed at Gihofi (64.06%). The entomological inoculation rates (EIRs) were lower in 2018, compared with 2017 data. However, the highest EIR in 2018, 8.12 infective bites/person/month, was observed in January, whereas the highest EIR in 2017, 31.0 infective bites/person/month, was observed in March. Program data shows that the IRS intervention was implemented late, after the peak of EIRs in Cankuzo and Gihofi, at the end of May and July, respectively, when EIR was low (0-0.6 infective bites/person/month). Therefore, revising the timing of IRS to February could prove more effective. In IRS intervention sites, most of the transmission occurred outdoors. The average infective bites observed indoors was 0.46 infective bites/person/month versus 2.93 infective bites/person/month outdoors. In non-IRS sites, the transmission is more or less similar indoors and outdoors with an average of 0.46 infective bites/person/month versus 0.68 infective bites/person/month, respectively. Additional vector control tools may be required to further reduce the residual transmission occurring outdoors in IRS areas.

1071

DIAGNOSTIC DOSE DETERMINATION AND EFFICACY OF CHLORFENAPYR AND CLOTHIANIDIN INSECTICIDES AGAINST *ANOPHELES* MALARIA VECTOR POPULATIONS OF WESTERN KENYA

Silas Okoth Agumba

Maseno University, Kisumu, Kenya

Malaria vector control is dependent on chemical insecticides applied to walls by indoor residual spraying or to long-lasting insecticidal nets. However, the emergence and spread of insecticide resistance in the major malaria vectors may compromise malaria control and elimination efforts. To maintain gains made in the fight against malaria, it is important to evaluate alternative insecticides for mosquito control. The aim of this study was to estimate a diagnostic dose for chlorfenapyr (class: pyrrole) and clothianidin (class: neonicotinoid) and assess the baseline susceptibility of wild *Anopheles* malaria vectors of western Kenya. Centers for Disease Control and Prevention (CDC) bottle assays were used to determine the diagnostic doses of chlorfenapyr and clothianidin insecticides against a susceptible laboratory strain, *Anopheles gambiae,* Kisumu strain. Probit analysis was used to obtain the lethal doses at which 50% (LD50) and 99% (LD99) of the susceptible mosquitoes would be killed 24, 48 and 72 hours following exposure for 1 hour. Insecticidal efficacy was then evaluated against field collected female *Anopheles* mosquitos sampled from Nyando, Bumula and Ndhiwa sub-Counties in western Kenya. Members of *Anopheles gambiae* and *An. funestus* complexes were identified using polymerase chain reaction (PCR). The determined diagnostic doses of chlorfenapyr and clothianidin insecticides were 50 μg/bottle and 150 μg/bottle respectively for *An. gambiae,* Kisumu strain. When exposed to the diagnostic dose, *Anopheles* malaria vector populations in western Kenya were susceptible with 100% mortality observed after 72 hours. Mortality of mosquitoes exposed to deltamethrin increased over time but did not reach 100%. Mortality of mosquitoes from Nyando exposed to deltamethrin was 83% at 24h, 88% at 48h and 94.5% at 72 h while mortality of mosquitoes from Ndhiwa was 89% at 24h, 91.5% at 48h and 94.5% at 72h. Mosquitoes of western Kenya, despite being resistant to pyrethroids, are susceptible to chlorfenapyr and clothianidin but field evaluations of formulated product are needed.

1072

PROGRESS TOWARD FIELD APPLICATION OF TRANSGENIC MOSQUITOCIDAL ENTOMOPATHOGENIC FUNGI: A SEMI FIELD TRIAL TEST IN A MOSQUITO-SPHERE IN BURKINA FASO

Etienne Bilgo

IRSS/Centre Muraz, Bobo Dioulasso, Burkina Faso

Malaria control efforts require implementation of new technologies that manage insecticide resistance. The fungus, *Metarhizium pingshaense* provides an effective, mosquito-specific delivery system for potent insect selective toxins. Here we report on a semi field trial testing the efficacy of a mosquitocidal *Metarhizium pingshaense* strain (Mp-Hybrid) engineered to express an insect-specific spider neurotoxin called Hybrid (Ca++/K+ channel blocker) and a Green Fluorescent Protein (GFP). The experiments were conducted in a multi-chambered MosquitoSphere constructed for this purpose in Soumousso, a region of Burkina Faso where malaria is endemic. We used the sphere to test a variety of low technology treatment protocols that could be used routinely by householders and found that suspending Metarhizium in locally produced sesame oil and spreading that on netting or black sheets achieves a long term effect in the sphere. Within 2.5 days mosquitoes exposed to Mp-Hybrid were dying faster than those exposed to wild-type virulence expressing Red Fluorescent Protein (Mp-RFP). For infected mosquitoes, median lethal times (LT50) values for Mp-Hybrid and Mp-RFP were 5.19 ± 0.163 and 8.73 ± 0.295 days, respectively. The number of mosquitoes surviving from the uninfected control never dropped below 83.7%. We also demonstrated that Met-Hybrid reduced blood feeding and flight capacity by infected mosquitoes. In addition, Mp-Hybrid infected mosquitoes laid eggs earlier (5.42±0.727 days) compared with Mp-RFP and untreated mosquitoes (6.88±1.40 and 7.02±0.640 days respectively). This is the first evidence that transgene expression can induce an increased terminal investment response, and it could potentially undermine transgenic control approaches by affecting the evolution of infected mosquitoes. Finally, as Mp-Hybrid lasted longer at least 11 weeks than Mp-RFP (4 weeks). This study represents an important step in the progression of transgenic mosquito control technologies into field application.

1073

THE COST-EFFECTIVENESS OF ITN DISTRIBUTION STRATEGIES IN SUB-SAHARAN AFRICA

Sara Scates[1], Olivier Briët[2], Janna Wisniewski[1], Angela Acosta[3], Hannah Koenker[3], Joshua Yukich[1]

[1]*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States,* [2]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [3]*Johns Hopkins Center for Communications Programs, Baltimore, MD, United States*

Insecticide-treated nets (ITNs) are one of the most cost-effective interventions for preventing malaria. WHO recommends both large-scale mass distribution campaigns (MC) in conjunction with continuous distributions (CD) as part of a multifaceted approach to achieve and sustain universal access to and coverage of ITNs. A combination of these strategies has been effective for scaling up net coverage. In order for policy makers to make informed decisions on how to efficiently implement CD strategies, information on the cost effectiveness of these delivery systems is vital. The OpenMalaria platform was used to develop simulations of the health effects of various ITN distribution scenarios and these results were combined with cost results from a systematic review of the literature. Incremental Cost Effectiveness Ratios (ICER) and CE expansion paths were estimated under varying transmission contexts and intervention deployment histories. Initial results demonstrated that ANC and EPI distribution alone is likely to be the most efficient (i.e. lowest cost per case of malaria averted) use of resources for ITN distribution under the most severely resource limited situations. As resource levels increase, some CD systems are expected to perform at similar levels of efficiency to repeated mass campaigns. However, campaigns every three years, without CD, are similarly cost effective in some subset of transmission contexts and vector control histories. Estimates of cost-effectiveness, and the decision rules derived from these, should ideally incorporate uncertainty. We develop a bootstrapping method to estimate the uncertainty around the expansion path for net distribution systems, incorporating uncertainty in both costs and effects.

1074

DECREASING INSECTICIDE-TREATED MOSQUITO NET EFFECTIVENESS ASSOCIATED WITH INCREASING PYRETHROID PREVALENCE ACROSS SUB-SAHARAN AFRICA

David A. Larsen, Rachael Church

Syracuse University, Syracuse, NY, United States

Malaria prevention primarily relies on pyrethroid class of chemicals, through the insecticide-treated mosquito net (ITN). Increasing reports of pyrethroid-resistance in malaria vectors has worried malaria control programs. A few geographically-limited studies have found reduced efficacy of ITNs in areas with established pyrethroid resistance, however no large-scale evaluation of ITNs in the presence of pyrethroid resistance has to date been conducted. We utilized recently published Malaria Atlas Project estimates of pyrethroid resistance across sub-Saharan Africa and nationally-representative two-stage cluster surveys conducted in 2010 or later to estimate the association between ITN ownership and having a *Plasmodium falciparum*infection in the presence of varying levels of pyrethroid resistance. We first extracted levels of pyrethroid resistance to the survey cluster. We second matched households on education, wealth, and region and then utilized mixed effects logistic regression model with the matched group as a random intercept to estimate the association between ITN ownership and a *P. falciparum* infection. We finally tested the model for an interaction between the ITN ownership and estimated pyrethroid resistance. We found that in areas with zero estimated pyrethroid resistance ITN ownership was associated with a reduction in the odds of having a *P. falciparum* infection (odds ratio [OR] = 0.60, 95% confidence interval [CI] = 0.40 - 0.90). In areas with complete pyrethroid resistance, ITN ownership was not associated with the odds of having a *P. falciparum*infection (OR = 1.00, 95% CI = 0.63 - 1.68). These results indicate widespread reductions in the protection provided by ITNs due to pyrethroid resistance.

1075

INSECTICIDE SUSCEPTIBILITY STATUS OF *ANOPHELES GAMBIAE* S.L. AND *AN. FUNESTUS* S.L. TO PUBLIC HEALTH INSECTICIDES FROM SENTINEL SITE SURVEYS IN UGANDA

Michael Okia

Abt Associates Inc., Kampala, Uganda

Insecticide resistance is an increasing threat to the two core vector control interventions in Uganda, indoor residual spraying (IRS) and long lasting insecticide treated nets (LLINs). Using the World Health Organization (WHO) susceptibility test method, we investigated the susceptibility level of *Anopheles gambiae* s.l. to three pyrethroids (alpha-cypermethrin, deltamethrin and permethrin), one organophosphate (pirimiphos-methyl), and one carbamate (bendiocarb) insecticide in 10 sentinel surveillance sites across Uganda in 2018. The susceptibility of the local vectors to clothianidin and chlorfenapyr was also assessed in 14 and 10 sentinel sites (districts), respectively. Oxidase resistance mechanisms were investigated with synergist assays using the World Health Organization (WHO) test protocol with to piperonyl butoxide (PBO). Intensity of resistance was assessed using both the Centers for Disease Control and Prevention (CDC) bottle and WHO tube assay methods. Three to five day-old female *Anopheles* mosquitoes reared from field-collected larvae or indoor-resting adults were morphologically identified and tested. *An. gambiae* s.l. was found generally susceptible (99-100% mortality) to organophosphates, clothianidin and chlorfenapyr. Possible resistance to carbamates was detected in one site, Hoima (97% mortality). Resistance to pyrethroids was widespread with varying exposure mortality ranging from 0% to 85%. *An. funestus* s.l. was found susceptible (99-100% mortality) to pirimiphos-methyl, bendiocarb, chlorfenapyr, and clothianidin in Katakwi and Soroti districts but was found resistant to pyrethroids in Katakwi and Soroti (2-52% mortality). Resistance intensity studies of *An. gambiae* s.l. using the CDC bottle and WHO tube assays provided differing resistance intensities. Pre-exposure of *An. gambiae* s.l. to PBO fully or partially restored susceptibility to pyrethroid insecticides in all test sites. The susceptibility of the two vectors to next-generation insecticides provide alternative insecticide choices for IRS, which can be rotated to help mitigate resistance.

1076

POSITIVE IMPACT OF PIRIMIPHOS-METHYL BASED IRS ON ENTOMOLOGICAL INOCULATION RATE (EIR) IN A CONTEXT OF MULTIPLE RESISTANCE MECHANISMS TO INSECTICIDES IN MALARIA VECTORS IN ALIBORI AND DONGA, TWO REGIONS OF NORTHERN BENIN

Razaki Osse

Cotonou Entomological Research Center, Cotonou, Benin

Widespread resistance to insecticides is a major concern for National Malaria Control Programs (NMCP) as this phenomenon remains a serious handicap for the success of insecticide-based control tools in some areas. In the current study, we investigated the impact of a pirimiphos-methyl based Indoor Residual Spraying (IRS) on EIR in two regions of Northern Benin where *An. gambiae* s.l. populations developed multiple insecticide resistance mechanisms. Entomological monitoring was conducted in five IRS districts in Benin including Kandi-Gogounou in the Alibori region and Djougou-Copargo-Ouake in the Donga region. Two unsprayed districts served as control. In all eight districts, frequencies of *kdr*-w and *Ace1R* and the expression of enzymatic activities compared to *Anopheles gambiae* Kisumu susceptible strain were evaluated. Mosquito collections were also organized before (2016) and after (2017) IRS implementation to assess the Entomological Inoculation Rate (EIR). Before IRS, the resistance frequencies in *An. gambiae* s.l. were between 0.67-0.88 for *kdr-w* and 0-0.06 for *Ace-1R* among sites. After IRS, the resistance frequencies in *An. gambiae*

s.l. were between 0.84-0.92 for *kdr-w* and 0.02-0.04 for *Ace-1R* among sites. Furthermore, the Gogounou district showed high oxidase activity while those of Ouake and Copargo displayed an elevated esterase activity. Both types of enzymatic activities were overexpressed in Djougou and Kandi. Despite these worrying indicators of resistance levels, a significant reduction in EIR was recorded after IRS [20.4 infected bites per person per night pre-IRS compared to 3.1 ib/p/n post-IRS (84.9% reduction, p<0.0001) and 2.3 ib/p/n in IRS districts compared to 13.6 ib/p/n in control districts (83.3% reduction, p<0.0001)]. Overall, our results show that the multiple insecticide resistance mechanisms were not a handicap for the efficacy of the pirimiphos methyl-based IRS on the EIR.

The durability ("average useful life") of long-lasting insecticidal nets (LLIN) varies by brand and country context. This study assesses and compares the physical and insecticidal durability of two LLIN brands (PermaNet 2.0 and DawaPlus 2.0), which are made from polyester fibers treated with deltamethrin. This was a three-year prospective cohort study of LLINs distributed through a mass campaign in 32 villages of Tamu Township, Sagaing Region, in December 2015. Within six months following the mass campaign, a representative sample of campaign nets was identified through a cluster household survey approach to form the study cohort. The attrition and physical conditions of the cohort LLINs were assessed at 6-, 12-, 24-, and 36-month follow-up intervals. Sub-samples of the campaign LLINs were selected for insecticidal effectiveness testing after 12, 24, and 36 months, using cone bio-assays with deltamethrin-susceptible mosquitoes. Insecticide chemical residue was tested after 24 and 36 months. A total 739 campaign LLINs from 300 households were included in the cohort, comprising 398 PermaNet 2.0 and 341 DawaPlus 2.0. Overall attrition of nets during the follow up were 19.9%, 22.0%, 27.8% and 34.2% at 6-, 12-, 24-, and 36-month, respectively. At 36 months, 79.6% of the observed nets had any holes, a marked increase from 15.1% at 6-month, 45% at 12-month, and 63.7% at 24-month. The median proportional hole index (pHI) were 23, 19, 34 and 43 over 4 rounds. There was no significant difference in the nets surviving in serviceable condition between two brands, which was 84.6% (95% CI 76.9-90.1%) for PermaNet 2.0 and 78.2% (95% CI 69.5-84.9%) for DawaPlus 2.0. In cone bio-assays conducted at 36-months, 24-hour mortality was 66.2% (95% CI 60.8-71.6%) and 57.0% (95% CI 51.6-62.4%), resulting in 86.7% of PermaNet 2.0 and 76.7% of DawaPlus 2.0 meeting WHO minimal effectiveness criteria. Deltamethrin chemical residue testing results at 36 months will be available in May 2019. In summary, most of the cohort LLINs nets were still in physically serviceable conditions at 36 months although insecticidal effectiveness had declined.

1078

FIPRONIL AND IVERMECTIN TREATMENT OF CATTLE REDUCES SURVIVAL AND OVARIAN DEVELOPMENT OF FIELD-COLLECTED *ANOPHELES ALBIMANUS* IN NORTHERN BELIZE

Jefferson A. Vaughan[1], Staci M. Dreyer[1], Donovan Leiva[2], Marla Magaña[2], Marie Pott[2], John P. Grieco[3], Nicole L. Achee[3]

[1]*University of North Dakota, Grand Forks, ND, United States,* [2]*Belize Vector and Ecology Center, Orange Walk Town, Belize,* [3]*University of Notre Dame, South Bend, IN, United States*

Most malaria vector control programs rely on indoor residual spraying of insecticides and insecticide-treated bed nets. This is effective against vector species that feed indoors at night and rest inside the house afterwards. In Central America, malaria vectors have different behaviors and are typically exophagic (*i.e.,* bite outdoors), exophilic (*i.e.,* remain outdoors after feeding), and zoophagic (*i.e.,* as likely to feed on non-humans as humans). Thus malaria elimination in Central America may require additional tactics. This pilot study investigated whether commercially-available products used to treat livestock for ticks could also be used to against zoophagic malaria vectors that feed on treated cattle in Belize. Cattle were treated with either a pour-on formulation of 1% fipronil (3 heifers) or injection of 1% ivemectin (1 heifer). Control heifers (n=2) were left untreated. Field-collected *Anopheles albimanus* contained in screen-top cages were strapped onto cattle and allowed to feed for 15 minutes. Mosquito feedings were conducted prior to treatment and at 2, 5, 7, and 14 days after treatment. Mosquito mortality was monitored once a day for 4 successive days. Surviving mosquitoes were dissected and ovarian development assessed. A total of 1,078 female *A. albimanus* mosquitoes were fed and monitored for mortality. Both fipronil and ivermectin significantly reduced survivorship of *A. albimanus* for up to 7 days after treatment. By 14 days, the ivermectin treatment completely lost its effectiveness. Fipronil-treated cattle were still killing significantly more mosquitoes than were untreated cattle but the magnitude of mosquito killing had diminished. Throughout the 14 day trial, both ivermectin and fipronil-treated cattle significantly reduced ovarian development (i.e., fecundity) in those mosquitoes that survived feeding on treated cattle. These results suggest that efforts towards eliminating residual transmission of malaria by zoophagic vectors in Central America may benefit by targeted treatment of livestock with parasiticides, such as fipronil or ivermectin.

ANOPHELES REPRODUCTIVE SWARM TRAPPING AS A POTENTIAL NEW MALARIA VECTOR CONTROL INITIATIVE IN THE GAMBIA

Benoît Sessinou Sessinou Assogba[1], Kevin O. Opondo[1], Musa Jawara[1], Jane Achan Achan[1], Charles Wondji[2], Abdoulaye Diabaté[3], Umberto D'Alessandro D'Alessandro[1]

[1]*MRC, Unit The Gambia at London School of Hygiene & Tropical Medicine, Banjul, Gambia,* [2]*Vector Group, Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*Institut de Recherche en Science de la Santé/ Centre Muraz, Bobodioulasso, Burkina Faso*

Malaria remains a major health problem and its control is currently based mainly on Long Lasting Insecticidal Nets and indoor residual spraying. The contribution of these vector control tools to the observed decline in the malaria burden has been estimated at 79%. However, such gains are threatened by the emergence and spread of insecticide resistance. Alternative vector control tools are thus needed. Targeting Anopheles reproductive behavior and disrupting mating between male and females' mosquitoes may reduce vector density. We investigated how Mass Trapping of Anopheles reproductive swarms (MST) can be used as a community-based approach to reduce malaria transmission. In 2017, we characterized *Anopheles* reproductive swarm's behavior, and the ecological and environmental parameters associated with their formation and spatial distribution in six villages in eastern Gambia. We collected

data on female *Anopheles* density per house, the *Plasmodium* infection rate in *Anopheles* and humans to estimate entomological inoculation rate and malaria prevalence. During the 2018 transmission season, swarms were collected twice per week from previously identified locations. Twenty-three swarming sites of *Anopheles gambiae s.l.* close to human habitats were identified. We collected 36,327 *Anopheles* males from those swarms during the 5-month intervention of MST. Our preliminary results indicate that MST intervention resulted in 90% reduction in vector density, from 53 *Anopheles gambiae s.l.* per house to 3.5. Laboratory analyses to determine the malaria infection rates among vectors and humans are currently ongoing. In conclusion, from these results MST appear to reduce vector density however, its impact in malaria transmission is yet to be determined. If MST intervention proves successful, a larger cluster randomized trial aiming at determining the effect of the intervention over a large population would be needed before considering this intervention as a possible tool for malaria control.

Kertajasa, Kuala Kencana, Papua, Indonesia,* [6]*Vector Borne Disease Sector, Disease Control Division, MOH, Kuala Lumpur, Malaysia,* [7]*Anti Malaria Campaign, Ministry of Health, Colombo, Sri Lanka,* [8]*Department of Entomology, National Institute of Malariology, Parasitology and Entomology (NIMPE), Hanoi, Vietnam,* [9]*Bureau of Vector Borne Disease, Department of Disease Control, MOPH, Bangkok, Thailand*

A knowledge of which vector species are present in a particular area, their abundance, feeding behavior, sporozoite infectivity, and insecticide susceptibility status are critical factors guiding malaria control programs in understanding transmission risk, implementing appropriately targeted vector control actions and monitoring impact of such interventions. A 'proof of concept' study was designed to evaluate the feasibility of replacing the outdoor human landing catch (HLC) with either the human double net trap (HDNT) or the host decoy trap (HDT) for outdoor biting mosquito populations in four Asian countries: Malaysia, Sri Lanka, Thailand and Vietnam. Two study sites, a rural village and a nearby forest settings, were selected in each country. The three outdoor trap methods were used concurrently each night at each study location, with each trap being rotated nightly between three set trapping positions, in a pre-assigned Latin Square Design. Each trap requires a human volunteer to serve as the primary attractant for host-seeking mosquitoes. Volunteers were rotated following the trap rotation to avoid bias. Six replicates, one replication comprising three consecutive nights of collections, were completed in Thailand, where a total of 1,555 mosquitoes were collected including 404 *Anopheles*, of which 396 (98%) *Anopheles* were captured from the forest site, whereas only 8 (2%) were collected from the village. Of forest *Anopheles*, 253 were collected from HLC, representing 63.8% of total forest collections, followed by HDT (73: 18.5%) and HDNT (70: 17.7%). A statistically significant differences in number of collected *Anopheles* was observed between the three trap methods ($P < 0.05$). We conclude that HLC is still the most productive and preferred method to collect outdoor *Anopheles* mosquitoes in Thailand. Species identifications and the outcomes from trials in Malaysia, Sri Lanka and Vietnam will be completed and summarized for presentation. Results will support national malaria programs in their efforts to improve entomological surveillance for evidence-based vector control strategies across APMEN.

ENDEMIC TYPHOID INCIDENCE, KILIMANJARO REGION, TANZANIA, 2007-2018

Elena R. Cutting[1], Deng B. Madut[2], Michael J. Maze[3], Nathaniel H. Kalengo[4], Manuela Carugati[2], Blandina T. Mmbaga[4], Ronald M. Mbwasi[4], Kajiru G. Kilonzo[4], Annette Marandu[5], Calvin Mosha[5], Furaha S. Lyamuya[4], Grace D. Kinabo[4], Anne B. Morrissey[2], Venance P. Maro[4], Matthew P. Rubach[2], John A. Crump[3]

[1]*Duke University School of Medicine, Durham, NC, United States,* [2]*Division of Infectious Diseases and International Health, Department of Medicine, Duke University, Durham, NC, United States,* [3]*Centre for International Health, University of Otago, Dunedin, New Zealand,* [4]*Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania,* [5]*Mawenzi Regional Referral Hospital, Moshi, United Republic of Tanzania*

Recent prospective surveillance studies have demonstrated a moderate to high incidence of typhoid fever in some settings in sub-Saharan Africa. Growing evidence suggests considerable variation in endemic typhoid incidence over time, yet few settings have multiple year incidence estimates to inform investments in typhoid control. We sought to describe a decade of variation in typhoid fever incidence in the Kilimanjaro Region of Tanzania. A case of typhoid fever was defined as a blood culture positive for *Salmonella enterica* serovar Typhi in a febrile person. Cases were identified among febrile patients at two sentinel hospitals during three distinct periods: 2007-08, 2011-14, and 2016-18. To account for under-ascertainment at sentinel facilities, we derived adjustment multipliers from healthcare utilization surveys done in the catchment area of the sentinel hospitals in 2011 and 2018. Confidence intervals (CI) for incidence point estimates were derived using the 95% CI of our observed typhoid fever prevalence, of the healthcare seeking adjustment multiplier, and of published blood culture sensitivity. Of 3,556 participants, 50 typhoid fever cases were identified. Of typhoid cases, 26 (52%) were male and the median (range) age was 22 (<1-60) years; 4 (8%) were aged <5 years and 10 (20%) were aged 5 to 15 years. By time period, 32 (3.7%) of 870 cases enrolled in 2007-08, 15 (0.9%) of 1,753 in 2011-14, and 3 (0.3%) of 935 in 2016-18. Typhoid fever incidence was estimated as 60 (95% CI 15-283), 5 (95% CI 1-48), and 4 (95% CI 1-69) per 100,000 persons in 2007-08, 2011-14, and 2016-18, respectively. There were no deaths among cases. We identified a moderate typhoid incidence point estimate in 2007-08 and low incidence point estimates during later surveillance periods, but with wide and overlapping CIs across study periods. Our data are consistent with evidence that endemic typhoid may vary substantially over time. Multiple year surveillance provides a clearer picture of typhoid incidence than single-year studies and may be warranted in locations making decisions about typhoid conjugate vaccine introduction and other control measures.

Shigella is one of the leading causes of diarrhea associated global morbidity and mortality. A lyophilized strain of *S. sonnei* 53G was produced under current good manufacturing processes (cGMP) and underwent a dose-finding assessment in a Phase 1 Controlled Human Infection Model (CHIM) to determine a dose that would safely induce shigellosis in ≥60% of volunteers. As *Shigella* is an enteric pathogen, characterizing the intestinal mucosal immune response post-infection is important in understanding the development of immunity against subsequent serotype-specific infection. Historically, mucosal immune responses have been measured directly via fecal IgA antibodies, however sample quality is a limiting factor. Antigen-specific IgA antibody responses determined in antibodies in lymphocyte supernatant (ALS) and antibody secreting cell (ASC) assays are also used, however both provide an indirect measurement of the mucosal response as homing patterns of these lymphocytes are unknown. A novel assay has been developed that separates lymphocytes based on the expression of the gut homing integrin, α4β7, allowing for a direct measurement of the mucosal immune response. Frozen peripheral blood mononuclear cells were thawed and magnetically separated into α4β7 positive (+) and negative (-) populations. Purity of cell populations post-separation was verified by flow cytometry and determined to be ≥90%. Both + and - cell populations were cultured *in vitro,* and ALS was collected and tested by ELISA to determine *S. sonnei* specific IgG and IgA endpoint titers. Oral inoculation with *S. sonnei* induced robust antigen-specific α4β7+ ALS IgG and IgA antibody titers, demonstrating that both IgA and IgG secreting B cells are homing to the gut and contributing to the mucosal immune response. A modest systemic immune response was induced post-infection, demonstrated by moderate antigen-specific α4β7- ALS IgG and IgA antibody titers. Finally, α4β7+ antibody titers correlated with multiple disease outcomes including disease severity score, dysentery, and diarrhea severity.

1083

CHILDHOOD STUNTING AND *CAMPYLOBACTER* COLONIZATION IN RURAL ETHIOPIA - FINDINGS FROM FORMATIVE RESEARCH OF THE *CAMPYLOBACTER* GENOMICS AND ENVIRONMENTAL ENTERIC DYSFUNCTION (CAGED) PROJECT

Dehao Chen[1], Sarah McKune[1], Nitya Singh[1], Jemal Y. Hassen[2], Wondwossen Gebreyes[3], Mark Manary[4], Kevin Bardosh[5], Yang Yang[1], Abdulmuen Mohammed[2], Yitagele Terefe[2], Kedir T. Roba[2], Mengistu Ketema[2], Negasi Ameha[2], Nega Assefa[2], Gireesh Rajashekara[3], Loic Deblais[3], Getnet Yimer[3], Isabel Ordiz[4], Nicholas Diaz[1], Arie H. Havelaar[1]

[1]*University of Florida, Gainesville, FL, United States,* [2]*Haramaya University, Dire Dawa, Ethiopia,* [3]*Ohio State University, Columbus, OH, United States,* [4]*Washington University, St. Louis, MO, United States,* [5]*University of Washington, Seattle, WA, United States*

Globally, 25% of children under 5 years of age are stunted, which has negative impacts throughout their life. Animal source foods (ASF) may reduce the risk of stunting. Poultry farming is one possibility for smallholder farmers to meet their household need for ASF. However, children's contact with poultry and their contaminated environments may increase *Campylobacter* exposure and colonization, which has been associated with Environmental Enteric Dysfunction (EED) and stunting. The formative research of the CAGED project includes an investigation of the burden of *Campylobacter* exposure in young children and other risk factors' association with stunting. This research will inform the design of a Cluster Randomized Controlled Trial to evaluate the effectiveness of a nutritional intervention using eggs combined with animal husbandry interventions in reducing exposure of children to animal feces. A cross-sectional study was conducted in Haramaya woreda in rural eastern Ethiopia. 102 children (age range: 360 - 498 days) were randomly selected for participation. Anthropometric measurements, *Campylobacter* colonization, EED biomarkers and questionnaire-based information on demographics, household wealth, hygiene and sanitation, nutrition, and women's empowerment were collected in late 2018. The prevalence of stunting and wasting was 42% (95% CI: 33% - 52%) and 5% (95% CI: 2% - 11%), respectively. A large majority (96%) of women are not empowered, according to the 5 domains of empowerment. Among children sampled, 88% were currently breastfed, and 56% consumed some ASF in the previous 24 hours. 47% and 50% of children had diarrhea and fever in the past 15-days, respectively. 54 of the 102 households kept chickens indoor overnight and only 26 of these households confined them. The prevalence of *Campylobacter* colonization of children by PCR was 78% (95% CI: 69% - 85%). No associations between stunting and potential explanatory variables were found. Despite adequate breastfed practices and some consumption of ASF, we find a high level of stunting, suggesting further investigation into the role of EED and *Campylobacter* infections are warranted.

1084

GENOME-WIDE ASSOCIATION STUDY OF ASTROVIRUS DIARRHEAL INFECTIONS IN BANGLADESHI INFANTS

Laura Chen[1], Rashidul Haque[2], Dylan Duchen[1], Genevieve Wojcik[3], Poonum Korpe[1], Beth Kirkpatrick[4], William A. Petri, Jr[5], Priya Duggal[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Stanford University, Stanford, CA, United States,* [4]*University of Vermont, Burlington, VT, United States,* [5]*University of Virginia, Charlottesville, VA, United States*

Astroviral infections are a common cause of acute nonbacterial gastroenteritis in children globally. However, there is no treatment available for Astrovirus, and huge Astroviridae strain diversity presents a challenge to potential vaccine development. We aimed to identify host genetic risk factors associated with astrovirus disease susceptibility that may explain disease mechanism and vaccine targets. We performed a genome-wide association study of children with and without astrovirus in the first year of life enrolled in PROVIDE or CRYPTO birth cohorts. Cases attributable to astrovirus were defined as diarrheal samples with qPCR Ct values >0 and <30, resulting in 119 cases and 314 controls in PROVIDE and 58 cases and 96 controls in CRYPTO. We independently analyzed each cohort under an additive genetic model in SNPTEST and then meta-analyzed the genome-wide results. A region on chromosome 1 near the *loricrin* gene (*LOR*) was associated with infection. Children with 1 copy of the A allele at SNP rs75437404 were 2x more likely to have an astrovirus diarrheal infection compared to children with the T allele, and this was consistent in both cohorts (meta-analysis p-value = 9.38×10^{-9}). We also identified an association with the *prolactin releasing hormone receptor* gene (*PRLHR*) on chromosome 10. Children with 1 copy of the G allele at SNP rs114810342 were about 3x more likely to have an astrovirus diarrheal infection compared to children with the A allele. We further stratified by WAZ and HAZ to account for any underlying malnutrition, and there were no differences. Loricrin is a major component of cornified cell envelopes. Previous studies suggest its expression in non-keritinizing epithelia represents a protective mechanism of the body. *PRLHR* encodes the receptor for prolactin-releasing peptide, which has been shown in mouse

models to influence feeding patterns and energy balance. This study identified 2 significant host genetic regions that may influence astrovirus infection susceptibility and should be considered in further studies.

1085

TYPHOID OUTBREAKS, 1989-2018: IMPLICATIONS FOR PREVENTION AND CONTROL

Grace D. Appiah[1], Alexandria Chung[2], Adwoa Bentsi-Enchill[3], Sunkyung Kim[1], John A. Crump[4], Vittal Mogasale[5], Rachel B. Slayton[1], Eric D. Mintz[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, Edinburgh, United Kingdom,* [3]*Department of Immunization, Vaccines and Biologicals, World Health Organization, Geneva, Switzerland,* [4]*Division of Infectious Diseases and International Health, Duke University Medical Center; Centre for International Health, University of Otago, Dunedin, New Zealand,* [5]*Policy and Economic Research Department, Development and Delivery Unit, International Vaccine Institute, Seoul, Republic of Korea*

Typhoid fever remains an important public health problem in low- and middle-income countries, with large outbreaks reported from Asia and Africa. While WHO recommends typhoid vaccination for control of confirmed outbreaks, data on the epidemiologic characteristics of typhoid outbreaks have not been reviewed to inform vaccine use in outbreak settings. We conducted a literature review for typhoid outbreaks published since 1989. We recorded cases and case definitions as reported by the authors and used WHO Regions to categorize outbreak locations. We also abstracted data from unpublished field investigation reports to summarize outbreak interventions. We defined multi-drug resistant (MDR) *Salmonella* Typhi strains as resistant to ampicillin, chloramphenicol, and trimethoprim-sulfamethoxazole; extensively drug resistant (XDR) strains were defined as MDR and resistant to fluoroquinolones and third generation cephalosporins. Forty-eight published typhoid outbreaks were reviewed for key outbreak characteristics. There were 37,670 cases in 24 countries from 1989 through 2018. Outbreak characteristics varied considerably by region, with median outbreak size ranging from 12 to 1,101 cases, median duration from 19 to 140 days, and mean case fatality ratio ranging from 0 to 44%. The largest proportion of outbreaks, 12 (25%) each, occurred in the WHO South-East Asia and African Regions. Among 44 outbreaks reporting a mode of disease transmission, 25 (57%) outbreaks were waterborne, 17 (39%) foodborne, and 2 (4%) person-to-person transmission. Among the 35 outbreaks with antimicrobial resistance data, in 25 (71%) *Salmonella* Typhi was resistant to >1 antimicrobial, 17 (49%) had MDR strains and 1 had XDR strains. Our review showed a longer median duration of outbreaks caused by MDR strains (90 days vs 30 days for susceptible strains) although this difference was not statistically significance. Control strategies focused on water, sanitation, and food safety, with vaccine use described in 6 (13%) outbreaks. As typhoid conjugate vaccines become more available, their potential impact and role in outbreak control warrants further evaluation.

REAL CONDITION SIMULATION STUDY ON THE THERMO-STABILITY FOR EUVICHOL-PLUS

Sunmi Han[1], Namseon Beck[1], Yun Chon[1], Yongsoo Chung[1], Julia Lynch[1], Jose Paolo M. Langa[2], Jucunu J. Chitio[2], Seukkeun Choi[3], Youngjin Lee[3]

[1]*International Vaccine Institute, Seoul, Republic of Korea,* [2]*INS Mozambique, Cuamba, Mozambique,* [3]*EuBiologics Co. Ltd., Seoul, Republic of Korea*

With over 30 million doses dispensed from the WHO/Gavi stockpile, Oral Cholera Vaccine (OCV) is a low cost, lifesaving intervention. Easy to administer in a mass vaccination campaign, OCV is recommended as a two dose regimen at 0 and 14 days. Growing evidence shows that OCVs can be safely kept outside the cold chain with considerable potential benefits including cost and manpower savings, prevention of vaccine damage caused by accidental freezing, and most importantly making it easier to reach people living in remote places who would otherwise remain unvaccinated. The study was conducted in Cuamba, Mozambique, as an effort to collect evidence facilitating 'delivery of the vaccine in resource limited settings' in parallel to a real preventive vaccination campaign using the same logistic resources. This 'Real Condition Simulation Study on Thermo-stability of Euvichol-Plus' aimed to verify vaccine potency after exposure to three different temperature conditions during the simulation period of vaccine delivery: 1) delivery in cold chain for the first and the second dose, 2) delivery in cold chain only for the first dose, and 3) outside cold chain for the first and second dose, assuming self-administration strategy for the second dose. The vaccines exposed to the three conditions were collected upon arrival at the beneficiaries and tested for potency using two different methods to assess the antigen content: On-site RDT tests (Crystal® VC Immunochromatographic One Step Rapid Visual Test for Vibrio cholera - Dipstick, ARKRAY Healthcare), and EuBiologics' ELISA potency test. While data from temperature loggers packaged with the vaccines showed the difficulty in temperature control in 'resource limited settings', neither RDT nor ELISA tests showed decrease of vaccine potency in any of simulated conditions. Percent changes of vaccine potency from the product release time were 12.6-14.1% for O1 Inaba, 0.9-4.8% for O1 Ogawa, and 15.2-19.6% for O139, respectively. These results are in line with the previous findings from various OCV stability studies and may support Euvichol-Plus' product quality in extended controlled temperature conditions.

1087

UPDATING OUR UNDERSTANDING OF SEVERE COMPLICATIONS OF TYPHOID FEVER: A CLINICAL STUDY IN BLANTYRE, MALAWI

Jillian S. Gauld[1], Franziska Olgemoeller[2], J.J. Waluza[3], Dalitso Zeka[3], Thomas Edwards[4], Steve Kamiza[3], Chisomo Msefula[3], Angeziwa Chirambo[5], Emma Thomson[3], Tiyamike Chilunjika[6], Jonathan Read[7], Eric Borgstein[3], Peter J. Diggle[7], Nicholas A. Feasey[4]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*Malawi-Liverpool Wellcome Trust Clinical Research Programme, Blantyre, Malawi,* [3]*University of Malawi College of Medicine, Blantyre, Malawi,* [4]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [5]*University of Liverpool, Liverpool, United Kingdom,* [6]*Queen Elizabeth Central Hospital, Blantyre, Malawi,* [7]*Lancaster University, Lancaster, United Kingdom*

Typhoid fever remains a major source of morbidity and mortality in low income settings. Its most feared complication is intestinal perforation. However, due to the paucity of diagnostic facilities in typhoid endemic settings, the etiology of intestinal perforation is frequently assumed, but rarely confirmed. This poses a challenge for accurately estimating mortality and severe complication rates. An epidemic of typhoid began in Blantyre, Malawi in 2011, increasing from approximately 14 cases per year (1998-2010), to more than 700 in 2013, accompanied by an increase in the number of intestinal perforations. We used a Poisson generalized linear model to estimate excess perforations attributed to the typhoid epidemic, using the temporal trend of S. Typhi throughout the epidemic as the predictor. We additionally recruited a longitudinal cohort of patients with confirmed intestinal perforation in 2016, in which enhanced microbiological investigations (blood and tissue culture, plus tissue PCR) were performed. Our model estimates that 1.50 [95% CI:1.15-1.84] intestinal perforations occur each month that are not attributed to typhoid fever, and that culture-confirmed cases of typhoid fever lead to 0.05 excess perforations per clinical typhoid fever case [95% CI:0.03-0.06]. The results from our surgical cohort are consistent with this model: 48% of the patients recruited to the cohort were culture or PCR positive for S. Typhi. For the same recruitment year, 2016, the model estimates that 42% of intestinal perforations were due to typhoid fever. Mortality from S. Typhi-attributed intestinal perforation remains high: 18% of the patients with culture-confirmed typhoid fever in the surgical cohort died. This study offers a valuable model for estimating perforation rates in Blantyre without

direct detection in the clinic, and provides an updated understanding of the rates of severe complications from typhoid fever. Our results help relate changes in typhoid incidence through control efforts to reductions in severe complications, and provide localized evidence to inform global mortality rates.

1088

PREDICTORS OF *SHIGELLA* SEVERITY AND DERIVATION OF A *SHIGELLA*-SEVERITY SCORE IN THE GLOBAL ENTERIC MULTICENTER STUDY

Patricia B. Pavlinac[1], James A. Platts-Mills[2], Jie Liu[2], Kirkby D. Tickell[1], Jane Juma[3], Furqan Kabir[4], Joesph Nkeze[5], Catherine Okoi[6], Darwin Operario[2], Jashim Uddin[7], Shahnawaz Ahmed[7], Pedro Alonso[8], Martin Antonio[6], Stephen M. Shigella is a leading cause of childhood morbidity and mortality and an important vaccine development target. Vesikari score, designed to define severity of rotavirus diarrhea, may not predict severe *Shigella*. Moderate to severe diarrhea (MSD) cases from GEMS with *Shigella* infection identified by either microbiological culture or molecularly at a diarrhea-associated quantity (cycle threshold {CT} <27.9) with known vital status at follow-up were included in this analysis. We derived a severity score based on risk of dying in the 14-days after MSD presentation using forward stepwise Cox proportional hazards regression and Akaike Information Criteria for model-selection. Model performance was compared using the area under the curve (AUC) with bootstrapped standard errors and a chi-square statistic. Among 1,481 *Shigella* MSD cases, 59% were < 24 months of age, 57% had bloody stool, 40% had severe dehydration, and 33% were stunted at MSD presentation. Forty-two (2.8%) *Shigella* MSD cases died over the 60-day follow-up, 22 (52%) of which occurred in the first two weeks after presentation. In univariate models, age < 12 months (hazard ratio {HR}: 3.8, 95% confidence interval {CI}: 1.2-12.0); duration of diarrhea ≥3 days (HR: 5.8, 95% CI: 1.7-19.6); caregiver reported vomiting ≥ 3 times per day (HR: 3.8, 95%CI: 1.6-8.8); severe dehydration (HR: 17.7, 95%CI: 2.4-132.2); stunting (HR: 3.6, 95%CI: 1.5-8.7); and mid-upper arm circumference (MUAC) < 12.5cm (HR: 6.0, 95%CI: 2.4-15.1) were associated with deaths in the first 14-days. The newly derived score, comprised of age, dehydration, diarrhea duration, fever, vomiting, and stunting, performed similarly at predicting 14-day mortality (AUC=.85, 95%CI: 0.76-0.92) to the Vesikari score (AUC=0.79, 95%CI: 0.70-0.87, p= 0.24). When considering deaths after 14-days among 1,459 14-day survivors, the new score performed better (AUC= 0.81, 95%CI: 0.70-0.92) than Vesikari (AUC: 0.67, 95%CI: 0.53-0.81, p=0.0025). Among children with *Shigella*-attributed MSD, Vesikari scores identified those at immediate, but not extended, risk of death.

1089

DISTRIBUTION OF *E. COLI* PATHOTYPES AND THE STRUCTURE OF THE HUMAN GUT MICROBIOME ACROSS AN URBAN-RURAL GRADIENT IN ECUADOR

Karen Levy[1], Maria J. Soto-Girón[2], Lorena Montero[3], Shanon M. Smith[1], Angela Pena-Gonzalez[2], Maritza Paez[3], Estefania Ortega[3], Janet K. Hatt[2], Pablo Endara[3], William Cevallos[4], Gabriel Trueba[3], Konstantinos Konstantinidis[2]

[1]*Emory University, Atlanta, GA, United States,* [2]*Georgia Institute of Technology, Atlanta, GA, United States,* [3]*Universidad San Francisco de Quito, Quito, Ecuador,* [4]*Universidad Central del Ecuador, Quito, Ecuador*

Previous studies have reported lower fecal bacterial diversity in individuals from urban compared to rural settings, which can potentially reduce resistance to enteric pathogen invasion. However, most of these studies compared geographically distant populations. Previous studies of diarrhea etiology have also captured between- but not within-country heterogeneities in enteropathogen prevalence and severity. Focusing on how gut microbial communities and enteric infection rates differ within the same country avoids confounding factors such as different cultural context or diet. We conducted a case-control study of diarrhea to understand how gut microbial communities and enteropathogen infections vary across a rural-urban gradient in four sites in northern Ecuador. Metagenomic analyses revealed small but significant differences in the abundances of several taxa in rural versus urban populations, including higher abundance of *Prevotella* spp. and lower abundance of *Bacteroides* spp. and *Alistipes* spp. Individuals with diarrhea showed greater metagenomic shifts in urban compared to rural individuals in taxon abundance, functional pathways, and taxon-taxon interactions. We also saw variability by site in enteropathogen prevalence and outcomes of infection. Any *E. coli* infection, coinfections, diffuse adherent *E. coli* (DAEC), enteroinvasive *E. coli* (EIEC), and rotavirus were significantly associated with diarrhea. DAEC was more common, and more associated with disease, in urban areas. Enteropathogenic *E. coli* (EPEC) and enterotoxigenic *E. coli* (ETEC) were more common in rural areas. Phylogenetic analysis revealed that associations with disease were not driven by any single clonal complex. Higher levels of antibiotic resistance occurred in rural areas. Collectively, our data suggested that patterns of gut microbial communities, enteropathogen prevalence, virulence, and antibiotic resistance, and microbiota alterations due to diarrhea varied substantially by geography. Our results suggest that control of pathogens in urban areas could be a strategy to control downstream effects on disease in rural areas.

IMMUNE RESPONSE TO ORAL CHOLERA VACCINE IN FORCIBLY DISPLACED MYANMAR NATIONALS IN BANGLADESH

Fahima Chowdhury

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

After the large influx of Rohingya nationals (termed Forcibly Displaced Myanmar National; FDMN) from Rakhine State of Myanmar to Cox's Bazar in Bangladesh, it was apparent that outbreaks of cholera was very likely in this setting where people were living under adverse water and sanitation conditions. Large campaigns of oral cholera vaccine (OCV) were carried out as a preemptive measure to control cholera epidemics. There was no evidence to demonstrate that the vaccine was immunogenic among the FDMN population. The aim of the study was to evaluate the immune responses of healthy adults and children after administration of two doses of OCV and compare with the response of Bangladeshi's vaccinated earlier. A cross-sectional immunogenicity study was conducted among FDMNs of three age cohort; 83 individual in the adult group (18+yrs), 63 in the older children group (6-17 yrs) and 80 in the younger children group (1-5 yrs). Two doses of OCV were given at 14 days interval with collection of capillary blood at three time points to measure the immune responses. We measured vibriocidal antibodies using either plasma or dried blood

spot (DBS) specimens. There was a significant increase of responder frequency of vibriocidal antibody titer at day 14 in all e groups for both *V. cholerae* O1, Ogawa and Inaba (Ogawa/Inaba: adults-64%/64%, older children-70%/89% and younger children-51%/75%). There was no overall difference of vibriocidal antibody titer between FDMN and Bangladeshi population at baseline (p =0.07- 0.08) and at day 14, day 28 in all age groups both for Ogawa and Inaba serotypes. The seroconversion rate and geometric mean titre (GMT) of either serotype were comparable using plasma and dried blood spot (DBS) methods where both specimens were tested. These results showed that oral cholera vaccine is capable of inducing robust immune responses in adults and children among the FDMN population which is comparable to that seen in Bangladeshi participants in different age groups or that reported from other cholera endemic countries and also suggest that the displaced population were exposed to *V. cholerae* prior to seeking shelter in Bangladesh

1091

CHARACTERIZATION OF CHOLERA ANTIGEN-SPECIFIC CELLS IN BLOOD AND MUCOSA

Md Taufiqur R. Bhuiyan

International Centre for Diarrhoeal Disease, Bangladesh, Dhaka, Bangladesh

We characterized the acute B cell responses in peripheral mononuclear cells and in lamina propria lymphocytes in *Vibrio cholerae* O1 infected participants by assessing the phenotypes of different subtypes of B cells. We sorted single plasmablasts, plasma cells and memory cells for generating cholera antigen specific monoclonal antibodies and for making clones of the specific cells. Earlier we have found that the cholera-induced responses were characterized by high levels of somatic hypermutation and large clonal expansions. We compared flow cytometry and nanowell technology first to validate data for this new technology. Comparable frequencies of $CD19^{+}$ B cells have been found by using this technology using epifluorescence microscopy. Then we moved forward with this nanowell technology for characterization and sorting of cholera antigen specific single cell. All the participants had a greater than 4-fold increase in their plasma vibriocidal antibody titer following cholera infection. We found that cholera induced a significant plasmablast ($CD27^{high}$ $CD38^{high}$) expansion in PBMCs at day 7 after cholera infection as compared to other days after cholera infection. However, for lamina propria lymphocytes, we did not observe any differences in the level of plasmablast and plasma cell responses. Meanwhile, we also noticed a significant increase of memory cell responses at convalescence in circulation (day 30) and LPLs (day 360). Using the microengraving technique, we also evaluated OSP and CT specific IgA and IgG isotype specific signals for sorting single antigen specific cells for production of human monoclonal antibodies. This technique appeared to be more advantageous than flow cytometry as we were able to sort both isotype and antigen specific single cell for exploring further details.

1092

ISOLATION OF *SALMONELLA TYPHI* AND *S. PARATYPHI* IN BLOOD AND STOOL FROM THE PATIENTS ENROLLED IN THE PASSIVE SURVEILLANCE IN DHAKA, BANGLADESH

Farhana Khanam

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Enteric fever causes over 21 million cases of febrile illness and 200,000 deaths annually worldwide. Predominantly due to infections caused by *Salmonella typhi* and *S. paratyphi* A. Rate of multidrug resistant (MDR) infections is increasing as well. Currently available data on enteric fever in Bangladesh are limited. As part of the Strategic Typhoid Alliance across Africa and Asia (STRATAA) consortium, a multicomponent study was designed to characterize the burden to generate evidence for implementation of typhoid vaccine in Bangladesh. Following an initial demographic census in Mirpur (wards 3 and 5), Dhaka, a passive surveillance system for typhoid was implemented. The census was updated biannually, with close out census conducted after two years. Passive surveillance was carried out from 21st August 2016 to 20th January 2019. Blood (N=6315) and stool (N=5829) specimens were collected for culture from enrolled patients. Blood was cultured using BacT/Alert automated system. Stool culturing was carried out to isolate *S*. Typhi and *S*. Paratyphi strains. Antimicrobial susceptibility profiles of isolated strains were assessed by disc diffusion method. Resistance pattern was determined as per the CLSI guideline. Baseline census was conducted from June, 2016 to August, 2016 in Mirpur and 110,731 individuals were enumerated in census. We found 385 *S*. Typhi, 100 *S*. Paratyphi A, 01 *S*. Paratyphi B bacteremic patients. Overall incidence of typhoid fever was 164 per 100,000 person-years and the highest incidence was found in children 5-9 years of age group. The incidence of paratyphoid fever is also high. Multi-drug resistance was observed in 38%; reduced susceptibility to ciprofloxacin and azithromycin was seen in 96% and 3% respectively for isolated *S*. Typhi strains from blood. In stool culture, 185 *S*. Typhi, 20 *S*. Paratyphi A and 5 *S*. Paratyphi B strains were isolated from the patients at acute stage of illness, among which 129 *S*. Typhi, 12 *S*. Paratyphi A, and 01 *S*. Paratyphi B were positive for both blood and stool. High disease burden and MDR typhoid fever in this population strongly support introduction of typhoid conjugate vaccine in efforts to control this disease.

1093

SENTINEL SURVEILLANCE FOR CHOLERA AND OTHER ENTERICS IN BANGLADESH: FINDINGS FROM NATIONWIDE HOSPITAL-BASED SURVEILLANCE

Ashraful I. Khan

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

The incidence of diarrhea remains high globally, although mortality has declined but significant morbidity still remains a concern. The objective of this study was to understand the epidemiology and disease burden of cholera and other common bacterial enteric diseases in Bangladesh. A nationwide enteric disease surveillance was initiated in Bangladesh in 2014 to conduct prospective surveillance in all divisions, initially at 10 sites for enteric pathogens (*Vibrio cholerae*, enterotoxigenic *Escherichia coli* (ETEC), *Shigella* and *Salmonella*) in collaboration with the Institute of Epidemiology, Disease Control and Research (IEDCR). From May 2016, surveillance was gradually expanded to an additional 12 health facilities focusing on cholera only. Stool specimens collected from diarrheal patients were transported and tested centrally at icddr,b using culture and PCR methods. Univariate and multivariate analyses were employed to identify risk factors. Of the cumulative 26,090 stool samples tested, 1606 (6.2%) were identified as *V. cholerae*. For ETEC, a total of 15,030 samples were tested and overall 3.1% (n = 463) were ETEC positive. Among 15,031 stool samples tested for *Salmonella* and *Shigella*, overall 2.7% (n=406) were positive for *Salmonella* and 236 (1.6%) were positive for *Shigella*. Along with the bi-annual cholera peak in each year, higher cholera positivity was observed during the post-monsoon season in the western regions, while cholera predominated during the pre-monsoon season in the eastern regions of Bangladesh. The risk of cholera was associated with age, occupation, and recent history of diarrhea inside households. Nationwide surveillance showed the presence of enteric pathogens including cholera in all geographical regions in Bangladesh. The information obtained from the surveillance can be used to plan future strategies for control of enteric diseases including cholera in Bangladesh. The best long-term public health control strategies will be to implement integrated comprehensive multi-sectoral approaches using both vaccination and appropriate water and sanitation interventions.

1094

PLASMA IGA AND IGG RESPONSES AGAINST TWO *SALMONELLA* ANTIGENS IDENTIFY PATIENTS WITH PARATYPHOID A FEVER

Jason Andrews[1], Farhana Khanam[2], Ariana Nodoushani[3], Nazia Rahman[2], Motaher Hossain[2], Isaac Bogoch[4], Krista Vaidya[5], Meagan Kelly[3], Stephen Calderwood[3], Taufiqur Rahman Bhuiyan[2], Edward T. Ryan[3], Firdausi Qadri[2], **Richelle C. Charles**[3]

[1]*Stanford University School of Medicine, Stanford, CA, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Massachusetts General Hospital, Boston, MA, United States,* [4]*University of Toronto, Toronto, ON, Canada,* [5]*Dhulikhel Hospital, Dhulikhel, Nepal*

There is a need for a reliable and simple diagnostic assay for enteric fever. Development of improved diagnostics for enteric fever have been primarily focused on typhoid fever. There are currently no available serologic assays for paratyphoid fever; and development and evaluation of new diagnostic assays for paratyphoid fever have been limited. We have previously demonstrated that assessing plasma IgA responses to HlyE, LPS, and MP are important predictors of acute typhoid infection, even in highly typhoid-endemic areas. Since these antigens are also present in *S*. Paratyphi A (*S*. PTA), we assessed IgA and IgG responses against HlyE, *S.* Typhi and *S*. PTA LPS, and *S.* Typhi MP (membrane preparation) via standard ELISA in plasma drawn on patients presenting with a febrile illness in Bangladesh and Nepal (day 0) who subsequently were determined to have *S*. PTA bacteremia (n=35). We compared these responses to those detected in healthy endemic zone controls in Bangladesh (n=10). Overall, anti- *S*. PTA LPS IgG could distinguish paratyphoid fever from endemic controls (AUC 0.9943; sensitivity of 100%, specificity of 90%). Anti- *S.* Typhi LPS IgG (Typhi shares an O12 antigen with PTA) had an AUC of 0.9886 (sensitivity 97%, specificity 90%). The next best predictors were HlyE IgA and *S*. PTA LPS IgA with an AUC of 0.9286 (sensitivity 94% and 91% respectively; specificity 80%). Our results suggest that development of a diagnostic assay focused on antibody responses against HlyE and LPS would identify patients with acute paratyphoid fever.

1095

PROVIDER ATTITUDES TOWARDS AN ELECTRONIC CLINICAL DECISION SUPPORT TOOL FOR PEDIATRIC DIARRHEA

Joel I. Howard[1], Ben Brintz[1], Adrew Pavia[1], Eric Nelson[2], Adam Aluisio[3], Adam C. Levine[3], Karen Kotloff[4], Daniel Leung[1]

[1]*University of Utah, Salt Lake City, UT, United States,* [2]*University of Florida, Gainesville, FL, United States,* [3]*Brown University, Providence, RI, United States,* [4]*University of Marlyand, Baltimore, MD, United States*

Diarrheal illness is a leading cause of mortality in children under 5 years old in Low and Middle Income Countries (LMICs). While some causes of infectious diarrhea can benefit from specific antimicrobials, in many resource limited settings, testing of stool to determine etiology is not feasible. Clinical decision support tools (CDSTs) are one potential solution to help in the management of diarrhea. These tools can have varying degrees of complexity, and the adoption may vary significantly. There are few data regarding the overall use of CDSTs in LMICs. This study was designed to identify the ability and willingness of healthcare providers to use an electronic CDST for management of diarrhea. We administered a web-based survey through various networks targeted at clinicians in healthcare institutions in LMICs. 39 Healthcare providers from 23 unique institutions representing 9 countries (5 in Africa, 3 in Asia) were identified and data was collected through a brief, anonymous one-time online survey in REDCap. The median age of respondents was 35 years (IQR 32.3-41) and 24 (61.5%) were male. 37 (94.9%) respondents endorsed having access to a smart phone or tablet at work, and 28 (71.8%) use an EMR at their main institution. There was a wide range in testing practices, with a large proportion (18 [46.2%]) reporting testing <4% of the time, while 5 (12.8%) endorsed testing >20% of stools. 19 (48.7%) said they almost never treat, and 30 (76.9%) say they treat <9% of cases. However, 3 respondents endorsed treating more than 50% of cases. Use of CDSTs was high, with 37 (94.8%) endorsing at least some use of a clinical calculator, and 18 (46.2%) using a clinical calculator at least daily. A majority of CDST use was done through a phone (33 [89.2%)]. Importantly, a large majority of respondents (37 [87.2%]) stated that they would be willing to enter 3 or more symptoms into an App and 27 (69.2%) respondents would use an app that predicted the etiology of diarrhea. This study is ongoing. Data from a larger number of respondents, as well as a results from a qualitative survey will be presented.

1096

GEOGRAPHIC INEQUALITY IN CHILDHOOD DIARRHEAL MORBIDITY AND MORTALITY IN LOW-INCOME AND MIDDLE-INCOME COUNTRIES, 2000-2017

Robert C. Reiner, Kirsten Wiens, Aniruddha Deshpande, Paulina Lindstedt, Brigette Blacker, Simon Hay

University of Washington, Seattle, WA, United States

Across low-income and middle-income countries (LMICs), one in ten deaths in children under the age of 5 are attributable to diarrhea, resulting in the loss of more than 530 000 young lives annually. Previous studies have documented substantial country-to-country variation in both diarrhea incidence and mortality. Identifying regions with the highest burden and corresponding risk factors is necessary to reduce the preventable burden of childhood diarrhea. We used Bayesian model-based geostatistics and an extensive geolocated dataset in combination with established methods from the GBD 2017 study to estimate posterior distributions of continuous continent-wide surfaces of diarrhea prevalence, incidence, and mortality. Further, we investigated the drivers of the observed subnational patterns of burden by synthesizing our estimates and similarly created aggregated risk factor estimates. Regions in south and southeast Asia, and South America saw the greatest declines in diarrhea burden. While many children in Sahelian Africa are still at extremely high risk of death due to diarrhea, regions with the most deaths were outside Africa. Indonesia exhibited the greatest relative geographic inequality globally, with some regions nearly four times the country average mortality rate. Some of the highest reductions in mortality were driven by similar reductions in low oral rehydration solution coverage, poor sanitation, or childhood stunting, while most high-risk areas still had substantial mortality attributable to at least one of those three risk factors. By co-analyzing geospatial trends in both diarrheal burden and its key risk factors from 2000 to 2017, we are able to understand the drivers of death reduction in regions that improved. Similarly, by overlaying remaining burdens with these same risk factors, we can identify optimal intervention strategies for vulnerable populations. Given the competing demands and limited resources in many LMICs, accurate quantification of both the burden of diarrhea and its drivers are critical for precision public health.

1097

GEOGRAPHICAL DISTRIBUTION OF HUMAN LEPTOSPIROSIS INCIDENCE IN THE UPPER YANGTZE AND PEARL RIVER BASIN, CHINA: TOOLS TO SUPPORT SURVEILLANCE AND FOCUSED INTERVENTION

Pandji W. Dhewantara[1], Abdullah A. Mamun[2], Wenyi Zhang[3], Danhuai Guo[4], Wenbiao Hu[5], Wenwu Yin[6], Fan Ding[6], Ricardo J. Magalhaes[1]

[1]*School of Veterinary Science, The University of Queensland, Gatton, Australia,* [2]*Institute for Social Science Research, The University of Queensland, Brisbane, Australia,* [3]*Center for Disease Surveillance and Research, Institute of Disease Control and Prevention of PLA, Beijing, China,* [4]*Scientific Data Center, Computer Network Information Center, Chinese Academy of Sciences, Beijing, China,* [5]*School of Public Health and Social Work, Queensland University of Technology, Brisbane, Australia,* [6]*Chinese Center for Disease Control and Prevention, Beijing, China*

The incidence of leptospirosis in China remained steady at low-level since 2011 nearing elimination. Residual hotspots of leptospirosis are

still exist mainly in southwest along Upper Yangtze and south China along Pearl River basin. To help guide health authorities to identify areas where interventions should be improved, this study was carried out to quantify the effect of environment and socioeconomic factors on the spatial distribution of leptospirosis incidence and to develop predictive maps of leptospirosis incidence for the Upper Yangtze and Pearl River basin. Data on human leptospirosis reported during 2005-2016 across the two regions were geolocated at the county-level and included in the analysis. Bayesian zero-inflated Poisson conditional autoregression (CAR) models were developed incorporating environmental and socioeconomic data such as precipitation, normalized difference vegetation index (NDVI), normalized difference water index (NDWI), land surface temperature (LST), elevation, slope, land cover, crop production, livestock density, gross domestic product (GDP) and population density. The effect of environmental and socioeconomic variables was heterogeneous between regions. After adjusting the effect of environment and socioeconomic factors, the distribution of the high incidence areas is more widespread both in the Upper Yangtze and Pearl River region. In the Upper Yangtze, the highest predicted incidence was found along the border of Chongqing and Guizhou towards Sichuan basin and northwest Yunnan. The highest predicted incidence was also identified in counties in the middle and lower reaches of the Pearl River. This study demonstrated significant geographical heterogeneity in leptospirosis incidence within the Upper Yangtze and Pearl River basin. The surveillance and control strategies should be improved and extended towards counties adjacent to the high-incidence counties. In addition, public health interventions should be targeted on the population at-risk on the areas where incidence is predicted to be high.

1098

A STUDY ON THE SPLEEN MICROBIOME OF WILD RODENTS AND SHREWS CAUGHT IN MARIGAT COUNTY, KENYA

Rehema M. Liyai[1], Clement Masakhwe[2], Gathii Kimita[2], David O. Miruka[1], John N. Waitumbi[2]

[1]*Maseno University, kisumu, Kenya,* [2]*United States Army Medical Research Directorate, Kenya, kisumu, Kenya*

There is a global increase in emerging infectious diseases, with 13% of over 1400 known human pathogens being classified as emerging or re-emerging. Majority of the emerging pathogens cause zoonoses and wild mammals are reservoirs. This study used 16S rRNA metagenomics to evaluate the diversity of bacteria pathogens hosted by wild caught rodents and shrews. 54 small mammals were trapped from different sites in Marigat, Baringo County, Kenya. Taxonomy of the small mammals was confirmed by amplification of cytochrome B (*Cytb*) and cytochrome oxidase subunit 1 (*COI*) genes. Genomic DNA was extracted from the spleen biopsy samples and the V3-V4 regions of the 16S rRNA amplified by PCR. The generated amplicon were sequenced on the Illumina MiSeq to identify the diversity of bacteria community. Sequence data was analyzed with Mothur v1.35, queried against the Silver database and visualized on R. By molecular taxonomy, the small mammals were classified as 41 rodents and 13 shrews. In total, 175,629 sequences passed the$^{i\ ise}$t quality controls and classed into 987 (N) operational taxonomic units (OTUs) that mapped to 18 bacteria phyla, with *Proteobacteria* accounting for 55% (538/N), *Actinobacteria* 22% (220/N), *Firmicutes* 12% (114/N) and *bacteriodates* 5% (54/N). These 4 phyla accounted for 94% of the total OTUs. Of the remaining 6%, the phyla *Acidobacteria* and *Verrucomicrobia* were the most dominant. We identified 213 bacterial genera. On a heat map, *Bartonella* sequences predominated and accounted for 38% of the reads. There was no other dominant bacteria in the remaining 62% of the reads and were contributed by *Anaplasma*, *Methylobacterium, Coxiella*, *Salmonella, acinetobacter, Elrichia*, *Delftia*, *Rickettsia,* and *Brucella* among others. In conclusion, this study identified about 1000 distinct bacteria OTUs in the spleen of wild small mammals. Future studies will need to perform advanced characterization to identify the bacteria species.

1099

EXPRESSION OF VIRULENCE GENES ASSOCIATED WITH PHYLOGROUPS IN VAGINAL STRAINS OF *ESCHERICHIA COLI*

Eric Monroy[1], Gloria Luz Paniagua Contreras[1], Areli Bautista Cerón[1], Nancy Nolasco Alonso[2], Susana González Almazán[1], Ma. Patricia Sánchez Yáñez[1]

[1]*Universidad Nacional Autónoma de México, Estado de México, Mexico,* [2]*Instituto Mexicano del Seguro Social, Estado de México, Mexico*

The pathogenicity of *Escherichia coli* strains that cause cervico-vaginal infections (CVI) is due to the presence of several virulence genes. The objective of this study is to determine the expression patterns of virulence genes associated with antibiotic resistance genes and phylogenetic groups in cervico-vaginal *E. coli* (CVEC) strains. A total of 200 *E. coli* strains isolated from Mexican women with CVI from two medical units of the Mexican Institute of Social Security were analysed. *E. coli* strains and antibiotic resistance genes were identified using conventional polymerase chain reaction (PCR), and phylogenetic groups were identified using multiplex PCR. Virulence gene expression was measured through real-time PCR after infection of the vaginal cell line A431.The most common antibiotic resistance genes among the CVEC strains were *aac(3)II*, *TEM*, *dfrA1*, *sul1*, and *qnrA*. The predominant phylogroup was B2. The genes most frequently expressed in these strains were *fimH*, *papC*, *irp2*, *iroN*, *kpsMTII*, *cnf1*, and *ompT*. A total of 134 expression patterns of virulence genes were associated with antibiotic resistance genes and phylogenetic groups in CVEC strains. The genetic diversity of CVEC strains was high. These strains have a large number of expression patterns of virulence genes, and one-third of them carry three to seven antibiotic resistance genes.

1100

MOLECULAR CHARACTERIZATION OF PLASMID MEDIATED PENICILLIN AND TETRACYCLINE RESISTANCE IN *NEISSERIA GONORRHOEAE* ISOLATES RECOVERED FROM KENYA BETWEEN 2013 AND 2018

Mary Wandia Kivata[1], Margaret Mbuchi Mbuchi[2], Fredrick Lunyagi Eyase[2], Wallace Dimbuson Bulimo[2], Cecilia Katunge Kyanya[2], Valerie Oundo[2], Willy Sang[2], Wilton Mwema Mbinda[1], Ben Andagalu[2], Olusegun O. Soge[3], R. Scott McClelland[3], John Distelhorst[2]

[1]*Karatina University, Karatina, Kenya,* [2]*US Army Medical Research Directorate-Africa, Nairobi, Kenya,* [3]*University of Washington, Departments of Global Health and Medicine, Washington, WA, United States*

Emergence of high level gonococcal penicillin and tetracycline resistance is mediated by plasmid-borne genes. Knowledge of plasmid types and plasmid-borne resistance genes in gonococci is useful in monitoring spread of antibiotic resistance. To our knowledge, no report exists on plasmid types and genes mediating penicillin and tetracycline resistance in Kenyan gonococci. We investigated plasmid mediated resistance in *Neisseria gonorrhoeae* (GC) isolates recovered from four locations in Kenya. Plasmid and genomic DNA were extracted from 37 sub-cultured multidrug resistant GC isolates. Whole genomes were sequenced using Illumina platform. Reads were assembled *de novo* using CLC Genomics Workbench. Assembled sequences were mapped to FA 1090 reference and unmapped contigs searched against the NCBI database. Genome annotation was performed using Rapid Annotation using Subsystem Technology and Geneious Prime 2019. Susceptibility results were interpreted with reference to European Committee on Antimicrobial Susceptibility Testing standards. Twenty four (64.9%) isolates had both β-lactamase (TEM) and class M tetracycline resistance determinant (TetM) encoding plasmids whereas 8.1% isolates lacked either of the plasmids. TEM encoding plasmids were identified in 27 isolates, of which 26 had a backbone corresponding to that of African plasmid (pDJ5) while only 1 had a backbone corresponding to that of Asian plasmid (pDJ4). Of the 37 isolates, 31 (83.8%) had TetM encoding plasmids, 30 of which had American TetM determinants, whereas 1 had a Dutch TetM determinant. 88.9% isolates harboring

TEM encoding plasmids were penicillin resistant. All isolates with TetM determinants were tetracycline resistant and had increased doxycycline MICs. All analyzed isolates had non mosaic PenA mutations and S10 V57M mutation. High penicillin and tetracycline resistance in the analyzed GC isolates is mediated by plasmid-borne *blaTEM,* and *tetM* genes. An Asian TEM plasmid type and a Dutch TetM determinant which are less described in African gonococci were detected in Kenyan GC. The African TEM plasmid type, TEM1 and American TetM were most prevalent.

A COMPARISON BETWEEN IGM-ELISA AND IGM RAPID IMMUNOCHROMATOGRAPHY TEST IN THE DIAGNOSIS OF LEPTOSPIROSIS DURING THE ACUTE PHASE OF ILLNESS IN SOUTHERN SRI LANKA

Weerasinghe M. D. G. B. Wijayaratne[1], Champika K. Bodinayake[1], L. Gayani Tillekeratne[2], Wasantha KodikaraArachchi[3], Vasantha Devasiri[1], Truls Ostbye[2], Ruvini P. Kurukulasooriya[1], Nishantha Gunasekara[1], Megen Reller[2], Chris W. Woods[2], Ajith Nagahawatte[1]

[1]*University of Ruhuna, Galle, Sri Lanka,* [2]*Duke University, Durham, NC, United States,* [3]*Teaching Hospital Karapitiya, Galle, Sri Lanka*

Leptospirosis is diagnosed on clinical grounds and confirmed by the immunological gold standard, microscopic agglutination testing (MAT). Leptospira IgM enzyme-linked immunosorbent assay (ELISA) has been shown to be more sensitive than MAT when performed during the acute phase of illness. This study assesses the usefulness of two immunodiagnostic assays, the IgM-ELISA (Serion-Virion) and rapid immunochromatography test (Leptocheck-WB), in the diagnosis of leptospirosis in the acute phase of illness in a cohort of clinically diagnosed leptospirosis patients. Both tests were performed on acute phase serum of 170 patients with clinically diagnosed leptospirosis (per modified WHO definition) admitted to the Teaching Hospital Karapitiya, Sri Lanka. Positive, indeterminate and negative anti-leptospiral IgM cutoff titers of IgM-ELISA were>20 IU/ml, 15-20 IU/ml and <15 IU/ml, respectively. Appearance of bands in both control and test windows were considered as positive for Leptocheck-WB test. The test positivity of IgM-ELISA and Leptocheck-WB during the acute phase of the illness were 51.18% (87/170) and 47.65% (81/170), respectively. When compared to IgM-ELISA, the sensitivity, specificity, positive predictive value and negative predictive value of Leptocheck-WB were 86.21%, 93.24%, 93.75% and 85.19%, respectively. Acute-phase IgM-ELISA and Leptocheck-WB had a Kappa coefficient of 0.789 indicating a good agreement between the two test results. Only 54.7% of clinically diagnosed patients were confirmed by any of the two methods during the acute stage. The results conclude that both IgM-ELISA and Leptocheck-WB were effective in the diagnosis of leptospirosis during the acute phase of the illness. Leptocheck-WB is a rapid and easy-to-use alternative that is as effective as IgM-ELISA for the diagnosis of acute leptospirosis.

DIARRHEAL ENTERIC PATHOGENS ASSOCIATED WITH PEDIATRIC LINEAR GROWTH FALTERING: A SYSTEMATIC REVIEW OF THE LITERATURE

Caroline Zellmer, Shrish Budree, Majdi Osman, Pratik Panchal

OpenBiome, Cambridge, MA, United States

Acute diarrhea is a leading global cause of death in children under five. However, we are only scratching the surface on the true morbidity of diarrheal disease. Recent studies like GEMS and MAL-ED identified six of the most common causes of acute pediatric diarrhea: *Norovirus*, *Rotavirus*, *Campylobacter*, *Shigella*, *Cryptosporidium*, and *Astrovirus*. Linear growth faltering has been correlated to diarrhea, and we wanted to collate the available evidence to assess how this understanding has evolved with modern diagnostic and genomic capabilities. We conducted a systematic review to determine the association of these specific enteric pathogen diarrhea with linear growth outcomes in children. This query identified 404 unique papers from nine databases (Medline, Embase, Cochrane database of systematic reviews, Web of Science and regional databases including IMSEAR, AIM, LILACS, IMEMR, WPRIM). These databases were searched from inception to 05/18/2018 and were not limited by English language requirement. Papers were included if they described a pediatric population, mentioned the diarrhea etiology and were conducted in a low or middle income country. Data was extracted from 46 papers. Study quality was assessed as per PRISMA guidelines using the QUADAS II score. 36.9% (17/46) papers were located in Asia, 23.9% (11/46) were conducted in Africa and 19.6% were completed in South America, with six conducted across multiple, cross continental sites. All but eight (17.4%) studies took place in at least one rural setting. Study sample sizes ranged from 20 to 83,073 children. The most commonly evaluated pathogen considered within the context of linear growth faltering was *Cryptosporidium* (with 22/46 studies including it in the analysis). *Shigella* (45.7% of studies) and *Rotavirus* (26.1% of studies) were the next most frequent. Asymptomatic carriers were noted in 43.4% of papers. This review is unique as it collates all current evidence of key pathogen linkage to stunting. Next steps are to meta-analyze the effects and the strength of the association.

1103

NATIONWIDE SEROPREVALENCE OF LEPTOSPIROSIS AMONG YOUNG THAI MEN, 2012

Siriphan Gonwong, Thippawan Chuenchitra, Patchariya Khantapura, Dilara Islam, Nattaya Ruamsap, John M. Crawford, James W. Jones

Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand

Leptospirosis, a global neglected zoonotic disease, is an important public health problem in Thailand. Leptospirosis is caused by a Gram-negative spirochete belonging to the genus Leptospira. Humans and animals are infected with Leptospira through direct contact with the urine of an infected animal or indirectly through environmental contamination such as soil and water. Due to its nonspecific symptoms, lack of laboratory confirmation, and underreporting contribute Leptospirosis' status as a neglected disease. To better understand the distribution of leptospirosis exposure in Thailand, a retrospective leptospirosis seroprevalence study was conducted on repository serum specimens obtained from young Thai men entering the Royal Thai Army during 2012 (n = 6,627) by using ELISA. The overall nationwide leptospirosis IgG seroprevalence among these young Thai men was 18% (95% confidence interval = 17-19%) and the range by region was 15-25% confirming leptospirosis as an endemic disease throughout Thailand. Group of individual with the lowest education, living in rural areas and working in agriculture had the highest leptospirosis seroprevalence. The highest seroprevalence was in the South region contrary to current morbidity reports supporting poor clinical diagnosis of leptospirosis in Thailand especially in the South region as has been reported. This nationwide distributed seroprevalence data of leptospirosis raise concerns regarding implementing public health interventions such as improved reporting and surveillance, better access to diagnostic tools for enhanced disease awareness, and effective public health education and awareness to prevent this disease.

1104

EVALUATION OF DIAGNOSTIC TESTS FOR HUMAN LEPTOSPIROSIS IN DIFFERENT STAGES OF THE DISEASE

Virginia C. Rodríguez, Ronald Soto, Ana M. Castro, Alfonso Calderón, Maria F. Yasnot

Universidad de Córdoba, Monteria, Colombia

Leptospirosis is the world's most important zoonotic disease, although there is limited knowledge due to the lack of data in the clinical identification, diagnosis, treatment and surveillance processes. A prospective, descriptive study was conducted to evaluate four diagnostic tests on humans with leptospirosis in different stages of the disease. By a convenience sampling were evalauted 118 patients with clinical

symptoms of leptospirosis. These patients signed a consent form and were requested to fill out an epidemiological record. Serum, blood and urine samples were obtained from these patients in the acute and convalescent phase. Microagglutination (MAT), IgM antibody by ELISA screening, immunochromatographies (Leptocheck WB) and polymerase chain reaction (PCR) were conducted in the acute phase. MAT, IgM antibody by ELISA screening, and immunochromatographies were performed in the convalescence phase. Positive and negative predictive values, Kappa coefficient, sensitivity and specificity were calculated taking into account the final MAT as a reference point. During the acute phase, the MAT had 58,8% and 100% of respectively. When comparing with the MAT, ELISA and Leptocheck WB had identical sensitivities (64.7%) and similar specificities (95, 8% -95%), respectively. The predictive values of the tests were variable. The majority of the evaluated tests increased their sensitivity and specificity during the convalescence phase. The consistency between ELISA and MAT was considerable in both phases. A positive PCR in blood or urine increased the probability that the patient was ill. The increase of positive results in the convalescence phase was demonstrated in a similar way for the ELISA and Leptocheck WB serological tests. Paired samples of MAT will behave as the best confirmatory test for leptospirosis. The PCR allowed the diagnosis of acute phase leptospirosis. IgM ELISA is a valid option for diagnosis in the acute phase of the disease, but its results should be confirmed by MAT. The Leptocheck WB can serve as a screening option in places with difficult geographic access.

1105

BORDERLINE METHICILLIN RESISTANT *STAPHYLOCOCCUS AUREUS,* AN UNDERAPPRECIATED AND EMERGING PUBLIC HEALTH THREAT

Rebecca S. Fischer[1], Naledi Mannathoko[2], Heather T. Essigmann[3], Oluwakemi D. Alonge[1], Eric L. Brown[3]

[1]*Texas A&M University Health Science Center, College Station, TX, United States,* [2]*University of Botswana, Gaborone, Botswana,* [3]*The University of Texas Health Science Center, Houston, TX, United States*

Asymptomatic carriage of *Staphylococcus aureus*, an opportunistic pathogen of major medical importance worldwide, is a primary risk factor for infection and an important source of transmission. Understanding characteristics of *S. aureus* circulating in a community can guide clinical awareness (e.g. most likely disease manifestations) and management (e.g. effective antibiotics). The global spread of methicillin-resistance (MRSA) has received important attention; rare but increasing reports of borderline-resistant (BORSA) strains, which hyperproduce β-lactamase and respond incompletely to standard therapy, highlight it as an emerging public health threat. As part of a carriage study in Botswana, nasal swabs from HIV+ and HIV- outpatients in 2013 revealed a 39.3% carriage prevalence. We further characterized 499 *S. aureus* isolates, recovered from the 225 carriers (90.2% adult; 80.2% HIV+), by oxacillin E-test for MRSA, 18 antibiotics by disc diffusion, and *spa* sequence typing (Ridom) for strain lineage. MRSA was rare (4.6%; 23 isolates), but highly-resistant (4 isolates), MDR (15 isolates), and 25 (5.0%) isolates of BORSA were observed; only 90.4% of *S. aureus* was MSSA. Cefoxitin disk had low sensitivity to detect MRSA and failed to detect BORSA. Resistance was low to TMP-SXT (11%) but high to cloxacillin (87%). Isolates were from 77 *spa* types and 20 clonal complexes [mainly t891 (8%) and CC45 (20%)], as well as 15 novel *spa* types and 55 isolates that were 'non-typable' by the standard method. Several clinically important findings emerged:(1) both MRSA and BORSA are circulating in the community; (2) cloxacillin as empiric therapy requires reconsideration; and (3) Cefoxitin for MRSA detection was inadequate. This investigation of molecular and epidemiologic features of *S. aureus* in Botswana documents BORSA for the first time in this part of the world, as well as novel and nontypable *S. aureus*. Local understanding of epidemiologic and other characteristics of *S. aureus* can inform clinical guidelines and practices, judicious antibiotic prescribing, and interventions to prevent spread.

1106

A RARE COMPLICATED CASE OF PRIMARY PARIETAL PLEURAL HYDATID CYST RUPTURE; INVASIVE IN MULTIPLE ORGAN SITE

Giovanna F. Ramirez-Barbieri[1], Yurydia Jorge[2], Marcel C. Casasola Medrano[3], Jesus Garcia-Pinzas[4]

[1]*Beth Israel Deaconess Medical Center, Boston, MA, United States,* [2]*MedSpan Associates Inc. New York University Langone Hospital, Brooklyn, NY, United States,* [3]*Mount Auburn Hospital, Cambridge, MA, United States,* [4]*National Hospital Cayetano Heredia, Lima, Peru*

Echinococcosis Cyst an endemic parasitic infestation caused by *Echinococcus granulosus*. In humans can develop one or more hydatid cysts; common location is liver and lungs. The incubation period can last many years until hydatid cysts grow to the extent that triggers clinical signs. Primary pleural is a rare variant, and its complication of rupture consequently invade other organs. We will report this untypical case. A 55-year-old, male, comes to the hospital in Lima, Peru, with one year of intermittent left side dull chest pain with non-radiation and persistent chronic dry cough. Patient refers diagnostic of empyema with thoracentesis four years ago. On current evaluation emergency chest x-ray and CT-scan was performed; showing multi-cystic masses in both hemithorax with significant predominance on the left hemithorax and abdominal organs. Surgical Intervention was indicated and during resection, confirmed multiple hydatid cyst invasion on the interior surface of the parietal pleura chest wall and other abdomen organs. There were no complications in the postoperative period and before patient discharge a chest x-ray was performed with complete eradication of hydatid cyst. Albendazole was started 400mg/day oral to continue postoperative prophylactic measure to prevent recurrence. Early diagnosis of the hydatid cysts is difficult because of the long latency period between exposure and manifestation of the disease. We consider chest x-ray and CT-scan are essential tools for efficacy and follow-up treatment management. The involvement of hydatid disease could be seen as a uniloculated or multiloculated cyst with a thin or thick wall as we see in this patient; however, may see a solid mass which is difficult to differentiate from other tumors or diseases. The primary treatment is surgical excision and the use of albendazole in the preoperative and postoperative. Pleural echinococcosis is rare. A high index of clinical suspicion is necessary for an accurate diagnostic to avoid complications. Surgery is the primary intervention with adjuvant treatment of albendazole.

1107

QUALITY OF LIFE IN PATIENTS WITH SYMPTOMATIC EPILEPSY DUE TO NEUROCYSTICERCOSIS

Willy R. Zapata[1], **Javier A. Bustos**[2], Isidro Gonzales[1], Herbert Saavedra[1], Hector H. Garcia[2], for the Cysticercosis Working Group in Peru .[2]

[1]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru*

Neurocysticercosis (NCC) is the most common cause of late-onset epilepsy in the world, but there is minimal information on its impact in patient's quality of life. The present study evaluated quality of life using the QOLIE (Quality of Life in Epilepsy)-31 scale in a series of patients with symptomatic epilepsy due to neurocysticercosis (NCC). Cross-sectional study of 155 patients 16-70 years of age with symptomatic epilepsy due to intraparenchymal NCC with viable cysts treated at the National Institute of Neurological Sciences (INCN) during the period 2006-2011 were applied the QOLIE-31 quality of life scale before receiving antiparasitic treatment. The number of epileptic seizures was recorded and grouped into categories. Bivariate analysis was performed using the Kruskal-Wallis test and multivariate analysis using a generalized linear model (GLM). The average quality of life score was 55.8 (SD ± 7.6), with 119 individuals (76.8%) qualifying as having poor quality of life. On bivariate analysis, a greater number of GTC or secondarily generalized epileptic seizures showed statistically significant association with a lower score in the quality

of life. The level of education showed a value of p=0.05. Other covariates such as sex, age, antiepileptic medication, number of parasitic cysts, and number of compromised brain regions did not show a significant association with quality of life. On multivariate analysis, a greater number of generalized epileptic seizures (GTC or secondarily generalized) maintained a statistically significant association with a detrimental quality of life score. Neurocysticercosis carries a significant impact in the quality of life of affected individuals. The number of prior generalized epileptic seizures was associated with deterioration in the quality of life in patients with symptomatic epilepsy due to intraparenchymal NCC.

1108

SEIZURE RELAPSE IN CALCIFIED NEUROCYSTICERCOSIS AFTER ANTIEPILEPTIC TREATMENT WITHDRAWAL

Javier A. Bustos[1], Gianfranco Arroyo[1], Isidro Gonzales[2], Herbert Saavedra[2], Armando Gonzalez[1], Robert H. Gilman[3], Hector H. Garcia[1], for the Cysticercosis Working Group in Peru .[4]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [3]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [4]*Universidad Peruana cayetano Heredia, Lima, Peru*

Neurocysticercosis is the infection of the human central nervous system by the cystic larval stage of the tapeworm *Taenia solium.* As part of their natural life cycle or subsequent to antiparasitic treatment, brain cysts degenerate and resolve, either disappearing or leaving a small calcified lesion. Factors that increase the risk of seizure relapse after antiepileptic dug (AED) withdrawal in calcified NCC are poorly known. This study involves the participation of patients who withdrew AED treatment. In the parent cohort, participants had a detailed history and clinical examination. During the follow-up, the study team carefully recorded dates and characteristics of seizure episodes, periods seizure-free, and day and reason of AED discontinuation. Patients were monitored by telephone every two weeks and also asked to attend a clinical visit at the study site every three months and instructed to immediately report to the study team any event compatible with a seizure. The study physician and neurologist confirmed the information and classified seizures according to the ILAE guidelines. Sixty three participants who withdrew AED were included in this sub-study. Their mean age was 38 (SD: 13.1) years and there were similar proportions of males (49%) and females (51%). Along a median follow up of 18.5 months, 18 (28.6%) patients presented seizure relapses. The incidence rate was 15 events per 1,000 patient-months with a cumulative survival incidence of 57.0% [95% IC 41.4%-78.4%] along a maximum of 53 months of follow-up. A cox regression model shows that having more than two years free of seizures is the main protective factor (HR 0.13 95% IC 0.03-0.57 p= 0.007), and having a history of 10 or more seizures (HR 3.6 95% IC 1.22-10.63 p= 0.02) represents an important risk factor for seizure relapse. Patients with more than two years without epilepsy and a history of 10 or more seizure are in a higher risk of having a seizure relapse when AED are withdrawn and should be kept under AED.

1109

HEPATITIS E AS AN UNRECOGNIZED CAUSE OF MISCATALOGED DRUG-INDUCED LIVER INJURY IN NEUROCYSTICERCOSIS PATIENTS DURING TREATMENT

Jesus T. Abanto[1], Arantxa Sanchez[1], Javier A. Bustos[1], Isidro Gonzales[2], Yesenia Castillo[1], Richard G. Madden[3], Harry R. Dalton[3], Hector H. Garcia[1], for the Cysticercosis Working Group in Peru Lima - Peru[1]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [3]*Royal Cornwall Hospital and European Centre for Environment and Human Health, University of Exeter Medical School, Truro, United Kingdom*

Hepatitis E virus (HEV) is the most common agent of liver infection worldwide and a growing cause of liver enzyme elevation initially miscataloged as drug induced liver injury (DILI). Although this infection is usually subclinical, some factors such as immunosuppression, age and pregnancy may condition to a more severe presentation. It has multiple transmission pathways that includes but are not limited to fecal-oral transmission and pork consumption which are shared with *Taenia solium* infection. This leads us to believe that there could be a relationship between these two infections with emphasis in those patients that presented with DILI during NCC treatment. In this study we determined the HEV serological status of neurocysticercosis (NCC) patients that received antiparasitic treatment compared to non-NCC neurological patients and healthy rural villagers by ELISA. We found that 23.8% of NCC patients had positive IgG serology for HEV. Both non-NCC neurological patients and healthy rural villagers showed similar and lower frequencies compared to the NCC patients (14.6%- p=0.046 and 14.4% - p=0.040 respectively). We also found difference in IgG ELISA ratios were higher in patients who already had liver enzyme elevation before starting NCC treatment compared to those that elevated after starting treatment. Healthy rural villagers also showed higher IgG ELISA ratios compared to non-NCC neurological patients. There was no difference in liver enzyme values according to HEV serological status in NCC patients. These findings suggest that HEV is a common entity that should be studied in cases of DILI in Peru and that the common transmission pathways with *Taenia solium* may play a role in its association with NCC. Both infections are closely related to sanitation and are endemic in poor settings. High IgG ELISA ratios in healthy rural villagers may also suggest a higher exposure in settings with poor access to sanitation.

1110

EVALUATION OF MICROGLIAL ACTIVATION AND NEURONAL DAMAGE IN THE CALCIFICATION PROCESS IN PIGS WITH NEUROCYSTICERCOSIS

Laura E. Baquedano Santana[1], Javier A. Bustos[2], Gianfranco Arroyo[1], Noemi Miranda[1], Armando E. Gonzalez[3], Robert Gilman[4], Hector H. Garcia[2]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [3]*Universidad Nacional Mayor de San Marcos, Lima, Peru,* [4]*Johns Hopkins University, Baltimore, MD, United States*

Neurocysticercosis NCC is a parasitic disease caused by the *Taenia solium* larval stage (cyst) in the central nervous system. It is the main cause of acquired epilepsy in endemic countries. Calcifications produced by this disease are associated with seizure in 20% of patients. The aim of this study was to evaluate the neuropathological findings of calcifications in the brain of pigs with NCC. We used 15 pigs naturally infected with *T. solium*and they received antiparasitic treatment. Then, were sacrificed 5 pigs at 4, 8 and 12 months post-treatment. Brains were perfused, removed and fixated in paraformaldehide. Samples were included in paraffin, sectioned and stained. Hematoxylin-Eosinand Masson's Trichrome were used to determinate the response inflammatory. Also, we use Von Kossa and Alizarin red stain to describe the presence of calcium deposits. Immunohistochemistry studies were evaluated with Anti-Iba1 (AB5076 polyclonal antibody; 1:400) and Anti-Neurofilament (NF) (monoclonal antibody, 2F11 clone; Dako). The pigs with NCC had a response inflammatory significant at different times after treatment. We found differences in collagen scarring, microglial reactivity, calcium accumulation and axonal damage in the classic morphological appearance of traumatic axonal injury in the three experimental groups. Histological examination showed in the group of 8 months a significant agglutination of calcium and the immunoreactivity was detected with high intensity around the parenchymal cyst. Our data provide novel insight into relationship between neuronal damage, microglial reactivity and the progression of calcification of the neurocysticercosis on the research of antiparasitic treatments.

1111

A CASE SERIES OF AN EXTENDED COURSE OF IRON TREATMENT FOR PRESUMPTIVE IRON-DEFICIENCY ANEMIA IN CHILDREN

John D. McLennan[1], Maria Mosquea[2]

[1]*Children's Hospital of Eastern Ontario - Research Institute, Ottawa, ON, Canada,* [2]*Servicio Nacional de Salud, Santo Domingo, Dominican Republic*

Childhood anemia is prevalent worldwide, particularly in low- and middle-income countries. Whereas iron-deficiency is known to be the most common etiological factor, optimal duration of iron treatment for iron-deficiency anemia in children is unknown. Whether greater resolution of anemia would be attained by extending the duration of iron treatment for those who do not fully recover with a standard 12-week course of iron treatment is unknown. This study examined the extent of hemoglobin (Hb) change in a cohort of anemic children who received a second course of iron treatment for persistent anemia in a low-income setting in the Dominican Republic. Data were available from a cohort of young children identified with anemia (Hb<11.0g/dl) within a well-baby clinic who had been offered two courses of iron treatment (using liquid ferrous sulfate) as they demonstrated persistent anemia after the first course. Analysis of data from 42 children (52.4% male; mean age at first Hb: 15.5 [SD 6.4] months) found minimal Hb increases after both the first and second 12-week courses of ≥3mg/kg/day of elemental iron, with mean Hb increases of 0.14 (SD 1.06) and 0.13 (SD 1.14) g/dl, respectively. A "probable iron deficient anemia" subgroup (n=22) defined as Hb≤10.0g/dl and Red Cell Distribution Width >15% had larger, though still modest, mean Hb increases, 0.40 (SD 1.16) and 0.50 (SD 1.36) g/dl, respectively. Extended iron treatment may have a role for those with "probable iron deficiency anemia" who have had an inadequate response to a standard course of treatment, however, other factors that may have accounted for the improvement over time in this subgroup in this study cohort cannot be ruled out. Controlled studies assessing different durations of iron treatment with more definitely defined iron-deficiency anemia samples are required.

1112

MORE THAN JUST A SIGN: THOMAS WINTERBOTTOM IN WEST AFRICA AT THE TURN OF THE 19TH CENTURY

David Adams, Valerie Adams

Point University, Midway, GA, United States

Thomas Winterbottom is perhaps best known for the eponymous Winterbottom's Sign. His travels in West Africa in the late 18th and early 19th century, however, are important for more than the bump that now bears his name. Indeed, his accounts of his journeys suggest an astute observer of cultures that bore little resemblance to his own. This presentation, based on Winterbottom's first-hand accounts and contemporary publications, will examine two aspects of his work. First, it will discuss its important medical aspect and, second, it will discuss his appreciation of foreign mores that he could have easily classified as alien and, perhaps, savage. Indeed, Thomas Winterbottom, the physician-anthropologist, was indeed a man ahead of his time.

1113

OXYGEN AVAILABILITY ON PEDIATRIC INPATIENT WARDS IN UGANDA AND EASTERN DEMOCRATIC REPUBLIC OF THE CONGO

Christopher E. Clarke[1], Robert O. Opoka[2], Namasopo Sophie[3], Kasereka Masumbuko Claude[4], Yiming Huang[1], Qaasim Mian[1], Michael Hawkes[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Makerere University, Kampala, Uganda,* [3]*Kabale Regional Referral Hospital, Kabale, Uganda,* [4]*Université Catholique du Graben, Butembo, Democratic Republic of the Congo*

Pneumonia is the leading cause of child mortality globally. Oxygen therapy is a vital component of treatment of pediatric pneumonia but is not available in many resource-limited settings. Previous studies have demonstrated that oxygen concentrators powered by solar panels are an effective alternative to oxygen cylinders in reducing mortality and recovery time among children with pneumonia. To determine if a gap in oxygen therapy exists, and the potential scalability of solar powered oxygen delivery in Uganda and Eastern Democratic Republic of Congo (DRC), we conducted a cross-sectional survey of oxygen delivery capabilities of pediatric wards at 55 district hospitals and health centers (39 in Uganda and 16 in the DRC). Between July 2017 and July 2018, we visited 55 health facilities in Uganda and Eastern DRC with inpatient pediatric services. While cylinder oxygen was available at 24/55 (44%) of sites, dedicated cylinders were not available on the pediatric wards of any health facility. Oxygen concentrators were present at 48 (87%) of sites. Of these, 37 concentrators (86%) were operational. Of these, only 18 (58%) produced oxygen with ≥ 80% purity. Additionally, only 23% of sites had oxygen concentrators available on pediatric wards. 39/54 (72%) of sites reported that power outages were frequent. While 49/55 (89%) of sites had generators available, only 9/49(18%) turned them on when children needed oxygen. Because electricity is necessary to run oxygen concentrators, this suggested that access to a reliable power source is a major obstacle in delivering oxygen therapy. Overall, only 28/55 (51%) of sites had oxygen available for pediatric use. These findings suggest that a high proportion of health facilities that treat children do not have reliable access to therapeutic oxygen. Solar powered oxygen delivery, generated autonomously on-site, may be a viable alternative.

1114

THE BURDEN OF SCABIES AND BACTERIAL SKIN INFECTIONS IN FIJI

Li Jun Thean[1], Lucia Romani[2], Aalisha Sahukhan[3], Mike Kama[4], Meciusela Tuicakau[4], Rachel Devi[5], Joseph Kado[6], Daniel Engelman[1], Natalie Carvalho[7], Adam Jenney[8], Handan Wand[9], Margot Whitfeld[9], Ross Andrews[10], John Kaldor[2], Andrew Steer[1]

[1]*Murdoch Children's Research Institute, Melbourne, Australia,* [2]*Kirby Institute, Sydney, Australia,* [3]*Fiji Centre of Communicable Disease Control, Suva, Fiji,* [4]*Twomey Hospital, Suva, Fiji,* [5]*Ministry of Health and Medical Services, Suva, Fiji,* [6]*Fiji National University, Suva, Fiji,* [7]*University of Melbourne, Melbourne, Australia,* [8]*Alfred Health, Melbourne, Australia,* [9]*University of New South Wales, Sydney, Australia,* [10]*Menzies School of Health Research, Brisbane, Australia*

Scabies in Fiji is highly endemic with a national prevalence of 23.6%. Scabies predisposes its host to impetigo which can progress to cellulitis, abscesses and more severe skin infections. Control of these complications and systemic bacterial diseases is a key motivation for scabies control, but there are few population-based data on their incidence in scabies endemic settings. In the context of a planned scabies intervention program, we conducted surveillance for hospital admissions and primary care presentations for scabies and bacterial skin infections in the Northern Division of Fiji (population 131,918). Surveillance for hospital admissions with skin or soft tissue infection was conducted at Labasa Hospital, the divisional referral centre. In addition, a monthly reporting system for scabies and bacterial skin infections was established at all primary health

facilities in the Northern Division. During the first 24 weeks of surveillance, which commenced in July 2018, there were 364 hospital admissions for skin and soft tissue infections (crude annual incidence 598 per 100,000 population). Incidence was highest in the 0-4 year age group (923 per 100,000). Of all admissions, 53.8% were male and median age was 31.6 years. The mean length of stay was 7.2 days and 65.9% required surgery. In the same period primary health facilities treated 5048 individual presentations for scabies or skin infections (annual incidence 8654 per 100,000), including 2736 (54.1%) for abscess, 1542 (29.2%) scabies, 1147 (22.7%) impetigo, 131 (2.6%) cellulitis and 46 (0.9%) severe skin infections. Of the impetigo cases, 47.3% also had scabies. Together, the hospital and primary care data demonstrate the huge inpatient and primary health burden of scabies and bacterial skin infections in this low resource setting. The annual incidence of hospital admissions for skin and soft tissue infection is demonstrably higher than that of neighbouring high-income countries (Australia has a crude incidence of 62 per 100,000). The proportion of these infections that are attributable to scabies, and therefore likely to be responsive to scabies control, remains to be established.

1115

THE EPIDEMIOLOGY AND CLINICAL FEATURES OF MELIOIDOSIS IN LAO PDR: A 17-YEAR PROSPECTIVE HOSPITAL BASED STUDY

Manophab Luangraj

Mahosot Hospital, Vientiane, Lao People's Democratic Republic

Burkholderia pseudomallei (*Bps*), an environmental Gram negative bacillus, is known to be present in soil and water in Lao PDR (Laos). The first case of melioidosis in Laos was diagnosed in 1999 by the Microbiology Laboratory of Mahosot Hospital. Since then, the number of cases diagnosed there has increased year by year. Tha aim was to review the epidemiology and clinical aspects of cases of culture-positive melioidosis diagnosed by the Microbiology Laboratory of Mahosot Hospital between 1999 and 2016. 1088 cases of melioidosis were identified during the study period. As elsewhere, the majority of the cases presented in the rainy season. Cases originated from every province in Laos except Luang Namtha, although the majority were from Vientiane Capital and Vientiane Province, the main catchment area for Mahosot Hospital. Ages ranged from 1 to 95 years (median 43 years). 639 (59%) were male. 314 (39.1% of adult cases) were rice farmers. The majority (987; 90.7%) presented with acute illness. 432 (39.7%) of patients were known to have underlying diabetes and a further 84 (7.7%) were diagnosed as diabetic during admission. Other underlying conditions included chronic kidney disease (67; 6.2%), kidney stones (62; 5.7%), steroid use (32; 2.9%), blood diseases (26; 2.4%) and joint diseases (16; 1.5%). More than half of the cases (602; 55.3%) had disseminated infection: 550 (50.5%) were bacteraemic, 401 (36.8%) had pulmonary involvement, 302 (27.8%) had cutaneous infection, and parotitis was present in 149 (52.5% of children). Liver and splenic abscesses were detected in 53 (4.8%) and 80 (7.4%) respectively. Joint involvement occurred 84 (7.7%), lymphadenitis in 66 (6%) and prostatic abscesses were only detected 8 (1.6% of adult male patients). There were also single cases of brain abscess and pericardial infection. The overall mortality was surprisingly low (288; 26.4%). In conclusion. this study confirms that Laos is highly endemic for Melioidosis. It is likely that the diagnosis is still being missed in much of the country.

1116

THE ETIOLOGY, NEUROIMAGING AND NEURODEVELOPMENTAL OUTCOME OF SEVERE FEBRILE ENCEPHALOPATHY IN MALAWIAN CHILDREN

Stephen TJ Ray[1], Charlotte Fuller[1], Elisabeth Stockdale[1], Reena Dwivedi[2], Karen Chetcuti[1], Christopher Moxon[3], Terrie Taylor[4], Yamikani Chimalizeni[4], Michael J. Griffiths[5], Karl B. Seydel[4]

[1]*Malawi-Liverpool-Wellcome Trust, Blantyre, Malawi,* [2]*Department of Neuroradiology, Salford Royal NHS Foundation Trust, Salford, United Kingdom,* [3]*Wellcome Centre for Molecular Parasitology, Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom,* [4]*Blantyre Malaria Project, Blantyre, Malawi,* [5]*Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom*

Febrile coma in children is a common presentation in sub-Saharan Africa. Historically, the majority of cases were attributed to cerebral malaria (CM), but with the recent drastic reduction in malaria incidence, non-malarial coma is a larger proportion, and determining the etiologies is often diagnostically challenging, particularly in resource-limited settings. Our aims were to (1) determine the etiology of febrile coma in Malawian children (2) determine if non-malarial coma has a higher mortality and/or morbidity than CM. This prospective case-cohort study, in Blantyre, Malawi, has been recruiting for 13 months. Subjects are febrile children aged 3 months to 14 years in deep coma (Blantyre coma score ≤2). We are investigating etiology via routine culture, PCR and metagenomic NGS on blood & CSF, assessing host response (RNA signatures/proteomics) and performing acute MRI and EEG. Detailed neuro-developmental outcomes are assessed 1 and 6 months post-discharge using locally validated tools. To date, we have recruited 128 participants (75 CM controls (59%) and 53 non-malarial cases (41%)). Non-malarial etiologies include 17 (13.2%) cases of acute bacterial meningitis, 7 (5.4%) encephalitides, 5 (3.9%) TB meningitis, 2 (1.6%) acute viral meningitis, 9 with an immediate post malaria neurological syndrome (7.0%) and 10 (7.8%) unknown encephalopathies. Of the 35 non-malarial cases who underwent MRI, 27 (77%) had informative CNS abnormalities, including rare diagnoses e.g. diffuse neurocysticercosis and ADEM secondary to *Salmonella typhi*. Mortality is higher in the non-malarial group (30% vs 12%), as are neurodisabilities ([median] moderate vs mild neurodisability), while developmental delays are comparable (46.8% vs 45.2%). Malaria remains the most common cause of coma in our setting, however non-malarial coma contributed more to the burden of mortality and morbidity. By using molecular diagnostics and neuroimaging, we were able to increase the syndromic classification of non-malarial coma from 7% to 64%. More detailed diagnostic characterization (NGS, transcriptomic, proteomic) of these cases and controls is underway.

1117

A NOVEL METHOD FOR ASSESSING THE CASE DEFINITION SENSITIVITY, SPECIFICITY AND OVERLAP BETWEEN CO-CIRCULATING INFECTIOUS DISEASES APPLIED TO DENGUE, CHIKUNGUNYA AND ZIKA

Laurel M. MacMillan[1], Corey B. Meyer[1], Mikaela A. Finnegan[1], Gautham Venugopalan[1], Landy T. Sun[1], Yaritbel Torres-Mendoza[2], Dianet Giraldo[1], Emily Billings[1], Shawn S. Jackson[1], Ana B. Gorini da Veiga[3], Gerardo Chowell[4], Neeraj Mistry[5], Margaret A. Rush[1]

[1]*Gryphon Scientific, Takoma Park, MD, United States,* [2]*University of Georgia College of Veterinary Medicine, Athens, GA, United States,* [3]*Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil,* [4]*School of Public Health, Georgia State University, Atlanta, GA, United States,* [5]*Department of International Health, Georgetown University, Washington, DC, United States*

Disease case definitions are used by public health professionals and medical practitioners to classify and diagnose illness in patients. Traditional methods for evaluating case definitions, which assess accuracy in differentiating between diseased and healthy populations, may not reflect real-world performance when multiple diseases with similar clinical presentations are co-circulating. To address this gap, we developed a novel method and metrics for evaluating multiple disease case definitions in tandem and piloted these methods by evaluating the performance of surveillance case definitions for dengue (DEN), chikungunya (CHIKV), and Zika (ZIK) used in the Americas. We estimated the prevalence of symptoms in each disease from clinical data, then used those data to simulate large patient populations for each disease. We classified each simulated patient by comparing their symptom profiles to DEN, CHIKV, and ZIK case definitions developed by WHO, the US, and several countries in the

Americas. Using these classified populations, we estimated the sensitivity and specificity of each case definition, as well as the overlap between case definitions developed by the same source (i.e., fraction of patients classified as having more than one disease). We found that DEN case definitions showed the highest sensitivity (range: 80%-97%), while CHIKV case definitions were less sensitive and more variable (range: 38%-84%). ZIK definitions showed the most variability in sensitivity (range: 14%-98%). Case definition specificity was low in all cases (DEN, 1%-18%; ZIK, 0.3%-64%; and CHIKV, 10%-50%). The percentage of patients classified as having more than one disease ranged from 67%-97% (DEN), 38%-86% (CHIKV), and 12%-84% (ZIK) indicating significant overlap between case definitions that may reduce the accuracy of surveillance. These methods and metrics can be applied to other sets of similar, co-circulating diseases such as tick-borne diseases or respiratory illnesses to better understand case definition performance and develop a foundation for using machine learning optimization methods to improve case definitions.

1118

EPIDEMIOLOGY AND OUTCOMES ASSOCIATED WITH FEBRILE ILLNESS DURING DEPLOYMENT AND TRAVEL

Tahaniyat Lalani[1], Kalyani Telu[1], Gregory Utz[2], Anjali Kunz[3], Drake H. Tilley[2], Heather Yun[4], Charla Geist[5], Christa Eickhoff[6], Jamie Fraser[1], Indrani Mitra[1], David Tribble[1]

[1]*Infectious Disease Clinical Research Program, Rockville, MD, United States,* [2]*Naval Medical Center San Diego, San Diego, CA, United States,* [3]*Madigan Army Medical Center, Tachoma, WA, United States,* [4]*Joint Base San Antonio, San Antonio, TX, United States,* [5]*Landstuhl Regional Medical Center, Landstuhl, Germany,* [6]*Naval Medical Center Portsmouth, Portsmouth, VA, United States*

The epidemiology of deployment and travel related febrile illness is relevant to travel medicine, global health and Force Health Protection. Several cohorts have evaluated febrile illnesses in travelers seeking medical care, but these studies underestimate the incidence and impact of common and/or self-limited febrile illnesses during travel. We evaluated the risk factors, syndromic profiles and outcomes of illnesses associated with a subjective fever in a prospective cohort of travelers and deployed military personnel, enrolled between 2010 and 2018 (TravMil). Subjects traveled to regions outside of the continental United States, Western or Northern Europe, Canada or New Zealand and completed a survey upon return. Poisson regression models with robust error variance were used to estimate the relative risk (RR) of a febrile illness. Of the 3938 adults enrolled pre-travel, 3089 (78%) completed a survey: 1660 (54%) travelers and 1429 (46%) deployed personnel. The incidence of febrile illness was 7.7% (n=239; 5.93 per 100 person-months; 95% CI: 5.18-6.68) with the following syndromes: febrile respiratory illness (35%), febrile diarrheal illness (32%) undifferentiated febrile illness (i.e. not associated with diarrhea or a respiratory infection - 19%). 14% reported more than 1 febrile illness. Travel duration > 10 days (RR: 1.68 [95% CI: 1.03-2.74]), partial or non-compliance with malaria chemoprophylaxis (RR: 1.38 [95% CI: 1.02-1.87]), fresh water exposure (RR: 1.47 [95% CI: 1.08-2.00]) and consuming food from street vendors (RR: 1.26 [95% CI: 0.92-1.70]) were associated with a febrile illness. The median duration of incapacitation was 2 days (IQR 1-4 days), and 24% (57/239) reported seeking medical care. Risk factors and incidence of febrile illness syndromes varied by region of travel. There was no significant difference in the duration of incapacitation or proportion of subjects seeking care by febrile syndrome or geographic region. The syndromic profile of febrile illness varies by geographic region and other risk factors and can inform strategies to reduce the burden of deployment and travel-related febrile illness.

1119

DETERMINANTS OF INAPPROPRIATE ANTIBIOTICS USE IN RURAL CENTRAL GHANA: A MIXED METHODS APPROACH

Samuel Afari-Asiedu[1], Ellen Boamah-Kaali[1], Martha Ali Abdulai[1], Stephaney Gyaase[1], Felix Boakye Oppong[1], Alma Tostmann[2], Marlies Hulscher[2], Kwaku Poku Asante[1], Heiman Wertheim[2]

[1]*Kintampo Health Research Centre/Ghana Health Service, Kintampo, Ghana,* [2]*Radboud University Medical Center, Nijmegen, Netherlands*

The consequences of antibiotic resistance is projected to be high due to inappropriate use in developing countries. This study examined determinants of inappropriate antibiotic use at the community level in rural Ghana. Inappropriate antibiotic use include taking antibiotic without prescription, not completing treatment and noncompliance with instructions for use. A mixed methods study was conducted among community members in Kintampo Districts of Ghana from July 2016 to September, 2018. Initial 16 In-depth Interviews (IDI) and 6 Focus Group Discussions (FGD) were conducted. Results from the IDI and FGD were used to design surveys, involving two contacts (6 month apart) with 1,100 randomly selected households over one year. The survey focused on antibiotic use in the past 1 month before the interview. Additional 4 IDI and 2 FGD were performed to explain the survey results. Qualitative data were coded with Nvivo 10 and thematically analyzed. Determinants of inappropriate antibiotic use were determined by chi-square test and multivariate logistic regression analysis. A total of 1,100 households were contacted and antibiotic use were identified in 585 (53.18%) households in the one year period. From these 585 households, 676/3193 (21.17%) members used antibiotics for 761 disease episodes. Of the 761 antibiotic use episodes, 659 (86.60 %) were used inappropriately. Overall, 489 (64.26 %) used antibiotics without prescription, 345 (45.34%) did not complete treatment and 336 (44.15%) did not follow instruction for use. Socioeconomic status, place of residence, paying for healthcare with national health insurance (OR: 0.26, 95% CI: 0.10-0.68), obtaining medicines from the pharmacy (OR: 0.24, 95% CI: 0.10-1.60) and drug peddlers and cost of antibiotics were predictors of inappropriate antibiotic use. The high inappropriate antibiotic use was influenced by socioeconomic status, place of residence, acquiring antibiotics from pharmacy and drug peddlers, paying for healthcare with national health insurance and cost of antibiotics. Continuous public health education on appropriate antibiotic access and use in rural settings is required.

SCALING UP THE USE OF HEAD START IN NIGER: EVALUATION AND RE-TRAINING OF 133 TRICHIASIS SURGEONS

Chano Hamiden[1], Mahamane Abdou[1], **Hadiara Adamou**[2], Kadri Boubacar[1], Tchouloum Toudja[2], Youssouf Yayé[2], Josette Vignon[2], Abdou Amza[1], Amy Veinoglou[3], Yaobi Zhang[4]

[1]*National Eye Health Program, Ministry of Health, Niamey, Niger,* [2]*Helen Keller International, Niamey, Niger,* [3]*Helen Keller International, New York, NY, United States,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Providing quality surgical services to trichiasis (TT) patients is one of the critical components in achieving trachoma elimination. Niger adopted the use of the HEAD START surgical mannequin in 2016 to improve TT surgeons' operating skills and ultimately increase the quality of TT surgeries. An evaluation conducted in 2016 in the Maradi region highlighted the advantages of using HEAD START for training of both new and experienced TT surgeons who were already trained in the TRABUT method. Between January and July 2018, the majority of surgeons in five regions of Niger (Diffa, Dosso, Tahoua, Maradi and Zinder) were re-trained using HEAD START and their skills evaluated by a master trainer. Each surgeon first conducted surgery on a human eyelid under the observation of the master trainer during a regularly scheduled TT surgery campaign. The HEAD START mannequin was then used to correct any deficiencies noted during the surgery and before the next operation on a human

eyelid. Following capacity building with HEAD START, the master trainer ranked surgeons' skills, assigning a score varying from 1 to 5 to each trainee according to a surgical skills evaluation sheet. Eleven skills were evaluated, ranging from the use of sterile gloves to the correctness of the incision and suturing. Each surgeons' final score was the average combined score for all 11 skills, with a score of 3-5 considered acceptable. A total of 133 surgeons were evaluated (6 in Diffa, 8 in Dosso, 6 in Tahoua, 41 in Maradi and 72 in Zinder region). Of these, 108 (81%) had a score greater than or equal to 3 (acceptable), and 25 (19%) had a score less than 3 (unacceptable); these 25 surgeons are targeted for further re-training. These results validate the use of HEAD START as a training tool to improve the skills of experienced TT surgeons and ultimately enhance the acceptability of surgery by TT patients and communities.

1121

RISK FACTORS ASSOCIATED WITH INCREASED MORTALITY FROM INTUSSUSCEPTION IN AFRICAN INFANTS

Talia Pindyck, Umesh Parashar, Jason Mwenda, Jacqueline Tate

Centers for Disease Control and Prevention, Atlanta, GA, United States

Intussusception, or the invagination of one segment of the intestine within another segment, has been associated with rotavirus vaccination in high- and middle- income countries. Because mortality from intussusception is higher in Africa than in other regions of the world, we examined potential risk factors to help inform the implementation of rotavirus vaccines in the region. Infants with intussusception from 7 sub-Saharan African countries (Ethiopia, Ghana, Kenya, Malawi, Tanzania, Zambia, and Zimbabwe) were enrolled through active, hospital-based surveillance from February 2012 to December 2016. We examined demographic, clinical, and socioeconomic factors associated with death or intestinal resection following intussusception, using multivariable logistic regression. A total of 1020 infants <1 year of age with intussusception were enrolled. Overall, 13% of children (133/1020) died during the hospitalization, and 48% (467/969) required intestinal resection. The median duration of symptoms prior to hospitalization at the sentinel facility was 3 days (interquartile range: 1-4), and the median duration of symptoms prior to hospitalization at any hospital was 2 days (interquartile range: 0-3). In multivariable analyses, female sex (OR 1.8, 95% CI 1.2-3), longer duration of symptoms prior to presentation (OR 1.1; 95% CI 1.0-1.2), and undergoing intestinal resection (OR 3.3; 95% CI 1.9-5.9) predicted death after intussusception. Radiologic diagnosis (OR 0.4; 95% CI 0.3-0.7), presence of electricity at home (OR 0.5, 95% CI 0.3-0.7), and employment by a household member (OR 0.6; 95% CI 0.4-0.9) were associated with a reduced likelihood of undergoing intestinal resection. Delays in hospital presentation and female sex were significantly associated with death, whereas higher socioeconomic status and availability of radiologic diagnosis reduced requirement for intestinal resection. Efforts are needed to improve the awareness, diagnosis, and management of intussusception in sub-Saharan Africa, especially in resource poor settings.

1122

CHARACTERIZATION OF DENV-2 INFECTIONS OCCURRING IN A DENGUE ENDEMIC AREA AND PRESENTING WITH AN INCREASED NUMBER OF SEVERE CASES

Benedito A. Fonseca, Marcus Vinicius G. Silva, Mayara R. Agostinho, Luiza A. Castro-Jorge, Taline M. Klein, Flavia M. Moraes, Marcio J. Siconelli, Vitor G. Floriano, Beatriz S. Ribeiro, Daniel M. Jorge, Daniel C. Araujo, Luzia M. Passos, Danielle C. Gentil

School of Medicine of Ribeirão Preto, Ribeirão Preto, S.P., Brazil

Dengue viruses (DENV) constitute a significant public health problem to tropical and subtropical regions of the world. Ribeirão Preto, a city in the northeast region of São Paulo state, Brazil, is endemic for dengue virus infections and serotype circulation has changed over the years. In the last decade, intense dengue serotype circulation has been as follows: DENV-3 (2008-2010), DENV-1 (2010-2012; 2014-2018), and DENV-4 (2012-2014). DENV-2 circulated at very low levels in 1998, 2001, and 2009, and this has implicated in a large number of dengue-experimented persons susceptible to DENV-2 infections. In 2019, an ongoing clinical and virologic surveillance detected an increased number of severe dengue cases associated to a new introduction of DENV-2. From January to March, acute-phase serum samples from dengue patients with positive NS1 antigen detection were assayed for serotype identification by RT-qPCR. All samples were positive for DENV-2. Men and women were equally distributed (23/46; 50%) among the patients. The most frequent symptoms were fever (95%), headache (89%) and myalgia (78%), nausea (57%), back pain (54%), retro orbital pain (35%), rash (32%), arthralgia (32%), vomit (30%) and arthritis (19%). Seven (15%) patients were hospitalized either to alarm signs (67%) or severe dengue (33%). All hospitalized patients had thrombocytopenia and the most frequent alarm sign was severe abdominal pain. Patients with severe dengue had dengue hemorrhagic fever (grade I or II). Secondary dengue infection was detected in 59% of the hospitalized patients. Additionally, molecular studies show that the DENV-2 genotype responsible for the current outbreak belongs to the Asian/American genotype, the same as the 2009 outbreak. However, the current DENV-2 genotype has 26 synonymous and 1 non-synonymous mutation in the prM-E nucleotide sequence compared to the virus that circulated in 2009. Increased severity of dengue cases observed in the current outbreak is probably due to a combination of higher prevalence of dengue secondary infections and an increased virulence of DENV-2 circulating genotype.

1123

ELEVATED ACTIVATION OF NEUTROPHIL TOLL-LIKE RECEPTORS IN PATIENTS WITH ACUTE SEVERE LEPTOSPIROSIS: AN OBSERVATIONAL STUDY

Janet C. Lindow[1], **Annie J. Tsay**[1], Ruth R. Montgomery[2], Eliana AG Reis[3], Elsio A. Wunder Jr[1], Guilherme Araújo[3], Nivison RR Nery Jr[3], Subhasis Mohanty[2], Albert C. Shaw[2], Patty J. Lee[2], Mitermayer G. Reis[3], Albert I. Ko[1]

[1]*Yale School of Public Health, New Haven, CT, United States,* [2]*Yale School of Medicine, New Haven, CT, United States,* [3]*Oswaldo Cruz Foundation, Salvador-Bahia, Brazil*

Leptospirosis is the leading cause of zoonotic morbidity and mortality globally, yet little is known about immune mechanisms contributing to pathogenesis and severe disease. Our pilot study examined immunopathologic role of neutrophils in severe leptospirosis by quantifying neutrophil activation markers during acute infection and convalescence in patients with different disease severities. Between July 2013 and August 2014, we identified 19 patients through active surveillance at a state-run infectious disease hospital in Salvador, Brazil. Among our cohort, 15 (79%) of 19 had laboratory-confirmed leptospirosis and 4 had febrile illnesses presenting similarly. We recruited 4 healthy Brazilian adults as controls. We collected baseline clinical characteristics and blood samples for the 19 patients 72-96h of hospital admission (acute samples) and 4 paired convalescent samples (32-57d post-admission). We categorized leptospirosis patients into 2 groups using severity of renal and/or pulmonary dysfunction. We quantified neutrophil activation markers, CD11b (β2 integrin) and CD62L (L-selectin), and assessed activation capacity (neutrophil marker levels following stimulation with Toll-like receptor agonists) for all samples using multi-parameter flow cytometry. Additionally, we assessed the levels of TLR2, TLR4 on neutrophils. We analyzed data from 50,000 $CD15^+$ cells and report percent of $CD15^+$ cells expressing activation markers or the fold-change in median fluorescent intensity (MFI). We observed no significant differences in neutrophil baseline activation or activation capacity regardless of disease severity (acute: 78.5% (75.5-84.3); severe: 86.0% (80.0-87.5)). However, patients with severe organ dysfunction had significantly higher TLR2, TLR4 expression than patients without organ dysfunction. Higher bacterial loads in whole blood positively correlated with higher expression of TLR2, TLR4 (TLR2: r=0.81 [0.47-0.94], TLR4: r=0.64 [0.13-0.88]). Our findings indicate higher initial bacterial loads or delayed neutrophil responses rather than TLR-driven inflammation, may drive severe disease outcomes.

1124

SOCIO-ECONOMIC BEHAVIORAL INDICATORS OF FALCIPARUM MALARIA PARASITEMIA AND MODERATE TO SEVERE ANEMIA AMONG PREGNANT WOMEN ATTENDING ANTENATAL CLINICS IN LAGOS, SOUTHWEST NIGERIA

Adeola Y. Olukosi[1], Oluwagbemiga O. Aina[1], Abiodun kanmi Olakiigbe[1], Olusola S. Ajibaye[1], Bassey A. Orok[1], Samuel Akindele[1], Adebayo T. Onajole[2], Samson T. Awolola[1], Tolulope Moji Arowolo[1], Bamgboye M. Afolabi[3]

[1]*Nigerian Institute of Medical Research, Lagos, Nigeria,* [2]*College of Medicine University of Lagos, Lagos, Nigeria,* [3]*Health, Environment and Development Foundation, Lagos, Nigeria*

Incidence of malaria and anemia are of public health importance especially in pregnant women in endemic regions, due to the negative health consequences to mother and fetus. The aim of this study was to assess the pattern of falciparum malaria infection and anemia, based on malaria prevention methods practiced by participants. A semi-structured tool was used to capture information on demographic, socio-economic and malaria prevention practices from 113 pregnant women attending antenatal clinics in 2 peri-urban health facilities in Lagos, Southwest Nigeria. Malaria microscopy was conducted and hematocrit measured. Logistic regression analysis was performed on the data collated from the survey. The prevalence of anemia among the pregnant women was 87.2%. The mean (±sd) Packed Cell Volume (%) of the 22 (19.5%) infected subjects (26.8±6.6), was significantly lower (t=-2.60, P-value=0.007) than that of the 91 (80.5%) uninfected subjects (30.8±6.0). The prevalence of infection was highest in the 3rd trimester (n=40, 35.4%) at 27.5% (11/40) and among those in their first pregnancy (n=32, 28.3%) at 25.0% (8/32). There was a significant difference (t=-2.23, P-value=0.01) in the mean PCV% of pregnant women who consumed herbal teas in pregnancy (28.2±5.2) compared to those who did not (30.8±6.6). Regression analysis showed that first pregnancy, "antimalarial" use and "Insecticide-treated nets" use night before study had increased odds of malaria infection in participants (OR=1.35, P=0.006, 95% CI=0.52-2.49; OR=2.3, P=0.005, 95% CI=0.14-0.41; OR=1.92, P=0.001, 95% CI=0.62-5.98) while IPT participation and formal education were strongly and significantly associated with lower risk of parasitemia (OR = 0.95, P= 0.025, 95% CI= 0.41-2.26; OR = 0.44 P= 0.005, 95% CI= 0.34-10.50). Interventions that will reduce malaria and moderate to severe anemia, especially in first pregnancy, should include education on correct use of LLIN, IPT and avoiding the dangers of herbal medication in pregnancy.

1125

PUTTING THE THREE DELAYS MODEL TO WORK: A PRAGMATIC 12-MONTH COMMUNITY-BASED COHORT STUDY TO ASSESS ACCESS TO EMERGENCY OBSTETRICAL AND NEONATAL CARE IN A REMOTE ISLAND COMMUNITY IN WESTERN KENYA

Nicholas DesLauriers[1], Evance Ogola[2], Gor Ouma[3], Brian Mattah[3], Louisa Ndunyu[2], Lily Muldoon[4], Richard Magerenge[3], Peres Okinyi[3], Marcus Salmen[3], Kelsi Hines[3], Robinson Okeyo[3], Ben Pedersen[5], John Ssenkusu[6], Shailey Prasad[1], Molly McCoy[1], Walter Opiyo[3], Hanna Nedrud[1], Kelsey Finn[1], Charles Salmen[1]

[1]*University of Minnesota, Minneapolis, MN, United States,* [2]*Maseno University, Maseno, Kenya,* [3]*Ekialo Kiona Centre, Kitawi Beach, Kenya,* [4]*University of California San Francisco, San Francisco, CA, United States,* [5]*Oregon Health and Sciences University, Portland, OR, United States,* [6]*Makerere University, Kampala, Uganda*

Mfangano Island is a remote fishing community in Lake Victoria, Kenya. Due to a fragmented health system, its residents experience critical delays in accessing emergency care as well as some of the highest maternal mortality rates in Kenya. In response, the Ekialo Kiona community-based organization developed the Health Navigation Program (HNP): a network of Community Health Volunteers (CHVs) who promote timely referral to health facilities and coordinate transfers to the mainland via a 24/7 on-call emergency boat. By applying the "Three Delays" framework, this rolling cohort study recruits all maternal and neonatal emergency cases referred by clinical staff to the mainland for higher level care or which resulted in a death on the island. A participatory case "audit" is completed with each participant after hospital discharge, capturing a narrative from symptom onset to definitive care, and measuring the three time delays (i.e. recognizing need, reaching care, receiving care) with a novel visual analog scale of events. The scale uses frames of reference such as sunrise and sunset to hone accuracy of recollection, and its validity will be assessed by comparing responses to real-time SMS timestamps sent by CHVs during cases. Delays will be compared between cases assisted by the HNP in participating communities and those proceeding through the pre-existing referral system alone. Preliminary data shows average time delay from symptom onset to reaching a facility is 11.7 hours (*N*=10, range 2-31.5), with delay from symptom onset to deciding to seek care averaging 10.2 hours. The delay from reaching a facility to initiation of definitive care on the mainland averages 14.9 hours (*N*=9, 6-25), with the delay from reaching a facility to departing the island after referral averaging 9 hours. Total delays from symptom onset to initiation of definitive care average 26.8 hours (*N*=9, 14.25-47). Developing practical ways to measure the "Three Delays", understanding barriers contributing to pre- and inter-facility delays, as well as the impact of the HNP, will inform interventions to improve access to emergency care in remote communities.

1126

CARDIAC INVOLVEMENT IN SCRUB TYPHUS IN A NORTHWESTERN INDIAN HOSPITAL

Navneet Sharma, Manisha Biswal, Manoj Kumar Debnath, Jyotdeep Kaur, Ashish Bhalla, Rajesh Vijayvergiya

PGIMER, Chandigarh, India

Scrub typhus (ST) is a disease caused by the bacterium *Orientia tsutsugamushi* transmitted to humans by the bites trombiculid mites. Cardiac involvement though less reported is being increasingly seen. A prospective study was carried out in 70 cases of ST (ELISA IgM antibodies against *O. tsutsugamushi)*. Measurements carried out in all cases were, left ventricular ejection fraction (LVEF) by 2D-Echocardiography and levels of troponin-T and serum creatine kinase-MB. The mean age was 34 ± 15 years and the male female ratio was 4:3. The mean duration of fever before presentation was 7.6±3.7 days. The most common symptoms were dyspnea 70%, altered sensorium 30%, abdominal pain 28.6%, decreased urine output 22.9%, jaundice 20% and headache 18.6%. Other clinical observations were tachycardia in 95.7%, tachypnea in 78.5%, splenomegaly in 77.1%, hepatomegaly in 67.1%, eschar in 12.8% and hypotension in 7.1%. On investigations, anemia occurred in 86%, leukocytosis in 47%, thrombocytopenia in 88% and elevated serum transaminase levels in 93% cases. On abdominal ultrasound, hepatomegaly was detected in 67.1%, splenomegaly in 77.1% and ascites in 22.9%. Complications seen were; acute respiratory distress syndrome in 87.1% and acute kidney injury in 38.5%. Although 2D Echocardiography showed a reduced LVEF in 42.8%, yet, clinical congestive heart failure was evident in 4.2% cases. The mortality rate was 7.1% (5 cases). On statistical analysis, a significant correlation was observed between the age and reduced left ventricular ejection fraction. The troponin-T level elevation in 72.8% and creatine kinase-MB elevation in 41.4% correlated with a decrease in the LVEF. Furthermore, patients with an elevated creatine kinase-MB levels also had an increased length of hospital stay. In conclusion, cardiac involvement occurred in 42.8% patients of ST, affected the younger age group and was easily recognisable with 2D Echocardiography showing a reduced ejection fraction and elevated levels of troponin-T and creatine kinase-MB.

1127

EFFICACY OF *IPOMEA PES-CAPRAE* OINTMENT AS AN ADD-ON THERAPY FOR JELLYFISH DERMATITIS: FINAL RESULT OF A SELF-CONTROLLED CLINICAL TRIAL

Watcharapong Piyaphanee[1], Vorada Choovichian[1], Keawmala Palakul[1], Jutarmas Olanwijitvong[1], Thitiya Ponam[1], Wasin Matsee[1], Thanasawat Chaiyakul[2]

[1]*Faculty Of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [2]*Naval Medical Department, Royal Thai Navy, Bangkok, Thailand*

Jellyfish sting is an important risk for among travelers who expose to seawater. In tropical countries, *Ipomea pes-caprae,* a medicinal plant, has been known as an effective treatment for jellyfish dermatitis. However, no clinical trial has been done to prove its efficacy. This was an open label, self-controlled clinical trial of *Ipomea pes-caprae* ointment in patient with jellyfish dermatitis. Adult patients with the onset of jellyfish dermatitis less than 7 days were invited to join. The investigator divided the dermatitis area of each patient into two parts (Test and Control area). Each patient received standard treatment depended on the severity of dermatitis in both areas. *Ipomea pes-caprae* ointment was applied only to the "test area" as an add-on therapy. Participants were re-evaluated 6 times in the 28-days study period. Primary outcome was the recovery time (non-active skin lesion) of both areas. The secondary outcomes were the duration of pain and itching after the treatment. Sixty patients with jellyfish dermatitis were enrolled. Their median age was 32 years, the majority of participants exposed to jellyfish on the day of enrollment. In total, 90% received topical steroid, 50% received oral antihistamine while 18% received oral prednisolone as standard treatment. The *Ipomea pes-caprae* ointment was applied to all patients but only on the test area. Time to non-active skin lesion in test area was shorter than control area (5.65 days VS 6.17 days, p=0.009). The duration of itching in test area was significantly less than the control area (3.33 days VS 3.73 days, p=0.044). However, there was no difference in duration of pain between test area and control area. Overall skin outcome (healing with/without scar) was the same in test and control area. We can conclude that *Ipomea pes-caprae* ointment was an effective add-on therapy in the treatment of jellyfish dermatitis. The recovery time and duration of itching in area that applied with the ointment were less than the control area. However, the overall skin outcome was the same in both areas.

1128

PROTEIN-ENERGY MALNUTRITION IN COMMUNITY-BASED EDUCATION AND SERVICE (COBES) CENTERS IN WESTERN KENYA DURING THE PERIOD 2017-2018

Arthur M. Kwena

Moi University, Eldoret, Kenya

COBES programme enables students to participate in various community projects during the period of their study at the College of Health Sciences of Moi University. In their second year of study, they are attached to 20 health Centres for a period of six weeks where they participate in community entry and Diagnosis. They determine the nutritional status of the community in which they are attached. The results reported here are for the latest data collected during the period 2017-18. The Broad objective of the study was to determine the current nutritional status in COBES centres in Western part of Kenya. Cross-sectional studies were carried out in March and May 2017 and 2018 in 20 COBES Health Centres in Western Kenya. Cluster sampling technique was used with each Health centre as the sampling unit. Anthropometric measurements were performed on all children aged 5-59 months within the households sampled. The nutritional status of the children was determined using the WHO recommended Z- score values as well as the Kenya Government Ministry of health recommended charts based on anthropometric measurements. Analysis of nutritional data was carried out using Epi-info 2000 program to determine the Z- score values from anthropometric data. A total of approximately 700 children were sampled in the seven Health Centers: (Stunting- HAZ<-2, Wasting-WHZ <-2, underweight -WAZ<-2 and MUAC, < 12.5mm). Results showed anthropometric measurements taken to fall within the WHO recommended reference values for ' normal' nutrition as exemplified by Kabuchai (WHZ>-1, WAZ>-1, HAZ >-1 and MUAC >-1) and Mosoriot Health Centres (WHZ> -2, WAZ=0, HAZ >-1, MUAC >-1). Preliminary published results indicated that Meteitei had the highest malnutrition prevalence (53% HAZ, 15% WHZ, 27% WAZ and 18.1 MUAC) whereas Chulaimbo showed the lowest prevalence (7% HAZ, 3% WAZ). The other centres showed mixed prevalence. Most COBES Health Centres showed improved nutrition status compared to previous results that showed one or two Centres to have extremely high malnutrition status.

1129

OCCURRENCE OF TYPHOID FEVER COMPLICATIONS AND ASSOCIATED RISK FACTORS: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

Ligia Maria Cruz Espinoza[1], Ellen McCreedy[2], Marianne Holm[1], Justin Im[1], **Ondari Mogeni**[1], Prerana Parajulee[1], Ursula Panzner[1], Se Eun Park[1], Trevor Toy[1], Andrea Haselbeck[1], Hye Jin Seo[1], Hyon Jin Jeon[1], Jong Hoon Kim[1], Soo Young Kwon[1], Jerome H. Kim[1], Christopher M. Parry[3], Florian Marks[1]

[1]*International Vaccine Institute, Seoul, Republic of Korea,* [2]*Center for Gerontology and Healthcare Research, School of Public Health, Brown University, Providence, RI, United States,* [3]*Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom*

Complications from typhoid fever (TF) disease have been estimated to occur in 10 to 15% of hospitalized patients with evidence of a higher risk in children and when there is a delay in implementing effective antimicrobial treatment. This study estimated the prevalence of complications in hospitalized, culture-confirmed TF patients, and the effects of symptom duration and age on the prevalence of complications. A systematic review and meta-analysis were performed using studies in the PubMed database. Any unfavourable evolution of the disease reported as a complication in a TF patient was considered a complication. We rated risk-of-bias of relevant publications and conducted random-effects meta-analyses. Analyses were stratified by symptom duration at hospital admission (SDA, <10 and ≥10 mean or median days of disease) and by age groups (children and adults). Differences in risk between SDA and age groups was assessed using odds ratios (OR) and 95% confidence intervals (CI). Heterogeneity and publication bias were evaluated. Twelve studies were included in the meta-analysis. The pooled prevalence of complications estimated among hospitalized TF patients was 25% (95%CI:20–29%, I^2= 88.2%, p=0.000). The stratified analysis revealed a higher prevalence of TF complications among cases reporting SDA≥10 (36%, 95%CI:29–43%) compared to cases with SDA<10 (16%, 95%CI:13–18%), translating into a three times greater risk of complications for those with prolonged symptoms duration at hospital admission (OR=3.00, 95%CI:2.14–4.17, p<0.0001). Similar higher risks were observed in specific complications. Likewise, a higher prevalence of complications was observed in children (27%, 95%CI:19–35%) compared to adults (17%, 95%CI:9–25%), however, the increased risk was not significant (OR=1.15, 95%CI:0.89–1.49, p=0.247). This review found limited quality evidence concerning TF complications. The meta-analysis identified a higher overall prevalence of complications than previously reported and a strong association between duration of symptoms prior to hospitalization and risk of serious complications.

1130

CLINICAL MANIFESTATIONS AMONG INDIVIDUALS BITTEN BY TRIATOMINES (KISSING BUGS) IN SOUTHERN ARIZONA

Norman L. Beatty[1], Nicole Behrens-Bradley[2], Shannon Smith[1], Maria Love[2], Justin O. Schmidt[3], Patricia L. Dorn[4], Nafees Ahmad[2], Stephen A. Klotz[1]

[1]*University of Arizona College of Medicine, Department of Medicine, Division of Infectious Diseases, Tucson, AZ, United States,* [2]*University of*

Arizona College of Medicine, Department of Immunobiology, Tucson, AZ, United States, [3]The Southwestern Biological Institute, Tucson, AZ, United States, [4]Loyola University New Orleans, Department of Biological Sciences, New Orleans, LA, United States

We surveyed residents (N=105) who were ≥18 years old from southern Arizona who had been bitten by triatomines (kissing bugs) to gather information regarding their experience. This included knowledge of the insect, behavioral changes after being bitten, and clinical manifestations of the bite. Median age was 58 years and 64% were female. Estimated total number of bites was >2,200 among the group (16% bitten once; 23% bitten between 2-4 times; 22% bitten between 5-10 times; 34% being bitten between 11-50 times; 5% bitten > 50 times). Most had been bitten while sleeping (N=90/105), with 62% sustaining more than one bite in the same night. The most common bite locations were in the extremities (legs, 54.3%; arms, 49.5%; back, 35%; face, 15%). Approximately one-third changed their sleeping habits as a result of a triatomine bite, and 14 individuals (13%) report now sleeping under mosquito nets. A large majority (N=91/105) experienced at least one localized cutaneous symptom (75% itchiness at bite site; 74% developed an erythematous welt; 55% experienced regional swelling), but only 19% described pain after being bitten. Systemic symptoms included a feeling of unease (N=23/105), diffuse pruritus (N=22/105), rash (N=20/105), shortness of breath (N=13/105), dizziness (N=12/105), and anaphylaxis (N=11/105). Seven individuals had one episode of anaphylaxis, one person had two episodes, one had three episodes, and two had greater than ten episodes in their lifetime. Those who had previously experienced anaphylaxis were now sleeping with an epinephrine autoinjector by their bedside. Thirty seven people (35%) took an over the counter medication in an attempt to alleviate the symptoms after being bitten. When asked to identify the three most common triatomines in Arizona amongst a panel of similar insects from the region, 93%, 91%, and 78% were able to correctly identify *Triatoma rubida, T. recurva,* and *T. protracta*. Bite exposure to triatomines in southern Arizona is common. Unlike the name "kissing bug" suggests, most individuals were bitten on the body. Bites can cause serious allergic reactions, including anaphylaxis, which can be fatal.

1131

A SINGLE CENTER, OPEN LABEL PILOT STUDY TO EVALUATE THE SAFETY AND EFFICACY OF CC-11050, A NOVEL PHOSPHODIESTERASE 4 INHIBITOR, IN NEPALESE PATIENTS WITH *ERYTHEMA NODOSUM LEPROSUM*

Mahesh Shah[1], Divya RSJB Rana[2], Kapil D. Neupane[2], Ken Arakawa[3], David M. Scollard[4], Preeti Maharjan[2], Vikram Khetani[3], Indra B. Napit[1], Deanna A. Hagge[2]

[1]*The Leprosy Mission Nepal, Anandaban Hospital, Kathmandu, Nepal,* [2]*The Leprosy Mission Nepal, Mycobacterial Research Laboratories, Kathmandu, Nepal,* [3]*Celgene Global Health, Summit, NJ, United States,* [4]*Department of Health and Human Services, Health Resources and Services Administration, Health Systems Bureau, National Hansen's Disease Programs (Retired Director), Baton Rouge, LA, United States*

Erythema Nodosum Leprosum (ENL) is an immunological complication that can occur before, during or even years after curative antibiotics in those affected by borderline lepromatous (BL) or lepromatous leprosy (LL). While prednisolone and thalidomide are recognized treatments for ENL, most patients require extended treatment, both drugs have significant side effects, and thalidomide is restricted or prohibited in some countries. Phosphodiesterase 4 inhibitors (PDE4i) are a class of compounds that affect cytokine production, neutrophil function, and antigen processing and presentation in pathways potentially relevant to ENL. Acting as a PDE4i, CC-11050 is a non-steroid, anti-inflammatory drug with few side effects that has been previously trialed and shown to be safe in humans. This study is a single center, phase 2, open-label trial, to be performed in two steps. Step 1 will evaluate immediate effect in safety and efficacy of CC-11050 treatment over 10-28 days in 10 males with a new or new recurrent episode of ENL. Upon review of Step 1 safety analyses and efficacy data by the Data Safety and Monitoring Committee (DSMB), a decision will be made whether to proceed to Step 2: an additional 40 ENL patients enrolled for up to 52 weeks of CC-11050 treatment. To date (April 10, 2019), 5 male subjects have been enrolled. According to preliminary observations, CC-11050 has been found safe and clinical improvements were observed in the first five subjects. Based on consensus between the study principal investigator and DSMB, the medication of the first five patients was extended from 10 to 28 days. No serious adverse events have occurred. The last therapeutic agent for ENL treatment was developed about 50 years ago; and there is an imperative need for new therapies with fewer side effects to be identified. DSMB review of CC-11050 Step 1 (10 patients) will determine progression to Step 2 (40 patients) of the study. Data analyses from ongoing enrolment is in process.

1132

ANTIBIOTICS AND ANTIMALARIAL DRUGS FOR CHILDREN AGED <5 YEARS HOSPITALIZED WITH ACUTE FEBRILE ILLNESS IN KENYA

Nailah Smith[1], Eric Ng'eno[2], Eric Osoro[2], Peninah Munyua[3], Doris Marwanga[4], George Agogo[3], Godfrey Bigogo[4], Victor Bandika[5], Paul Etau[6], John Wagacha Burton[7], John Kiogora[8], Terrence Lo[1], Lynda Makayotto[9], Joel M. Montgomery[1], Marc-Alain Widdowson[3], Jennifer R. Verani[3]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Washington State University, Nairobi, Kenya,* [3]*Centers for Disease Control and Prevention, Nairobi, Kenya,* [4]*Kenya Medical Research Institute, Nairobi, Kenya,* [5]*Coast Provincial General Hospital, Mombasa, Kenya,* [6]*Kenyatta National Hospital, Nairobi, Kenya,* [7]*United Nations High Commissioner for Refugees Kenya, Kakuma, Kenya,* [8]*International Rescue Committee, Kakuma, Kenya,* [9]*Kenya Ministry of Health, Nairobi, Kenya*

Acute febrile illness (AFI) is a common cause for pediatric hospitalizations in low- and middle-income countries and a major driver of antibiotic and antimalarial drug use; yet data on inpatient management of AFI in Africa are limited. We aimed to characterize antibiotic and antimalarial therapies used for patients admitted with AFI in Kenya. We analyzed data from children aged <5 years enrolled in AFI surveillance conducted at four sites: Kenyatta National Hospital (KNH) in Nairobi, Kakuma Refugee Camp General Hospital (KRCGH) in Turkana, Coast Provincial General Hospital (CPGH) in Mombasa and Kakamega County Referral Hospital (KCRH) in western Kenya. Patients admitted with temperature ≥38.0°C of <14 days duration had data collected through chart review. From 06/2017 to 07/2018, 1175 children aged <5 years were enrolled: 633 (54%) at KNH, 188 (16%) at KRCGH, 238 (20%) at CPGH, and 116 (10%) at KCRH. Median age was 11 months (interquartile range 5-21) and 56% were male. The most common clinical diagnosis overall was pneumonia (38%), though at KCRH malaria was most common (67%). Overall, 1063 (90%) received antibiotics and 230 (20%) received antimalarial drugs; 176 (15%) received both. Antibiotic use was >90% among cases at all sites except KCRH (67%). Among the sites, use of a penicillin class antibiotic ranged from 36-81%, cephalosporin 25-56%, and aminoglycosides 27-60%. Use of antimalarials was 77% at KCRH, 27% at KRCGH, 13% at KNH, and 5% at CPGH. Among the sites, use of artesunate ranged from 5-78%, artemeter-lumefantrine 1-23%, and quinine 0-18%. Use of both antibiotics and antimalarials was most common at KCRH (46%) and least common at CPGH (4%). Among cases treated with antimalarials, 33% (75/230) had a rapid malaria test, and 56% of those were positive. Most children admitted with AFI receive antibiotics; however, the frequency and type vary by location, as does the use of antimalarials, which were often prescribed despite negative rapid diagnostic testing. Further research is needed to assess appropriateness of antibiotics and antimalarials used and drivers of differences in clinical practice among sites.

NEUROLOGICAL SYNDROMES IN THE PEDIATRIC POPULATION DURING THE ZIKA VIRUS EPIDEMIC IN COLOMBIA 2015 TO 2016

Diana Marcela Walteros[1], Marcela Daza[2], Ana Cristina Suarez[1], Marcela Mercado[1], Franklyn Prieto[1], Angelica Rico[1], Maritza Gonzalez[1], Martha Opsina[1]

[1]*Instituto Nacional de Salud, Bogota, Colombia,* [2]*Zika research division, Vysnova Partners, Bogota, Colombia*

Background: During the Zika virus (ZIKV) epidemic, the association between viral infection and neurological involvement was identified. In Colombia, the Instituto Nacional de Salud (INS) established as mandatory the individual report of neurological syndromes (NS) in this period, allowing thorough analysis at a population basis. Methods: Cases compatible with ZIKV-related NS, in population under 18 years of age, reported to the surveillance system (Sivigila) from October 2015 to June 2016, were selected. Medical records were reviewed and clinical information was collected. The Brighton Collaboration criteria were used to classify the NS. Results: During the outbreak, 419 ZIKV-related NS were reported to Sivigila, 14 % (59/419) occurred in the pediatric population. Within these cases, 64% were male (38/59) and the median age was 10 years (IQR 6-14). The NS were classified as GBS (Guillain Barré syndrome) 68% (40/59), encephalitis 14% (8/59), myelitis 8% (5/59) and ADEM (acute demyelinating encephalomyelitis) 7% (4/59). Accounting for ZIKV-related symptoms, 92% (54/59) presented with fever, rash and myalgia before the onset of the NS. The average of days between these symptoms and neurological manifestations were: GBS: 10 days, encephalitis and myelitis: 7 days and ADEM: 2 days. The most frequent neurological manifestations for each NS were: GBS: hyporeflexia 98% and limb weakness 95%; encephalitis: seizures and changes in behavior 75%; myelitis: lower limb weakness 100%, hyporeflexia and respiratory distress: 60%, and ADEM: lower limb weakness 100%, dysarthria and hyporeflexia 50%. Mortality rate was calculated in 5.1%, being two GBS and one myelitis case. Conclusions: ZIKV infection accounts as a relevant etiological factor for NS, GBS was the most frequent condition in this cohort. The predominance of motor compromise and the different time frames between ZIKV-related symptoms and each NS should considered when caring for children with these pathologies. The higher mortality rate identified in this population, than reported by other authors warrants further analysis.

1134

PUBLIC HEALTH AND COST-EFFECTIVENESS IMPACTS OF "SCREEN-AND-VACCINATE" APPROACH WITH CYD-TDV IN PUERTO RICO

Edward W. Thommes[1], Laurent Coudeville[2], Riyadh Muhammad[1], Maria P. Martin[1], Christopher B. Nelson[1], Ayman Chit[1]

[1]*Sanofi Pasteur, Swiftwater, PA, United States,* [2]*Sanofi Pasteur, Lyon, France*

Dengue, a major public health problem in the tropics, is endemic in Puerto Rico and has been a reportable condition for several decades. A cost-effectiveness analysis is presented for a vaccination program using Sanofi Pasteur's CYD-TDV dengue vaccine in Puerto Rico. The analysis is based on a previously developed age-structured, host-vector compartmental model that reproduces the transmission dynamics of the four dengue serotypes. Parameters were estimated with 5-year data from two large-scale phase 3 efficacy trials conducted in 10 countries and territories including Puerto Rico. Following WHO guidance for the use of CYD-TDV, a "screen-and-vaccinate" approach was assumed: individuals without a documented prior dengue infection are first serologically tested for prior infection, and only those testing positive are vaccinated. We considered the use of two tests, a current enzyme-linked immunosorbent assay (ELISA) test, and a future rapid screening test with improved sensitivity and high specificity. Our base case scenario consisted of a CYD-TDV screen-and-vaccinate program in which 30% of 11-year-olds were tested via ELISA and those testing positive (50% of the screened individuals) were then vaccinated. Over a ten-year time horizon, such a program was predicted to prevent 24,781 [95% CI; 16,660; 33,164] cases of dengue, 2,000 [1,406; 2,623] dengue-associated hospitalizations, 558 [394; 721] severe cases of dengue, and 14 [7; 24] dengue-associated deaths. A vaccine price per dose of $255 [168; 572] or less was predicted to yield an incremental cost-effectiveness ratio (ICER) of $50,000 or less per disability-adjusted life year (DALY) averted from a payer perspective. From a societal perspective, the threshold price was predicted as $442 [315; 785]. A hypothetical future scenario, wherein serostatus is assessed via rapid screening test at the point of care, was predicted to have a substantially higher impact, driven primarily by the assumption that such a test would allow the screening rate to be more than doubled.

1135

APPLICATION OF TAQMAN ARRAY CARD IN THE PROJECT TO UNDERSTAND AND RESEARCH PRETERM PREGNANCY OUTCOMES AND STILLBIRTHS IN SOUTH ASIA (PURPOSE)

Jean Kim[1], Anna Aceituno[1], Elizabeth McClure[1], Robert Goldenberg[2], PURPOSe study investigators[3]

[1]*RTI International, Durham, NC, United States,* [2]*Columbia University, New York, NY, United States,* [3]*India, Pakistan*

Expanding our application of molecular tools to global health studies has afforded us the ability to better understand the causes of potential adverse outcomes specifically in the area of infectious disease. The Center for Disease Control and Prevention (CDC) has developed several robust quantitative reverse transcription polymerase chain reaction (qRT-PCR) assays allowing for multiplex identification using an array card platform (TaqMan Array Cards (TAC); Life Technologies). TAC has become a useful surveillance tool for the identification of pathogens and toxins in epidemiological studies such as the Aetiology of Neonatal Infection in South Asia (ANISA) study. Our study, Project to Understand and Research Preterm Pregnancy Outcomes and Stillbirths in South Asia (PURPOSe), has two objectives: (1) the primary objective is to determine the primary causes of death for preterm infants and stillbirths in South Asia (Pakistan and India), and (2) the secondary objective is to determine the proportion of stillbirths and neonatal deaths caused by infections. To accomplish these objectives, we implemented the TAC assays to identify 79 unique microorganisms and toxins from various tissues including the placenta and cord as well as fetal tissues using the minimally invasive tissue sampling (MITS) process, a novel and less invasive approach to autopsies relying on needle sampling. Additionally, histology performed on the various tissues will complement the TAC findings. In collaboration with the CDC, we helped establish and train the local scientists in Pakistan and India to perform the protocols for tissue processing, the TAC assay, and assay analysis. Here we describe this process and the challenges that we faced.

1136

VALIDATING A TOOL TO MEASURE THE CLINICAL IMPACT OF MERCURY TOXICITY AMONG INDIGENOUS MACHIGUENGA PEOPLE OF THE PERUVIAN AMAZON

George W. Hafzalla[1], Raveena Chhabria[1], Carlos Culquichicón[2], Stephanie M. Trujillo[2], Alycia Silman[3], Luis E. Fernandez[3], Andres G. Lescano[2], Claudia M. Vega[3], John W. Sanders[1]

[1]*Wake Forest School of Medicine, Winston-Salem, NC, United States,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Wake Forest University, Winston-Salem, NC, United States*

Organic mercury can be found in contaminated food and water, especially fish, and can cross the blood brain barrier and placenta, leading to neurological and cognitive deficits. In 2016, hair mercury levels in Madre de Dios, Peru were over tenfold the recommended level of 6 μg Hg/g. Unfortunately, current clinical assessment tools are inadequate, lacking regional cultural specificity. Our aim is to validate an adaptable neurocognitive battery sensitive to variable factors of language, numbering scale, environment, and culture, to assess neurophysiological status and impact of chronic mercury exposure, specifically short-term memory,

working memory, executive function, and attention. A cross-sectional study including physical exam, hair/urine/blood collection, and diet questionnaire was conducted on 114 Machiguenga volunteers living in the indigenous communities of Yomibato, Cacaotal, and Maizal. A subset (n=52) met criteria (age>10, and no pre-existing cognitive disorders) to undergo neurological and neurocognitive testing. Thus far, hair mercury levels have been analyzed for 39 participants. No physical findings of mercury toxicity were seen, but deficits were noted in neurocognitive tasks. 50% of our volunteers were underweight and 75% of adults presented with anemia (females <12 g/dL; males <13.5 g/dL). Initial data analyses suggest that increasing levels of mercury are correlated with declining performance on 6-sequence block tapping (testing visual short-term memory) and trail making (testing executive function and attention), but not 6-sequence word recall (testing auditory short-term memory) tasks. These findings need to be confirmed with higher level data analyses accounting for community variables. Malnutrition and lack of formal education could affect performance on neurocognitive assessments and will need to be considered in analyses. Further validation of this tool will require continued testing involving a broader population.

1137

CORRELATES OF FREQUENT HOSPITALIZATIONS IN CHILDREN DISCHARGED FROM HOSPITAL IN WESTERN KENYA (TOTO BORA TRIAL)

Rebecca Brander[1], Benson Singa[2], Kirkby Tickell[1], Christine McGrath[1], Hannah Atlas[1], Lucy Bunyige[2], Bertha Odhiambo[2], Grace John-Stewart[1], Barbra Richardson[1], Patricia Pavlinac[1], Judd Walson[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Kenya Medical Research Institute, Nairobi, Kenya*

Repeated hospitalizations are a significant burden to the families of children and to health systems in sub-Saharan Africa. Using baseline data from children under age 5 enrolled in a clinical trial of azithromycin given at hospital discharge at 3 hospitals in western Kenya (Toto Bora Trial, clinicaltrials.gov identifier NCT02414399), we evaluated frequency, admission diagnosis, and correlates of self-reported prior hospitalizations. Correlates were determined using log-binomial regression to estimate prevalence ratios adjusted for age and site (aPR) and 95% confidence intervals (CIs). Among 991 children enrolled to date, the most common reasons for hospitalization were pneumonia (29.5%), malaria (27.7%), diarrhea (17.5%), and sickle cell disease (SCD) (6.5%). One in 5 of these children (219, 22.1%) had at least 1 additional hospitalization in the past year, with 55.7% reporting 1 prior admission, 23.4% reporting 2, and 17.8% reporting 3 or more. Approximately half (110, 50.5%) were hospitalized in the prior year for the same condition as the index hospitalization. Of these prior hospitalizations that were due to the same condition as the index hospitalization, 13.3% were due to malaria, 11.9% to SCD, 11.1% to pneumonia, 8.3% to anemia, and 5.1% to convulsions. Children with SCD were more than twice as likely to report a previous hospitalization (aPR: 2.52 [95% CI: 1.74, 3.65]). Children diagnosed with convulsive disorder at the index hospitalization were also more likely to have been hospitalized previously (aPR: 2.29 [95% CI: 1.28, 4.06]). Neither HIV exposure nor infection were associated with prior hospitalization, nor were child's nutritional status, child's sex, breastfeeding history, or socioeconomic factors. Hospitalization presents an opportunity to identify children at high risk of subsequent re-hospitalization who are accessible for preventive interventions. In regions with high prevalence of malaria, pneumonia, and SCD, provision of tailored preventive interventions at discharge may have important public health impact in reducing hospitalizations.

1138

IN VITRO SUSCEPTIBILITY TESTING OF TEBIPENEM AGAINST EXTENSIVELY DRUG RESISTANT (XDR) *SALMONELLA TYPHI* ISOLATES

Sonia Qureshi[1], Farah Naz Qamar[1], Bushra Jamil[1], Elena Fernandez Alvaro[2], Nosheen Nasir[1], Aneeta Hotwani[1], Stephen Baker[3]

[1]*Aga Khan University Hospital, Karachi, Pakistan,* [2]*GSK, Madrid, Spain,* [3]*OUCRU, Ho Chi Minh City, Vietnam*

The XDR typhoid outbreak in Pakistan is the first of its kind, with resistance to 5 different antimicrobial classes. This isolate is susceptible to azithromycin and carbapenem only. Consequently, treatment options for XDR are limited with no existing clinical data for its treatment. The currently used carbapenems have significant cost implications as these drugs are expensive and require administration in hospital. Azithromycin resistance, although not reported from Pakistan, it is a very commonly used drug and resistance is inevitable and likely to spread rapidly. Hence it is imperative to find alternative treatment options that can offer an advantage to patients in improving clinical outcomes whilst also reducing treatment costs. Tebipenem (Orapenem), a novel oral carbapenem has been found to be effective *in vitro* against *E.coli* and *klebsiella*. Successful use for the treatment of community acquired pneumonia, and otitis media is reported. We propose the use of oral Tebipenem for the treatment of XDR-Typhoid in phase 1; we plan to demonstrate *in vitro* susceptibility of archived XDR *S.typhi* isolates from the outbreak Hyderabad to tebipenem. The MIC (Minimum Inhibitory Concentration) for respiratory pathogens is reported as: 1 ug/ml, 2 ug/ml and 4 ug/ml respectively for susceptible, intermediate and resistant isolates. We will test 85 *S. typhi* isolates for sensitivity against carbapenem using the same cut offs. *Klebsiella pneumoniae* ATCC was used as positive control by inoculating 5x 10^5 CFU/ml by Broth Micro dilution method. We have to date completed testing of 15 isolates and all were found to be sensitive to tebipenem with very low MICs. 4 (27%) have MIC of 0.25 ug/ml, 1(6.7%) has MIC value of 0.5 ug/ml and remaining 10 isolates have MIC of 0.12 ug/ml. Remaining 70 *S.typhi* isolates are being tested and results will be available by the time of presentation at ASTMH .We have screened tebipenem against MDR and XDR *S*. Typhi from Pakistan and found it to have excellent *in vitro* activity, making it a realistic oral treatment option for cases of XDR typhoid fever. However the results have to be validated in a randomized clinical trial.

EFFECT OF LYMPHATIC FILARIASIS AND HOOKWORM INFECTION ON PREGNANCY COURSE AND OUTCOME IN WOMEN OF REPRODUCTIVE AGE IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Jérémy Campillo[1], Cédric B. Chesnais[1], Jean Paul Tambwe[2], Naomi P. Awaca-Uvon[2], Michel Boussinesq[1], Sebastien Pion[1]

[1]*Institut de recherche pour le Développement, Montpellier, France,* [2]*Programme National de Lutte contre l'Onchocercose, Ministère de la Santé, Kinshasa, Democratic Republic of the Congo*

We evaluated the associations between (i) *Wuchereria bancrofti* and hookworm infections and (ii) pregnancy course and outcome in a group of 82 women of reproductive age (WRA) living in a rural area of the Democratic Republic of the Congo. Standardized questionnaires were used to collect demographics and information on past pregnancies. *W. bancrofti* and hookworm infections were diagnosed using a filarial antigen-detection test and the Kato-Katz method, respectively. Analyses consisted of multivariable logistic regressions adjusting on age, number of deliveries and history of anthelmintic treatment (AHT). Median age of WRA was 35 [interquartile range IQR: 30-44], and their median number of deliveries was 5 [IQR: 3-7]. *W. bancrofti* and hookworm infection rates were 42% and 43%, respectively. Filarial antigenemia and hookworm infection were not associated with the number of deliveries (p=0.161 and p=0.141, respectively). The proportions of WRA with a history of pregnancy resulting in neonatal death, miscarriage, premature birth, and postpartum

hemorrhage were 56%, 44%, 23% and 36%, respectively. History of pregnancy associated with neonatal death was less frequent in WRA who had taken AHT (adjusted odds-ratio (aOR) (95% confidence interval): 0.19 (0.04-0.82), p=0.026), tended to be more frequent in WRA with filarial antigenemia (aOR=2.68 (0.65-11.1), p=0.172), and was not associated with hookworm infection (aOR=1.36 (0.33-5.58), p=0.668). None of the three other pregnancy or birth events studied were associated with filarial antigenemia or hookworm infection (miscarriage: aOR=0.77 (0.19-3.28), p=0.729 and aOR=0.74 (0.14-3.86), p=0.726, respectively; premature birth: aOR=0.70 (0.09-5.71), p=0.741 and aOR=1.62 (0.12-21.40), p=0.712; post-partum hemorrhage: aOR=0.38 (0.09-1.53), p=0.174 and aOR=0.40 (0.08-2.03), p=0.269). The positive association found between history of AHT and lower risk of neonatal death warrants investigation in larger groups of WRA. Should it be confirmed, further studies should be conducted to determine whether it is due to biological causes (eg, anemia) or other (eg, sociological) determinants.

1140

EXPOSURE TO HOUSEHOLD AIR POLLUTION FROM BIOMASS COOKSTOVES AND BIOMARKERS OF SYSTEMIC INFLAMMATION FROM DRIED BLOOD SPOTS AMONG WOMEN IN RURAL HONDURAS

Megan L. Benka-Coker[1], Maggie L. Clark[2], Sarah Rajkumar[2], Bonie N. Young[2], Annette M. Bachand[2], David Diaz-Sanchez[3], Lucas M. Neas[3], Robert Brook[4], Tray Nelson[5], John Volckens[6], Steve J. Reynolds[2], Ander Wilson[7], Christian L'Orange[6], Nicholas Good[2], Casey Quinn[6], Kiersten Koehler[8], Sebastian Africano[9], Anibal Osorto Pinel[10], Jennifer L. Peel[2]

[1]*Department of Health Sciences, Gettysburg College, Gettysburg, PA, United States,* [2]*Department of Environmental and Radiological Health Sciences, Colorado State University, Fort Collins, CO, United States,* [3]*United States Environmental Protection Agency, Research Triangle Park, NC, United States,* [4]*University of Michigan Medical School, Ann Arbor, MI, United States,* [5]*Department of Health and Exercise Science, Colorado State University, Fort Collins, CO, United States,* [6]*Department of Mechanical Engineering, Fort Collins, CO, United States,* [7]*Department of Statistics, Colorado State University, Fort Collins, CO, United States,* [8]*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States,* [9]*Trees, Water, People, Fort Collins, CO, United States,* [10]*Asociación Hondureña para el Desarrollo, Tegucigalpa, Honduras*

Household air pollution from the burning of solid fuels is estimated to cause 1.6 million premature deaths worldwide each year. Cardiovascular-related disease contributes substantially to the burden, although evidence is limited. In a community-engaged project in rural villages of La Esperanza, Honduras, we measured 24-hour gravimetric kitchen and personal fine particulate matter ($PM_{2.5}$) and black carbon concentrations for 106 female primary cooks using wood-burning traditional and *Justa* (engineered combustion chamber and chimney) stoves. As indicators of cardiovascular disease risk, markers of systemic inflammation (C-reactive protein [CRP], Serum Amyloid A [SAA], Interleukin 1-β [IL-1 β], IL-8, Tumor Necrosis Factor-α [TNF- α], Intercellular Adhesion Molecule 1 [ICAM-1], and Vascular Cell Adhesion Molecule [VCAM-1]) were measured from dried blood spots collected via finger-stick. We used linear regression, adjusting for age, body mass index, education, and household assets, to evaluate the cross-sectional associations between the pollutants and inflammatory markers. The 24-hour median personal $PM_{2.5}$ concentration was 80 μg/m^3, IQR: 51-137 μg/m^3 (traditional stoves: 115 μg/m^3, IQR: 65-154 μg/m^3; *Justa* stoves: 52 μg/m^3; IQR: 39-81 μg/m^3). Pollution concentrations were higher in kitchens (vs. personal) and among traditional stoves versus *Justa* stoves. In adjusted models, increased concentrations of pollutants were associated with increased levels of CRP (e.g., a 25% higher personal $PM_{2.5}$ concentration was associated with a 10.5% increase in CRP levels [95% CI (confidence interval): 1.2-20.6]). We observed similar results for SAA. We observed a positive association between kitchen black carbon and IL-8, IL-1 β, and TNF- α. Associations with ICAM-1 and VCAM-1 with all pollutants were consistent with the null association. The results are consistent with the ambient air pollution literature and support the hypothesis that exposure to household air pollution is associated with increased systemic inflammation, which has been linked to cardiovascular disease.

1141

ACUTE FEBRILE ILLNESS SURVEILLANCE AT FOUR MILITARY SITES IN GHANA

Janice A. Tagoe[1], Clara Yeboah[1], Selassie Kumordzie[1], Shirley Nimo-Painstil[2], Naiki Attram[2], Eric Behene[1], David Wolfe[2], Anne Fox[2], Andrew Letizia[2]

[1]*Noguchi Memorial Institute for Medical Research, Greater Accra, Ghana,* [2]*Naval Medical Research Unit-3 Ghana Lab, Greater Accra, Ghana*

In malaria endemic regions, such as Ghana, acute febrile illnesses (AFIs) are often assumed to be due to malaria and presumptively treated with antimalarial drugs. The nonspecific clinical presentation of AFIs limit pathogen identification and epidemiology especially in resource-limited settings. AFIs require laboratory confirmed diagnoses which are cost-prohibitive and require special training which contributes to a lack of epidemiological knowledge in Ghana. Between July 2015 and December 2018, 284 patients were enrolled at 4 Ghanaian military treatment facilities. Inpatients or outpatients, 30 days to ≤65 years of age, with documented or reported fever (> 38°C) were eligible for the study. In addition to clinical and demographic information, blood specimens were collected for culture, serology and molecular testing. Among the 284 enrolled patients, 155 have been tested for *Coxiella burnetii* and *Leptospira* IgM and IgG with 8.4%, 4.9% and 0.7% sero-positive, respectively. Of 103 that were tested for chikungunya, 11.7% were positive for IgM and 7.8% for IgG. Of the 74 samples tested for West Nile Virus, 5.6% were seroreactivity for IgG and none for IgM. Out of 173 that were tested for dengue virus, 4% were positive for IgM and 39.6% for IgG. IgG reactive antibodies to spotted fever and scrub typhus *rickettsiae* was detected in 6% and 1% of the samples, respectively. 2.5% of blood cultures were positive for *Salmonella typhi*. This preliminary information demonstrates the requirement for expanded laboratory and diagnostic capabilities in Ghana to elucidate and understand the many potential etiologies of AFIs. Understanding the burden posed by both malarial and non-malarial agents in Ghana is essential for patient care and public health.

1142

ANTIPYRETIC USE AMONG FEBRILE PATIENTS ATTENDING EMERGENCY DEPARTMENTS IN RIO DE JANEIRO, BRAZIL: A CROSS-SECTIONAL, OBSERVATIONAL STUDY

José Moreira, Roxana Mamani, Patricia Brasil, Andre Siqueira

Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Fever is a common reason for seeking care in Emergency Departments (ED). Data about the prevalence of antipyretic use at arrival at the ED and how it may relate to outcomes is sparse. We did a cross-sectional analysis of patients presenting to two urban ED in Rio de Janeiro between October 2018 and March 2019. Eligible subjects had either a history of fever before arrival at the ED or axillary temperature ≥ 37.5 °C at arrival at the ED. Information about recent use of antipyretics, measured temperature at the ED, tests performed at the ED were collected. The outcomes were to describe the use of antipyretics preceding the ED visit, the measured temperature at triage, the rate of diagnostic testing, and the treatment administrated between subjects who had or had not received recent antipyretic prior to ED. Categorical variables were compared with the Fischer exact test, while continuous variables with the T-test or Mann-Whitney. We triaged 1551 subjects, and 374 [24.1% (95% CI 22-26)] had a history of fever at home or a measured fever at arrival at the ED. The mean age was 30.6 [0-84] years, adults (82.5%) and females (54.8%) predominated. 198 febrile patients had a suspicion of infection, and upper respiratory infection (42.4%) followed by undifferentiated febrile illness (15.7%) and urinary infection (14.6%) were the source of infection. 249 [87.6% (95% CI 83.1-91.1)] subjects reported taking an antipyretic

before ED visit. Dipyrone (72.2%) was the antipyretic most frequently administered followed by acetaminophen (14.3%), and ibuprofen (6.3%). The mean temperature at arrival at the ED (37.08 ± 0.99 *vs*. 36.85 ± 0.86, p=0.26), and the rate of diagnostic testing (31.1% *vs*. 32.1%, p=0.91) did not differ between subjects treated with any antipyretics and untreated subjects, respectively. Antipyretic users had a higher proportion of antibiotic prescription compared to untreated ones (56.3% *vs*. 21.4%, p<0.001). The use of antipyretics among febrile patients attending EDs in Rio de Janeiro is common, but their effects on ED temperatures are minimal. These findings might have implications in the designing of fever etiology studies.

1143

URINARY FINDINGS AT HEALTHY COMMUNITY SCREENINGS IN A REGION OF NICARAGUA WITH A HIGH BURDEN OF UNEXPLAINED KIDNEY DISEASE

Anna Strasma[1], Hannah Worrall[2], Sreedhar Mandayam[1], Reyna Silva[3], **Rebecca S. Fischer**[4]

[1]*Baylor College of Medicine, Nephrology, Houston, TX, United States,* [2]*Baylor College of Medicine, Tropical Medicine, Houston, TX, United States,* [3]*Amigos for Christ, Chinandega, Nicaragua,* [4]*Texas A&M University Health Science Center, College Station, TX, United States*

A large and ongoing epidemic of kidney disease of unknown etiology affects the rural poor from Mexico to Panama and has resulted in greater than 50,000 deaths. Mesoamerican nephropathy (MeN) is a devastating and rapidly progressing disease that affects primarily young agriculture workers who are otherwise healthy and lack traditional risk factors for kidney disease. Very little is known about renal function in the community-at-large, especially among children. Urine specimens were collected from individuals of all ages at health fairs in 4 rural, agricultural communities in the Pacific lowland areas of Nicaragua, a region heavily affected by MeN and where morbidity and mortality due to the epidemic has more than quadrupled since its emergence. Semi-quantitative dipstick and microscopic analysis were performed on fresh specimens. We generated descriptive statistics and tested for differences by age and community by Chi-squared and ANOVA in Stata 15. Urine from 471 community residents, ages 3 months to 89 years (median 21 years) were analyzed. Almost all individuals (99%) were shedding leukocytes, many (21%) with >5 per field. Renal cell shedding (11%), hematuria (13.4%) were also noted. Proteinuria was rare (3.2%). Hematuria and leukocytosis varied by locale (p<0.05). In this community-based sample, clinical urine specimens indicate an underlying prevalence of markers of impaired renal function. Further investigations into MeN should target populations other than agricultural workers and should specifically look at renal function in children. Geographic differences in clinical indicators may also point to the highest risk communities.

1144

FINE SCALE LYMPHATIC FILARIASIS MICROFILARIAE AND RISK FACTOR MAPPING IN A HIGHLY ENDEMIC VILLAGE IN THE MADANG PROVINCE OF PAPUA NEW GUINEA

Melinda Susapu[1], Leo Makita[1], Winter Deikore[1], Hannah Betts[2], Louise Kelly-Hope[2]

[1]*National Department of Health, Port Moresby, Papua New Guinea,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Papua New Guinea (PNG) has an estimated 4 million people at risk of lymphatic filariasis (LF). LF is a debilitating disease caused by nocturnal periodic nematodes *Wuchereria bancrofti* and transmitted by *Anopheles* mosquitoes, similar to malaria. Although national data exists, the burden of disease and associated risk factors of LF within a smaller endemic unit (village level) are currently not well defined. This study investigated microfilariae (MF) prevalence and potential risk factors of LF in an endemic village, comprising 3 hamlets within 5kms^2 in a rural area of Madang Province. MF infection (night bloods), and a short demographic, housing infrastructure and intervention risk factor survey was administered to 301 individuals. In total 90 individuals (29.9%) were found to be MF positive, which varied significantly across the hamlets by prevalence as well as average MF count; Korona (24.6%; 16.6/µl; n=46/187), Koinduna (31.9%; 21.6/µl; n=15/47) and Tongona (43.3%; 17.3/µl; n=29/67). Males (34.5%) were found to have a significantly higher prevalence than females (23.4%). Overall there was an increasing trend in prevalence with age with significant differences found between certain age groups. No individuals living in permanent houses were positive, compared with 12.1% and 35.3% recorded for the semi-permanent and bush material houses respectively. People who used mosquito coils/mortein sprays in their house (n=6, 12.2%) had a significantly lower prevalence than those who didn't (n=73, 33.2%). Interpolation maps of Mf positives per house in each hamlet with the house/ roof type and mosquito coil/mortein spray data overlaid showed that more semi-permanent houses and use of house spray was spatially associated with low risk areas. The finer scale mapping of MF and different risk factors provides key information to the National LF Programme which will help to target public health intervention campaigns. It will also provide important sentinel site information to monitor the impact of any intervention scaled up in this area over time.

1145

COMPARISON OF HEMATOLOGICAL INDICES BETWEEN MICROFILAREMIC AND IVERMECTIN TREATED AMICROFILAREMIC ONCHOCERCIASIS PATIENTS IN THE UPPER PART OF THE VOLTA REGION OF GHANA

Joshua Labadah, Kwadwo A. Kusi, Michael D. Wilson

West African Centre for Cell Biology of Infectious Pathogens, Accra, Ghana

Onchocerciasis is a neglected tropical disease of the skin and eye caused by *Onchocerca volvulus*, a helminth nematode parasite that is transmitted by blackflies. The pathology of the disease is largely associated with the microfilaria. Full blood counts are almost always requested by physicians in the diagnosis and management of diseases. Full blood count results from a total of 80 participants aged 18-70 in the Nkwanta North District in Ghana; 33 (18 male, 15 female) individuals having microfilaria (mf) diagnosed by skin snips and 47 (25male, 22 female) individuals who are positive by serology, negative for skin microfilaria and have taken ivermectin 3 months prior were compared by Mann-Whitney test. p values at 0.05 α for the median and interquartile ranges was reported. Total white blood cell (10/uL) for microfilaremic (mf) individuals 445 (367.50-590) was lower (p=0.0455) than of amicrofilaremic (amf) individuals 547 (446-634). Basophil count (10/uL) was lower (p<0.0001) for the mf 3 (2-11.50) compared to amf individuals 16 (11-20). Lymphocyte count (10/uL) was lower (p=0.0060) for the mf 191 (161.50-233) compared with amf individuals 230 (195-288). Eosinophil count (10/uL) was not different (p=0.5207) between mf 43.00 (22.50-67.50) and amf 39 (17-61). Neutrophil of mf individuals 136.50 (52-234) was not different (p=0.1236) from amf 162.5 (121-251). Monocytes of the mf individuals 52 (34.50-69) was not different (p=0.6920) from amf 50 (40.00-66.00). Red Blood Cell (10^4/uL) was lower (p=0.0235) for mf 449 (409.00-511.50) compared to amf 491 (438-532). The Hemoglobin concentration (g/L) was not different (p=0.6599) between mf 136.00 (127.00-147.00) and amf 134 (122-148). Hematocrit, HCT (%) was lower (p=0.0003) for mf 38.05 (34.88-40.63) compared to amf 41.80 (38.10-45.20). Platelet count, PLT (10^3/uL) was not different (p=0.2941) between mf 175 (121.50-231.50) and amf 197.00 (143-276). The geometric mean for microfilaria for the mf group is 25.7. *Onchocerca volvulus* microfilaria has an impact on some hematological parameters of its human host and these parameters could be used in the understanding and management of the disease.

1146

DRUG DISCOVERY AND DEVELOPMENT APPROACHES FOR THE TREATMENT OF HELMINTHIASIS

Natalie A. Hawryluk

Celgene Global Health, San Diego, CA, United States

Helminths are the most infectious agents of humans in developing countries. The most common helminthiases are those caused by infection from soil-transmitted nematodes (STH), platyhelminth trematodes (schistosomiasis), and the filarial nematodes. Helmianthiases have been targeted for elimination under the London Declaration on Neglected Tropical Diseases, therefore, Celgene Global Health (CGH), in collaboration with DNDi, academia, and Zoetis, is focused on finding novel chemical entities to treat these diseases. Using a distributed research model, CGH has on-going screening and dedicated medicinal chemistry efforts focused on human and animal filarial and soil transmitted nematodes and trematodes. Celgene Global Health has identified novel macrofilaricidal onchocerciasis compounds which will be discussed

1147

HOW PHARMACOKINETICS IMPACT DRUG OPTIMIZATION IN NEGLECTED DISEASES

Julius Lim Apuy, Geraldine Hernandez

Celgene Corporation, San Diego, CA, United States

Pharmacokinetics had been used in the pharmaceutical industry to study the absorption, distribution, and elimination of drugs in different model species including humans. The pharmacokinetic parameters and profiles generated by different drug-like molecules, various formulations, specific dose levels, and different dosing routes inform PK scientists concerning systemic exposure, oral bioavailability, linearity of response, and half-life of the molecule. These parameters help assess whether a compound had sufficient exposure to enable pharmacological efficacy. The general PK workflows in the pharmaceutical industry are customized to the unique scientific challenges of neglected diseases that are host/vector specific, or target species other than human. In neglected disease, new animal models and new disease specific *in-vitro* and *in-vivo* assays have to be developed to complement the PK workflow. Herein, we present how we modified the PK workflow to address the unique challenges in specific neglected disease such as filariasis and cow wasting disease.

1148

ACCEPTABILITY AND EFFECTIVENESS OF IVERMECTIN MASS DRUG ADMINISTRATION AND DOXYCYCLINE TEST AND TREAT IN SEMI-NOMADIC COMMUNITIES IN MASSAGAM HEALTH DISTRICT, CAMEROON

Rogers Nditanchou[1], Laura Senyonjo[2], Kareen Atekem[1], Ruth Dixon[2], Benjamin Biholong[3], Joseph Oye[1], Joseph Kamgno[4], Joseph Okeibunor[5], Daniel Boakye[6], Elena Schmidt[2]

[1]*Sightsavers, Yaounde, Cameroon,* [2]*Sightsavers, Haywards Heath, United Kingdom,* [3]*Ministry of Health, Yaounde, Cameroon,* [4]*University of Yaounde* [1] *and CRFilMT, Yaounde, Cameroon,* [5]*University of Nigeria, Nsukka, Nigeria,* [6]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana*

After 20 years of ivermectin mass drug administration (MDA), there is an on-going high level of transmission of onchocerciasis in Massangam health area (HA) in the West Region of Cameroon. An alternative treatment strategy (ATS) has been implemented to accelerate progress, which includes using doxycycline, which target the adult *Onchocerca* parasite through a test and treat strategy. A large number of nomadic herdsmen has been identified as a potential reservoir of infection supporting transmission in the area. This qualitative study explored opportunities and barriers for the MDA and ATS in the Massangam HA with a particular focus on the nomadic populations, through 15 focus group discussions and 31 In-depth interviews. Specifically, the study focused on 1) the experiences of reaching the nomadic communities with annual ivermectin MDA and 2) the acceptability of the doxycycline test and treat approach. The nomadic communities welcomed the MDA but there were issues with the delivery and distribution of the drug. Remote camp settlements were usually missed, as they are not systematically considered during census and MDA planning. Even when the Community-directed Distributors (CDDs) managed to reach the camp, a large proportion of the population, particularly men, were away and could not receive the drug. There were also linguistic and cultural barriers with the CDDs coming from outside the community, which inhibited the awareness and the acceptability of the campaign. The doxycycline test and treat strategy was generally acceptable and welcomed but there were fears and suspicion of the testing process, including the concern over the skin taken for biopsy. In conclusion, social, cultural and environmental barriers need to be taken into account in the MDA and ATS campaigns targeting hard-to-reach nomadic communities in the West Region of Cameroon. Interventions need to be adapted to accommodate the nomad routine, make efforts to reach them in the remote locations and ensure culturally appropriate messages and practices to improve their awareness, treatment uptake and equity.

1149

LONG-TERM IMPACT OF ALBENDAZOLE PLUS IVERMECTINE DOUBLE DOSE, TWICE-YEARLY ON THE SUPPRESSION OF *MANSONELLA PERSTANS* MICROFILARIAL LOAD

Yaya I. Coulibaly[1], Housseini Dolo[1], Tounko Fayinke[1], Abdoul F. Diabate[1], Siaka Y. Coulibaly[1], Moussa B. Sangare[1], Lamine Soumaoro[1], Michel E. Coulibaly[1], Salif S. Doumbia[1], Abdallah A. Diallo[1], Benoit Dembele[2], Dramane Sanogo[1], Siaka Konate[3], Sekou F. Traore[1], Adama D. Keita[4]

[1]*ICER-Mali, Bamako, Mali,* [2]*Helen Keller International, Bamako, Mali,* [3]*International Committee of the Red Cross - ICRC, Geneva, Switzerland,* [4]*Université des Sciences, des Techniques et des Technologies, Bamako, Mali*

Mansonella perstans is asymptomatic in most individuals. A variety of symptoms have been described including angioedema, pruritus, fever and eosinophilia. To date, effective treatment options are limited to relatively long course such as doxycycline 200 mg daily for 6 weeks and diethylcarbamazine plus mebendazole administered for 21 days. Less constraining microfilaria suppression could potentially offer better treatment option for *M. perstans.* To determine the effect of increased dose and frequency of albendazole-ivermectin treatment on microfilarial clearance, 34 *M. perstans* microfilaremic residents of a *W. bancrofti* endemic area in Mali were randomized to receive 2 doses of annual, standard-dose albendazole-ivermectin therapy (400 mg and 150 µg/kg; n = 18) or 4 doses of twice-yearly, increased-dose albendazole-ivermectin therapy (800 mg and 400 µg/kg; n = 16). This was a secondary analysis of a *W. bancrofti* targeted albendazole and ivermectin trial. After baseline, the follow-up periods were at M6, M12, M18, M24, M30 and M36. Although microfilarial levels decreased significantly after therapy in both groups as compared to baseline, levels were significantly lower in the high-dose, twice-yearly group at 12, 18, 24, 30, 36 months with all p< .05, Wilcoxon matched pairs rank test at any time points. In the group of annual, standard-dose albendazole-ivermectin, a significant difference was observed at 24 and 30 months (p<.05, Wilcoxon matched pairs rank test) as.compared to baseline. Furthermore, clearance of detectable microfilariae at 36 months was more common within the 11 patients in the twice-yearly therapy group (100%) than the annual therapy group with 4 out of 16 patients (66.7%) (p=0.04, Fisher›s exact test). These findings suggest that increasing the dosage and frequency of albendazole-ivermectin treatment enhances suppression of *M. perstans* microfilaria even though the standard treatment on the long run may also get rid of this filarial infection. These observations need to be assessed with a more powered study.

1150

BIOACCUMULATION OF COMPOUNDS IN VARIOUS FILARIAL PARASITES

Geraldine Hernandez[1], Julius L. Apuy[2], Natalie A. Hawryluk[1], Tamara Kreiss[3], John Siekierka[3]

[1]*Celgene Global Health, San Diego, CA, United States,* [2]*Celgene, San Diego, CA, United States,* [3]*Sokol Institute of Pharmaceutical Life Sciences, Montclair, NJ, United States*

Filarial diseases caused by parasitic nematodes are responsible for significant morbidity and life-long disease in humans. There is an unmet medical need for drugs that can treat filarial diseases. In drug discovery, host pharmacokinetic studies provide a theoretical volume of distribution, the distribution of compound into body tissues. One can theoretically utilize the volume of distribution to correlate to how much compound is distribution into the parasitic nematode; however a direct measure of the amount of compound accumulated into the parasite is needed. In developing novel anti-filarial agents there is a need to understand the accumulation and distribution of compounds into the parasite. The objective in this study is to develop ex-vivo methods for determining compound bioaccumulation in a variety of filarial parasites and correlating compound levels with parasite motility and viability.

1151

EVALUATION OF THREE DIAGNOSTIC TESTS FOR MONITORING OF LYMPHATIC FILARIASIS ELIMINATION IN AHANTA WEST, NZEMA EAST AND ELLEMBELLE DISTRICTS, WESTERN REGION, GHANA

Frances Amonoo McCarthy[1], Dziedzom K. de Souza[1], Francis Anto[2], Michael D. Wilson[1], Irene O. Owusu[1]

[1]*Noguchi Memorial Institute for Medical Research, Accra, Ghana,* [2]*University of Ghana School of Public Health, Accra, Ghana*

Wuchereria bancrofti is a filarial parasite which causes one of the most important neglected tropical diseases; Lymphatic filariasis. The disease is known to be responsible for much morbidity and deformity which brings about social and economic burdens on affected persons. The disease requires diagnostic tools that show high specificity and sensitivity in addition to their feasibility in terms of field implementation and efficiency. This study was a community based cross-sectional survey involving persons aged 5 years and above living in Ahanta West, Ellembelle and Nzema East districts which was aimed at evaluating the performance of three diagnostic tools; filarial test strip (FTS), microscopy and Wb123 ELISA for monitoring of LF elimination in the three districts. Day-time finger prick blood samples were obtained from 1371 participants recruited from households in 18 selected communities and tested for *W. bancrofti* antigen using FTS. Antigenemia positive individuals were followed up for collection of night blood samples to investigate the presence of microfilariae by microscopy. Filter blood spots were obtained for participants aged between 5 to 10 years and antigenemia positive individuals. These samples were tested for the presence of IgG4 antibodies specific for stage L3 of *W. bancrofti* using Wb123 ELISA. One hundred and thirteen (8.2%) of the tested individuals were antigenemia positive, 12 (12.4%) were mf positive and 14 (14.4%) were positive for IgG4 antibodies for *W. bancrofti.* The performance of FTS, Wb123 ELISA and microscopy were compared. FTS had 9.0% score over Wb123 ELISA (1.1%) and microscopy (1.0%). FTS was found to be more reliable in terms of diagnosis of LF compared to the other two diagnostics and could therefore be employed for use in areas with low endemicity rates. This study demonstrated the performance of filarial test strip, Wb123 ELISA test and microscopy for point of care monitoring following mass drug administration to reduce time spent in diagnosing in areas where bancroftian filariasis is endemic.

1152

IN VITRO MAINTENANCE OF *MANSONELLA PERSTANS* MICROFILARIAE AND ITS RELEVANCE FOR DRUGS SCREENING

Abdel Jelil Njoeundou[1], Chi Anizette Kien[1], Manuel Ritter[2], Mathias Eyong Esum[1], Patrick W. Ndongmo[1], Fanny Fri Fombad[1], Narcisse Victor Gandjui[1], Flobert Njiokou[1], Peter Enyong[1], Kenneth Pfarr[2], Joseph Turner[3], Laura E. Layland[4], Achim Hoerauf[4], Samuel Wanji[1]

[1]*University of Buea, Buea, Cameroon,* [2]*Institute of Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany,* [3]*Department of Tropical Disease Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [4]*German Centre for Infection Research (DZIF), Bonn - Cologne partner site, Bonn, Germany, Bonn, Germany*

Mansonellosis affects millions of people of the tropics. In addition to the lack of suitable safe drug recommended for its control, the *in vitro* maintenance of *Mansonella perstans* stages with regards to drug development is not well documented. This study evaluated the survival of *M. perstans* microfilariae (mf) under *in vitro* conditions that have been shown to promote survival of *Loa loa,* a close related filarial nematode with blood dwelling microfilariae. Further, the *in vitro* microfilaricidal effect of 17 antiparasitic agents was assessed on these parasites. The performance of the two basic culture media Dulbecco's Modified Eagle's Medium (DMEM) and Roswell Park Memorial Institute (RPMI-1640) supplemented with 10% Fetal Bovine Serum and Monkey Kidney epithelial Cell line on the survival of *M. perstans* microfilariae was investigated. Then, anthelminthics (6), anti-malarials (5), anti-wolbachia (3), trypanocidal (2) and anti-cancer (1) agents were tested *in vitro* against these parasite stages. The suitability of the culture media as well as the effect of the anti - infective agents on the mf survival was assessed by scoring their motility. Serum supplement and LLC-MK_2 co-cultures significantly improved the survival of microfilariae in DMEM and RPMI-1640. RPMI-1640 supplemented with 10 % FBS and co - cultured with LLC-MK_2 sustained the maintenance of microfilariae for at least 20 days (100.00 ± 0.00 % survival). In co-cultures with LLC-MK_2 cells and in absence of serum, *M. perstans* microfilariae were maintained in DMEM and RPMI-1640 without serum (FBS) by day 5, with motility above 99 % respectively. Mefloquine displayed the highest microfilaricidal effect *in vitro* followed by Artesunate. Both RPMI and DMEM in the presence of Monkey kidney epithelial cells are suitable for the maintenance of *M. perstans* microfilariae *in vitro*. In absence of the feeder cells, the addition of 10 % FBS to RPMI improved the parasite survival rate and motility. The microfilaricidal activity of mefloquine and artesunate on *M. perstans* microfilariae can be considered as reference for further screening of agents against this parasite stage

1153

OPTIMIZATION AND EVALUATION OF THE ESPERANZA WINDOW TRAP TO REDUCE BITING RATES OF *SIMULIUM DAMNOSUM* SENSU LATO IN NORTHERN UGANDA

Denis Loum[1], Devon Cozart[2], Thomson Lakwo[3], Peace Habomugisha[4], Benjamin Jacob[2], Eddie W. Cupp[2], **Thomas R. Unnasch**[2]

[1]*Nwoya District Local Government, Gulu, Uganda,* [2]*University of South Florida, Tampa, FL, United States,* [3]*Vector Control Division, Kampala, Uganda,* [4]*The Carter Center Uganda Office, Kampala, Uganda*

The Esperanza Window trap (EWT), a simple trap originally developed to replace human landing collections for entomological surveillance of *O. volvulus* transmission was optimized, resulting in a 17-fold improvement in trap performance. The optimized trap was tested in trials in schools and in agricultural fields to determine if it could reduce vector biting locally. The traps resulted in a 90% reduction in biting in the school setting. In the field setting, results varied. In one location, the traps reduced biting by roughly 50%, while in a separate trial, the traps did not significantly reduce the biting rate. Examination of the two settings suggested that trap

placement may be critical to their success. These results suggest that the optimized EWT might be capable of reducing local vector black fly biting in areas commonly frequented by residents. Together with other recently developed methods of community directed vector control, the traps may augment ivermectin MDA, bringing the goal of onchocerciasis elimination within reach in much of Africa.

1154

TESTING STRATEGIES TO BETTER INFORM PARTICIPANTS OF AN ANTHELMINTHIC CLINICAL TRIAL

Marta S. Palmeirim[1], Shaali M. Ame[2], Said M. Ali[2], Ulfat A. Mohammed[2], Jan Hattendorf[1], Brigit Obrist[1], Jennifer Keiser[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*Public Health Laboratory Ivo de Carneri, Chake Chake, United Republic of Tanzania*

Obtaining informed consent from participants is an ethical and legal requirement in clinical research. This step commonly relies on the informed consent form alone, yet this may not guarantee the participant's true understanding. Therefore, new methods of conveying information should be tested. We aimed at comparing the impact of different methods of conveying this information on the knowledge of caregivers of participants of a double-blind, randomized clinical trial on Pemba Island, Tanzania. This trial compared the safety and efficacy of two different regimens of mebendazole (3 days 100 mg bid *vs* 500 mg) against hookworm infections in school-aged children. A total of 252 caregivers were assigned to receiving (i) a pamphlet (n=63), (ii) an oral information session (n=61), or (iii) both the pamphlet and the oral information session (n=63) all covering the clinical trial procedures, their rights, benefits and potential risks. Before consenting to their child's participation in this trial, 252 caregivers responded to a knowledge assessment questionnaire about the study. One group of caregivers (n=65) did not receive any information before they responded to the questionnaire, serving as control. Cure rates of mebendazole against hookworm were significantly higher in the multiple dose arm (98%) than in the single dose arm (13%). Although the pamphlet did not have any effect on caregivers' understanding, attending an information session significantly increased caregivers' knowledge for some questions, mostly concerning the parasite and trial procedures. However, because this method did not properly convey all the important messages, we will explore new methods such as a theatre and slideshow during the information sessions of an upcoming clinical trial evaluating the efficacy, safety and acceptance of chewable mebendazole. The results of the latter will also be discussed in this presentation.

1155

FORECASTING THE IMPACT OF MASS DRUG ADMINISTRATION IN A HETEROGENEOUS ENVIRONMENT WITHIN THE DEWORM3 TRAIL IN BENIN, MALAWI AND INDIA

James Truscott[1], Robert J. Hardwick[1], Marleen Werkman[1], Judd Walson[2], Roy M. Anderson[1], DeWorm Trial Team[2]

[1]*Imperial College London, London, United Kingdom,* [2]*University of Washington, Seattle, WA, United States*

Soil-transmitted helminths (STH) affect 1.45 billion people worldwide, and high intensity infections are associated with morbidity especially in children. Annual mass-drug administration targeting children has some impact on morbidity but fails to break the parasite transmission cycle. The DeWorm3 project is a cluster-randomized trial to test the feasibility of interrupting the transmission of soil-transmitted helminths through twice-yearly community-wide MDA at a high coverage level in arms that treat just children or the whole community. The project has study sites in India, Benin and Malawi. We fit epidemiological parameters to the study baseline data using Bayesian techniques and a dynamic model of parasite transmission and MDA impact. We then use the fitted parameters to forecast by forward projection the impact of the MDA coverage achieved in the first round on parasite burdens at the study end point and beyond, when interventions have ceased or returned to standard annual school-based MDA programmes. We examine various assumptions concerning MDA coverage at rounds post the first round, and individual compliance to treatment on these projections. The ability to predict whether the project's goals have been met depends on the uncertainty in the values of the fitted parameters which reflect the diagnostic techniques used to collect the data. We examine the effect of more sensitive diagnostic techniques (e.g. qPCR) on the degree of confidence in the forecasts. The considerable variability in the prevalence and intensity of parasite burden between study sites and across the clusters in a given site means that the impact of MDA will vary between clusters by the end of the project. We investigate the relationship between MDA coverage, prevalence heterogeneity at baseline and the site level effect on the likelihood of interrupting transmission and the achievement of the WHO elimination of morbidity goals. We discuss how baseline information on heterogeneity can be used to optimize MDA public health interventions to achieve a given target.

1156

STATUS OF SOIL TRANSMITTED HELMINTH INFECTIONS IN SEMARANG, CENTRAL JAVA, INDONESIA

Johanna M. Kurscheid[1], Budi Laksono[2], Archie Clements[3], James McCarthy[4], Susana V. Nery[5], Donald Stewart[6], Darren Gray[1]

[1]*Australian National University, Acton, Australia,* [2]*Yayasan Wahana Bakti Sejatera Foundation (YWBS), Semarang, Indonesia,* [3]*Curtin University, Curtin, Australia,* [4]*QIMR Berghofer Medical Research Institute, Brisbane, Australia,* [5]*University of New South Wales, Kensington, Australia,* [6]*Griffith University, South Brisbane, Australia*

Indonesia carries the heaviest burden of soil-transmitted helminth (STH) infection in Southeast Asia with more than 62 million children requiring preventative chemotherapy in 2017 alone. Prevalence data for many parts of the country are out-dated and knowledge of the risk factors involved in transmission are not clearly understood. The aim of this study was to determine human STH prevalence and knowledge and practices relating to hygiene behaviour in rural communities in Central Java. A cross-sectional survey of 16 villages was conducted in Semarang, Central Java in 2015. Data on demographic, household and knowledge and practices were elicited through face-to-face interviews. Stool samples were collected and examined using the flotation method. Children (2-12 years) also had their haemoglobin (Hb) levels, height and weight data collected, and BMI computed. A total of 6466 individuals from 2195 households were interviewed. One-third of the cohort were infected with at least one species of STH, with differing burdens of the four species identified. Risk of infection was significantly associated with several demographic and household factors. Infection with STH was not associated with negative health impacts (e.g. diarrhoea, low BMI or Hb levels); however rates of anaemia among surveyed 2-12 year olds were high (33%) especially in school-age children. Knowledge of and behaviour related to hygiene and gastrointestinal diseases varied widely and were generally not associated with STH infection. The limited number of associations identified in this study suggests other undetermined risk factors may play a role in STH infection. The study also revealed that STH infection still persists in Central Java despite ongoing deworming programs. Therefore, current control efforts would benefit from being re-evaluated to determine the best way forward.

1157

COMPLIANCE TO TREATMENT IN THE GESHIYARO PROJECT: TESTING THE FEASIBILITY OF INTERRUPTING TRANSMISSION

Alison K. Ower[1], Nebiyu Nigussu[2], Fikreselasie Seife[2], Kalkidan Mekete[3], James Truscott[1], Robert Hardwick[1], Heven Sime[3], Gemechu Tadesse[3], Julia Dunn[1], Obiora Eneanya[1], Emily McNaughton[1], Ebba Abate[3], Anna Phillips[1], Roy Anderson[1]

[1]*Imperial College London, London, United Kingdom,* [2]*Federal Ministry of Health, Addis Ababa, Ethiopia,* [3]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*

The Geshiyaro project is a 4-year programme which seeks to test the feasibility of interrupting the transmission of STH and SCH in the Wolayita zone of south-western Ethiopia through two interventions: (i) expanded MDA through biannual community-wide treatment and (ii) provision of water sanitation and hygiene (WaSH) with complementary behaviour change communication (BCC). Achieving high coverage and individual compliance to treatment across treatment rounds is imperative, with systematic non-compliance having the potential to result in reservoirs of infection allowing for continued transmission. We seek to determine the likelihood of achieving the project aims based on baseline prevalence of infection and compliance to treatment in our first round of mass drug administration (MDA). Using baseline parasitological data from 13,700 individuals across 137 villages (kebeles) in the Wolayita zone, we estimate the variation in the basic reproductive number, R_0, and the magnitude of parasite aggregation parameter, k, across study sites using a simple parasite transmission model and Gibbs-sampling MCMC techniques. A stochastic model of STH transmission is used to forecast the effect of biannual MDA rounds. Individuals residing in the pilot district were registered with two identifiers at census, (i) biometric and (ii) study ID card. These two identifiers were used at MDA to register individual treatment records which could subsequently be linked to household census and parasitology data and allow for the future longitudinal analysis of individual compliance across the project. The results of this study will outline the utility of individual identifiers, study ID card compared to biometric, for the capture of treatment compliance data and subsequent treatment coverage estimates. The results of this study will influence the recommendations for expanded community wide MDA in areas of low STH prevalence, depending on the local transmission patterns and conditions, to reach transmission elimination.

1158

SOIL-TRANSMITTED HELMINTH INFECTIONS IN PRE-SCHOOL AND SCHOOL-AGED CHILDREN AND THE SCHOOL ENVIRONMENT IN SOUTHERN INDIA: BASELINE SURVEY RESULTS FROM THE DEWORM3 STUDY

Saravanakumar Puthupalayam Kaliappan[1], Katherine E. Halliday[2], Gokila Palanisamy[1], Janarthanan Maniyarasu[1], Jasmine Farzana[1], Rajeshkumar Rajendiran[1], Chinnadurai Pandi[1], David Kennedy[2], William Oswald[2], Kristjana Ásbjörnsdóttir[3], Gagandeep Kang[1], Judd L. Walson[3], Sitara S R Ajjampur[1]

[1]*Christian Medical College Vellore, Vellore, India,* [2]*The London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*University of Washington, Seattle, WA, United States*

Soil-transmitted helminths (STH) affect ~1.5 billion people worldwide and the current WHO strategy of targeted deworming of pre-school and school-aged children (PSAC and SAC) is aimed at controlling morbidity. School environments in endemic communities potentially have an important role to play in the transmission of STH within these age-groups. The DeWorm3 study is a series of cluster randomized trials underway in three countries (Benin, India, and Malawi) to test the feasibility of interrupting STH transmission with bi-annual community-wide MDA compared to the standard-of-care (school based bi-annual deworming in India). The study is being carried out in two sub-sites in India, Timiri (rural plains) and Jawadhu Hills (tribal area) in Tamil Nadu in a censused population of 140,932 demarcated into 40 clusters. During the baseline survey (Dec 2017 - Feb 2018), 2484 stool samples (1179 PSAC and 1305 SAC) were collected and the unweighted prevalence among PSAC and SAC for any STH infections was 3.1% and 7.1% and 2.7% and 6.7% for hookworm alone. In July 2018, a school survey was conducted to assess school environment including the presence of water and sanitation facilities and performance of school-based deworming. We plan to analyse prevalence of STH in PSAC and SAC alongside school environment characteristics to determine any associations between the two. A total of 445 schools in Timiri (307) and Jawadhu Hills (138) were enumerated of which 93% were public schools. The majority of schools had water available during the survey (97%), and 90% had a protected water source (well/bore well or piped water). Handwashing facilities were available in 72% of schools but only 50% had soap and water available. Toilets were present in 81% of schools. There were a total of 1090 toilets (98% of which were flush or pour-flush type) for 36,931 children of which, 830 (81%) were found to be usable (functional with sufficient privacy) equating to one toilet per 44 children. Water and sanitation facilities were comparable between the two sub-sites. School based deworming on the last National Deworming Day was recorded as having been conducted in 97% of the schools.

1159

CLINICAL CASE OF INFANTILE HOOKWORM IN THE PERUVIAN AMAZON AND LITERATURE REVIEW OF EFFICACY OF CURRENT ANTI-HELMINTHIC THERAPIES

Brian J. Medernach[1], Steven Goicoechea[2], Ravi Durvasula[3], Prakasha Kempaiah[3]

[1]*Center for Community and Global Health, Loyola University Chicago Stritch School of Medicine; Department of Medicine, Loyola University Medical Center, Maywood, IL, United States,* [2]*Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States,* [3]*Loyola University Chicago Stritch School of Medicine and Department of Medicine, Loyola University Medical Center, Maywood, IL, United States*

A 5-week-old female infant presented to a rural hospital in the Peruvian Amazon as a referral from the vaccine team for poor feeding and pallor. The child was born in her community at home on a dirt floor. Mother did not receive pre-natal care. Upon initial examination in the ER the child appeared ill and found to be pale and lethargic. The infant was afebrile with tachypnea and tachycardia. Laboratory findings were significant for anemia with hematocrit of 6 and creatinine of 1.0. Child was admitted for stabilization and further examinations. Stool study was positive showing eggs of intestinal hookworm infection (Necator americanus or Ancylostoma duodenale). She received blood transfusion and albendazole 200mg orally for 3 days and was discharged after recovery. Parents also tested positive for intestinal hookworm and were treated with albendazole 400mg orally for 3 days. Soil transmitted intestinal helminths (STH), belonging to phylum Nematoda (roundworms), infect ~1.5 billion people worldwide annually. These include Ascaris lumbricoides, Trichuris trichiura and hookworm morbidity is related to infection intensity and can cause many issues including dietary deficiencies like iron deficiency anemia, delayed cognitive and physical development. STH are most common in places without modern sanitation and infection occurs through contaminated soil, food and water with eggs. The primary anti-helminthic drug benzimidazoles (albendazole and mebendazole) have low efficacy against T. trichiura (whipworm) with inadequate egg reduction and cure rates. Current treatment and prophylaxis programs rely on single dosing of anti-helminthic agents which pose a risk for development of drug resistance. Recent studies have focused on combination drug therapy and identified several drug combinations with higher efficacy than single-dose albendazole for T. trichiura including albendazole-ivermectin, albendazole-oxantel pamoate, mebendazole-ivermectin, and tribendimidine-oxantel pamoate. However, there is a need for further research and development of anti-helminthic drugs.

1160

IDENTIFICATION OF PARASITES WITH METAGENOMIC BARCODING CONFIRMS MICROSCOPY FINDINGS AND DETECTS ADDITIONAL ORGANISMS

Leah A. Owens[1], Sagan L. Friant[2], Sarah Phillips-Garcia[3], Melissa Emery-Thompson[3], Tony L. Goldberg[1]

[1]*University of Wisconsin-Madison, Madison, WI, United States,* [2]*Pennsylvania State University, University Park, PA, United States,* [3]*University of New Mexico, Albuquerque, NM, United States*

Although microbiome research has led to an explosion of knowledge about prokaryotic communities and their influence on host health, a parallel revolution for eukaryotic communities has yet to be realized. The field of parasitology in particular would benefit from a metagenomic method for characterizing eukaryotes. We used a metagenomic barcoding approach to detect eukaryotic parasites in fecal samples using published pan-eukaryotic primers. After creating a validation set of parasites, we extracted genomic DNA, amplified a common barcode region (18S ribosomal RNA gene), and deep sequenced the amplicon. This approach identified 100% (n=6 helminths, n=6 protozoans) of organisms in the validation sample, 75% (9/12) to the species level and 25% (3/12) to the genus level. We then repeated the process with samples from wild nonhuman primates where matched fecal samples had been previously characterized by microscopy in published studies, adding steps to enrich for parasite DNA. Results were analyzed with a combination of mothur, qiime, and custom python scripts using the SILVA132 database. The percentage of host reads ranged from 2.77% to 5.1% with a mean= 3.79% and median= 3.45%. In one representative sample, 5.24% of filtered reads mapped to a ciliate species found via microscopy and 4.42% mapped to a protozoan not identified by microscopy but expected to be present based on PCR-based diagnostics. This work demonstrates the potential of a metagenomic barcoding approach for identifying eukaryotic gastrointestinal parasites.

1161

COMPARISON OF REAL-TIME POLYMERASE CHAIN REACTION AND PARASITOLOGICAL METHODS FOR DETECTION AND POSTTREATMENT FOLLOW-UP OF *STRONGYLOIDES STERCORALIS* IN FECAL SPECIMENS OF PATIENTS COINFECTED WITH HTLV-1

Sapha Barkati[1], Maria Gabriela Gastanadui Gonzalez[2], Milli B. Nath-Chowdhury[3], Rohan Mahimkar[3], Michael D. Libman[1], Cedric P. Yansouni[1], Momar Ndao[3], Martin Montes[2]

[1]*J.D. MacLean Centre for Tropical Diseases, McGill University Health Centre, Montreal, QC, Canada,* [2]*Instituto De Medicina Tropical "Alexander Von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*National Reference Centre for Parasitology, Research Institute of the McGill University Health Centre, Montreal, QC, Canada*

Strongyloides stercoralis (*SS*) is an intestinal nematode infecting over 100 million people worldwide, primarily in tropical and subtropical regions. The infection can remain quiescent indefinitely, but when associated to iatrogenic immunosuppression and/or HTLV-1 coinfection, parasites can rapidly replicate and lead to hyperinfection and death. Coinfection has also been associated with lower cure rates that lead to persistent low parasite burden. Parasitological methods such as Baermann (BM) and agar-plate culture (APC) are cumbersome and may have lower sensitivity when trying to define larvae eradication in coinfected patients due to periods of scant intermittent larvae output. Recent PCR methods have shown better performance for earlier detection of low parasite-load infections. We aimed to compare the performance of parasitological methods and PCR in detection and posttreatement follow-up of patients coinfected with *SS* and HTLV-1. Seven HTLV-1 positive patients with active *SS* coinfection were enrolled and followed-up at 2, 4 and 12 weeks after treatment, which consisted of 2 doses of oral Ivermectin 200μg/kg/day repeated at the 2-week visit. At initial and each subsequent visits, BM and APC were performed. Frozen stool samples were kept for real-time PCR targeting the 18s small subunit following a modified protocol for multiplexing qPCR. Twenty-seven specimens were tested with an overall agreement of 81.5% (22/27). A total of 9 specimens (33.3%) were positive by at least one of the methods. Amongst the positive specimen, 5 (55.6%) were positive by qPCR and at least by one other method. At follow up, 1 patient showed treatment failure, with a prolonged excretion of larvae only detected by qPCR. The sensitivity of qPCR, BM and APC for the detection of *SS* compared to a combination of all diagnostic techniques was 66.7%, 77.8% and 75.0% respectively. In patients coinfected with HTLV-1, combination of parasitological methods and qPCR may increase the sensitivity of detection of *SS* larvae and may be a major tool for early detection of treatment failure. A larger patient cohort will allow us to define the best diagnostic and follow-up strategy.

1162

APPLICATION OF STH QPCR DIAGNOSTIC ASSAYS TO SCREENING ENVIRONMENTAL SAMPLES

Brian Abrams[1], Nils Pilotte[1], Gretchen Walch[1], Maya Nadimpalli[2], Amy Pickering[2], Steven Williams[1]

[1]*Smith College, Northampton, MA, United States,* [2]*Tufts University, Medford, MA, United States*

Worldwide, approximately 1.5 billion people are infected with at least one species of soil-transmitted helminth (STH). Yet despite soil and drinking water serving as important environmental reservoirs for STH transmission, current molecular methods for monitoring STH infection rely solely on the sampling and testing of human stool. While effective, human sampling is cumbersome and frequently associated with significant stigma. Recognizing these limitations, previous work has demonstrated the potential utility of environmental sampling for monitoring STH rates. However, all such work has utilized microscopy-based techniques. In response, we developed and optimized methods for the extraction and detection of DNA from STH eggs existing in soil and drinking water. By spiking *Necator americanus* and *Ascaris suum* eggs into known quantities of both environmental materials, we conducted a controlled comparison evaluating a variety of commercially available DNA extraction kits for this purpose. Following DNA extraction, samples were analyzed using our established STH qPCR assays. Testing revealed that environmental detection of STH was possible at concentrations as low as 5 eggs/20 grams of soil and 50 eggs /4 liters of water. These results provide proof-of-concept for the recovery and detection of STH DNA from both soil and drinking water samples. As such, the potential to use soil and water sampling for detecting STH may be feasible. Future work will focus on correlating environmental STH rates, as determined by qPCR, with infection rates in the human population.

1163

INDOOR EXPOSURE OF INTESTINAL PARASITES AND RELATION TO INFECTION IN ECUADORIAN CHILDREN

Victor Seco Hidalgo[1], Diana Garcia Ramon[1], Evelyn Calderón Espinosa[1], Andrea Lopez Rodas[1], Philip Cooper[1], Rojelio Mejia[2]

[1]*Universidad Internacional De Ecuador, Quito, Ecuador,* [2]*National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States*

Soil-transmitted helminths and protozoa with a fecal-oral route of infection all have an outdoor environmental stage of their life cycle. In extreme poverty settings, many houses have dirt floors, outdoor latrines, and multiple children sleeping in the same bed. A parasite prevalence study in rural Ecuador with stools and dust were collected by aspiration at the doorway inside the house and the children's bed. Stools were examined by Kato-Katz microscopy. Dust was processed using a novel DNA extraction method and analyzed by multi-parallel quantitative real-time PCR (qPCR). All samples were analyzed in Ecuador. A total of 87 dust samples from each house were positive for *Ascaris lumbricoides* (38.7%), *Ancylostoma duodenale* (9.3%), *Necator americanus* (1.3%), *Strongyloides stercoralis* (52%), *Toxocara canis/cati* (22.7% and 4.0%), *Trichuris trichiura* (4.0%), *Blastocystis* (79.7%), and *Giardia lamblia* (24.3%). Of the children living

in these homes, stool microscopy detected positives for *Ascaris* (17.4%), hookworm (2.9%), *Strongyloides* (0%), and *Trichuris* (20.3%). There was a positive correlation of having *Ascaris* on Kato-Katz stool microscopy and having *Ascaris* contamination in bed dust (p = 0.0019). This correlation was also seen with a mean *Ascaris* burden in the stools with the bed dust (Low 602 epg, p = 0.0412; Medium 4643 epg, p = 0.0076; High 57,451 epg, p = 0.023, interquartile levels, respectively). For both the bed and doorway being qPCR positive, there was an odds ratio of 6.944 (1.246 - 36.21), p = 0.0140 for *Ascaris*; and 16.69 (4.752 - 49.10), p = < 0.0001 for *Strongyloides*. This study showed the risk for parasite contamination also occurs inside the households. Extreme poverty leads to poor sanitary conditions. This may be another route of parasite infection. Future work will be to determine if dust has viable parasites by searching for mRNA using molecular methods.

1164

A CLUSTER-RANDOMIZED CONTROLLED TRIAL COMPARING SCHOOL AND COMMUNITY-BASED DEWORMING FOR SOIL TRANSMITTED HELMINTH CONTROL IN SCHOOL-AGE CHILDREN: THE CODE-STH TRIAL PROTOCOL

Naomi E. Clarke[1], Dinh Ng-Nguyen[2], Rebecca J. Traub[3], Archie CA Clements[4], Kate Halton[5], Roy M. Anderson[6], Darren J. Gray[7], Luc E. Coffeng[8], **Susana Vaz Nery**[1]

[1]*University of New South Wales, Sydney, Australia,* [2]*Tay Nguyen University, Buon Ma Thuot, Vietnam,* [3]*University of Melbourne, Melbourne, Australia,* [4]*Curtin University, Perth, Australia,* [5]*Queensland University of Technology, Brisbane, Australia,* [6]*Imperial College, London, United Kingdom,* [7]*Australian National University, Canberra, Australia,* [8]*University Medical Center, Rotterdam, Netherlands*

Current control guidelines and targets for soil-transmitted helminths (STH) focus on deworming school-aged children, given the high risk of associated morbidity in this age group. STH control programs are therefore often founded on a school-based deworming approach. However, expanding deworming programs to all age groups may achieve improved STH control among not only the community in general, but also the high-risk group of school-aged children, by reducing transmission in the total population. The CoDe-STH trial is a cluster-randomized controlled trial (RCT), aiming to compare the impact of school-based targeted deworming and community-wide mass deworming on STH infections among school-aged children. The trial is being conducted in 64 primary schools in Dak Lak province, Vietnam. Schools in the control arm receive one round of school-based targeted deworming with albendazole. In the intervention arm, community-wide mass deworming with albendazole is additionally implemented through house-to-house visits. STH infections will be measured in school-aged children using quantitative PCR, at baseline and 12 months following deworming. The primary outcome is the comparison of hookworm prevalence in school-aged children 12 months after deworming. Analysis will be intention-to-treat, with outcomes compared between study arms using generalised linear and non-linear mixed models. Additionally, cost-effectiveness of mass and targeted deworming will be calculated and compared; feasibility and acceptability of deworming approaches will be examined; and individual based stochastic models will be used to predict the impact of mass and targeted deworming strategies beyond the RCT timeframe. The CoDe-STH trial is the first large-scale trial comparing mass and targeted deworming for STH control in Southeast Asia. This study will provide key information for policymakers regarding optimising the design of STH control programs at a time when the future of STH control is being vigorously discussed. We will present results from a rapid prevalence assessment and implementation of baseline surveys.

1165

MALARIA CARE-SEEKING BEHAVIOR AMONG HIV-INFECTED PATIENTS RECEIVING ANTIRETROVIRAL TREATMENT IN SOUTHEASTERN NIGERIA: A CROSS-SECTIONAL STUDY

Uchechukwu Chukwuocha[1], Gregory Iwuoha[2], Geoffrey Nwakwuo[3], Chidinma Ezeihekaibe[4], Christopher Ekiyor[3], Ikechukwu Dozie[2], Sahai Burrowes[4]

[1]*University of Massachusetts, Amherst, MA, United States,* [2]*Federal University of Technology, Owerri, Nigeria,* [3]*RAHI Medical Outreach, Port Harcourt, Nigeria,* [4]*Touro University, Vallejo, CA, United States*

This study assesses malaria prevention and treatment behaviour among people living with HIV/AIDS (PLWHA) in Owerri, South Eastern Nigeria. Although Nigeria bears one of the world's largest burdens of both malaria and HIV, there is almost no research studying how co-infected patients manage their care. We systematically sampled 398 PLWHA receiving care at Imo State Specialist Hospital and the Federal Medical Centre in Owerri to complete a structured, pre-tested questionnaire on malaria care-seeking behaviour. Descriptive statistics were reported and chi-square tests and multivariate logistic regressions were also used. The majority of HIV-infected patients (78.9%) reported having had an episode of suspected malaria quarterly or more often. There was a large variation in care-seeking patterns: on suspicion of malaria, 29.1% of participants engaged in self-medication; 39.2% went to drug shops, and only 22.6% visited HIV/AIDS care centres. Almost 40% waited more than 24 hours before initiating treatment. Most (60.3%), reported taking recommended artemisinin-based combination treatments (ACT) but a significant minority took only paracetamol (25.6%) or herbal remedies (3.5%). Most (80%) finished their chosen course of treatment; and completion of treatment was significantly associated with the frequency of suspected malaria occurrence (p=0.03). Most (62.8%) did not take anti-malaria medication while taking antiretroviral treatment (ART) and almost all (87.6%) reported taking an ACT regimen that could potentially interact with Nigeria's first-line ART regimen. Our findings suggest the need to pay more attention to malaria prevention and control as a crucial element in HIV/AIDS management in this part of Nigeria and other areas where malaria and HIV/AIDS are co-endemic. Also, more research on ART-ACT interactions, better outreach to community-level drug shops and other private sector stakeholders,and clearer guidelines for clinicians and patients on preventing and managing co-infection may be needed. This will require improved collaboration between programmes for both diseases.

1166

HIGH PREVALENCE OF HIV AMONG PREGNANT WOMEN ATTENDING ANTENATAL CLINICS IN GABON

Saskia Dede Davi[1], Ghyslain Mombo-Ngoma[1], Johannes Mischlinger[2], Marylyn Addo[2], Michael Ramharter[2]

[1]*Centre de Recherches médicales de Lambaréné and Department of Tropical Medicine Bernhard Nocht Institute for Tropical Medicine, Lambaréné, Gabon,* [2]*Department of Tropical Medicine, Bernhard Nocht Institute for Tropical Medicine and I Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

The National HIV/AIDS Control Programme of Gabon has established the screening of HIV among antenatal clinics (ANCs) attendees as one of the methods for collecting data on HIV prevalence for pregnant women to strengthen the prevention of mother to child transmission (PMTCT) of HIV. This study provides trends on HIV prevalence for 21 ANCs during the year 2018 in seven towns of Gabon. The surveillance population included all pregnant women attending the ANCs of selected centres in Libreville, the capital city, and Lambarene, Fougamou, Tchibanga, Mayumba, Oyem, and Bitam. Testing of HIV from blood samples after counselling was done anonymously according to the national guidelines for diagnosis of HIV/AIDS. Prevalence trends were calculated as the number of positive cases by the number of women tested during the period evaluated. Overall, 16417 pregnant women had been screened for HIV in 2018 in the 21 evaluated ANCs. The overall prevalence was 4% (646/16417). There was a marked

variability between ANCs within Libreville, from 2% to 10% of prevalence. Between provinces, there was also an observed variability in prevalence as the northern province, Woleu-Ntem (Oyem and Bitam) had 6% prevalence while the Moyen-Ogooue province (Lambarene) in the centre, and the Ngounie and Nyanga provinces in the south had respectively 5%, 4%, and 2% prevalence of HIV among pregnant women attending the ANCs. The findings show a high prevalence of HIV among pregnant women in the evaluated settings in Gabon suggesting a high risk of mother to child transmission of HIV that should be actively prevented by existing interventions. The variability of HIV prevalence between the different geographical locations may encourage integrated approaches taking into account specificities of each localities.

HOMOZYGOUS DELETION OF BOTH GSTM1 AND GSTT1 GENES IS ASSOCIATED WITH HIGHER CD4+ T CELL COUNTS IN GHANAIAN HIV PATIENTS

Joshua A. Kuleape[1], Emmanuel A. Tagoe[2], Peter Puplampu[3], Evelyn Y. Bonney[4], Osbourne Quaye[5]

[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), University of Ghana, Accra, Ghana,* [3]*Department of Medicine, Korle Bu Teaching Hospital, Accra, Ghana,* [4]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana,* [5]*West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), Department of Biochemistry, Cell and Molecular Biology, University of Ghana, Accra, Ghana*

Glutathione S-transferase (GST) family of enzymes are involved in a two-stage detoxification process of a wide range of environmental toxins, carcinogens and xenobiotics. The GST enzymes play important roles in oxidative stress pathways, and polymorphisms in the GSTM1 and GSTT1 genes mediate susceptibility and outcome in different diseases. Human immunodeficiency virus (HIV) infection is associated with oxidative stress, but there is limited data on the frequency of deleted GSTM1 and GSTT1 genes in HIV/AIDS patients and their effect on progression among Ghanaians. This study sought to investigate the association between homozygous deletion of GSTM1 and GSTT1 genes (both null deletion) with HIV/AIDS disease progression in Ghanaian patients. HIV-infected individuals on antiretroviral therapy (ART), ART-naïve HIV patients, and HIV seronegative individuals were recruited for the study. HIV/AIDS disease progression was assessed by measuring CD4+ cell count and viral load of the patients, and GST polymorphism was determined by amplifying the GSTT1 and GSTM1 genes using multiplex PCR, with CYP1A1 gene as an internal control. The mean CD4+ count of patients that were naïve to ART (298 ± 243 cells/mm^3) was significantly lower than that of patients on ART (604 ± 294 cells/mm^3), and viral load was significantly lower in the ART-experienced group (30379 ± 15073 copies/mm^3) compared to the ART-naïve group (209882 ± 75045 copies/mm^3). Frequencies of GSTM1 and GSTT1 deletions were shown to be 21.9% and 19.8%, respectively, in the HIV patients, and patients with homozygous deletion of both GSTM1 and GSTT1 were more likely to have their CD4+ count rising above 350 cells/mm^3 (OR = 6.44, 95% CI = 0.81-51.49, p = 0.039) suggesting that patients with homozygous deletion of GSTM1 and GSTT1 genes have slower disease progression. The findings of this study show that double deletion of glutathione S-transferases M1 and T1 is statistically associated with normal CD4+ count in patients diagnosed with HIV/AIDS. Further study is required to investigate the clinical importance of the both null deletion in HIV patients.

1168

FEMALE GARMENT WORKERS' UNDERSTANDINGS OF HIV/AIDS IN BANGLADESH

Shakeel Ahmed Ibne Mahmood

The University of Newcastle, Newcastle, Australia

The proposed objective is to examine female garment workers' (FGWs) personal understandings and experiences of their human immunodeficiency virus (HIV) in Bangladesh. A systematic and comprehensive literature search has been conducted, focusing on FGWs HIV health in Bangladesh, published between 1989 and 2018. Relevant information from selected articles extracted, presented and attempted to contribute to existing literature in the form of new findings and critically interpret existing findings. The corresponding review of the literature continues to form inherent components of the debate. According to one study (Hasan, et al., 2013), FGWs are an at risk group, who are regularly engaged in illegal and unsafe sex. Major causes of HIV vulnerability of FGWs are gender inequality, multiple sex partners, drug abuse and rape violence. These poor FGWs are not informed about contraceptive methods, safe sex, menstruation, hygiene and HIV infection due to their low literacy rate. In another study (Mondal, et al., 2012), FGWs revealed that 43% do not use condoms and 95% believe that HIV is treatable. Thus, HIV related risk behaviors of FGWs demonstrate a potentially substantial impact on the future course of HIV epidemic in Bangladesh. This research contributes to broader disciplinary knowledge and/or policy practice on HIV prevention within FGWs of Dhaka City. Empowering FGWs through formal health education on HIV is essential, including prevention of work place violence and intimate partner violence related training. Community leaders, private sector involvement and NGOs focusing on HIV need to be encouraged to aware the FGWs regarding safe sex. Counselling and additional information are critical components to support women in making sexual intercourse decisions and carrying them out both voluntarily and safely at the same time. To this point in time, surveillance has only been conducted in key population. Therefore, the results of the study recommend a large-scale study of the general female population in Bangladesh to guide policymakers and researchers on how to prevent HIV and improve FGWs health over time.

1169

THE MISSING 90 IN THE HIV CASCADE OF CARE: LATE PRESENTATION IN CARE IN THE DOMINICAN REPUBLIC

Leandro Tapia[1], Rosa M. Rodriguez-Lauzurique[1], Merelin Muñoz[2], Robert Paulino-Ramirez[1]

[1]*Instituto de Medicina Tropical y Salud Global UNIBE, Santo Domingo, Dominican Republic,* [2]*Centro de Orientación e Investigación Integral, Santo Domingo, Dominican Republic*

Current biomedical interventions are aimed to reduce the impact of HIV in the immune system, and diagnosis of opportunistic infections. The objective of this study was to evaluate patient engagement in the continuum of HIV care for HIV, and to evaluate factors associated with late diagnosis and attrition from care. We included all patients attending a primary care unit in Santo Domingo (Capital city) for HIV care during two years, data collected included age, gender identity, year of first positive HIV test, CD4 cell count (cells/uL), drug use, and HIV viral load. Late presentation at the time of entering into care was defined as a CD4 cell count <200 cells/uL or an AIDS-defining event (based on CDC stages) within 3 months of the first positive test. To evaluate the factors associated with late presentation. Significant factors ($p<0.10$) in the univariate model were included in the multivariate model. Descriptive statistics for the categorical variables were analysed using the Pearson test to evaluate correlation between late presentation and other variables. A total of 257 HIV (+) patients were enrolled in care during a period of 24 months. The mean age was 35.7 years old, with 55% being males. The mean of CD4 count on the first visit was 370 cells/uL, and viral load (SD: 701,626 copies/mL). Analysis of correlation between variables (Pearson Test) was -0.155 significant for late presentation and the use of drugs. No correlation was found on age, nationality or gender. This study reveals the importance of intensive case finding among key populations to reduce the impact on expenditure and clinical management of complications related to opportunistic infections, and transmission pockets among drug users and other populations.

1170

EPIDEMIOLOGY OF TUBERCULOSIS AND HIV COINFECTION AND ITS COLLABORATIVE SERVICES TOWARDS ENDING THE TB EPIDEMIC IN ETHIOPIA

Yalemzewod Assefa Gelaw[1], Ricardo J. Soares Magalhães[2], Yibeltal Assefa[1], Gail Williams[1]

[1]*School of Public Health, The University of Queensland, Brisbane, Australia,* [2]*UQ Spatial Epidemiology Laboratory, School of Veterinary Science, Faculty of Science, The University of Queensland, Gatton, Australia*

The co-epidemics of HIV and tuberculosis (TB) is an important public health challenge in Ethiopia. This study aimed to describe the burden, distribution and trends of HIV and TB co-infection in the adult population (aged 15-years and above) in Ethiopia. This is an ecological descriptive study based on the national sentinel TB and HIV co-infection surveillance data from the Ethiopian Public Health Institute from 2010 to 2015. The annual proportion of co-infection rate for each specific year in the region/city administration was reported using notification rate ratios and 95% CI. GIS was used for visualization. A TB and HIV collaborative activities have increased by 31.5 % in 2015 compared from 11.6 % in 2010 with considerable variations within regions/city administrations. TB notification among HIV positives during the study period included 4,230 cases (range, 237 – 1095), with the annual notification rates of 7.5 % (7.2, 7.7) range between 4.5% (3.8, 5.1) in Tigray and 10.8 % (9.3, 12.5) in Afar region. The estimated annual notifications of HIV infection among all and new TB patient was 18.11% (17.8, 18.4) and 18.1% (17.7, 18.5), respectively. The rate notifications of HIV infection in TB was higher in Addis Ababa city 31.0% (29.5, 32.5) and lower in Harari region 4.4 % (4.0, 5.0). The TB-HIV collaborative activities have found increased and the notification rates of co-infection decreased. Exploring the burden of HIV and TB co-infection and its trend at the sub-national level could assist the needs of TB and HIV collaborative activities in finding the missed cases of both TB and HIV at the delivery of health care services.

1171

HIGH RESISTANCE TO NEVIRAPINE AND EFAVIRENZ IN HIV-1 SUBTYPE *CRF02_AG* AND DUAL *CRF02_AG/G* -INFECTED PATIENTS IN GHANA

Selase D. Deletsu[1], Edward K. Maina[2], Osbourne Quaye[3], William K. Ampofo[4], Gordon A. Awandare[3], Evelyn Y. Bonney[4]

[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*Centre for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya,* [3]*West African Centre for Cell Biology of Infectious Pathogens, Department of Biochemistry, Cell and Molecular Biology, Accra, Ghana,* [4]*Department of Virology, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana*

The increasing prevalence of HIV drug resistance (HIVDR) is a global health issue and an obstacle to successful antiretroviral therapy (ART). Information on HIVDR is important for initiating ART, and deciding on choice of drugs for subsequent regimens. We evaluated HIV-1 subtypes and drug resistance mutations among 51 ART exposed and 12 ART naïve patients in two public health centres in Ghana. Blood samples were collected and processed into plasma and PBMC fractions. HIV RNA was extracted from plasma and the *protease* and *reverse transcriptase* genes were amplified and sequenced.Of the sixteen patient` samples successfully sequenced, we identified a predominance of HIV-1 subtype *CRF02_AG* (11/16, 68%). Subtypes *G* (2/16, 13%), dual *CRF02_AG/G* (2/16, 13%) and *CRF01_AE* (1/16, 6%) were also observed. Major nucleoside reverse transcriptase inhibitor (NRTI)-associated drug resistance mutations (DRMs) (*M184I/V*, *D67N*, *T215F* and *K70R/E*), non-nucleoside reverse transcriptase inhibitor (NNRTI)-associated DRMs (*K103N*, *Y181C*, *V90I*, *F227L* and *V106A*), and protease inhibitors (PI)-associated mutations (*M46I*, *I54V*, *V82A*, *L90M* and *I471V*) were present in the *CRF02_AG* and subtype *G* sequences from ART-exposed individuals. Two NRTI-associated DRMs (*D67N* and *T69N*) were present in the *CRF02_AG* sequences from one ART-naive individual. No DRM was present in the *CRF01_AE* sequences.The detection of these DRMs in individuals on NRTI/NNRTI-containing first-line regimen is an evidence of prolonged drug exposure without viral load monitoring This is a real global health problem giving the importance of effective treatment in achieving UNAIDs 90/90/90 goal. Routine viral load monitoring and drug resistance testing would be respectively useful for early detection of virologic failure and informed choice of drugs in the subsequent regimens of such patients.

1172

RETROSPECTIVE ANALYSIS OF HIV-TB CO-INFECTION IN GOVERNMENT MEDICAL COLLEGE AURANGABAD

Jyoti Anil Iravane, Maitrik Dave, Shaikh Ambreen Fatema Hafiz

Government Medical College, Aurangabad, Aurangabad, India

According to UNAIDS data 2018, India has the third largest HIV epidemic in the world. In 2016, 12% of people newly enrolled in HIV care in India had active TB. Of the 410,000 people who died of TB in 2017, 11,000 were HIV positive. A retrospective study was conducted among HIV/TB co-infected patients attending ICTC centre in the Department of Microbiology, Government Medical College & Hospital Aurangabad for a period of 3 years from 2016 to 2018. A total of 901 HIV positive cases were screened for TB in our TB Culture & DST laboratory. 216 (23.97%) cases were found to be TB positive either by CBNAAT (Cartridge Based Nucleic Acid Amplification) or LPA (Line Probe Assay). Pulmonary & extra pulmonary samples were screened by microscopy. The smear negative samples were tested by GeneXpert and the smear positive samples were tested by line probe assay for first line drugs. Out of the 216 cases, 199 (92.12%), were sensitive to Rifampicin & INH. Rifampicin resistance was detected in 10 cases (4.62%) and Rifampicin & INH resistance was found in 4cases (1.85%). A total of 62 Extra pulmonary TB samples (EPTB) were screened, amongst which 16(25.80%) were positive for MTB and one (6.25%) was an MDR case. In our study, the major determinants of HIV TB confection were identified to be low CD4 counts and ART (Anti-retroviral therapy). We also studied the correlation of low CD4 counts and presence of MDR cases. HIV TB co infection constitutes a serious diagnostic and therapeutic challenge particularly in resource limited countries and it is important to screen MDR-TB cases to identify early resistance and also to prevent the spread of MDR-TB.

1173

PREDICTORS OF MORTALITY IN HIV PATIENTS WITH SEVERE *PNEUMOCYSTIS CARINII* PNEUMONIA ADMITTED TO INTENSIVE CARE UNIT: A SYSTEMATIC REVIEW

Amanuel Lomencho[1], Helena Fantaye[2]

[1]*Emerald Medical, AMC Infectious Diseases Center, Addis Ababa, Ethiopia,* [2]*Federal Ministry of Health, Addis Ababa, Ethiopia*

Despite current developments in HIV medicine and wide scale use of antiretroviral therapy (ART), Pneumocystis Carinii Pneumonia (PCP) still remains to be an important cause of respiratory failure requiring ICU (Intensive Care Unit) care in developing countries. To date, there have been published studies on mortality predictors in PCP patients in ICU but to the best of our knowledge there are no systematic reviews.We aimed to look in to mortality predictors in HIV patients with severe PCP receiving ICU care.A systematic review was done to look for predictors of mortality in HIV patients with confirmed severe PCP admitted to ICU. Eligible studies were cohort and case control study designs that report predictors of ICU mortality. Studies that reported separate outcome for ICU patients with HIV/PCP were included. PubMed, Embase and Medline search was made from 2005-2018. Two authors independently screened titles and abstracts of all citations identified in the search. Quality assessment of relevant articles was made using CASP tool for cohort study appraisal. Initial search resulted 257 articles, out of which a final 9 were included in the synthesis. Most studies were in the pre-HAART era. All studies had a cohort design. Trimethoprim/Sulfamethoxazole, Pentamidine and steroids were used for treatment. Overall mortality ranged from 53%-81% in the pre-HAART which reduced to 25% following introduction of HARRT. In

the high quality studies, need of mechanical ventilator, development of pneumothorax, and duration of medical therapy prior to ICU admission were significantly associated with mortality. Higher quality studies reporting separate mortality predictors for patients put on respiratory support showed statistical significance for acidosis and high PEEP(Positive End Expiratory Pressure) requirement but failed to do so for APACHE II, Acute Lung Injury Score, indices of oxygenation (PaO2, alveolar arterial oxygen gradient), serum lactate dehydrogenase and severity of chest X-ray. ART improved ICU mortality among HIV patients with severe PCP. Mortality predictors generally were comparable in pre and post HAART era.

1174

DETERMINANTS OF ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG PERSONS LIVING WITH HUMAN IMMUNE DEFICIENCY VIRUS IN THE UPPER EAST REGION

Gifty Apiung Aninanya, Gilbert A. Abiiro, Michael W. Wombeogo

University for Development Studies, Tamale, Ghana

Antiretroviral therapy (ART) suppresses HIV replication and decreases progression to Acquired Immune Deficiency Syndrome (AIDS). High levels of adherence to ART are required to improve the quality of life of persons living with HIV and AIDS (PLHIV). But, little evidence exists on determinants of ART adherence in the Upper East Region of Ghana.This qualitative study examined determinants of ART adherence among PLHIV in the Upper East Region. Using descriptive phenomenology approach to qualitative enquiry, we conducted five focus group discussions (n=30) and twenty (20) in-depth interviews with persons living with HIV. In addition, twelve in-depth interviews were conducted with health staff. Purposive sampling technique was used to select study participants. Colaizzi's descriptive phenomenology approach was adopted and used to code the data with the aid of Nvivo 11 software before thematic content analysis. Barriers that affected adherence to antiretroviral medicines were lack of nutritional support, side effects of ART, occasional travels, inadequate social support, lack of health insurance, access to transportation, economic problems, lack of confidentiality, negative attitudes of some health staff, queuing up for antiretroviral, non-disclosure of HIV status and stigma and discrimination. Perceived facilitators to ART adherence were appropriate counselling and education, provision of nutritional support, improved health status due to ART, the use of reminder aids, pregnancy and stigma-reduction policies. Several factors have been found to have a negative effect on PLHIV adherence to antiretroviral therapy. Nonetheless, it is recommended that effective and appropriate counselling techniques, provision of food supplements, stigma-reduction policies and regular training programmes for health staff on HIV case management could help to improve adherence to antiretroviral therapy by PLHIV. If all these measures are executed, Ghana will achieve its aim of having zero AIDS-related deaths by 2030.

1175

INTESTINAL PARASITES INFECTIONS AMONG HIV INFECTED CHILDREN UNDER ANTIRETROVIRALS TREATMENT IN YAOUNDE, CAMEROON

Celine N. Nkenfou[1], William B. Abange[2], Hortense G. Kamga[3], Clement N. Assob[2], William Estrin[4]

[1]*CIRCB, Yaounde, Cameroon,* [2]*University of Buea, Buea, Cameroon,* [3]*University of Yaounde I, Yaounde, Cameroon,* [4]*California Pacific Medical Center, San Franscisco, CA, United States*

Intestinal parasitic infections are among the most common communicable diseases worldwide, particularly in developing countries. HIV causes dysregulation of the immune system through the depletion of CD^4+ T lymphocytes which gives rise to opportunistic infections. A cross-sectional study was conducted from January to October 2018. Stool and blood samples were collected from participants aged 1 to 19. Stool samples were analysed for intestinal parasites using microscopy techniques. Blood samples were analysed for HIV and CD^4 + T cell counts. Out of 214 children enrolled, 119 (55.6%) were HIV infected and 95 (44.4%) were HIV non-infected. All infected children were on antiretroviral treatment (ART). The prevalence of intestinal parasites was 20.2% in HIV infected and 15.8% in non-infected children. Among the 119 HIV infected children, 33 (27.7%) of them had a CD^4+ T cell count less than 500 cells/mm^3, and 7 children (5.9%) had a CD^4+ T cell count less than 200 cells/mm^3. Among HIV infected children, Cryptosporidium spp. was most frequently detected, 7/119 (5.9%), followed by Giardia lamblia 5/119 (4.2%) then Blastocystis hominis 3/119 (2.5%) and Entamoeba coli 3/119 (2.5%). Participants on ART and prophylactic co-trimoxazole for >10 years had little or no parasite infestation. In conclusion, although ART treatment in combination with prophylactic co-trimoxazole reduces the risk of parasitic infection, 20.2% of HIV infected children harbored intestinal parasites including Cryptosporidium spp. Stool analysis should be routinely performed on HIV+ children to detect Giardia lambia, Blastocystis hominis, and Entamoeba species in order to initiate treatment and thereby improve the quality of life in these children.

1176

EPIDEMIOLOGY OF CUTANEOUS AND MUCOCUTANEOUS LEISHMANIASIS IN NICARAGUA

Santiago Ernesto Hernandez[1], Gerardo Blass[2], Manuel Gomez[2]

[1]*University of South Florida, Tampa, FL, United States,* [2]*Universidad Nacional Autonoma de Nicaragua-Managua, Managua, Nicaragua*

Leishmaniasis continues to be a major public health burden in the world. The disease is present in five continents and 97 countries and occurs mostly in the rural sylvatic areas with favorable conditions for the reproduction of vectors and intermediate hosts. It is considered a major Neglected Tropical Disease (NTD) which puts a huge economic burden on already meager financial resources. The World Health Organization (WHO) has estimated an annual incidence of 700,000-1,000,000 cases and about 20,000-30,000 deaths per year. This number might be underestimated due to misdiagnosis of cases in rural areas of endemic countries and inconsistent reporting guidelines. Cutaneous leishmaniasis and mucocutaneous leishmaniasis are endemic in 18 countries of the Americas. Approximately 66,941 cases of CL are reported annually in the Americas. In Central America, approximately 39,000 cases are reported annually. Most of the cases are reported in Nicaragua, Panama and Costa Rica. In recent years, Nicaragua has presented alarmingly high numbers of cases and elevated incidence rates. In 2016, the incidence rate was 84.30 per 100,000 habitants. Five-thousand and ninety-three cases of leishmaniasis were reported in the ¨Sistemas Locales de Atención Integral en Salud¨ (SILAIS) of Jinotega (2,378), Matagalpa (1,544), Las Minas (651) and Nueva Segovia (415). The municipalities which presented the highest incidence were El Cuá (965), San José de Bocay (867), Rancho Grande (384) and Wiwilí (383). In 2017, Nicaragua had a 157% increase in its incidence

rate. This rise in the number of cases was recorded as the highest rate in the Americas due to an outbreak in El Cua, which is a town located in Jinotega Department

1177

SEROPREVALENCE OF CHAGAS DISEASE AMONG BLOOD DONORS IN THE STATE OF BAHIA, BRAZIL

Diego L. Miranda[1], Gilmar R. Júnior[2], Fernanda C. Lanza[2], Fred Luciano Santos[2], Renato B. Reis[2], Deborah B. Fraga[2], Luciano K. Silva[2], Marinho M. Neto[3], Iraildes J. Santana[3], **Mitermayer G. Reis**[2]

[1]*Faculty of Medicine of the Federal University of Bahia, Salvador, Brazil,* [2]*Oswaldo Cruz Foundation, Salvador, Brazil,* [3]*Foundation of Hematology and Hemotherapy of Bahia, Salvador, Brazil*

Chagas disease affects 5.7 to 7 million individuals in the world. In the state of Bahia, Brazil, its prevalence has reached 25.1%. There is an association between CD and the social profile of the population and a risk of re-emergence of the disease also due to non-vectorial transmission, such as blood transfusion. The aim of this study was to describe the seroprevalence of *T. cruzi* infection among blood donors in the state of Bahia, Northeastern Brazil, and their epidemiological profile in the last 10 years. It was conducted as a descriptive, cross-sectional study, through database review. Data was gathered from patients who had a non-negative result for *T. cruzi* infection over the last 10 years. 3,084 (0.62%) non-negative samples were identified in a first sample, and 810 (0.16%) were again defined as non-negative for *T. cruzi* infection in a second sample. Correlation between infection and age (30 years and older) and infection and lower educational level (12 years or less) in both samples was statistically significant. Males presented a higher risk for T. cruzi infection only in the first sample. 99,52% of the municipalities of Bahia were identified as cities of residence among all blood donors. Livramento de Nossa Senhora was the most prevalent city in both samples and the capital, Salvador, presented the greatest recurrence of cases. The seroprevalence found in these populations is lower compared to other similar studies conducted in Brazil, but some condensed areas with higher prevalence were found. In general, the epidemiological profile was in agreement with previous studies.

1178

INTEGRATION OF PHLEBOTOMINE ECOLOGICAL NICHE MODELLING, AND MAPPING OF CUTANEOUS LEISHMANIASIS SURVEILLANCE DATA TO IDENTIFY AREAS AT RISK OF UNDER-REPORTING

Clara B. Ocampo[1], Lina Guzmán-Rodríguez[1], Mabel Soraya Moreno[2], Carlos Valderrama Ardila[3], Neal Alexander[1]

[1]*Centro Internacional de Entrenamiento e Investigaciones Médicas (CIDEIM), Cali, Colombia,* [2]*Secretaria de Salud Pública Municipal, Cali, Colombia,* [3]*Universidad Icesi, Cali, Colombia*

Passive surveillance systems are thought to under-estimate the true incidence of cutaneous leishmaniasis (CL) by two- to five-fold, although this factor is intrinsically difficult to estimate. Here we report an integrated approach to identifying areas at risk of under-estimation. The project is taking place in one municipality of each of three departments (states) of Colombia: Risaralda, Tolima (Andean region) and Nariño (Pacific coast). The objective is to identify one or more townships (*veredas*) with high unreported incidence. The rationale is that a competent vector must be present in such townships, and that they are likely to be located nearby sites where the surveillance data indicate disease incidence. Results of ecological niche mapping, are used as risk factors in multivariable spatial analysis, more specifically, conditional autoregressive (CAR) Poisson regression. Maximum entropy niche models for the species of *Pintomyia* (*Pifanomyia*) *longiflocosa* and *Psychodopygus panamensis* have been developed from existing published and unpublished researcher data, using the MaxEnt software, Digital Elevation Models, and WorldClim layers of temperature, precipitation and Normalized Difference Vegetation Index. *Pi. longiflocosa* is the main vector in the township of Rovira, Tolima, and the niche modelling shows highest probability of presence midway up the eastern slope of the central range of the Andes. *Pi. panamensis* is the main vector in Pueblo Rico, Risaralda, and the model shows highest probability towards the higher elevations of the western range. Surveillance data on disease incidence, and field collections of sand flies have substantiated the risk of transmission in the Risaralda study site. Here, 11 phlebotomine species, with *Ps. panamensis* predominating, were found in 5 townships suggested by the niche model. The incidence of CL will be estimated in these and other areas identified at being at high risk of under-estimation, using a combination of methods, including chain referral and community-based active case detection, in order to quantify the extent of under-estimation.

1179

HOTSPOTS OF TRANSMISSION OF LEISHMANIASIS IN SRI LANKA

Nadira Karunaweera[1], **Guofa Zhou**[2], Samitha Ginige[3], Sanath Senanayake[1], Hermali Silva[1], Nuwani Manamperi[4], Nilakshi Samaranayake[1], Yamuna Siriwardana[1], Deepa Gamage[3], Upul Senerath[1]

[1]*Faculty of Medicine, University of Colombo, Colombo* [8]*, Sri Lanka,* [2]*University of California, Irvine, CA, United States,* [3]*Ministry of Health, Colombo* [10]*, Sri Lanka,* [4]*Faculty of Medicine, University of Kelaniya, Ragama, Sri Lanka*

Leishmaniasis outbreak due to *L.donovani* in Sri Lanka is perceived as a serious public health issue. A retrospective analysis of data from human leishmaniasis cases conducted from 2001 to 2018 demonstrated continuous increase in case incidence, steady expansion in risk areas and 2 persistent hotspots of disease in the country. A prominent rapid rise in the case incidence during the year 2018 was also evident. The disease hot spot in the north-central region showed a location shift and shrinkage in size over time, whereas the one in the southern coastal region remained at the same location with expansion in size over the years. There was significant difference in age and sex distribution of cases between the two regions. In the northern region males 15-49 yrs were mainly affected during 2001-03, but the pattern has changed significantly with ≥50 yrs of both sexes affected during 2015-18. There was no such change noted in the south. Enhanced surveillance, public awareness, and appropriate interventions are urgently needed to halt the outbreak.

1180

LEISHMANIASIS IN ABANCAY (PERU) DURING THE LAST DECADES. RETROSPECTIVE ANALYSIS AND STUDY OF THERAPEUTIC RESISTANCE

Natalia Cánovas García[1], **Roque Diaz Diaz**[1], Jesus Lopez Fidalgo[2], Bartolome Ribas[3], Jose Juarez[4], Paul Nguewa[1]

The estimated incidence of cutaneous leishmaniasis is 0.7-1 million cases worldwide, 90% of which occurs in Afghanistan, Pakistan, Syria, Saudi Arabia, Algeria, Iran, Brazil but also in Peru. Treatments include paromomycin, liposomal amphotericin B and pentavalent antimonials…. However, the incidence of resistant forms is not uncommon, and a better description and understanding of these is critical for the development of more effective therapeutic regimens. We performed the data analysis (age, sex, clinical form, occupation, environment…) from patients affected by cutaneous leishmaniasis in Abancay (Peru) during the last decades. We shed some light on strategies applied to dramatically reduce the infection. Finally, we also studied the relapsing and resistant cases after treatment administration.

1181

IMPACT OF EXPERIMENTAL INFECTION OF DOGS WITH *LEISHMANIA TROPICA* ON THE DEVELOPMENT OF CUTANEOUS AND VISCERAL LEISHMANIASIS

Nourhane Msallem[1], Malek Trimeche[1], Ifhem Chelbi[1], Abhay Satoskar[2], **Elyes Zhioua**[1], Thouraya Boussofara[1]

[1]*Institut Pasteur de Tunis, Tunis, Tunisia,* [2]*Ohio State University, Columbus, OH, United States*

Canine leishmaniasis is a vector-borne zoonosis caused by protozoa of the genus *Leishmania* (Kinetoplastida: Trypanosomatidae). In dogs, the infection can be asymptomatic or symptomatic, and fatal if left untreated. Canine leishmaniasis is endemic in Tunisia. The isoenzymatic typing of the different strains isolated from dogs revealed the incrimination of *Leishmania infantum* zymodeme MON-1. Nevertheless, visceral canine infection with *Leishmania tropica*, the etiological agent of anthroponotic cutaneous leishmaniasis in neighboring countries such as Morocco, led us to explore the outcome of dog infection with *L. tropica*. The aim of this work is the development of a canine model for experimental infection with *L. tropica*. Dogs were infected intradermaly with 6 $x10^7$ metacyclic promatisgotes. A follow-up of the biochemical, hematological, parasitological, molecular and serological parameters, during 6 months post-infection, allowed us to conclude that *L. tropica* induce cutaneous lesions at the site of the injection as well as visceralization of the parasite. Dog infected experimentally with *L. tropica* could be used as a model to test new drugs or vaccines against cutaneous leishmaniasis and visceral leishmaniasis and the epidemiological role of dogs as a potential reservoir host of *L. tropica*.

1182

INEQUALITIES IN THE SOCIAL DETERMINANTS OF HEALTH AND CHAGAS DISEASE TRANSMISSION RISK IN INDIGENOUS AND CREOLE HOUSEHOLDS IN THE ARGENTINE CHACO

Maria P. Fernandez[1], Maria S. Gaspe[2], Ricardo E. Gürtler[2]

[1]*Columbia University, New York, NY, United States,* [2]*Universidad de Buenos Aires, Buenos Aires, Argentina*

The social determinants of health (SDHs) condition disease distribution and the ways they are handled. Socio-economic inequalities are closely linked to the occurrence of Neglected Tropical Diseases, but empirical support is limited in the case of Chagas disease, caused by the protozoan *Trypanosoma cruzi*. Herein we assessed the relationship between key structural SDHs and the risk of *T. cruzi* vector-borne transmission in rural communities of the Argentine Chaco occupied by creoles and an indigenous group (Qom). We used multiple correspondence analysis to quantify the household-level socio-economic position (social vulnerability and assets indices), access to health and sanitation services, and domestic host availability. We identified the most vulnerable population subgroups by comparing their demographic profiles, mobility patterns and distribution of these summary indices; then assessed their spatial correlation and household-level effects on vector domiciliary indices as transmission risk surrogates. Qom households had higher social vulnerability and fewer assets than creoles', as did local movers and migrant households compared with non-movers. We found significantly positive effects of social vulnerability and domestic host availability on infected-*Triatoma infestans* abundance, after adjusting for ethnicity. Access to health and sanitation services had no effect on transmission risk. Only social vulnerability displayed significant global spatial autocorrelation up to 1 km. A hotspot of infected vectors overlapped with an aggregation of most vulnerable households. This synthetic approach to assess socio-economic related inequalities in transmission risk provides key information to guide targeted vector control actions, case detection and treatment of Chagas disease, towards sustainability of interventions and greater reduction of health inequalities.

1183

HIGH VARIABILITY BETWEEN THE INCIDENCE OF CLINICAL LESION OF LEISHMANIASIS AMONG THREE HIGH ENDEMICITY NEIGHBORING VILLAGES OF DIEMA DISTRICT IN 2016: A WESTERN PART OF MALI

Oumar Thiero[1], Bourama Traoré[1], Ousmane Faye[1], Dieudonne Somboro[2], Adama Dicko[2], Cheick A. Coulibaly[1], Ibrahim M. Sissoko[1], Samake Sibiry[1], Sekou F. Traoré[1], Seydou Doumbia Doumbia[1]

[1]*International Center of Excellence in Research (ICER-MALI), University of Sciences, Techniques and Technology (USTTB) of Bamako, Bamako, Mali,* [2]*Centre National d'Appui à la Lutte contre la Maladie (CNAM), Bamako, Mali, Bamako, Mali*

Leishmaniosis is a neglected tropical-diseases(NTDs) which occurs commonly in the setting of extreme-poverty, rural and some disadvantaged urban populations. The disease is known to be highly-endemic in western Mali, with LST+prevalence=50.7%reported. This study was undertaken to estimate the incidence-rate and the risk-associated with Active-Cutaneous-Leishmanias (ACL) detected from participants with negative LST in three_villages of the Diema-Districts: Famoune-Nafadji, Guemou and Debo-Massassi. After initial screening by LST and clinical examination, the participants aged 0-18-year-olds were follow-up house-to-house visits for ACL through active case detection every three-months during-one-year-2016. The count of new-infected-subjects with clinical-lesion ACL were recorded for the incidence rate-per-1000-person-year (IR). The relative-risk (RR) was adjusted for the risk-factors, the time-to-exposure and time-to-event using Poisson-Regression-models and Generalized-Estimating-Equations for the repeated-measure, alpha was set-at-10%. From 1798-participants, the overall IR was 6.4 (11/1730). The age group-0-6-years-old (representing 52%), has the highest IR=10.1 (RR=6.6, p=0.08) vs. IR=1.6 (RR=ref) and IR=5.3 (RR=3.0,p=0.42) for 7-12-years-old and 13-18-years-old respectively. The female (53.7%) has significant IR=9.7 compared to male, IR=2.5, the (RR=3.9, p=0.08). The IR=13.1 among the sarakole(31.4%) ethnic-group, and IR=3.7 among the Bambara/Malinke(61.0%), (RR=1.5, p=0.6), no cases among the Peulh-ethnic-group. The IR varies among the three-villages: 11.2, 2.5 and 1.9 respectively for Famoune-Nafadji, Guemou and Debo-Massassi, (RR=4.1,p=0.23) and (RR=1.3,p=0.86), respectively, Debo-Massassi=reference. In conclusion, the discrepancy between high incidence of LST positive and the clinical incidence ACL may be due to immunity to leishmania parasite acquired through higher levels of antibodies to sand fly salivary proteins positively correlated with LST+. Further studies are needed to understand the difference in RR among ethnicity and villages.

1184

EVALUATING THE INCIDENCE OF LEISHMANIASIS SKIN TEST POSITIVITY (LST+) WITHOUT CLINICAL DISEASE IN DIEMA DISTRICT, IN 2016: A HIGH ENDEMICITY AREA IN WESTERN MALI

Oumar Thiero[1], Bourama Traoré[1], Ousmane Faye[1], Cheick A. Coulibaly[1], Sekou F. Traoré[1], Adama Dicko[2], Ibrahim M. Sissoko[1], Sibiry Samake[1], Seydou Doumbia[1]

[1]*International Center of Excellence in Research (ICER-MALI), University of Sciences, Techniques and Technology of Bamako (USTTB), Bamako, Mali,* [2]*Centre National d'Appui à la Lutte contre la Maladie (CNAM), Bamako, Mali*

Cutaneious leishmaniasis (CL) has been reported endemic disease in western region of Kayes, Mali. We carried out a study aimed to evaluate the risk factors associated with the conversion to Leishmaniasis Skin Test (LST) positiveness without active CL in volunteers in active follow up setting. Located at 215 km from Bamako in the western part of Mali, from Diema District, three villages, Famoune/Nafadji, Guemou and Debo/Massassi in Diema Districts, which shared the same topography and climate condition, were selected for this study. country. Participants with negative LST were retested after one year to estimate the annual incidence

rate (IR) and the relative risk (RR) of LST+. The data was stratified by village and the RR was adjusted using Poisson Regression and the Generalized estimating equation was used for parameters estimations. A total of 574, 381 and 463 of LST negatives aged 0-18 years-old from Famoune/Nafadji, Guemou and Debo/Massassi respectively, participated to the study. The IR for LST+ was respectively 230, 362 and 138, per 1000-person year. The 3 models indicated no significant gender association with LST+, p>0.05. The RR for age groups 13-18 vs 0-6 were 3.6, 3.8 and 3.5 (all p<0.01) for the 3 villages respectively. The RR for age groups 7-12 vs 0-6 were 2.4, 3.0 and 2.4 (all p<0.0001) for the 3 models, respectively in Famoune/Nafadji, Guemou and Debo/Massassi. The RR =0.28, p=000, for Ethnicity group Marka/sarakole vs Bambara/kakole was only significant in Famoune/Nafadji but no difference between ethnic groups elsewhere.The incidence rate between gender were similar within all the villages (all p>.1). In conclusion, although, this study has shown that age remain an important risk factor for LST+, the relative high IR for LST+ across groups without the clinical disease might be explained by the immunity acquired through the exposure to sand fly saliva as the antibody proteins was high correlated to LST+. Further investigation is needed to explore the co-infections effect on clinical leishmaniasis incidence.

1185

BRUCELLOSIS CONTROL IN TANZANIA - THE EFFECTS OF PASTORALISTS' PERCEPTIONS AND PRACTICES

Caroline Mwihaki Mburu[1], Salome Atieno Bukachi[1], Khamati Shilabukha[1], Mangi Ezekiel[2], Kathrin Heitz Tokpa[3]

[1]*University of Nairobi, Nairobi, Kenya,* [2]*Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania,* [3]*Centre Suisse de Recherches Scientifiques en Cote d'Ivoire, Abidjan, Côte D'Ivoire*

Brucellosis, a highly contagious zoonotic disease is endemic in many countries in Africa. In Tanzania, brucellosis has been identified as one of the six high priority zoonotic diseases, especially in pastoral systems because of animal product handling and consumption practices, low awareness and difficulty in implementing control measures. Therefore, the control and prevention of brucellosis partly depends on a holistic approach to understand the interaction of factors such as lay perceptions and practices of the local communities especially those related to animal husbandry practices. Our study describes those beliefs and the associated customs that impact on the transmission of brucellosis among pastoralists in the Kilombero valley of Tanzania. The ethnographic study used information from participant observation, focus group discussions and in-depth interviews to identify the key issues related to perceived risk factors, awareness and interactions in the human-livestock-wildlife interface. The findings reveal insufficient knowledge of the risk factors and suggest that consumption habits were not considered as a potential pathway for infection with brucellosis in humans. This was related to the misdiagnosis of the disease by health providers, causing a lack of public concern for the zoonosis. This study also provides novel, in-depth information on the communities' awareness and risk perception related to human brucellosis. Understanding these dynamics is essential for the development of suitable health communication and mitigation strategies that are contextually specific and more likely to be adopted by the local communities.

1186

ONGOING RIFT VALLEY FEVER TRANSMISSION AT HUMAN-ANIMAL INTERFACES IN TWO DISTINCT CLIMATIC ZONES IN TANZANIA

Robert D. Sumaye[1], Goodluk Paul[2], Brian H. Bird[3], Christopher Kilonzo[3], David J. Wolking[3], Amina Abdalla[1], Peter I. Pazia[1], Walter Simon[2], Feisal Hassan[1], Honorati Masanja[1], Jonna K. Mazet[3], Rudovick R. Kazwala[2], Woutrina A. Smith[3]

[1]*Ifakara Health Institute, Ifakara, United Republic of Tanzania,* [2]*Department of Veterinary Medicine and Public Health, Sokoine University of Agriculture, Morogoro, United Republic of Tanzania,* [3]*One Health Institute, School of Veterinary Medicine, University of California, Davis, CA, United States*

Rift Valley fever (RVF) is a re-emerging vector-borne zoonotic disease that causes outbreaks in human and animals across the African continent. To better understand impacts at the human-animal interfaces, integrated surveillance and risk characterization in people, animals, and mosquitoes were conducted. The study aimed to use a One Health approach to strengthen local technical capacity for RVF surveillance and pathogen detection to better inform management and control strategies. We conducted multi-year sampling of people, livestock, and mosquitoes in two distinct Tanzanian climatic zones, the relatively drier Ruaha ecosystem with high-level human-livestock-wildlife interactions and the relatively wetter Kilombero River Valley area with annual flooding. Across these ecologic zones, a total of 4,824 acutely febrile human patients, 4,468 livestock, and 3,447 mosquito pools were sampled. Using molecular and serological laboratory testing (RT-qPCR and IgM/IgG ELISA), we then determined exposure in people and animals. Findings indicated ongoing RVF virus (RVFV) transmission as measured by seroconversion in sentinel livestock herds across study districts, evidence of exposure among humans throughout the study regions, and detection of RVFV among infected mosquitoes. Despite over 12 years since the last large reported RVF outbreak in 2006-2007, it is clear that RVF risk continues and remains an under-reported health challenge to people and animals in the region. The findings from this integrated One Health surveillance approach are a call to action to proactively reduce the burden of this disease through measures such as vaccination to reduce the impact of this significant health threat.

1187

THE EPIDEMIOLOGY OF RICKETTSIAL DISEASES, SCRUB TYPHUS AND Q FEVER IN BHUTAN: A FIRST REPORT

Tshokey Tshokey[1], John Stenos[2], David N. Durrheim[3], Keith Eastwood[3], Tenzin Tenzin[4], Kinzang Dukpa[4], Ratna Bdr. Gurung[4], Stephen R. Graves[2]

[1]*JDW National Referral Hospital, Thimphu, Bhutan,* [2]*Australian Rickettsial Reference Laboratory, Geelong, Australia,* [3]*Population Health, Hunter New England Local Health District, Newcastle, Australia,* [4]*National Centre for Animal Health, Thimphu, Bhutan*

Except for few scattered reports on scrub typhus (ST), no data were available on the Spotted Fever Group (SFG) & Typhus Group (TG) *Rickettsia* and Q fever (QF) in Bhutan prior to this study. Following an outbreak of ST in 2009, heightened awareness increased case notifications from 91(no deaths) in 2010 to 753 (3 deaths) in 2017. Another outbreak of ST in 2014 saw two deaths. In this study, blood (human & animal) and ticks from animals were collected from Bhutan and analyzed at the Australian Rickettsial Reference Laboratory using an immunofluorescence assay (IFA) and a qPCR. Findings suggest that about 15% (159/1044) of patients with acute undifferentiated fevers attending 14 Bhutanese hospitals were due to a rickettsiosis, ST being the commonest (6.7%), followed by SFG (4.4%), QF (2.8%) and TG (0.4%). About 49% of 864-healthy Bhutanese showed evidence of past exposure to ST (22.6%), SFG (15.7%), QF (6.9%) and TG (3.5%). ST and SFG exposure significantly increased with age and farming activities. Trongsa district residents had the highest exposure to ST but residents at altitudes >2000M were relatively protected. In domestic animals, overall seropositivity of 46% (106/294) with SFG (36%), ST (21%), TG (15%), and QF (4%) was seen. Seropositivity differences between animal species appeared to be significant. Two-hundred ticks from 155 domestic animals were identified; the commonest tick species being *Rhipicephalus microplus* followed by *R. haemaphysaloides*, Haemaphysalis sp. near ramachandrai, *H. tibetensis*, *H. bispinosa*, *Haemaphysalis sp*, Haemaphysalis sp. near davisi, *R. sanguineus*, *H. shimoga*, *H. hystricis*, *Ixodes ovatus* & *Amblyomma testudinarium*. Twenty-nine (15%) of the 188 ticks subjected to a qPCR to detect rickettsial DNA were positive and the *Rickettsia* belonged to three major groups: *R. sibirica*, *R. raoultii* and *R. japonica* in the phylogenetic tree. Our findings constitute baseline data for Bhutan & serve to prompt further

research. Health services should be equipped to manage these infections by developing diagnostic & clinical guidelines. Human-livestock sector collaborations should increase through a 'One Health' approach.

1188

TRENDS AND CLINICO-EPIDEMIOLOGICAL FEATURES OF HUMAN RABIES CASES IN BANGLADESH 2006-2018

Sumon Ghosh[1], Md. Sohel Rana[1], Md. Kamrul Islam[1], Sukanta Chowdhury[2], Najmul Haider[3], Mohammad Abdullah Kafi[2], Sayed Mohammed Ullah[1], Md. Rashed Ali Shah[1], Be-Nazir Ahmed[1], Umme Ruman Siddiqui[1], Sanya Tahmina[1]

[1]*Disease Control Unit, Communicable Disease Control, Directorate General of Health Services, Dhaka, Bangladesh,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Technical University of Denmark, Section for Epidemiology, National Veterinary Institutes, Copenhagen, Denmark*

Vaccinating dog against rabies is an effective means of reducing human rabies. We analyzed 1327 clinically diagnosed human rabies death and mass dog vaccination (MDV) data during 2006-2018 to quantify the impacts of MDV on human rabies incidence in Bangladesh and a subset of rabies death data (422) for clinico-epidemiological study. We found a positive and increasing trend of dog population immunization ($p=0.01$ and tau=0.71) and a negative and declining trend ($p<0.001$ and tau = -0.88) of human rabies cases. The rabies cases in humans and the number of immunized dogs were correlated (adjusted $R^2=0.55$) indicating that immunization in dogs helped in reducing the rabies cases in humans. Among 422 human rabies death cases, the majority (78%) of the victims sought treatment from traditional healers and 12% received post-exposure prophylaxis (PEP). The mean incubation period of rabies in cases with exposure sites on the head and neck (35 days) were shorter than upper limb (mean=64 days, $p=0.02$) and lower limb (mean=89 days, $p<0.01$). MDV is effective to reduce human rabies cases in Bangladesh. Increasing mass awareness, ensuring better accessibility and availability of rabies PEP, and continuing to scale up MDV can help to prevent human rabies deaths.

1189

MOLECULAR DETECTION OF *BARTONELLA* IN SOUTH AMERICAN FUR SEALS (*ARCTOCEPHALUS AUSTRALIS*) FROM CHILEAN PATAGONIA

Ananda Müller[1], Pedro Bittencourt[1], Mauricio Seguel[2], Sandra Pérez[3], Paulina Sepúlveda[3], Ricardo Gutiérrez[4], Yaarit Nachum-Biala[4], Shimon Harrus[4]

[1]*Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis,* [2]*University of Georgia, Athens, GA, United States,* [3]*Universidad Austral de Chile, Valdivia, Chile,* [4]*Koret School of Veterinary Medicine, The Hebrew University of Jerusalem, Rehovot, Israel*

The aim of this study was to perform a molecular survey of *Bartonella* spp. in free-ranging South American Fur Seals (*Arctocephalus australis*) from Guafo Island, Chilean Patagonia. A total of 69 blood samples taken from 11 lactating South American Fur Seals and 58 pups from on Guafo Island,southern Chile. DNA extracted from the samples was submitted to Real Time PCR (qPCR) for *Bartonella* spp. 16S–23S internal transcribed spacer (*ITS*). Positive samples on *ITS* qPCR screening were further submitted to four qPCR assays targeting *Bartonella* spp.: *16srRNA*, *rpoB*, *gltA* and *SsrA* gene fragments. All positive qPCR products were purified and subsequently sequenced for speciation. Two out of 11 (18%) Fur Seal adults were positive for *Bartonella* spp. *ITS* gene, and none of the 58 pups was positive. *ITS* fragments from sequenced *Bartonella* spp. showed that sample #H1 (142bp sequence, not deposited on GenBank) had 100-100% identity with *B. henselae* isolates and sample #H2 (124bp sequence, not deposited on GenBank) shared 100-99% identity to *B. clarridgeiae*. Of the two *ITS* qPCR-positive samples, none showed positive results in cPCR assays based on *gltA, SsrA* and *16s rRNA* genes. Sample #H2 was positive in the *rpoB* gene (169bp sequence, not deposited on GenBank) and shared 100% identity with *B. Rochalimae*. This is the first report of *Bartonella* positivity in *Arctocephalus australis*. Little is known about geographic distribution and potential reservoir of *Bartonella* species infecting marine mammals. *Bartonella henselae* was detected in harbor porpoises (*Phocoena phocoena*), captive and free ranging, hunter-harvested beluga whales (*Delphinapterus leucas*), harbor seals (*Phoca vitulina*) and captive cetaceans. Further studies are necessary to fully characterize which *Bartonella* species are present in South American Fur Seals and it's potential role in the ecology of those organisms.

1190

NEW HIGH RESOLUTION MELTING SYSTEM FOR GENOTYPIFICATION OF PATHOGENIC *LEPTOPIRA* SUBSPECIES IN URINE SAMPLES OF DOMESTICATED ANIMAL RESERVOIRS FROM BELEN, IQUITOS, PERU

Anika Guadalupe Eca Avila, Karen Lisbet Ocampo Cardenas, Jessica Ricaldi Camahuali, Katherine Torres Fajardo

Universidad Peruana Cayetano Heredia, Lima, Peru

Leptospirosis is widely prevalent in the Peruvian Amazon. Animal reservoirs contaminating water sources likely drive seasonal outbreaks of severe human leptospirosis. Knowing animal isolate genotypes would help us understand the transmission dynamics of leptospirosis in this environment. Culturing *Leptospira* from animals is challenging in this setting, so we aimed to develop a genotyping system based on High Resolution Melting (HRM) for the identification of pathogenic subspecies of *Leptospira*, directly from animal urine samples from a flood-prone area of Belen, Iquitos, Peru. HRM profiles of 19 *Leptospira* reference strains were determined using *lipL32, lpxC and secY* marker genes. Urine samples were collected from 63 dogs and 88 pigs from homes and a unlicensed slaughterhouse, and assayed using *lipL32*-qPCR to detect pathogenic *Leptospira*. Genotypes of DNA in positive samples were determined by HRM and verified by sequencing. The reproducibility, typing efficiency and discriminatory index (DI) values of our test were 100%, 85% and 0.94, respectively. In total, 14 dog urine samples (22.2%) and 13 pig urine samples (14.8%) were positive to *lipL32* qPCR. HRM showed 11 of the dog urine samples contained a genotype 2 leptospire (serovars: *L. interrogans* Australis, *L. interrogans* Autumnalis, *L. interrogans* Djasiman and *L. interrogans* Copenhageni), one sample showed serovar *L. kirschneri* Grippatyphosa. Only four pig urine samples contained genotype 2, however, four contained a *L. santarosai*, and one each *L. kirschneri* and *L. noguchii*. Two samples from dogs and three samples from pigs did not amplify. We show that HRM has high discriminatory power for genotyping pathogenic subspecies of *Leptospira* spp. Furthermore, three pathogenic *Leptospira* species (*L. santarosai, L. kirschneri and L. noguchii*) had not been previously identified in pigs in this area. In conclusion, HRM can be a useful tool to investigate the genetic epidemiology of leptospirosis when culture is not possible.

1191

AVIAN INFLUENZA SURVEILLANCE IN WILD BIRDS AT NORTHERN AND SOUTHERN PERU DURING MIGRATORY SEASON

J. Catherine Dupont-Turkowsky

Naval Medical Research Unit-[6]*, Callao, Peru*

Avian influenza is a public health relevant disease caused by influenza A virus which is responsible for widespread disease outbreaks in animals and human worldwide. Wild birds have been described as natural reservoirs, particularly the orders Anseriformes (waterfowl) and Charadriiformes (gull and shorebirds). Performing surveillance in wild birds contributes to the global avian influenza surveillance as part of a strategy to characterize influenza virus diversity. For this purpose, NAMRU- 6 began a sentinel surveillance in 2017 in wild birds in the south (Paracas) and northern coast of Peru (Piura). In January 2017 we began the collection of cloacal swab samples in Paracas and in December 2018, environmental fecal samples in Piura. Sampling was conducted during migratory season (December to March, 3 to 5 days per site per month) when hundreds of thousands of

individuals come together from North and South America and co-mingle, providing an opportunity for transmission of influenza. To date, we have collected 1060 samples belonging to 35 different bird species (i.e *Arenaria interpres, Calidris alba* and *Anas bahamensis*). Approximately, two thirds of the samples (623/1060) have been egg cultured so far and 4 (0.6%) were positive for hemagglutination inhibition. From those 4 positive samples, 3 resulted positive to Influenza A by real-time RT-PCR. Targeted amplification approach was used to obtain the 8 Influenza A virus segments and then they were sequenced on the Ilumina MiSeq platform. We identified Influenza A subtype H6N2 from a *Calidris alba* and subtype H2N6 from an *Arenaria interpres*. In the sample that resulted negative by RT-PCR, we conducted an unbiased amplification and sequencing approach identifying an Avulavirus APMV-15 from an *Arenaria interpres*. Both species, *Arenaria interpres* and *Calidris alba*, are migratory birds and were previously describe as reservoirs for the virus. These samples were collected from Paracas where surveillance has never been performed. With these results we can confirm the presence and circulation of avian influenza in migratory birds in Peru.

1192

POLITICAL ECONOMY OF BAT HUNTING: BAT-BORNE DISEASES PERSPECTIVE IN BANGLADESH

A.K.M. Dawlat Khan

University of Dhaka, Dhaka, Bangladesh

Bats harbor many infectious agents like Nipah virus (NiV) that spillover from bat to human through date palm sap, partially eaten fruits or bat's secretions. NiV also can transmit from person to person. Since 2001 in Bangladesh, NiV human outbreaks have occurred with a >70% case fatality. Butchering and consumption of bat meat caused of Ebola and a Nipah-like henipavirus infection to humans in Africa. Bat hunting is a common practice in several parts of Bangladesh. I conducted an ethnographic study among a 60-household bat hunter community in the central part of Bangladesh to understand political economy of bat hunting during May 2017-April 2018.Community people used to work as day laborer in jute mills and storehouses. During harvesting season, majority people had work to earn livelihood. Yet, during the non-harvesting season particularly in winter, the community people were in lack of work. Therefore, some of them hunted bats and sold meat. To the hunters, bat hunting was a laborious job as they had to climb up long trees to hang the net and with risk of falling to ground. They were compelled to do this work finding no other alternatives. During catching, slaughtering/ butchering; the hunters were exposed to bat urine and saliva. Moreover, this bat slaughtering was placed at their homestead that also could lead the risk of infections to family members. In Bangladesh no direct evidence of NiV cases found among bat hunters. However, one hunter had developed Nipah like encephalitis syndromes and died before tested. Improper disposal of carcasses could pose threat to other animals. NiV is a WHO listed 'Blueprint priority disease'. However in Bangladesh, poster and pamphlet were distributed to communities and its surroundings where a NiV case was found to discourage only the consumption of raw date palm sap. During my study I found 50% people did not have formal education unlike the national average of 30%.The per capita income was low (USD 530 vs. national USD 1751). Absence of effective drug or vaccine against NiV can worsen with its pandemic threat. We need to adopt a culture-sensitive intervention with economic activities for the hunters to reduce the threat.

1193

INFLUENZA SURVEILLANCE IN SMALL SCALE SWINE PRODUCTION SYSTEMS IN PERU

Maria Claudia Guezala[1], Yeny O. Tinoco[1], Jorge Mantilla[2], Maria E. Silva[1], Christopher D. Cruz[1], Gilda Troncos[1], Roger M. Castillo[1], Christian Quiroz[3], Eugenio J. Abente[1]

[1]*Naval Medical Research Unit-6, Callao, Peru,* [2]*Servicio Nacional de Sanidad Agraria - SENASA, Lima, Peru,* [3]*Servicio Nacional de Sanidad Agraria - SENASA, Callao, Peru*

Pandemic influenza A virus (IAV) strains wreak havoc on public health systems and most recently resulted in an estimated 284,400 (range of 151,700 to 575,400) deaths in the first year following the emergence of the 2009 H1N1 pandemic virus. All four reported IAV pandemics in humans have resulted from the introduction and adaptation of animal-origin IAV, including swine IAV in 2009, highlighting the need for sustained surveillance efforts to better understand the risk of emergence of future pandemic strains. In Peru, the lack of systematic surveillance in swine populations is an important gap to address. Of particular interest are small scale swine production systems which lack stringent sanitary control measures and account for 25% of the Peruvian pork market. Since August 2018, the Naval Medical Research Unit No. 6 has collaborated with the Peruvian Agriculture Health Service (SENASA) to monitor one of the largest small scale swine production areas in Lima, Peru that encompasses approximately 100,000 pigs. This pig population represents 17% of swine produced in Lima and 7% of the total swine production in the country. SENASA regularly performs syndromic surveillance and collects nasal swabs from respiratory symptomatic swine. From August 2018 through February 2019 a total of 151 nasal swabs were collected and tested for IAV by reverse-transcription PCR. One (1/151) sample that was collected in August 2018 was positive for IAV. Phylogenetic analysis identified the hemagglutinin gene as a pandemic 2009 H1 within the clade 1A.3.3.2. Continued surveillance in the swine population is critical to better characterize circulating IAV in swine in Peru to determine the potential risks of interspecies transmission to humans. Notably, it has been documented that human-origin IAV frequently infects and is sustained in swine where antigenic evolution and divergence in pigs could result in a virus with potential to re-emerge in humans with little population immunity, further warranting surveillance efforts.

1194

SELF-MEDICATION AS THE FIRST RECOURSE FOR THE CARE OF SICK ANIMALS IN COTE D'IVOIRE

Danielle Naugle[1], Natalie Tibbels[1], Abdul Dosso[2], William Benié[2], Walter Kra[3], Corinne Fordham[1], Mieko McKay[2], Valère Konan[4], Jeanne Brou[5], Jocelyne Nebre[5], Adaman Kouadio[4], Zandra Andre[6], Diarra Kamara[2], Stella Babalola[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Johns Hopkins University, Abidjan, Côte D'Ivoire,* [3]*Alassane Ouattara University, Bouaké, Côte D'Ivoire,* [4]*Department of Veterinarian Services Ministry of Animal Resources and Fisheries, Abidjan, Côte D'Ivoire,* [5]*National Institute of Public Hygiene, Abidjan, Côte D'Ivoire,* [6]*U.S. Agency for International Development, Abidjan, Côte D'Ivoire*

The 2014-2016 Ebola outbreak in West Africa shed new light on the epidemic potential of zoonotic diseases in the region. Though Côte d'Ivoire (CdI) was not directly affected by the Ebola epidemic, the threat of major infectious disease outbreaks persists, in part, due to socio-cultural practices that potentially expose populations to risk. It is within this framework that a qualitative study of socio-cultural practices and beliefs around care and management of sick animals was conducted to understand the determinants of risk and preventive behaviors. The study involved 32 focus groups, 32 individual interviews, 20 observations and 20 community mapping with 234 adult men and women from four urban sites. The study focused on risk and prevention behaviors around five priority zoonotic disease groups in CdI: rabies, mycobacteria, bacterial and parasitic diseases (i.e. brucellosis), viral hemorrhagic fevers, and respiratory

zoonoses like avian influenza. The interviews were recorded, transcribed, coded and analyzed according to key themes. The results indicate that the general population and those engaged in animal husbandry mainly use self-medication and rely on their own or their peers' past experiences in the care of sick animals. Veterinary technicians are only consulted when there is a deterioration in the animal's health, the animal is of value, and/or many animals are exhibiting the same symptoms. The accessibility of veterinary technicians, the perceptions that actors have of technicians, and the cost of technicians' services constitute barriers to the use of appropriate care. The widespread use of inappropriate medications likely contributes to the growing challenge that antimicrobial resistance poses in Sub-Saharan Africa. Social and behavior change programs should focus on interventions that promote the economic benefits of proper prevention and treatment for animals and should work with both veterinarians and chicken and livestock breeders to improve relationships between the two groups.

EVALUATION OF THE ROLE OF MMPL3 GENE AS A CANDIDATE GENE FOR PYRAZINAMIDE RESISTANCE IN *MYCOBACTERIUM SMEGMATIS*

Luz A. Saavedra, Ricardo Antiparra, Mirko Zimic, Patricia Sheen

Universidad Peruana Cayetano Heredia, Lima, Peru

Efflux pumps are one of the principal systems used by bacteria to reduce antimicrobial activity. Since they prevent the accumulation of antibiotics and toxic metals, efflux pumps are highly conserved among bacterial species. For example, in *Mycobacterium tuberculosis* (MTB), this is a critical adaptation and involves a serious public health concern. It has been suggested that MTB uses this machinery to modulate the antimicrobial activity of the first-line drug pyrazinamide (PZA), by interfering with the normal efflux of its active form "pyrazinoic acid" (POA). However, the identity of these efflux pumps are still unknown. mmpL3 is a membrane transporter that is part of the RND family, widely associated with multidrug resistance. What is more, recent data from our group have found mutations in these gene associated to clinical resistant MTB isolates. Consequently, the main objective of this project was to study the function of its orthologous gene in the strain naturally resistant to PZA *Mycobacterium smegmatis* (Msm) by using the CRISPR interference (CRISPRi) system. First, we corroborated that expressing only the Cas9 protein had no silencing effects over mmpL3 expression ($p>0.05$). Next, we generated our recombinant Msm strain that harbored the complete CRISPRi system to knock down the gene mmpL3. Induction of the CRISPRi system was possible by a treatment with 100 ng/ml Anhydrotetracicline (ATc). After an incubation of 14 hours with ATc, this strain was used for further validation, enzyme activity essays and subsequent POA efflux rate quantification. In all the cases, comparisons were made between treated and non treated cultures. After inducing the CRISPRi system, our mmpL3 recombinant strain showed no phenotypic defect in growth on plate ($n=5$) and we could confirm a 10 fold RNA repression by RTqPCR ($p<0.0001$, $n=5$). Our results indicate that after knocking down the expression of mmpL3, there is no change in the POA efflux ve*loci*ty when compared to non treated cultures (0.66 mM POA/min Vs 0.61 mM POA/min; $p>0.05$, $n=3$). In conclusion, mmpL3 is not a POA efflux pump in Msm, which ultimately suggest an unlikely role in MTB.

1196

RISK FACTORS FOR UNFAVORABLE OUTCOMES IN DRUG-SUSCEPTIBLE *MYCOBACTERIUM TUBERCULOSIS* TREATMENT IN UGANDA

Michael S. Harper[1], Stella Zawedde-Muyanja[2], Yukari Manabe[1]

[1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [2]*Makerere University, Kampala, Uganda*

One of the targets of the WHO END TB Strategy is a treatment success rate of >90%. The success rate of treatment in Uganda, a TB high-burden country, is currently below this target. We sought to evaluate risk factors for unfavorable treatment outcomes for drug-susceptible *Mycobacterium tuberculosis* in 10 healthcare facilities in central and eastern Uganda. Patients diagnosed with bacteriologically confirmed TB using Xpert MTB/RIF testing between January 2018 and June 2018 at 10 facilities (3 Health Center IV, 4 District Hospitals, 3 Regional Referral Hospitals) with rifampicin-sensitive TB, and 15 years of age or older were included. Unfavorable treatment outcomes were defined as death, loss to follow up, or treatment failure during the study period. A total of 441 patients ages 15-90 were enrolled; 396 patients had treatment outcomes ascertained before the censor date and were included in the final analysis. The overall treatment success rate was 74% (293/396), with a mortality rate of 6.6% (26/396) similar to nationally reported treatment success rate, but below the 90% target set by WHO. Using multivariable logistic regression, there was no association with sex, delayed treatment, or distance from the healthcare facility with unfavorable treatment outcomes or mortality. Infection with HIV, however, was associated with unfavorable treatment outcomes (aOR 2.91, 95% CI 1.71 - 4.96) and mortality (aOR 10.3, 95% CI 3.49-30.4). The majority (70%) of HIV-infected patients were on ART at diagnosis, and 27 patients (22%) were started on ART during TB treatment. Initiation of ART after TB diagnosis was not associated with unfavorable treatment outcomes or mortality compared to patients already on ART. These data show that TB patients co-infected with HIV are particularly vulnerable to death and unfavorable outcomes during TB treatment. Improvements in TB/HIV care integration, which has previously been shown to reduce mortality in this population, may be needed to meet target treatment success rates.

1197

A STUDY OF THE DETERMINANTS OF TB DIAGNOSIS DELAY IN THE BAMBEY HEALTH DISTRICT IN 2017 (SENEGAL)

Jean S. Kaly

Bambey sanitary district, Bambey, Senegal

In Senegal, the diagnosis of tuberculosis faces two problems: under-screening and delayed diagnosis. The overall goal was to identify the determinants of delayed diagnosis of TB in the Bambey Health District in 2017. A comprehensive, cross-sectional, descriptive and analytical study of patients with pulmonary tuberculosis was conducted in the Bambey Health District from 3 to 7 September 2018. The data were collected at the Bambey Treatment Center with the help of a semi-structured questionnaire in an individual interview after informed consent. The capture and analysis was done using EPI INFO software version 3.5.3 with a 95% confidence interval, α risk of 0.05. A total of 229 patients were enrolled including 81.6% of TPM +. The average age was 35.1 years + or - 16; sex ratio 2.7. The knowledge of cough was 95.2%, contagiousness 83.3%, suspicion 45.4%, knowledge of the effectiveness of treatment 84.8% and the free 70.1%. The median consultation time was 30 days with a 75% delay. This delay was statistically related to: education (OR = 2.8, CI [1.09 - 8.62]), suspected tuberculosis (OR = 4.1, CI = [1.7-10, 2]), the use of traditional medicine (P = 0.0001, OR = 3.9) and the type of provider consulted (OR = 2.7, CI = [1.2 - 6.3]) and suspicion of tuberculosis (OR = 7.7, CI = [3.9-15.4]). In conclusion Early diagnosis of tuberculosis requires public awareness of the disease, training of health care providers and collaboration between traditional healers and health care providers.

1198

COMPARISON OF CLINICAL CHARACTERISTICS BETWEEN INFLUENZA A AND INFLUENZA B VIRUS INFECTIONS IN IQUITOS, PERU

Crystyan Siles[1], Joan Neyra[2], Anna Kawiecki[3], Stalin Vilcarromero[1], Amy C. Morrison[3], Carolina Guevara[2], Julia S. Ampuero[2]

[1]*U.S. Naval Medical Research Unit Six, Iquitos, Peru,* [2]*U.S. Naval Medical Research Unit Six, Lima, Peru,* [3]*University of California, Davis, CA, United States*

Infections with influenza A and B virus (IAV, IBV) are a worldwide public health concern that causes recurrent epidemics and unpredictable pandemics in humans. In 2009 an H1N1 virus, A(pH1N1)pdm09, caused a pandemic that resulted in severe disease and death mostly in children. It was recently reported that in the United States IBV is as clinically severe as IAV (H1N1, H3N2) infections although this has not been examined in Peru. We performed clinic-based surveillance at twelve health facilities in Iquitos, Peru to compare clinical symptoms among confirmed cases of influenza illness. From December 2010-November 2014, we enrolled 1,032 participants with acute influenza like-illness (ILI) from whom pharyngeal swabs, epidemiological and clinical information were collected. The samples were tested by virus isolation in cell culture and/or subtype/lineage specific real-time reverse transcription PCR (rt RT-PCR) for detection of influenza virus RNA. 41.2% of the samples were positive for influenza by one of the two methods. From the rt RT-PCR positive samples, we detected 115 A(H1N1)pdm09 (10.6%), 169 A(H3N2) (15.6%) and 141 IBV (12.2%). We divided our population into 4 groups: children (5-11 years), adolescents (12-17 years), young adults (18-29 years) and adults (30 years or more). For each age group, we assessed the association between symptoms and type of influenza virus detected utilizing prevalence odds ratio (POR). In children, nausea had a significant association with IBV (POR: 4.7, [2.2-10.15]). In adolescents, ear ache showed a significant association with IBV (POR: 4.9, [1.4-17.4]). In young adults, respiratory symptoms, such as cough and rhinorrhea were predominant, although only conjunctiva injection was associated with A(H1N1)pdm09 (POR: 3.0, [1.4-6.3]). In adults, myalgia was associated with A(H1N1)pdm09 (POR: 4.1, [1.4-12.4]). Although few differences were identified among clinical symptoms within age-groups, most clinical symptoms presented for ILI were not significantly different when comparing IAV and IBV.

1199

EPIDEMIOLOGY AND VIRAL ETIOLOGY OF ACUTE RESPIRATORY INFECTIONS IN AN ACTIVE SURVEILLANCE IN THE PERUVIAN AMAZON FROM 2009-2017

Isabel Bazán[1], Eugenio Abente[1], Amy C. Morrison[2], Carolina Guevara[1], Juan Pérez[1], Regina Fernández[1], Stalin Vilcarromero[1], Carlos Alvarez[3], Julia S. Ampuero[1]

[1]*U.S. Naval Medical Research Unit No. 6, Lima, Peru,* [2]*U.S. Naval Medical Research Unit No. 6 , University of California, Davis, USA, Iquitos, Peru,* [3]*Dirección Regional de Salud, Loreto, Perú, Iquitos, Peru*

Acute respiratory infection is one of the leading causes of morbidity and mortality worldwide. In developing countries it is an important public health concern because access to etiological diagnosis is limited, hindering effective treatment. The present study was carried out in Iquitos, Peru, which has a tropical climate and is surrounded by tributaries of the Amazon River. Active surveillance was conducted by going door-to-door three times per week in designated neighborhoods and volunteers who met the following inclusion criteria were enrolled: fever and one other respiratory symptom such as cough and/or sore throat. A total of 4,387 oropharyngeal swab samples were collected between September 2009 and December 2017. Oropharyngeal samples were assayed by real-time reverse transcription PCR (rt RT-PCR) and/or virus isolation and subsequent pathogen identification by immunofluoresence. A total of 1,961 pathogens were detected in forty-four percent of the total number of samples collected (1,914/4,387). The pathogen most frequently detected was influenza A virus (IAV; 1,574/1,961), although parainfluenza virus (154/1,961), adenovirus (98/1,961), enterovirus (81/1,961) , herpes simplex virus (26/1,961), human metapneumovirus (17/1,961) and respiratory syncytial virus (11/1,961) were also detected. IAV remains a significant burden and continued surveillance is warranted to better inform on viruses circulating to better match vaccine strains to viruses circulating and causing visits to clinics and hospitals. Additionally, our data supports use of IAV rapid diagnostics to guide use of anti-IAV therapeutics.

LUNG ULTRASOUND FINDINGS IN PULMONARY TUBERCULOSIS

Matthew Fentress[1], Robert Gilman[2], David Moore[1], Cesar Ugarte-Gil[3]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Universidad Peruana Cayetano Heredia, Lima, Peru*

Current diagnostic algorithms for pulmonary tuberculosis (PTB) rely primarily on sputum microscopy, chest x-ray (CXR) and nucleic acid amplification tests (NAAT). Lung ultrasound is increasingly used for diagnosis of pneumonia with excellent performance characteristics compared to conventional radiography. Inexpensive portable ultrasound machines are increasingly available in resource-limited settings, but data on the use of lung ultrasound for diagnosis of PTB is limited. The aims of this pilot study are to describe abnormal sonographic lung findings in patients with confirmed PTB, describe the changes in these sonographic lesions during anti-tuberculosis treatment, and compare the sonographic findings with CXR. This multi-center prospective cohort study will consecutively enroll participants ≥18 years of age with microbiologically-confirmed PTB within 1 week of treatment initiation. Each participant will have a comprehensive lung ultrasound exam at enrollment by a clinician trained in the study protocol, and a repeat ultrasound at 8 weeks post-enrollment. Representative video clips will be saved and reviewed by an expert sonographer. Our results will describe the frequency and location of each of six sonographic lung lesions - consolidations, small subpleural consolidations, cavities, miliary patterns, pleural effusions and B-lines. We will also analyze the change in sonographic lesions between 0 and 8 week exams. Finally, we will compare ultrasound and chest x-ray for identifying consolidation, miliary pattern, cavitation and pleural effusion as binary variables. Preliminary data on the first 6 enrolled participants demonstrates excellent sensitivity (100%) of the ultrasound technique for PTB. Final results (predicted n=60) will be available October 2019. This pilot study will assess the utility of point-of-care lung ultrasound to detect pulmonary lesions in PTB. If findings are positive, further studies with symptomatic and asymptomatic controls will be indicated to determine what role portable lung ultrasound may play in point-of-care diagnostic algorithms for PTB.

1201

HUMAN BOCAVIRUS DETECTED IN UGANDAN CHILDREN WITH HYPOXEMIC PNEUMONIA: PATHOGEN OR BYSTANDER?

Jack Underschultz[1], Robert O. Opoka[2], Andrea L. Conroy[3], Sophie Namasopo[4], Michael Hawkes[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Makerere University, Kampala, Uganda,* [3]*Indiana University School of Medicine, Indianapolis, IN, United States,* [4]*Kabale Regional Referral Hospital, Kabale, Uganda*

Pneumonia is the leading infectious cause of childhood mortality globally, with high disease burden in sub-Saharan Africa. Human bocavirus (HBoV) has been detected in patients with pneumonia but its pathogenic role remains unclear. Here, we describe a detailed case series of Ugandan children under 5 years of age hospitalized in a resource-limited setting with hypoxemic pneumonia and in whom HBoV was detected. Respiratory samples from the children's nasopharynx were collected and analyzed using multiplex PCR. Clinical characteristics were abstracted from the chart

record and novel biomarkers were quantified from plasma by enzyme-linked immunosorbent assay (ELISA). HBoV was detected in 12/130 (9.2%) of children with hypoxemic pneumonia. In all cases, at least one other micro-organism was co-detected in the nasopharynx. Most patients experienced cough, difficulty breathing, tachycardia, tachypnea, nasal flaring, chest indrawing, and crackles on auscultation. Radiographic infiltrate was present in 6/11 (55%) cases. Elevated levels of C-reactive protein, Chitinase-3-like protein 1, Lipocalin 2, and surfactant protein D, previously associated with severe or fatal pneumonia, were present in 5 (42%), 3 (25%), 0, and 2 (17%) patients, respectively. All patients received antibiotics and supplemental oxygen (median duration2.0 days [IQR 1.6-3.0]). The median length of hospital stay was 3.0 days (IQR 2.7-4.5), and there were no fatalities. Clinical and radiographic signs, as well as host biomarkers suggest that HBoV may participate in the pathogenesis of severe pneumonia in African children. However, co-detection of other potential pathogens suggests that HBoV1 may be a co-pathogen or bystander.

1202

INFLUENZA INFECTION IN THE YUCATAN DURING THE YEAR 2018

Luis O. Bobadilla-Rosado[1], Rodrigo G Díaz-Novelo[1], Diego O. Quijano-Torres[1], **Nina Mendez-Dominguez**[1], Salvador Gómez-Carro[2], Barbara C. Hoil Vales[1]

[1]*Universidad Marista de Merida, Merida, Mexico,* [2]*Epidemiological Unit, General hospital Agustin O'horán, Merida, Mexico*

Introducción: Influenza viruses are notable for their adaptability which often results in a yearly appearance between October and February in the northern hemisphere. It is estimated that 15% of the world population becomes infected with the influenza virus each year, resulting in deaths worldwide. The clinical presentation of this disease is characterized by headache and severe, often generalized, myalgia, it debuts with inflammation of the nasal mucosa; the pharynx; and conjunctiva. The purpose of this study is to compare the signs and symptoms presented by patients with confirmed diagnosis who were treated hospitalized or as ambulatory. Methods.This descriptive, observational cross-sectional retrospective study included all hospitalized and ambulatory patients during the 2018 season. All data was obtained from the hospitals´ epidemiological surveillance service at the general hospital located in the city of Merida, Mexico. *Results.*A total of 264 influenza cases occurred in 119 (45%) were men and 145 (55%) were women, 11(7%) of the later were pregnant while infected. Patients mean age was 27, 172(67%) were adults, 43 (26%) were vaccinated. Ambulatory patients were out of which 8 (8%) had the influenza vaccine. No vaccinated patient died. The incidence during the year 2018 was 17.65 cases per 100 000 exposed people. Adults were more prone to be hospitalized when havingdyspnea (OR 4.70) and tachypnea (OR 8.22), while polypnea associated to pediatric hospitalizations (OR 16.93). Tachypnea was associated with the general mortality (p<0.000); when in both, adult (p<0.000) and pediatric patients (p<0.017). Rhinorrhea (OR 0.25).and vomit (OR 0.23) correlated inversely with hospitalization. *Discussion and conclusions.*Hospitalized patients were more prone to present with polypnea, tachypnea, dyspnea, while correlated inversely with headache rhinorrhea and vomit. Vaccination inversely associated with mortality and even when headache is considered a diagnostic clinical criteria, it did not predict hospitalization or death.

1203

IMPACT OF EBOLA OUTBREAK ON TB TREATMENT ADHERENCE AND OUTCOMES IN SIERRA LEONE

Kathryn M. Hogan[1], Jia-Fu Jiang[2], Henry S. Bangura[3], Stephen Sevalie[2], Ya-Jun Song[2], Yi Sun[2], Jing Li[2], Zhong-Peng Zhao[2], Jun Jiao[2], Foday Sahr[4]

[1]*George Mason University, Glendora, NJ, United States,* [2]*Beijing Institute of Microbiology and Epidemiology, Beijing, China,* [3]*Public Health Department,* [34] *Military Hospital, Wilberforce, Sierra Leone,* [4]*College of Medicine and Allied Health Sciences, Freetown, Sierra Leone*

The 2014-2015 Ebola outbreak was devastating to West Africa, with an estimated 28,637 cases and 11,315 deaths as of January 2016. Beyond this, the outbreak had detrimental effects on the already fragmented health care system in Sierra Leone. This data specifically examines the impact of the Ebola outbreak on treatment and health outcomes of patients infected with tuberculosis in Sierra Leone at the time. During the outbreak, healthcare systems experienced great stress, often halting services such as treatment delivery and testing due to curfews, border closures, and lack of healthcare workers. This retrospective study reviewed data from the 34 Military Hospital at the Wilberforce Barracks in the Western province of Sierra Leone, a facility that provides services for soldiers, their families, and civilians. Patient Hospital Register TB Records from 2012 to 2016 from 1,264 patients were analyze using STATA (v.14). Preliminary testing using chi-squared test of associations were executed to determine whether any demographic characteristics such as age, sex, and occupation were associated with entry point, HIV co-infections, loss to follow up of treatment, or death. Logistic regressions were used to assess the level of association between number of deaths, losses to follow up, or defaults and year, adjusting for age, sex, and entry point. Preliminary results showed an increase in the number of deaths and number of patients lost to follow up after the Ebola outbreak. Chi-squared tests also showed a significant association between entry point and loss to follow up (χ^2 =19.1, p< 0.001), and occupation and loss to follow up (χ^2 = 29.82, p < 0.001). Further statistical analysis is required to understand the magnitude and factors associated with the impact of the Ebola outbreak on TB patient follow up and survival. Information from this study will indicate the percent reduction in treatment rates and related number of deaths before and after the Ebola outbreak. This can be used to improve the understanding of the indirect impacts of the Ebola outbreak on diseases other than Ebola.

1204

A CLINICAL CHALLENGE TRIAL DELIVERING AEROSOL BCG AS A CONTROLLED HUMAN INFECTION IN HEALTHY BCG-NAÏVE, UK ADULTS: ESTABLISHING OPTIMAL DOSE AND EVALUATING SAFETY

Julia L. Marshall[1], Iman Satti[1], Stephanie Harris[1], Rachel Wittenberg[1], Raquel Lopez Ramon[1], Michael Riste[1], Pedro Folegatti[1], Rebeccca Powell-Doherty[1], Alison M. Lawrie[1], Samantha Vermaak[1], Morven Wilkie[1], Paul Moss[2], Henry Bettinson[3], Helen McShane[1]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*NIHR / Wellcome Trust Birmingham Clinical Research Facility, Birmingham, United Kingdom,* [3]*Oxford Centre for Respiratory Medicine, Oxford, United Kingdom*

Human challenge models are a quick cost-effective way to assess candidate vaccine efficacy. Bacille Calmette-Guérin (BCG), a live-attenuated strain of *Mycobacterium bovis*, could be used as a surrogate *M. tuberculosis* challenge. BCG is licensed for human use and is protective against *M. tuberculosis* in UK populations. Intradermal BCG challenge can distinguish BCG naïve and prior-BCG vaccinated in UK adults, however an aerosol model would better mimic the natural infection route. We therefore undertook a randomized control trial to establish safety and optimal dose of aerosol BCG challenge in healthy mycobacteria-naive UK adults. Following dose escalation and satisfactory safety reviews, blinded volunteers were randomized to receive aerosol BCG with intradermal

saline placebo, or intradermal BCG with aerosol saline. Volunteers underwent a bronchoscopy 14 days post-challenge, completed a symptom diary, and were followed up for 6 months. 46 volunteers were enrolled and 12 volunteers inhaled the target dose of $1x10^7$ cfu BCG Bulgaria. There was no significant difference in the frequency or severity of either systemic or respiratory adverse events (AEs) by infection route. In both groups, most volunteers experienced at least one AE in the two weeks following BCG infection, the majority of which were mild and all of which were transient. There were no SUSARs and all bronchoscopies following aerosol BCG were normal. Local mucosal immune responses following BCG aerosol inhalation were higher than the corresponding systemic response. We have developed a controlled human mycobacterial challenge model and demonstrate here that delivery of inhaled BCG at doses of up to $1x10^7$ cfu is safe and feasible.

1205

NATIONAL MAPPING OF SOIL-TRANSMITTED HELMINTHIASIS AND SCHISTOSOMIASIS IN ETHIOPIA

Gemechu Tadesse Leta[1], Kalkidan Mekete[1], Yonas Wuletaw[1], Abeba Gebretsadik[1], Heven Sime[1], Sindew Mekasha[1], Adugna woyessa[1], Oummer Shafi[2], Michael French[3], Jozef Vercruysse[4], Bruno Levecke[4], Jack Grimes[5], Lasely Drake[5], Iain Gardiner[5], Wendy Harisson[6], Alan Fenwick[6]

[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia,* [2]*Federal Ministry of Health, Addis Ababa, Ethiopia,* [3]*RTI International, USA, Washington, DC, United States,* [4]*Ghent University, Merelbeke, Belgium,* [5]*Partnership for Child Development, London, United Kingdom,* [6]*Schistosomiasis Control Initiative, London, United Kingdom*

Geographical distribution of both soil-transmitted helminths (STHs; *Ascarislumbricoides*, *Trichuristrichiura*, and the hookworms (*Necatoramericanus* and *Anycylostomaduodenale*) and schistosomes (SCH; *Schistosomamansoni* and *S. haematobium*) is pivotal to design and implement mass drug administration programs. Currently, up to date data on the distribution of both STH and SCH is not available for Ethiopia. Between 2013 and 2015, we assessed the distribution of STHs and SCH in a nationwide survey covering 153,282 school aged children (age 5 to 15) from 833woredas (districts) representing all 9 Regional States and 2 City Administrations of Ethiopia. From these disease maps, recommendations were made on the implementation and frequency of mass drug administration programs. The prevalence of any STHs across the study population was 21.7%, with *A. lumbricoides* (12.8%) being the most prevalent, followed by hookworms (7.5%) and *T. trichiura* (5.9%). The prevalence for any SCH was 3.8%, with *S. mansoni* (3.5%) being the dominant and *S. haematobium* (0.3%). STHs were more prevalent in south west Ethiopia, whereas SCH most found in the west and north-east of the country. The prevalence of moderate-to-heavy intensity infections equalled 2% for STHs and 1.6% for SCH. Based on the disease maps for STH, 215 out of 833woredas(25.8%)require mass drug administration once a year and 279(33.5%)twice a year. For SCH, mass drug administration once a year is recommended for 69 woredas (8.2%) and once every two years for 153woredas (18.4%). The results confirm that Ethiopia is endemic to both STHs and SCH, and both diseases pose problem to public health. Following the WHO recommendations on mass drug administration, 18 and 14 million school age children are in need for mass drug administration for STHs and SCH respectively.

1206

EVIDENCE OF HYBRIDIZATION BETWEEN *SCHISTOSOMA HAEMATOBIUM* AND *S. BOVIS* IN CÔTE D'IVOIRE

Kpongbo Etienne Angora[1], Jean-François Allienne[2], Olivier Rey[2], Hervé Menan[3], William Yavo[3], André Offianan Touré[4], Jean Coulibaly[5], Giovanna Raso[1], Jürg Utzinger[1], Oliver Balmer[1], Jérôme Boissier[2]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*IHPE, University Montpellier, CNRS, Ifremer, University Perpignan Via Domitia, Perpignan, France,* [3]*Université Félix Houphouët-Boigny, BPV* [34]*, Abidjan, Côte D'Ivoire,* [4]*Institut Pasteur de Côte d'Ivoire, Abidjan, Côte D'Ivoire,* [5]*Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire*

Schistosomiasis is the most prevalent neglected tropical disease in sub-Saharan Africa. In Côte d'Ivoire, *Schistosoma haematobium* causes urogenital schistosomiasis in humans, and *S. bovis* causes intestinal schistosomiasis in livestock. Both species are phylogenetically closed and hosted by the same freshwater snails of the genus *Bulinus*. There is no data available about hybridization between these species. So, this study aims to identify hybrids between *S. haematobium* and *S. bovis* in urines from schoolchildren in Côte d'Ivoire. A cross-sectional study was carried out in four locations in Côte d'Ivoire from January to April 2018. Urine samples from schoolchildren were examined to detect *S. haematobium* eggs using filtration method. Miracidia or eggs from positive samples were collected on Whatman® FTA cards and transferred to «Interactions Hôtes- Pathogènes- Environnement» (IHPE) laboratory in Perpignan (France) for genetic analysis. A RD-PCR test using mitochondrial Cox1 gene was performed and some miracidia DNA were sequenced. Of 1187 schoolchildren included in the survey, 116 (13.98%) were infected with *S. haematobium* microscopically. A total of 2688 miracidia or eggs were collected from 90 positive schoolchildren. The molecular analysis of schistosome miracidia or eggs confirmed infection with *S. haematobium* but also *S. haematobium-S. bovis* hybrids. Forty-eight percent of the miracidia or eggs were hybrids and 52 % were pure *S. haematobium*. Hybridization between schistosomes is present in Côte d'Ivoire. Therefore, further large-scale studies will be needed to identify all potential hybrids zones. Understanding such inter-species interactions is essential for optimizing control strategies.

1207

EFFECT OF SCHISTOSOMIASIS ON THE HEMATOLOGICAL PROFILE OF SCHOOL CHILDREN LIVING IN LAMBARÉNÉ, A SEMI-URBAN AREA IN GABON

Jean Claude Dejon Agobé[1], Yabo Josiane Honkpehedji[1], Jeannot Fréjus Zinsou[1], Jean-Ronald Edoa[1], Bayodé Roméo Adégbitè[1], Bertrand Lell[1], Peter Gottfried Kremsner[2], Ayola Akim Adegnika[1], Martin Peter Grobusch[3]

[1]*Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon,* [2]*Institut für Tropenmedizin, Eberhad Karls Universität Tübingen and German Center for Infection Research (DZIF), Tübingen, Germany,* [3]*Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands*

Schistosomiasis is a highly-prevalent parasitic infection in sub-Saharan Africa where school-aged children bear the brunt of the burden of disease. Schistosomiasis is a chronic disease, and the presence of blood in urine and/or in stool - occurring by blood-spilling during egg excretion - is the main symptom of the disease. In endemic areas where the full blood count (FBC) is very often used by clinicians as orientating examination in case of suspicion of an infectious disease, we assessed the impact of urogenital schistosomiasis on the hematology profile. A cross-sectional study was conducted among school children living in Lambaréné. Urine filtration technique was performed for the detection of *Schistosoma* eggs. Rapid Deep Stick (Combur[10] test) was performed for the detection of blood in urine while hematology parameters were evaluated using a Pentra ABX 60® analyzer. A total of 614 school children were included in the analysis. Mean age was 10.9 (SD = 2.7) years, with a 1.05 girl-to-boy sex ratio. The prevalence of schistosomiasis was 26%. Full blood counts (FBC) showed a decrease of hemoglobin levels (mean: 11.3 g/dL *vs* 11.7 g/dL, *p-value* = 0.0006), an increase of WBC (mean: 7.9 10^3/mm^3 *vs* 7.1 10^3/mm^3, *p-value* = 0.0008) and of platelet (mean: 258 10^3/mm^3 *vs* 231 10^3/mm^3, *p-value* = 0.001) levels among the schistosoma-infected children compared to their non-infected counterparts. Hematuria was found to be associated with schistosomiasis (RR=5.54, *p*-value < 0.001) with a sensitivity and specificity of 60% and 92%, respectively. Predictive positive and negative values were 73% and 87%, respectively. The prevalence of

schistosomiasis is moderate in Lambaréné, where children with infections exhibit a distinct FBC profile, indicating the necessity to take into account schistosomiasis as a co-morbidity when managing other infectious diseases in schistosomiasis-endemic areas.

ASSOCIATION OF RIVERINE PRAWNS AND INTERMEDIATE HOST SNAIL AND CORRELATION WITH HUMAN SCHISTOSOMIASIS IN TWO RIVER SYSTEMS IN SOUTHEASTERN COTE D'IVOIRE

Nana Rose Diakite epse Ngoran

Universite Felix Houphouet Boigny, Abidjan, Côte D'Ivoire

The current emphasis of schistosomiasis control is placed on preventive chemotherapy using praziquantel. However, reinfection may occur rapidly in the absence of complementary interventions. Recent studies from Senegal suggest that predatory prawns might feed on intermediate host snails and thus impact on schistosomiasis transmission. We designed a study with four repeated cross-sectional surveys pertaining to prawns and snails, coupled with a single cross-sectional parasitological survey among humans. We assessed for potential associations between the presence/density of prawns and snails and correlation with Schistosoma infection in a composite sample of school-aged children and adults. The study was carried out between October 2015 and December 2016 in 24 villages located near the Agnéby and Mé coastal river systems in south-eastern Côte d'Ivoire. At each site, snails and prawns were collected, and in each village, 150 individuals were subjected to stool and urine examination for the diagnosis of Schistosoma mansoni and S. haematobium. We found peaks of relative abundance of intermediate host snails in the villages of the Agnéby River system, while predatory prawns were predominantly recorded in the Mé River system. A negative association was observed between intermediate host snail densities and riverine prawns; however, no pattern was found between this trend in the predator-prey relationship and the prevalence of human schistosomiasis.

1209

PREGNANCY INCREASES RISK OF *SCHISTOSOMA HAEMATOBIUM* INFECTION AND DISEASE SEVERITY AMONG REPRODUCTIVE AGE WOMEN IN MUNYENGE, SOUTH WEST REGION, CAMEROON. A CASE-CONTROL STUDY

Judith K. Anchang-kimbi[1], Godlove B. Wepnje[1], Vicky D. Ndassi[1], Irene U. Sumbele[1], Helen K. Kimbi[2]

[1]*University of Buea, Buea, Cameroon,* [2]*The University of Bamenda, Bambili, Cameroon*

Pregnancy is found to be associated with increased parasitic infections. In this study, we hypothese that pregnancy predisposes reproductive age women to higher *S. haematobium* infection rate and disease severity. The study was a case-control study carried out from November 2017 to January 2018. Pregnant women who reported for antenatal care clinic were enrolled as cases. Non-pregnant reproductive aged (15-45 years) females were selected from the same community and sampling period as the cases. Two control were enrolled for each case. Semi-structured questionnaires was used to collect information on socio-demographic data and water contact behaviour. Urine samples were obtained and analysed for the presence of microhaematuria and/or *Schistosoma haematobium* ova using test strip and filtration methods respectively. Haemoglobin levels were measured using haemoglobinometer. Data were analysed using univariate and multivariate regression analyses. A total of 300 (100 pregnant: 200 non-pregnant) females were enrolled into the study among whom 11.7% (35) were diagnosed for urogenital schistosomiasis (UGS). In univariate analysis, pregnancy status ($\chi^2 = 15.54$; $p < 0.001$), maternal age ($\chi^2 = 8.04$; $p = 0.018$), stream usage ($\chi^2 = 4.08$; $p = 0.043$) and degree of contact with stream (domestic activity and/or bathing) ($\chi^2 = 17.03$; $p < 0.001$) were factors associated with occurrence of the infection. Logistic regression analysis revealed pregnancy status as the only predictor of UGS (aOR = 7.83; 95% CI: 3.14 - 19.52) where pregnant females were seven-fold more likely to be infected than their non-pregnant counterparts. Fewer (< thrice/day) or no visit to stream (aOR = 0.49; 95% CI = 0.30 - 0.83) reduced exposure to infection. Haematuria ($\chi^2 = 9.99$; $p = 0.002$) and anaemia ($\chi^2 = 26.23$; $p < 0.001$) were more common among pregnant (15.0% vs 67%) than non-pregnant (4.5% vs 35.6%) females respectively. Urogenital schistosomiasis affects non-pregnant and pregnant women alike, but the later may be susceptible to greater disease severity as a result of their physiological state. Efforts to curtail maternal UGS in this setting cannot be overemphasized.

1210

EVALUATION OF THE EFFECT OF ARTEMISININ-BASED COMBINATION THERAPIES ON URINARY SCHISTOSOMA HAEMATOBIUM WHEN ADMINISTERED FOR THE TREATMENT OF MALARIAL CO-INFECTION

Dearrie Glory Okwu, Rella Zoleko Manego, Michael Ramharter, Ghyslain Mombo-Ngoma

Centre de Recherche Médicales de Lambaréné (CERMEL), Lambaréné, Gabon, Lambarene, Gabon

Schistosomiasis(STS) is the most prevalent water borne disease affecting 230 million people worldwide, of which 90% live in Africa. In 2007, a study presented the efficacy of Artemisinin based Combination Therapies (ACTs) in the management of STS when administered in the treatment of uncomplicated malaria. Praziquantel (PZQ) is presently the drug of choice for treating all forms of STS, however, this drug is found to be ineffective in immature stages. Additionally, parasite resistance and consequent rapid reinfection require the development of new therapies. ACTs could be combined with PZQ thus targeting different stages of parasite development to improve treatment outcomes. The evaluation of the efficacy of Artemisinin derivatives in the treatment of schistosomes is of great importance. The study is an open-label non- randomized trial to assess the efficacy and safety of artemisinin derivatives versus non- artemisinin drugs on *S. haematobium* infection while administered for the treatment of malaria. Study population included all patients in the study area diagnosed with malaria-STS co-infection. Those excluded from the study were treated with PZQ in the preceding 6 weeks, have drug intolerance or are pregnant. Basic demographic data and history of hematuria were recorded. During the follow up visits, urine samples were collected on day 28 and day 42 (6 weeks post treatment). Post treatment assessment was done on urine samples collected on at least two consecutive days. All subjects were treated with single dose PZQ (40mg/kg) as recommended by the WHO at the end of follow up. A total of 331 subjects were screened, 40 positive subjects were enrolled and treated with artesunate-pyronaridine. Median age is 12 years (Interquartile Range (IQR) 9-17), sex ratio of Male: Female is 2:1, Median baseline eggs is 30(IQR 6-256) while the median post treatment eggs is 22(IQR 4-304). One of the subjects cleared eggs in the urine by day 43.The study demonstrates some effect of ACTs on STS. Preliminary results are going to be presented at the ASTMH

1211

PERFORMANCE OF THE POINT OF CARE URINE CIRCULATING CATHODIC ANTIGEN TEST IN A SCHISTOSOMIASIS CONTROL PROGRAM SETTING IN WESTERN KENYA, 2017-2018

Anne Straily[1], Emmy K. Awino[2], Madeline Usey[1], Susan P. Montgomery[1], Ryan E. Wiegand[1], Alie Eleveld[2], Alex Mwaki[2], William E. Secor[1], Maurice R. Odiere[3]

[1]*Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States,* [2]*Safe Water and AIDS Project (SWAP), Kisumu, Kenya,* [3]*Kenya Medical Research Institute (KEMRI), Kisumu, Kenya*

Schistosoma mansoni control programs have traditionally used the Kato-Katz fecal exam method (KK) for monitoring and evaluation of infection control programs. The commercially available point of care urine circulating cathodic antigen (POC-CCA) test might be an improvement over KK but before transitioning to the POC-CCA, it is necessary to determine how

it performs in a program setting. Single urine and stool specimens were collected from students in 30 schools in western Kenya prior to mass treatment with praziquantel and again one year later. Prevalence and intensity of infection were determined by both KK and POC-CCA. We compared changes in prevalence and intensity of the two tests among all the schools as well as when groups of schools were separated according to baseline KK prevalence (0-10%, >10-20%, >20%). Prevalence by POC-CCA was higher than by KK for all schools at both time points. Mean POC-CCA score and mean intensity decreased after one year when all schools were analyzed collectively ($p<0.0001$). The proportion of egg-positive (by KK) and POC-CCA positive individuals was significantly different between baseline and one year ($p<0.001$); notably, with POC-CCA there were significantly fewer "trace" results and more +2 and +3 results. The POC-CCA results did not vary in proportion to the KK results thus, the translation of historical data and programmatic guidelines based on KK results to the POC-CCA may not be straightforward. The reduction in the proportion of "trace" results suggests that persons with light infections were less likely to be re-infected during the course of the following year. POC-CCA may be useful as tool to evaluate the effectiveness of schistosomiasis control programs, but where programs wish to switch to the POC-CCA from historical KK testing use, it may be necessary to establish new prevalence maps and programs using only the POC-CCA.

1212

UTILIZATION OF THE COVERAGE SUPERVISION TOOL DURING SCHISTOSOMIASIS MASS DRUG ADMINISTRATION

Ibrahim Kargbo Labour[1], Habib I. Kamara[2], Mohamed Turay[2], Abdul Conteh[1], Abdulai Kandeh[2], Victoria Redwood-Sawyer[2], Mohamed Kallon[2], **Mustapha Sonnie**[2], Mary Hodges[2]

[1]*Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone,* [2]*Helen Keller International, Freetown, Sierra Leone*

Since 2009 mass drug administration (MDA) with praziquantel has been used for schistosomiasis (SCH) control and independent monitoring used to help monitor the MDA process and validate reported coverage. World Health Organization guidelines recommend a Supervisor's Coverage Tool (SCT) for use in supervising the MDA to ensure effective coverage. This study in 2018 was to assess coverage and factors affecting compliance in 7 districts using CST for the first time in Sierra Leone. HKI recruited and trained supervisors at district level in Makeni. The chiefdoms with SCH prevalence >20% at the last national survey (2016) were selected and assigned into 16 Supervision Areas (SAs): Bombali: 1, Kenema: 4, Kailahun: 4, Kono: 2, Koinadugu: 4 and Tonkolili: 1. 20 villages per SA were randomly selected. One household per village was randomly selected. One school-aged child (5-14 years) was randomly selected and interviewed. If the child was <10 years, their caregiver was interviewed. In total 320 children were selected (boys: 51.6%, girls: 48.4%). Overall coverage was 79.4% (boys: 82.4%, girls: 76.1%). Six SAs reached acceptable coverage (≥18 children treated). However, 7 SAs failed to conclusively reach acceptable coverage (13-17 children treated) and 3 SAs had inadequate coverage (≤12 children treated). Reasons for noncompliance (66) were: not offered drug (31), community not reached (18), out of area (7), sick (4), no knowledge of MDA (3), afraid of side effects (2) and mother not allowing child to take the drug (1). Findings were relayed to the health units responsible for the catchment communities, the district NTD focal person and the national NTDP in order that the mop-up MDA could be performed. All SAs with inadequate coverage were from Karene (Bombali) and Falaba (Koinadugu) which are notorious for being underserved by health facilities per square kilometer and health workers per population and are in the process of being designated as new districts in recognition of the need. Implementation of the SCT was smooth and quickly determined villages where MDA had been ineffective.

1213

POST-TREATMENT SURVEILLANCE CRITERIA FOR *SCHISTOSOMA MANSONI*: WILL ELIMINATION OR RESURGENCE OCCUR AFTER STOPPING MASS DRUG ADMINISTRATION?

Jaspreet Toor[1], James E. Truscott[1], Marleen Werkman[1], Hugo C. Turner[2], Anna E. Phillips[1], Charles H. King[3], Graham F. Medley[4], Roy M. Anderson[1]

Schistosomiasis remains an endemic parasitic disease affecting millions of people around the world. The World Health Organization has set elimination (breaking transmission) as the end goal for schistosomiasis. However, there is currently a lack of guidance on what treatment programs should do once very low prevalence levels have been reached to determine whether elimination or resurgence of the infection will occur after stopping mass drug administration (MDA). Using a mathematical model and positive predictive values, we define the post-treatment surveillance criteria which can be used to detect *Schistosoma mansoni* elimination. We determine the prevalence threshold, i.e. prevalence of infection, below which the parasite cannot maintain transmission leading to elimination. We find that a prevalence threshold of 0.5% by Kato-Katz is sufficient for surveillance six months after the last round of MDA. However, as such a low prevalence can be difficult to measure in the field, we recommend using a prevalence threshold of 1% by Kato-Katz at two years (or later) after the last round of MDA with a sample size of 200 individuals across the entire community. Higher prevalence thresholds can be used but require a longer post-treatment surveillance period. For treatment programs where elimination is highly likely (due to maintenance of high MDA coverage), higher thresholds could be used sooner. Overall, our results provide guidance on the post-treatment surveillance which needs to be carried out when approaching elimination of *S. mansoni* transmission in a defined area.

1214

OPTIMIZING SURVEY STRATEGIES FOR PRECISION MAPPING OF SCHISTOSOMIASIS TO GUIDE MASS DRUG ADMINISTRATION: A VALUE-OF-INFORMATION ANALYSIS

Nathan C. Lo[1], Yi Liu[2], Giovanna Raso[3], Jean T. Coulibaly[4], Hugh J.W. Sturrock[5], Jürg Utzinger[3], Isaac I. Bogoch[6], Jason R. Andrews[7]

[1]*Stanford University School of Medicine; University of California San Francisco, Stanford; San Francisco, CA, United States,* [2]*University of Chicago, Chicago, IL, United States,* [3]*Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland,* [4]*Swiss Tropical and Public Health Institute, University of Basel, Université Félix Houphouët-Boigny, Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire,* [5]*University of California San Francisco, San Francisco, CA, United States,* [6]*University of Toronto, Toronto, ON, Canada,* [7]*Stanford University School of Medicine, Stanford, CA, United States*

WHO surveillance guidelines for schistosomiasis are designed to estimate prevalence to inform a decision on mass drug administration (MDA). However, the current sampling strategy for these prevalence surveys do not account for prior sources of data (e.g. historical surveys, geospatial risk maps), the 10% prevalence threshold for an MDA decision, or the costs and health impact of a "right" or "wrong" decision. We developed a value-of-information model that integrated prior information on prevalence, sampling theory, and cost-effectiveness analysis to improve efficiency of sampling. The model used prior prevalence data to estimate the optimal sample size for district prevalence surveys to guide MDA decisions based on value-of-information. We defined "value" of collecting stool sample data in US$ based on whether this information changed an MDA decision. We used person-level data on S. mansoni from Côte d'Ivoire (< 2011) to construct a prior prevalence estimate by district.

Simulations computed the value of collecting stool samples (N=0-5,000) from schools testing all possible prevalences and using Bayesian updating. The model used a dynamic transmission and cost-effectiveness model to estimate the total programmatic cost (US$) and health impact (disability adjusted life-years) of the MDA decision over 5 years. We evaluated the model optimal sample size and classification accuracy compared to WHO surveillance guidelines using person-level data on S. mansoni from 25 districts in Côte d'Ivoire (2011-2012). The model recommended a mean sample size of 45 total children (range: 0-61 children) chosen amongst 2-4 schools per district, compared to WHO recommendation of 250 children chosen amongst 5 schools. The model correctly classified the district MDA decision in 90% of cases with the full dataset as reference, while reducing total sampling by 82% (95%UI: 80-87%). Prevalence surveys using a value-of-information approach to estimate sample size can reduce sampling effort with high classification accuracy for MDA decisions, which can be applied to precision mapping of endemicity at a community level and future WHO surveillance guidelines.

1215

A BETTER UNDERSTANDING OF THE BASIC PARASITE LIFE CYCLE AND TRANSMISSION DYNAMICS IS CRUCIAL TO MOVE TOWARD THE ELIMINATION OF SCHISTOSOMIASIS

Louis-Albert Tchuem Tchuenté

University of Yaoundé I, Yaoundé, Cameroon

Within the past decade, significant progress has been made on the control and elimination of neglected tropical diseases (NTDs). Today, the 'preventive chemotherapy' is the primary strategy for the control of 4 helminthiasis from the 20 diseases that are listed by the World Health Organization as the group of NTDs, i.e. schistosomiasis, soil-transmitted helminthiasis, onchocerciasis and lymphatic filariasis. The major intervention for schistosomiasis control is mass administration of praziquantel to those shown to be, or presumed to be, at-risk of infection, on the basis of disease mapping. However, using praziquantel alone has not been proven to be able to lead to elimination in high transmission settings. The interruption of schistosomiasis transmission involves several challenges due to multiple epidemiological and ecological factors such as climatic and physical conditions, type of water body, snail species and population dynamics, impact of reservoir hosts, and intensity of water contacts. Schistosomes have a complex life cycle and their transmission is highly focal. Reaching the endgame requires the implementation of alternative integrated multi-interventions approach, guided by a better understanding of the transmission of schistosomiasis in the targeted settings. The presentation will highlight and discuss some of the key factors and considerations that should guide optimizing our interventions to overcome the impact of schistosomiasis and accelerate toward the elimination of schistosomiasis in sub-Saharan Africa.

1216

INDIVIDUAL AND VILLAGE-LEVEL CONNECTIVITY AND RISK OF *SHISTOSOMA JAPONICUM* INFECTION IN SICHUAN, CHINA

Andrea Geri Buchwald[1], Elise Grover[1], Julia Van Dyke[1], Ding Lu[2], Yang Liu[2], Bo Zhong[2], Elizabeth J. Carlton[1]

[1]*University of Colorado School of Public Health, Aurora, CO, United States,* [2]*Sichuan Centers for Disease Control, Chengdu, China*

Human population movement (HPM) is vital to pathogen spread and transmission. *Schistosoma* parasites have a complex life cycle: transmission is dependent on a variety of ecological pathways including transport of larval stages via water and movement of snails and mammalian hosts. Human migration has been shown to contribute to schistosome emergence, and accounting for short-scale parasite movement improves performance of schistosomiasis transmission models, suggesting that HPM also plays a role in schistosomiasis maintenance and transmission. However, the mechanisms by which HPM contributes to individual-level *Schistosoma* infection risk are poorly characterized. In endemic areas, travel outside the region may be protective against infection, while certain types of travel may increase exposure and infection risk. Utilizing data collected from detailed monthly travel surveys from residents in 28 communities in Sichuan, China where *S. japonicum* is present, we aimed to describe short-term HPM and to determine the strongest travel-related predictors of *S. japonicum* infection. Candidate predictors included timing, frequency, distance, duration, and purpose of recent travel, as well as known demographic risk factors. Village connectivity was measured as travel distance from nearest city and frequency of travel outside the village by residents. As this was a large set of correlated variables, Random Forest was used to investigate the contribution of HPM variables to individual-level infection risk, and multi-level general estimating equations (GEE) were used to disentangle the effects of individual vs community-level HPM on population prevalence. Age, the number of years a person has lived in the village, travel in August and September, and mean number of days traveled were the factors most predictive of *S. japonicum* infection. In GEE models, village-level predictors of distance from the city and increasing frequency of travel were more strongly associated with increased individual *S. japonicaum* risk, suggesting that community connectivity plays a more important role than individual travel in *S. japonicum* transmission.

1217

BIOGEOGRAPHICAL CHARACTERISTICS OF *SCHISTOSOMA MANSONI* ENDEMIC AREAS IN ETHIOPIA

Keerati Ponpetch[1], Berhanu Erko[2], Lindsay Richards[3], Yang Yang[4], Song Liang[1]

[1]*Department of Environmental and Global Health, University of Florida, Gainesville, FL, United States,* [2]*Aklilu Lemma Institute of Pathobiology, Addis Ababa University, Addis Ababa, Ethiopia,* [3]*Department of Microbiology and Cell Science, University of Florida, Gainesville, FL, United States,* [4]*Department of Biostatistics, University of Florida, Gainesville, FL, United States*

Schistosomiasis is a neglected tropical disease affecting 258 million people in 78 countries worldwide with over 90% of cases occurring in sub-Saharan Africa. In Ethiopia, schistosomiasis is caused by *Schistosoma mansoni* and *S. hamaetobium* with the former being widely distributed and prevalent - more than 4 million people are infected by *S. mansoni* annually with 35 million at risk of infection. Although many school- and community-based epidemiological surveys were conducted in the past decades, the national distribution of schistosomiasis endemic areas and associated socio-environmental determinants remain little understood. The present study aims to delineate biogeographical characteristics of *S.mansoni* endemic areas in Ethiopia. Through a systematic review, we compiled a comprehensive dataset on *S.mansoni* surveys. A total of 95 survey sites were identified and geo-referenced. Sites are distributed in six regional states - Southern Nations, Nationalities, and Peoples' Region (SNNPR), Tigray, Addis, and Beneshangul Gumuz, with the majority of surveys in Amhara and Oromia. The surveys exhibited a wide range of prevalence of infections from 0.43% to 95.06%, and 20% of the sites had >50% prevalence of infection, followed by 47% and 33% of the sites in the ranges of 10%-50% and <10%, respectively. A meta-analysis using a random effect model generated pooled estimates of 45.67%, 24.56%, and 19.84% for the prevalence in SNNPR, Tigray, and Oromia regions, respectively. Based on landscape features, these areas are broadly classified into the following ecozones: Afroalpine, East Montane, Eastern, Northeastern, Rift Valley, Western, and West Mountain. The Western Ecozone had the highest prevalence at 38.4%, followed by 38.14% and 34.8% in Rift Valley and East Montane Ecozones, respectively. In addition, endemic sites with >50% prevalence of infection were found at altitudes from 1,010 to 2,016 meters above sea level, annual mean temperatures between 18.6 - 25.64 degree Celsius, annual cumulative precipitation between 652 - 1754 millimeters, and normalized difference vegetation index between 0.28 - 0.74.

1218

MODELLING THE IMPACT OF VACCINATION STRATEGIES ON THE TRANSMISSION OF SCHISTOSOMIASIS

Klodeta Kura, James Truscott, Jaspreet Toor, Roy Anderson

Imperial College London, London, United Kingdom

Schistosomiasis is one of the most important neglected tropical diseases (NTDs) affecting millions of people in 79 different countries. The World Health Organization (WHO) has specified two control goals to be achieved by 2020 and 2025. These are morbidity control and elimination as a public health problem goals. Mass drug administration (MDA) is the major method for schistosomiasis control but it has proved difficult in the past to both secure adequate supplies of the most efficacious drug praziquantel to treat the millions infected either annually or biannually, and to achieve high treatment coverage in targeted communities in regions of endemic infection. The development of alternative control methods remains a priority at present. Using an individual based stochastic model, we analyze whether the addition of a novel vaccine alone or in combination with drug treatment, is a more effective control strategy, in terms of achieving the WHO goals, as well as the time and costs to achieve these goals when compared to MDA alone. The key objective of our analyses is to help facilitate decision making for moving a promising candidate vaccine through the phase I, II and III trials in humans to a final product for use in resource poor settings. The simulation studies indicate that a vaccine is needed to both reduce the probability of reinfection and eliminate transmission within a reasonable time frame. The value of the vaccine depends on vaccine efficacy, the duration of vaccine protection, the goal (reduction in prevalence of infection or prevalence of heavy-intensity infection) and the cost of the treatment. In high transmission settings, vaccination alone may achieve the morbidity control goal, but integrated MDA plus vaccination is required to achieve the elimination as a public health problem goal.

1219

SCHISTOSOMIASIS IN BURKINA FASO: TIME TO CHANGE CONTROL STRATEGY IN FOUR PERSISTENT HOTSPOTS

Hamado Ouédraogo[1], Clarisse Bougouma[1], Dieudonné Nare[2], Jean-Paul Djiatsa[2], Amy Veinoglou[3], Achille Kaboré[4], Fanny Yago-Wienne[2], Yaobi Zhang[5]

[1]*NTD Control Program, Ministry of Health, Ouagadougou, Burkina Faso,* [2]*Helen Keller International, Ouagadougou, Burkina Faso,* [3]*Helen Keller International, New York, NY, United States,* [4]*Family Health International 360, Washington, DC, United States,* [5]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

The baseline mapping of schistosomiasis in Burkina Faso in 2004-2005 showed high level of endemicity for *Schistosoma mansoni* and *Schistosoma hematobium*, with prevalence ranging from 1.67% to 89.4% across the country. The country has three ecological zones with the following baseline prevalence: a) Sahelian zone with the highest prevalence of 89.4% in the North and Sahel regions, b) Sahelo-Sudanese zone with a prevalence of 51.1% in the Center East, Haut Bassins and Boucle du Mouhoun regions, and c) Sudanese zone with a prevalence of 34.3% in the South West. Mass treatment campaigns with praziquantel have been implemented since 2004. *S. hematobium* is predominant in the Sahel region whereas *S. mansoni* is more prevalent in the south and Haut Bassins. After more than 10 years of mass drug administration (MDA), the prevalence from sentinel sites decreased significantly from between 1.7% and 89.4% (mean prevalence of 53.9%) to between 0% and 23.9% (mean prevalence of 5.6%) in 2016. By 2017, the prevalence in previously high endemic region dropped to less than 5%. As of June 2016, the villages of Panamaso (Haut-Bassins), Nagbingou, Tougouri (Center-East) and Dori (Sahel) had prevalence of 26.85%, 29.9%, 20% and 14.81% respectively. In the district of Dafra, two sentinel site villages were surveyed (Sogossagasso and Panamasso). All positive cases were found in the village of Panamasso which was previously documented as a persistent hotspot with increase in prevalence (8.3% in 2005, 25% in 2013 and 26.9% in 2017) despite annual MDA with good coverage (>75%). Although MDA has been implemented with satisfactory coverage (>75%) for over 14 years, schistosomiasis remains a public health issue in these few isolated areas in the country. Some behavior issues might be contributing to frequent reinfection of people in these hotspots. The situation calls for a change in treatment strategies, for socio-science investigation and for the roll-out of multi-sectoral interventions involving WASH, intensive health education or snail control, to permanently bring the prevalence down in the hotspots.

1220

EFFICACY OF BIENNIAL TREATMENT OF SCHISTOSOMIASIS IN MODERATE AND HIGH ENDEMIC AREAS IN BURKINA FASO

Hamado Ouédraogo[1], Clarisse Bougouma[1], Dieudonné Nare[2], Jean-Paul Djiatsa[2], Amy Veinoglou[3], Achille Kaboré[4], Fanny Yago-Wienne[2], Yaobi Zhang[5]

[1]*NTD Control Program, Ministry of Health, Ouagadougou, Burkina Faso,* [2]*Helen Keller International, Ouagadougou, Burkina Faso,* [3]*Helen Keller International, New York, NY, United States,* [4]*Family Health International 360, Washington, DC, United States,* [5]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

The World Health Organization (WHO) guidelines recommend mass drug administration (MDA) with praziquantel to control schistosomiasis (SCH) according to district level prevalence. In districts with prevalence between 10 and 50%, WHO recommends biennial MDA (once every 2 years). Baseline mapping in 2004 in Burkina Faso showed an overall prevalence of between 1.7% and 89.4% in high endemic zones (Sahel region). Burkina Faso adopted a biennial treatment strategy across the regions targeting school age children (5 to 15 years old) and adults. At baseline, 23 sentinel sites (schools) were established, among which 5 had prevalence above 50%, 15 had prevalence between 10% and 50% and 3 had prevalence below 10%. For sentinel site survey, a systematic sampling method was applied to select children in each school, 160 children aged 7 to 11 (32 children in each classroom with equal number of girls and boys). For urinary schistosomiasis, one urine specimen was collected from each child to determine *S. haematobium* infection using the filtration method and microscopy. For intestinal schistosomiasis, a single stool sample was collected from each child. Duplicate Kato-Katz slides were prepared from each sample and examined for *S. mansoni* infections. Out of 22 sentinel sites surveyed between 2016 and 2018, 18 have SCH prevalence less than 5%. The other 4 have prevalence of 26.9%, 23.9, 6.3% and 5.6% respectively. After more than 10 years, the biennial MDA with satisfactory coverage (>75%) has been successful in controlling SCH not only in moderately endemic districts (10-50% baseline prevalence) but also in 4 out of 5 highly endemic districts (>50% baseline prevalence). The Strategy has brought the prevalence down to less than 1% and 5% respectively in 13 and 4 sentinel sites (out of a total of 22). Only 4 sentinel sites have prevalence above 5% in 2018. It is likely that the country could achieve elimination of SCH as public health problem by 2025 if more efforts are deployed to maintain the gains and to wipe out the last areas where SCH is still prevalent.

1221

DECISION MAKING FOR MASS DRUG ADMINISTRATION FOR SCHISTOSOMIASIS AFTER IMPACT SURVEYS IN SENEGAL, 2016-2018

Boubacar Diop[1], Fatou Ndiaye Badiane[1], Amadou Doucoure[1], Mawo Fall[2], Daniel Albert Cohn[3], Achille Kabore[3]

[1]*Direction de Lutte contre la Maladie, Ministère de la Santé et de l'Action Sociale, Dakar, Senegal,* [2]*RTI International, Dakar, Senegal,* [3]*FHI 360, Washington, DC, United States*

Since 2016, Senegal's National Bilharzia and Soil-Transmitted Helminths Control Program (PNLBG) has closely followed World Health Organization guidelines for decisions about the frequency or stopping of treatment

for schistosomiasis (SCH) in districts already under treatment with praziquantel. From 2016-18 the PNLBG conducted SCH evaluations in districts that had completed 5-6 rounds of MDA, per WHO guidelines. The evaluations followed the standard protocol, adapted to the local context (at each site, 50 children aged 7-14 years were selected), and used standard diagnostic techniques (Kato-Katz for *S. mansoni*; reagent strips and urine filtration for *S. haematobium*). Sites were selected from those previously surveyed, choosing those with the highest prevalence of SCH (of either species). The highest-prevalence finding in each homogeneous ecological zone (2016 evaluations) or district (2017-18), by site, by species, and by diagnostic, was retained for the entire zone or district. The 2016 evaluation, in three ecological zones of the Senegal River Basin, found that the Haut Bassin (10 districts), the Vallée (6 districts), and the Delta (8 districts) zones all had SCH prevalence ≥50%, meaning MDA should be conducted twice per year (per WHO guidance). The 2017 evaluation, in 8 districts, found 1 district with prevalence ≥50%, (twice per year MDA); 2 districts with prevalence ≥10% and <50% (continue MDA with same frequency); 3 districts with prevalence ≥1% and <10% (biennial MDA); and 2 districts with prevalence <1% (no further MDA). The 2018 evaluation, in 3 districts, found 1 district with prevalence ≥50% (twice per year MDA); and 2 districts with prevalence ≥10% and <50% (continue MDA with same frequency). The PNLBG has maintained or adjusted the frequency of district-level MDA in line with WHO guidance based on the prevalences found, except where twice-yearly MDA is recommended; in these areas the PNLBG has maintained once-yearly treatment for reason of available internal and external resources, including the donation of praziquantel. This approach has enabled Senegal's NTD Control Program to focus its resources where they are most needed.

1222

RELATIONSHIP BETWEEN GUT MICROBIOTA AND *FASCIOLA HEPATICA* INFECTION IN CHILDREN FROM A COMMUNITY IN CAJAMARCA, PERU

Hugo Carrillo-Ng[1], Yordi Tarazona[1], Miguel A. Aguilar-Luis[2], Wilmer Silva-Caso[2], Carmen Tinco-Valdez[1], Carlos Palomares-Reyes[2], Ronald Aquino-Ortega[1], Johanna Martins-Luna[1], Isaac Peña-Tuesta[1], Juana M. del Valle-Mendoza[2]

[1]*Instituto de Investigacion Nutricional, Lima, Peru,* [2]*Investigation Center and Innovation of the Health Sciences Faculty, Universidad Peruana de Ciencias Aplicadas (UPC), Lima, Peru*

Fasciola hepatica infection is one of most important zoonosis affecting the liver in Peru. The highest prevalence of human fascioliasis has been reported in the Andean valleys with a prevalence that can reach up to 27%. The intestinal microbiota is an essential part of the gut homeostasis, it participates in the development of intestinal mucosa and immune system of the host. Recent studies have shown that parasitic infections can cause a negative effect on gut microbiota. However, *Fasciola hepatica* infection and its relationship with the gut microbiota have not been studied yet. The aim of this study was to describe the prevalence of 13 representative bacteria from the gut microbiota in stools samples from children with *Fasciola hepatica* infection and children without the infection. A prospective cross-sectional study was conducted in 103 children between 5 and 12 years old from a community in San Pablo (Cajamarca,Peru). A stool sample was collected from each patient. The presence of *Fasciola hepatica* was determined by ELISA using the commercial kit Bio-X Fasciola hepatica antigenic ELISA kit (Bio-X diagnostics, Belgium) . DNA extraction was performed using the commercial kit innuPREP Bacteria DNA kit (Analytik Jena, Germany) and 13 bacterial pathogens were amplified using PCR. Of all 103 patients, 16 (15.53%) cases were positive for *Fasciola hepatica.* The most common isolated bacteria from patients with *Fasciola hepatica* infection were Proteobacteria (68.5%), followed by Bacteroides (37.5%), Lactobacillus (37.5%) and Clostridium (12.5%), these pathogens were significantly lower compared with patients negative for *Fasciola hepatica* with prevalence of Proteobacteria (86.2%), Bacteroides (70.1%), Lactobacillus (72.4%) and Clostridium (69%). The prevalence of *Fasciola hepatica* infection was associated with contact with animals, this being significant with 15/16 cases (94.62%). *Fasciola hepatica* infection has a high prevalence in school-aged children from Cajamarca, Peru. It has a negative impact on the presence of some gut bacteria such as Bacteroides, Lactobacillus, Proteobacteria and Clostridium.

1223

ACCESSIBLE-OMICS: ADVANCES IN SCRNA TRANSCRIPTIONAL SIGNALING AND THE CREATION OF A TRANSCRIPTOMIC ATLAS OF ZAMBIAN ADULTS WITH LIKELY ENVIRONMENTAL ENTEROPATHY

Thomas Wallach[1], Conner Kummerlowe[2], Travis Hughes[2], Paul Kelly[3], Alex Shalek[2], Zev Gartner[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Massachusetts Institute of Technology, Cambridge, MA, United States,* [3]*University Teaching Hospital, Lusaka, Zambia*

The intestinal epithelium comprises a diverse population of cells that must collaborate to maintain gut function. Understanding the normal cellular composition of this population, and how it might differ between the developing and developed worlds, is key for addressing poorly understood non-focal conditions such as Environmental Enteropathy (EE). EE is characterized by poor growth and increased intestinal permeability, and typically found in areas with poor access to clean water. Its effects persist into adulthood, with persistent intestinal epithelial changes and increased risk of infection and metabolic syndrome. Its restriction to low-income regions of the world has limited application of cutting-edge molecular profiling techniques until the recent advent of Seq-Well. Seq-Well is a massively-parallel single-cell RNA-Seq platform that leverages advances in materials technology to allow for on-site, simple processing without complicated peripherals, facilitating creation of cDNA libraries anywhere. This allows for shipment of cDNA to facilities with the equipment for sequencing and associated computational approaches. We have successfully demonstrated single cell analysis of both duodenal and jejunal epithelium obtained from biopsies from 17 Zambian adults residing in high EE risk regions. We have identified enteroendocrine L cells via PYY production, but noted an absence of GLP1 and GLP2 transcripts. We see a high level of Enteroendocrine D cells with high somatostatin production. Decreased GLP2 is correlated with increased issues with insulin insensitivity (Amato et al, 2016), and somatostatin has been shown to support barrier function while inhibiting proliferation, these findings support a possible compensatory mechanism to recurrent enteric infection consistent with secondary findings of EE such as increased risk of metabolic syndrome and diminished crypt:villus ratio. Characterization of these pathways can be used for identification of not only new possibilities for non-invasive disease assessment and monitoring, but also possible therapeutic or prophylactic interventions.

1224

A WATERBORNE DISEASE INDEX (WBDI) FOR RURAL COMMUNITIES IN THE CARIBBEAN

Akilah T. Stewart[1], Vrijesh Tripathi[1], Azad Mohammed[1], Catherine Seepersad[1], Adrian Cashman[2], Dave D. Chadee[1], Adesh Ramsubhag[1]

[1]*The University of the West Indies, St. Augustine, Trinidad and Tobago,* [2]*The University of the West Indies, Cavehill, Barbados*

Within rural communities, socio-economic resource issues can impact access to potable water. However, these issues are often not well captured at a national level but need to be considered in developing national water resource management policies. A Waterborne Disease Index (WBDI) is a new tool that can be used by policy makers to make decisions on allocation of critical water resources. It integrates water stress and scarcity measures from a Water Poverty Index (WPI) survey instrument with microbiological water quality data. In this study a WBDI was developed for rural communities in the southern Caribbean based on a study in communities of Carriacou, Grenada, Nariva, Trinidad and Speightstown, Barbados. A structured questionnaire was administered to 606 households and included five key sections: Demographics, Water

Use & Water Quality, Environmental Health, Agricultural Activities and Climate Change Perceptions. Microbial data from 303 domestic water samples were analysed for pathogens of human health interest. Calculated WPI values scores out of 100 were similar in the mid-range for the three communities. The categories of Use (the different ways in which water is used) and Environment (health status of the environment) values account for the major vulnerabilities within these communities. The microbial water quality results also showed widespread occurrence of DNA from pathogenic organisms from all the rural communities suggesting potential exposure concerns which is reflected in the WBDI values. This tool can be more widely applied in the Caribbean region to characterize water resource status as it includes data beyond water scarcity and can highlight areas that require improvement. These results can complement health data to develop a comprehensive picture of water resources issues in the study areas of interest.

1225

RECOMMENDATIONS FOR BUCKET CHLORINATION IMPLEMENTATIONS IN EMERGENCY CONTEXTS AND CHOLERA OUTBREAKS

Gabrielle String, Mustafa Sikder, Yarmina Kamal, Annie Huang, Karin Gallandat, Daniele Lantagne

Tufts University, Medford, MA, United States

Bucket chlorination (BC) is a commonly implemented intervention for water treatment, particularly in cholera outbreaks. In bucket chlorination, agents stationed near a water source dose beneficiaries' water containers with chlorine. International guidelines suggest two recommendations for chlorine dosage: a fixed dosage (2 mg/L for <10 NTU, 4 mg/L for >10 NTU) or a variable dosage that provides a free chlorine residual (FCR) of 0.5 mg/L 30 minutes after dosing. To understand the effectiveness of these guidelines and the factors that impact their implementation, we investigated BC in laboratory studies and field evaluations. In the laboratory, using spread plates and viability qPCR, we assessed the inactivation of *V. cholerae* in prepared challenge waters after treatment with three different chlorine types at the two recommended dosages. Preliminary results indicate that all chlorine types and dosages achieved >3-log reduction in *V. cholerae* 30 minutes post-treatment. At 24 hours, culturable *V. cholerae* was present in ≥5 NTU water when it was not detected at 30 min due to incomplete inactivation. Variable dosages provided higher FCR at 30 min than fixed dosages for high organic demand water. Finalized results will include whether recommended dosages inactivate *V. cholerae* and maintain 0.2 mg/L FCR 24 hours post-treatment. In field evaluations, we conducted key informant interviews, structured observations of chlorination points, chlorine solution testing, focus groups, and household surveys. Drinking water samples were collected at the household and source. Four evaluations were completed in DRC (2), Cox's Bazar (1), and Haiti (1), including 40 chlorination points and 702 households. Preliminary results indicate variability in average chlorine solution concentration (0.18-3%). *E. coli* levels were generally reduced from source to storage in a majority of households 30 minutes post-treatment; however, presence of total coliforms and non-detect FCR (80% and 11% of households respectively) indicates recontamination risk. Recommendations on chlorine efficacy, dosage, manufacture, and monitoring will be presented.

1226

IDENTIFYING PSYCHOSOCIAL DETERMINANTS OF WASH BEHAVIORS FOR THE DEVELOPMENT OF THE EVIDENCE-BASED BABY WASH INTERVENTIONS (REDUCE PROGRAM)

Ronald Saxton[1], Jennifer Kuhl[1], Jamie Perin[1], Nicole Coglianese[2], Elizabeth Thomas[1], Sarah Bauler[2], Anthony Koomson[2], Phil Moses[2], Geoffrey A. Nyakuni[3], Amagana Togo[3], Ruthly Francois[1], Patrick Mirindi[3], Lucien Bisimwa[3], Christine Marie George[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Food for the Hungry, Phoenix, AZ, United States,* [3]*Food for the Hungry, Bukavu, Democratic Republic of the Congo*

To develop theory-based behavior change techniques for a Baby WASH intervention, we examined psychosocial factors associated with caregiver WASH behaviors in an ongoing USAID Office for Food for Peace funded cohort study in South Kivu, Democratic Republic of Congo. Caregivers of children <5 years (N=385) answered a 54-item psychosocial factor questionnaire derived from the IBM-WASH, and RANAS models. The following WASH behaviors were assessed by 5-hour structured observation: 1) handwashing with soap; 2) stopping children from mouthing fomites and food with visible dirt; and 3) water treatment (caregiver report). Caregivers that strongly agreed that their child contracting diarrhea would severely impact their life (perceived severity) were significantly more likely to stop their child from putting visibly dirty food in their mouth. Caregivers that strongly agreed that their child was at high risk of diarrhea (perceived susceptibility) were significantly more likely to wash their hands with soap. Caregivers that strongly agreed that visibly clean hands had no germs on them (dirt reactivity) were significantly less likely to wash their hands with soap. Caregivers that strongly agreed that it was hard to find wood or charcoal were significantly less likely to report boiling their water. Caregivers that strongly agreed that visitors would respect them more if they provided boiled water for drinking (injunctive norms) were significantly more likely to report boiling their water. We developed pictorial modules to target these significant psychosocial determinants of WASH behavior including: 1) a child mouthing pictorial module emphasizing the high risk for diarrhea and impaired growth from children mouthing dirt and dirty items and encouraging caregivers to supervise their child during play; 2) handwashing with soap pictorial module showing that hands that appear clean can have microbes and that not washing hands with soap puts children at risk for diarrhea; and 3) a pictorial module showing chlorine as a water treatment method not requiring fuel. This study presents an evidence-based approach for development of a Baby WASH intervention.

1227

EVIDENCE-BASED DEVELOPMENT OF BABY WASH INTERVENTIONS TO REDUCE EXPOSURE TO FECAL PATHOGENS (REDUCE PROGRAM)

Jennifer Kuhl[1], Ronald Saxton[1], Jamie Perin[1], Nicole Coglianese[2], Elizabeth Thomas[1], Sarah Bauler[2], Anthony Koomson[2], Phil Moses[2], Geoffrey A. Nyakuni[3], Amagana Togo[3], Ruthly Francois[1], Patrick Mirindi[3], Lucien Bisimwa[3], Christine Marie George[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Food for the Hungry, Phoenix, AZ, United States,* [3]*Food for the Hungry, Bukavu, Democratic Republic of the Congo*

Findings from large scale WASH intervention trials focused on "F diagram" fecal exposure pathways have not shown expected improvements on child health, highlighting the need for further research identifying the unique exposure pathways to fecal pathogens for pediatric populations, and WASH interventions tailored to young children. The REDUCE study focuses on identifying exposure pathways to fecal pathogens that are significant contributors to morbidity for young children in the Democratic Republic of the Congo, and on developing and evaluating scalable interventions to reduce fecal contamination from these pathways. Our recent cohort study found unsafe feces disposal, child mouthing of contaminated fomites, and contact with animals to be associated with diarrhea and

stunting among young children. Formative research, including 31 semi-structured interviews and 6 focus group discussions, was conducted to inform development of interventions to target these identified high risk behaviors. Contextual, psychosocial, and technological factors identified were analyzed using the IBM-WASH framework to inform intervention development. Lack of adequate child supervision due to parents working outside the home, and lack of clean child play spaces were factors limiting caregivers' ability to stop children from mouthing contaminated fomites. Using rice bags and plastic flooring as a playmat for young children emerged as a locally sourced solution to prevent children touching and ingesting dirt. Fear of theft, lack of resources to separate animals and children, and a long generational history of living with animals were factors driving the high contact observed between children and small animals. Locally sourced hutches for small animals were recommended to separate children from animals. Pictorial modules were developed to target the contextual, psychosocial, and technological factors identified. Pilot-testing of these Baby WASH interventions in 50 households is ongoing. This study presents a theory and evidence-based approach for the development of a Baby WASH intervention. This study was funded by the USAID Office of Food for Peace.

1228

COMPARISON OF SANIPATH EXPOSURE ASSESSMENTS IN LOW-INCOME URBAN AREAS IN EIGHT COUNTRIES

Wolfgang Mairinger, Yuke Wang, Suraja Raj, Habib Yakubu, Casey Siesel, Jamie Green, Sarah Durry, **Christine Moe**

Emory University, Atlanta, GA, United States

The SaniPath exposure assessment tool compares risks of exposure to fecal contamination in urban environments across multiple exposure pathways. The tool has been deployed in 39 neighborhoods in 8 cities: Accra, Ghana, Vellore, India; Maputo, Mozambique; Siem Reap, Cambodia; Dhaka, Bangladesh; Atlanta, United States; Lusaka, Zambia; and Kampala, Uganda. Ten exposure pathways were investigated (open drains, ocean water, surface water, floodwater, public latrines, soil, bathing water, raw produce, drinking water, and street food) through behavior surveys and environmental sample analyses. Exposure was expressed as monthly dose (average amount of fecal contamination ingested as measured by *E. coli* colony-forming units [CFU]) and the percent of population exposed to fecal contamination for each pathway. Magnitude of fecal contamination, frequency of exposure behavior, and estimated fecal exposures were compared across pathways, neighborhoods and cities. The most common dominant exposure pathways for adults were raw produce, open drains, and street food and for children were open drains, produce, and floodwater. For produce, the dose was usually very high (>10^6 CFU/month), and a large percent of the population was exposed (>80%). For street food, average *E. coli* concentration ranged from $10^{1.3}$ CFU/serving in one neighborhood in Lusaka, Zambia to $10^{5.5}$ CFU/serving in one neighborhood in Dhaka, Bangladesh. Exposure to open drains resulted in high doses (>10^4 CFU/month), but the population exposed varied (5%-92%) even within the same city. Exposure to fecal contamination via floodwater, usually affected a high percent of population (>80%) but had variable doses ($10^{2.5}$-10^{10} CFU/month). Both dose and percent of population exposed varied for public latrines and municipal piped water. This information can help city governments choose effective interventions to reduce the risk of exposure to fecal contamination. Widespread risks from contaminated produce and street food within and across cities underscore the link between excreta management and food safety and need for global action.

1229

RANDOMIZED CONTROLLED TRIAL OF THE CHOBI7 MOBILE HEALTH PROGRAM TO REDUCE PEDIATRIC DIARRHEA

Christine Marie George[1], Fatema Zohura[2], Shirajum Monira[2], Elizabeth Thomas[1], Tasdik Hasan[2], Tahmina Parvin[2], Maynul Hasan[2], Khaled Hasan[1], Mahamud-ur Rashid[2], Md. Sazzadul Islam Bhuyian[2], Camille Morgan[1], Peter J. Winch[1], Ronald Saxton[1], Alain Labrique[1], Kelsey Zeller[1], Farzana Begum[1], David A. Sack[1], R. Bradley Sack[1], Jamie Perin[1], Munirul Alam[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh*

The Cholera-Hospital-Based-Intervention-for-7-Days (CHoBI7) is a handwashing with soap and water treatment intervention program delivered by a health promoter bedside in a health facility and through home visits to diarrhea patients and their household members during the 7 days after admission to a health facility. In a RCT of cholera patient households in Bangladesh, the CHoBI7 program significantly reduced cholera and led to sustained improvements in drinking water quality and handwashing with soap 12-months post intervention. In an effort to develop a low cost scalable approach to deliver this program in Bangladesh without the need for in-person visits, we have developed a mobile health (mHealth) module for the CHoBI7 program to reinforce the WASH behavioral recommendations given in the health facility. To evaluate the efficacy of this program in reducing pediatric diarrhea, we are conducting a RCT of 825 children under 5 years in Dhaka, Bangladesh. Diarrhea patients and their household members presenting at icddr,b Dhaka Hospital or Mugda Hospital were recruited for this study. The "Standard Message" arm received the standard message in Bangladesh given to diarrhea patients on the use of oral rehydration solution. The "Hospital Visit + mHealth" arm received: (1) the standard message; (2) one visit by a promoter to deliver the CHoBI7 pictorial module at the health facility during the time of illness; and (3) CHoBI7 mHealth voice and text messages at least once every two weeks for 12 months. The "Hospital/Home Visits + mHealth" arm received these same activities plus two home visits by a promoter during the first week of intervention delivery. Monthly diarrhea surveillance was conducted. In this abstract we present the findings from the first 11 months of this ongoing 12 month trial. The CHoBI7 mHealth program resulted in a significant reduction in pediatric diarrhea in both the Hospital Visit + mHealth arm (Prevalence Ratio (PR): 0.80, 95% CI: 0.67, 0.95) and the Hospital/Home Visits + mHealth arm (PR: 0.71, 95% CI: 0.60, 0.85). This result suggests WASH mHealth programs present a promising approach to reduce diarrhea among young children.

1230

FORMATIVE RESEARCH FOR THE DESIGN OF THE CHOBI7 BABY WASH MOBILE HEALTH PROGRAM

Shwapon Biswas[1], Jahed Masud[1], Elizabeth D. Thomas[2], Fatema Zohura[1], Tasdik Hasan[1], Tahmina Parvin[1], Md. Sazzadul Islam Bhuyian[1], Fatema Tuz Johura[1], Marzia Sultana[1], Jamie Perin[2], Shirajum Monira[1], Munirul Alam[1], Christine Marie George[2]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh,* [2]*Johns Hopkins University, Baltimore, MD, United States*

Mobile Health (mHealth) programs present a promising low-cost, scalable approach to improve WASH practices and reduce diarrhea. The recent RCT of the CHoBI7 WASH mHealth program significantly improved WASH behaviors and reduced pediatric diarrhea. Building on this work, this USAID funded WASHPaLS study aims to develop three Baby WASH mHealth modules targeting safe child feces disposal, improved food hygiene, and safe child mouthing practices. Formative research was conducted in Dhaka, Bangladesh for the development of the mHealth program, including 5 focus group discussions, 21 semi-structured interviews, 6 mHealth workshops, and a pilot study of 50 households.

Drivers of child feces disposal, food hygiene, and child mouthing behaviors were identified using the Integrated Behavioral Model for Water, Sanitation and Hygiene framework. Self efficacy, existing habits, perceived disease risk, and availability of child potties were drivers of child feces disposal behaviors. Gender roles, hot and cold weather, access to soap, fly covers, and gas supply, perceptions that storing food in a food rack was sufficient to keep food safe, and availability of a refrigerator were drivers of food hygiene behaviors. Caregivers said children always play outside and that it is difficult to control what they put in their mouth during play. Descriptive norms around child mouthing behaviors, lack of adequate support for supervision, lack of clean play spaces, and elders perceiving that eating soil was good for child health were drivers of child mouthing behavior. Mobile messages were developed targeting "System 1" drivers (relatively automatic, cue-driven drivers) of behavior change to leverage context changes, highlight descriptive norms around key behaviors, piggy back on to existing behaviors, and manage availability of enabling technology. Dr. Chobi, the sender of program messages, was well received and considered a credible source of health information. This study presents a theory and evidence-based approach for intervention development that can be implemented for the development of future Baby WASH mHealth programs in low-resource settings.

1231

A LONGITUDINAL STUDY OF CHRONIC LEAD EXPOSURE IN BENINESE CHILDREN

Shukrullah Ahmadi[1], Roméo Zoumenou[2], Barbara Le Bot[3], Séverine Durand[3], Nadine Fievet[2], Pierre Ayotte[4], Achille Massougbodji[5], Michel Cot[6], Philippe Glorennec[3], **Florence Bodeau-Livinec**[3]

[1]*INSERM U*[1153]*, Paris, France,* [2]*IRD MERIT, Cotonou, Benin,* [3]*EHESP, Paris, France,* [4]*INSPQ, Québec, QC, Canada,* [5]*IRCB, Cotonou, Benin,* [6]*IRD MERIT, Paris, France*

Lead is a well-known neurotoxic metal. Children are particularly vulnerable to its adverse neurocognitive effects. Within a birth cohort, elevated Blood Lead Levels (BLL) (>50 μg /L) were observed in one-year-old infants in Benin in 2011-13. Sources of exposure included the presence of paint chips in the house and consumption of animals killed by lead bullets. We aimed to investigate lead exposure in the same children at six years of age in 2016-18. 424 children with BLL at one year of age and reassessed at six years of age were included in the analysis. Blood samples were drawn and analyzed by inductively coupled plasma mass spectrometry. The study took place in the district of Allada, Benin. We estimated geometric mean BLL. Using the Wilcoxon rank-sum test BLL between boys and girls are compared. The proportion of children with BLL above 50 μg/L and above 100 μg/L are described and compared at both periods. Among 424 children (208 boys and 215 girls), the geometric mean BLL in children was 56.5 μg/L (95% CI: 53.5-59.7) at one year of age, and 56.3 μg/L (95% CI: 53.9 - 58.6) at six years of age. The distribution of BLL between boys and girls was not statistically different at any given age. The proportions of children with BLL >50 μg/L at one and at six years of age were not statistically different (55.0% versus 59.7%, respectively; McNemar's p=0.1183). However, the proportion of children with BLL >100 μg/L was higher at one year of age than at six years of age (14.2% versus 8.3%, respectively; McNemar's p=0.002). Children continue to suffer from elevated BLL and thus constitute an important public health problem in this population of children, and deserves preventive strategies. Sources of exposure may evolve and merits further investigation.

1232

IDENTIFICATION OF COCCIDIAN ISOLATES PATHOGENIC TO HUMANS IN SOURCES OF POTABLE WATER IN CAPE COAST METROPOLIS, GHANA

Priscilla Ankamaa Opare[1], Samuel Addo Akwetey[2], Joana C. Silva[3], Godwin Kwakye-Nuako[1]

[1]*University of Cape Coast, Department of Biomedical Sciences, School of Allied Health Sciences, College of Health and Allied Sciences, Cape Coast, Ghana,* [2]*University of Cape Coast, Department of Microbiology and Immunology, School of Medical Sciences, College of Health and Allied Sciences, Cape Coast, Ghana,* [3]*University of Maryland School of Medicine, Institute for Genome Sciences and Department of Microbiology and Immunology, Baltimore, MD, United States*

Water is a necessity of life. However, millions of humans die annually as a result of waterborne diseases, with 88% associated with unsafe water supply, poor sanitation, and lack of good hygienic practices. Possible contaminants making drinking water unsafe include microorganisms, chemicals and sewage. Most of the microorganisms that are present in water sources are a result of fecal matter contamination from sewage discharges, runoffs from animal lots as well as seepages from septic tanks. The aim of this study is to detect human-pathogenic coccidians, namely *Microsporidia*, *Cryptosporidia* and *Cyclospora*, in various potable water in Cape Coast Metropolitan District, in Ghana. A total of 100 samples from different sources of drinking water were sampled within the Cape Coast Metropolis for the detection of human-pathogenic coccidian taxa, including well water, pipe-borne water, boreholes, streams, underground water and harvested rain water. Each sample was initially stained with modified Zeihl-Neelsen stain and observed microscopically. Total genomic DNA of the various water samples have been extracted using the Ezup Column Blood Genomic DNA Extraction Kit in preparation of PCR-based taxonomic validation. Microscopy analysis revealed that about 60% of the samples collected were contaminated with microorganisms. The breakdown among coccidians was as follows; 23% *Microsporidium*; 13% *Cryptosporidium* and 11% *Cyclospora* oocysts. Other parasites of medical importance included *Sarcocystis*, present in 3% of the samples. These preliminary data obtained thus far suggest that water consumed by the majority of the Cape Coast population is contaminated with parasites and may be the predominant cause of diarrheal cases in the metropolis as well as of other asymptomatic infections. The study is to be expanded to PCR amplification and sequencing of the 18S rDNA and other *loci* and phylogenetic analysis.

1233

IDENTIFYING BARRIERS TO ADOPTION OF HOUSEHOLD DISINFECTION KITS FOR ENVIRONMENTAL INFECTION CONTROL OF CHOLERA TRANSMISSION

Camille Heylen, Daniele Lantagne

Tufts University, Medford, MA, United States

Cholera is a disease resulting from infection by *Vibrio cholerae* that can cause death from dehydration if untreated. Environmental infection control interventions are key to interrupting within household cholera transmission in outbreaks and two approaches for household disinfection (HD) currently exist: 1) household spraying (HS), where a dedicated team sprays patients' households with chlorine; and, 2) distribution of household disinfection kits (HDK), which contain cleaning materials so that household members can perform disinfection themselves. Despite the fact that international agencies no longer recommend HS, this intervention remains widely implemented. Therefore the main objectives of this research are: 1) To identify the barriers for adopting HDKs by interviewing 15 key-informant responders on the decision-making and implementation of HD Interventions in their organization; 2) to assess the training of beneficiaries to use HDKs, an identified barrier to adopting HDKs; and, 3) to inform the ongoing discussion on HD interventions. To date, 10 of 15 planned key-informant interviews (KII) have taken place and whereas participants indicated many barriers that make the implementation of HDK difficult (e.g. context adaptability, uncertainty of the method, etc.), one commonly cited barrier was beneficiary training to educate households on how to utilize the kit appropriately. Trainings should be effective to prevent cholera but logistically feasible and therefore a trade-off between a fast, inexpensive and easy-to-implement training and an effective hands-on training should be considered. To assess the effectiveness of these two training modalities, we are planning a trial in Haiti in Summer 2019. Study personnel will visit households and conduct (before and after clean with HDK) household surveys and environmental sampling for *E. coli*on

surfaces. This presentation will include results from KIIs with responders about household disinfection interventions and the field evaluation of HDK training, and will present a comparison of the benefits and challenges of HS and HDK interventions to inform outbreak responders.

1234

PREVALENCE OF FECAL PATHOGENS IN SOIL, FOOD, HAND AND SURFACE SAMPLES FROM HOUSEHOLDS IN SLUMS OF DHAKA, BANGLADESH (CHOBI7 TRIAL): EVIDENCE-BASED DEVELOPMENT OF BABY WASH INTERVENTIONS

Fatema Tuz Johura[1], Christine Marie George[2], Indrajeet Barman[1], Fatema Tuz Jubyda[1], Mohd. Riajul Islam[1], Jarin Tasnim[1], Sahitya Ranjan Biswas[1], Kazi Sumaita Nahar[1], Md. Wali Ullah[1], Shirajum Monira[1], Fatema Zohura[1], Tasdik Hasan[1], Tahmina Parvin[1], Md. Sazzadul Islam Bhuyian[1], Shwapon Biswas[1], Jamie Perin[2], Elizabeth Thomas[2], Marzia Sultana[1], Munirul Alam[1]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh,* [2]*Johns Hopkins University, Baltimore, MD, United States*

Diarrheal disease is the second leading cause of death in children under five years of age globally. Findings from large scale WASH intervention trials focused on "F diagram" fecal exposure pathways have not shown expected improvements on child health. This has highlighted the need for further research identifying the unique exposure pathways to fecal pathogens for pediatric populations, and WASH interventions tailored to young children. The objective of this USAID WASHPaLS funded study was to identify pathways of fecal contamination for a susceptible pediatric population in Bangladesh, and to develop interventions to target these pathways. This study is nested within the CHoBI7 Baby WASH mobile health program. A total of 259 soil, food, hand, and surface samples were collected from households with a child under 5 years of age. Soil samples were collected from spaces where children were observed playing during structured observation, hand rinse samples were collected from children under 5 years of age and their caregiver, samples of the food given to the child under 5 years of age in the home was collected, and surface samples were collected of objects children put in their mouth during structured observation. All samples were analyzed using the IDEXX Quanti-Tray System (Colilert-18 media; IDEXX Laboratories, Inc., Westbrook, ME) to enumerate *Escherichia coli* using the most probable number (MPN) method. The median concentration of *E. coli* in soil was 134.6 (N=46) (Range: 1-2500). Thirty three percent (N=63) of child hand rinse samples had *E. coli* (Median: 0, Range: 0-2500), and 46% (N=28) of caregiver hand rinse samples collected had *E. coli* (Median: 0, Range: 0-613.1). Thirty five percent (N=66) of surface samples had *E. coli* (Median: 0, Range: 0-2500) among them balls were the most commonly contaminated item. Twenty nine percent (N=56) of food samples had *E. coli* (Median: 0, Range: 0-2500) among them rice was the most commonly contaminated food item. These results indicate that WASH interventions are needed to reduce child contact with contaminated fomites and to promote food hygiene and handwashing with soap practices.

A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE ASSOCIATION BETWEEN WATER, SANITATION, HYGIENE AND FOOD EXPOSURES AND TYPHOID FEVER IN CASE-CONTROL STUDIES

Sarah Brockett[1], **Marlene Wolfe**[1], Asa Hamot[1], Grace Appiah[2], Eric Mintz[2], Daniele Lantagne[1]

[1]*Tufts University, Medford, MA, United States,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Typhoid transmission occurs through ingestion of fecally-contaminated food or water; case-control studies are often used to identify outbreak sources and transmission vehicles. The majority of typhoid cases occur where access to safe water, sanitation, and safe food practices is limited. There is currently no summary of the associations between water, sanitation, hygiene (WASH) and food exposures from case-control studies of typhoid outbreaks. We conducted a systematic review and meta-analysis of case-control studies to evaluate the associations between typhoid fever with 13 predicted WASH and food exposure risk factors and 7 predicted protective factors. Overall, 19 manuscripts describing 22 case-control studies were included. In quality assessment, two studies were categorized as having low risk of bias, one as medium risk, and 19 as high risk. In total, 9 of 13 predicted risk factors were associated with increased odds of typhoid while 5 of 7 predicted protective factors were associated with lower odds. For WASH exposures, good household hygiene and water treatment demonstrated the greatest reductions in odds of typhoid (OR=0.52 and 0.59, respectively), while poor hygiene and untreated water demonstrated the greatest increases (OR=2.2 and 2.4, respectively). Protective food practices such as cooking food thoroughly and using hygienic practices in food preparation were significantly associated with lower odds of typhoid (OR=0.74), while risky food practices and eating and drinking outside the home were associated with significantly higher odds (OR=1.6-1.7). Results highlight: the importance of household hygiene transmission pathways; the need for further research around appropriate food interventions and the risk of consuming specific foods and beverages outside the home; and, the absence of any observed association between sanitation exposures and typhoid fever. The high bias of identified studies was a limitation of this meta-analysis. Household hygiene and water treatment interventions can reduce typhoid risk; more detailed information about WASH and food exposures could inform more targeted interventions.

HRP2 AND HRP3 ANTIGEN CROSS-REACTIVITY ON HRP2-BASED MALARIA RAPID DIAGNOSTIC TESTS AND ITS IMPLICATIONS FOR *HRP2* GENE DELETION SURVEILLANCE

Michael Aidoo[1], Amy Kong[1], Scott Wilson[2], Ah Yong[2], Jeffrey Glenn[1], Eric Rogier[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*The CDC Foundation, Atlanta, GA, United States*

Plasmodium falciparum histidine rich protein 2 (HRP2) is targeted by majority of malaria rapid diagnostic tests (RDTs) because of its abundant production by parasites, stability under high temperature conditions and detection sensitivity. However, reports from many countries indicate some parasites have the *hrp2* gene deleted, making them undetectable by HRP2 RDTs. HRP2 is paralogous to *P. falciparum* HRP3, and antibodies to HRP2 can detect similar epitopes on HRP3. HRP2/HRP3 cross-reactivity on HRP2 RDTs has not been systematically determined. Parasites have been described with deletions of one or both of *hrp2* and *hrp3* genes and how the various combinations of *hrp2* and *hrp3* deletions affect RDT sensitivity is unclear. Serial dilutions ranging from 100,000 to 0.01 parasites/μL of four *P. falciparum* culture parasites, 3D7 (*hrp2*+/*hrp3*+), Dd2 (*hrp2*-/*hrp3*+), HB3 (*hrp2*+/*hrp3*-) and 3BD5 (*hrp2*-/*hrp3*-) were prepared. HRP2 and *Plasmodium* lactate dehydrogenase (pLDH) concentrations were determined for the diluted samples using a multiplex bead assay. The samples were tested on three RDT products from the same manufacturer that detect *P. falciparum* by HRP2 alone or in combination with pLDH. At clinically relevant parasite densities (≥1000 parasites/μL), the *hrp2*-/*hrp3*+ parasite Dd2 was always detected on HRP2-based RDTs. With Dd2 even at a density of 100 parasites/μL, which is often associated with asymptomatic infection in high transmission areas, HRP2 bands on the three RDTs were reactive, although at low band intensities. An additive effect of intact *hrp2* and *hrp3* was observed, with 3D7 having much higher measured HRP2 concentration at 1000 parasites/μL (47.8 ng/mL) when compared with HB3 (3.0 ng/mL), Dd2 (0.198 ng/mL) and 3BD5 (0.0 ng/mL). Only the *hrp2*/*hrp3* double-deleted parasite 3BD5 caused HRP2 RDTs to give false negative results at all parasite densities. These results suggest substantial cross-reactivity between HRP2 and HRP3 antibodies and that studies of *hrp2* deletions and their possible effects on HRP2 RDTs must consider the presence or absence of *hrp3*. It remains to be tested how product-specific antibody types influence reactivity

1237

SURVEILLANCE FOR *PFHRP2/3* DELETIONS AND NON-FALCIPARUM MALARIA IN THREE PROVINCES IN MOZAMBIQUE, 2018

Mateusz Plucinski[1], Baltazar Candrinho[2], Mercia Dimene[2], James Colborn[3], Austin Lu[4], Doug Nace[5], Rose Zulliger[6], Eric Rogier[5]

[1]*CDC Malaria Branch and United States President's Malaria Initiative, Atlanta, GA, United States,* [2]*National Malaria Control Program, Maputo, Mozambique,* [3]*Clinton Health Access Initiative, Maputo, Mozambique,* [4]*Georgia State University, Atlanta, GA, United States,* [5]*CDC Malaria Branch, Atlanta, GA, United States,* [6]*CDC Malaria Branch and United States President's Malaria Initiative, Maputo, Mozambique*

Rapid diagnostic tests (RDTs) that detect the *Plasmodium falciparum*-specific histidine rich protein 2 (PfHRP2) antigen are the primary method for malaria diagnosis in Mozambique. However, these tests do not detect infections with non-falciparum malaria or *Pfhrp2/3*-deleted *P. falciparum* parasites. To assess the appropriateness of PfHRP2-only RDTs for malaria diagnosis in Mozambique, samples collected during a health facility survey conducted in Mozambique were screened with serological and molecular techniques. Samples from 1861 outpatients of all ages and symptoms attending 117 randomly-selected public health facilities in April and May 2018 in Maputo, Zambézia, and Cabo Delgado Provinces were analyzed with an ultra-sensitive bead-based immunoassay for the presence and concentration of PfHRP2, pan-*Plasmodium* Aldolase (pAldo), and pan-*Plasmodium* lactate dehydrogenase (pLDH). The concentration of PfHRP2 in patient blood was compared to the results of PfHRP2-based RDTs performed during the routine health facility consult and during the survey exit re-examination. Samples with discordant antigen profiles were further characterized by PCR. Using the bead-based laboratory assay as the gold standard, the sensitivity of the RDTs administered during the health facility consult and the exit interview were 90% and 83%, respectively, and specificity was 91% and 97%. Of 710 samples positive for at least one antigen, 704 (99.2%) were positive for PfHRP2. Of the 6 (0.8% of total) discordant samples lacking PfHRP2 but positive for pAldo and/or pLDH, 3 (0.4% of total) were *P. ovale* mono-infections or co-infections where *P. ovale* was the dominant species. The remaining 3 discordant samples were negative by PCR. The sensitivity and specificity of the RDTs performed in the health facility consults and survey exit interviews were acceptable, and there was no evidence of *Pfhrp2/3*-deleted parasites. Mono-infections with non-falciparum malaria species comprised <1% of total malaria infections. Nearly all malaria antigen-positive patients had detectable PfHRP2, confirming this as an appropriate malaria diagnostic target for Mozambique.

AUTOMATED DIGITAL MICROSCOPY USING ARTIFICIAL INTELLIGENCE FOR THE POINT-OF-CARE MALARIA DIAGNOSIS

Hans-Peter Beck[1], Armin Passecker[1], Youngmin Shin[2], Chae Y. Bae[2], Younghoon Song[2], Jiyeon Lee[2], Mijin Kim[2], Raeeun Chung[2], Douglas Lungu[3], Donyoung Lee[2]

[1]*Swiss Tropical and Public Health Institution, Basel, Switzerland,* [2]*Noul Inc. Ltd., Yongin-si Gyeonggi-do, Republic of Korea,* [3]*Wezi Medical Centre, Mzuzu, Malawi*

Besides the very frequent use of rapid diagnostic tests (RDTs) for malaria diagnosis in the field, expert microscopy is still used for reliable diagnosis. In contrast to microscopy, RDTs are unable to quantify parasitemia, identify gametocytes, and cannot distinguish all malaria species. Furthermore, the rapid spread of *Plasmodium* parasites having the *hrp2/hrp3* gene deleted compromises the reliable use of RDTs. Here we present an innovative platform that is designed to be employed in endemic areas that automatically generates microscopic blood smears termed miLab. These smears are liquid-free stained using a hydrogel-based stamping technology coupled with automatic digital microscopy. All images captured are being analysed by a machine-learned algorithm to quantify and identify malaria parasites. We have validated the instrument on full human blood samples spiked with various numbers of synchronized and non-synchronized cultured *P. falciparum* parasites. In addition, we have used cultures and induced gametocytes for training the algorithm to also detect gametocytes. After training and validation the platform was employed in a clinical field study in Lilongwe, Malawi in which collected clinical samples were analysed. For further performance tests of the miLab platform, dried blood spots were collected on filter paper for subsequent quantitative PCR and slides were prepared for expert microscopy testing at Swiss TPH. We will present and describe the platform, its performance characteristics and initial results from this field study conducted in Malawi.

A NOVEL LATERAL FLOW ASSAY FORMAT WITH INTEGRATED CATCH-AND-RELEASE BIOMARKER CONCENTRATION FOR DETECTION OF LOW PARASITEMIAS AT THE POINT-OF-CARE

Nathaniel Z. Piety, Carson P. Moore, Kristina A. Pieterson, David W. Wright

Vanderbilt University, Nashville, TN, United States

Malaria control and elimination strategies require the detection of *Plasmodium* parasites in both symptomatic and asymptotic individuals in order to guide treatment and disrupt transmission. Benchtop techniques such as polymerase chain reaction or microscopic diagnosis are both sensitive and specific, but are prohibitively expensive and complex for the resource-limited regions where the burden of malaria is highest. Lateral flow assays (LFAs) are easy-to-use, low-cost, rapid and do not require equipment, and have therefore become a principal method of malaria screening in resource-limited settings. However, most conventional LFAs have limits of detection (LOD) of ~200 parasites/μL, which is not sufficiently low to detect malaria in asymptomatic individuals who may have parasitemias in the single digits. As such, asymptomatic infections may go undetected and untreated by malaria control and elimination campaigns guided by conventional LFAs and continue to serve as transmission reservoirs. To address the need for LFAs with lower LOD, we have developed an LFA format which utilizes a sliding, zinc-iminodiacetic acid (Zn-IDA) functionalized cellulose membrane for catch-and-release concentration of malaria biomarkers *Plasmodium falciparum* histidine-rich protein 2 (*Pf*HRP2) and *Plasmodium* lactate dehydrogenase (*P*LDH). The affinity between divalent zinc ions and histidine residues enabled membrane capture of *Pf*HRP2 with 99% efficiency, and histidine$_6$-tagged anti-pLDH antibodies enabled simultaneous capture of *P*LDH with 80% efficiency. Both biomarkers could then be released with >80% efficiency using an EDTA buffer which chelates zinc. By flowing a sample volume ~50× times larger than conventional LFAs could accommodate through the functionalized membrane into absorbent pads, then sliding the membrane – a single additional user step compared to conventional LFAs – and eluting captured biomarkers onto the LFA in a smaller volume, the amount of biomarker delivered to the LFA was significantly increased and the LOD was improved to 3.2 parasites/μL for *Pf*HRP2. This improved LOD is sufficient to detect most asymptomatic infections.

AUTOMATIC BLOOD SMEAR ANALYSIS WITH ARTIFICIAL INTELLIGENCE AND SMARTPHONES

Hang Yu[1], Stefan Jaeger[1], Feng Yang[1], Kamolrat Silamut[2], Richard Maude[2]

[1]*National Institutes of Health, North Bethesda, MD, United States,* [2]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand*

MalariaScreener is the first software using artificial intelligence, in particular deep learning, to process both thin and thick blood smear images on smartphones. When running on a phone attached to the eyepiece of a microscope, MalariaScreener can detect parasites in thick smear images captured by the smartphone's camera. It can also discriminate between infected and uninfected red blood cells in thin blood smear images. The idea is to provide a cost-effective alternative for malaria

diagnosis in resource-limited regions that does not depend on expert knowledge. This could also help in standardizing parasite counts, which often depend on the experience and skill of the microscopist. We trained our system on hundreds of thousands of manually annotated parasites and blood cells, in images from hospitals and clinics in Bangladesh and Thailand, so that it captures the typical shape and appearance of parasites and cells. The trained system can detect parasites in thick smears and discriminate between infected and uninfected red blood cells in thin smears. For thick smears, we measure an area under the ROC curve (AUC) of 85% on patient level. For thin smears, using ensemble techniques, we achieve an AUC of 99.92% for cell classification (infected/uninfected). The underlying algorithms utilize customized convolutional neural network models (CNNs). An embedded database system can store patient data, screening results, disease severity, and patient histories. Moreover, researchers can save blood smear images captured during the screening process together with their manual counts of parasites and blood cells, which can then be used later for training to improve future automated screening. The internal algorithms have been optimized for fast processing speed and leave a small memory footprint. The user interface allows easy access to the image data and review of all stored information. MalariaScreener is currently being field-tested in several countries. Due to its modular and flexible design, Malaria Screener could be extended to support screening of other blood-based diseases and beyond, when given the properly trained machine learning models.

DETECTION OF SUB-MICROSCOPIC BLOOD LEVELS OF *PLASMODIUM FALCIPARUM* USING TANDEM OLIGONUCLEOTIDE REPEAT CASCADE AMPLIFICATION (TORCA) ASSAY WITH AN ATTOMOLAR DETECTION LIMIT

Andrey L. Ghindilis[1], Olga Chesnokov[2], Billy Ngasala[3], Maria W. Smith[1], Kenneth Smith[1], Andreas Mårtensson[4], **Andrew V. Oleinikov**[2]

[1]*TORCATECH, LLC, Mukilteo, WA, United States,* [2]*Florida Atlantic University, Boca Raton, FL, United States,* [3]*Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania,* [4]*International Maternal and Child Health (IMCH), Uppsala University, Uppsala, Sweden*

Tandem Oligonucleotide Repeat Cascade Amplification (TORCA) approach is a novel, isothermal, highly sensitive, and low-cost method of target nucleic acid detection. TORCA based on signal rather than target amplification under isothermal conditions. The initial signal is generated by hybridization of single stranded DNA targets to immobilized recognition probes followed by hybrid cleavage with specific restriction endonuclease (REase), and release of trigger oligonucleotides (Tr1), attached to recognition sequence. The released Tr1 is transferred into signal amplification chamber. The signal amplification chamber contains two bead types (each carrying single-stranded "amplification probe") and two "amplification REases". The probes consist of multiple tandem repeats of either Tr1 or another trigger Tr2, with the tandem-Tr1 anchored to the beads through the antisense Tr2 linker and vice versa. Addition of the recognition reaction solution and Tr1 hybridization to the anti-Tr1 linkers initiates cleavage and release of Tr2. Hybridization of released Tr2 to the anti-Tr2 linkers initiates cleavage and release of Tr1. Because each Trigger sequence is also attached to horseradish peroxidase (HRP), release and transfer of this enzyme into detection chamber generates signal measured colorimetrically. Thus, the cleavage cascade results in exponential signal amplification proportional to the initial amount of target sequence in the recognition chamber. This TORCA assay was developed for detection of *Plasmodium falciparum* parasites in blood using Pf-specific recognition probes. It demonstrated the detection limit in the attomolar concentration range, successfully detecting sub-microscopic *P. falciparum* infections in laboratory and field samples down to less than 0.075 infected erythrocytes per microliter. Further TORCA optimization will likely produce the quantitative isothermal alternative to PCR at a fraction of its cost.

1242

PROSPECTIVE PERFORMANCE EVALUATION OF A COMBINED MALARIA/CRP RAPID DIAGNOSTIC TEST IN INDIA

Sandra Incardona[1], Bina Srivastava[2], Supriya Sharma[2], Stefano Ongarello[1], Shubhada Shenai[3], Prabakaran Loganathan[3], Sanjay Sarin[3], Anupkumar R. Anvikar[2], Sabine Dittrich[1]

[1]*FIND, Geneva, Switzerland,* [2]*National Institute of Malaria Research, New Delhi, India,* [3]*FIND India, New Delhi, India*

The integrated management of febrile patients is difficult in low resource settings where good quality diagnostics are not always available. This emerged as a particular challenge in low malaria endemic settings where the number of malaria-negative tests is increasing, especially in Asia and South East Asia. Recent studies in this region have shown that C-Reactive Protein (CRP) can be a suitable marker to guide antibiotic treatment for non-malarial patients with fever alone or with respiratory symptoms. Currently, there is no integrated test that combines both malaria and CRP; yet such a tool is envisioned to improve individual care, triage decisions and to support malaria elimination efforts through continued malaria testing and surveillance. To address this gap, FIND partnered with SD Biosensor to develop a simple RDT combining malaria diagnosis (pfHRP2 and panLDH antigens) with semi-quantitative detection of CRP at a 20mg/L cut-off to provide an indication of bacterial infections. A prospective clinical trial is being conducted in India (North-East, South, and Central) to assess the performance (sensitivity, specificity, positive and negative predictive values) of a Malaria/CRP combination test when used at the point-of-care, with a target sample size of 1800 febrile patients (expected accuracy: 95% CI of ± 5%, 80% power). The malaria test lines will be assessed against expert malaria microscopy and nested PCR as the reference standards, while the CRP test line will be assessed against a commercial CRP quantification test on a chemistry analyzer. The ease of use and acceptability of this new test will also be evaluated through interviews with standardized questionnaires. The results of this trial will be instrumental to confirm that this test meets all technical needs for implementation and use, especially in low malaria endemic countries. The data from this study, combined with work that evaluates the utility and safety of CRP alone will inform priority implementation efforts and can be used towards a dossier to support the use of this and similar tools in the frame of an integrated fever management approach more widely.

1243

TRANSPLACENTAL ANTIBODY TRANSFER AMONG WOMEN LIVING WITH HIV

Lisa M. Bebell[1], Mark J. Siedner[1], Joseph Ngonzi[2], Audrey L. Butler[3], Julian Adong[2], Sepideh Dolatshahi[3], Ingrid V. Bassett[1], Drucilla J. Roberts[1], Galit Alter[3]

[1]*Massachusetts General Hospital, Boston, MA, United States,* [2]*Mbarara University of Science and Technology, Mbarara, Uganda,* [3]*The Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard, Cambridge, MA, United States*

HIV-exposed, uninfected (HEU) children have an elevated risk of severe early-life infections and increased immune activation compared to HIV-unexposed children. Immunologic differences in HEU children may be linked to changes in transplacental transfer of IgG subclasses and the Fcγ receptors (FcγR) they bind. Altered transplacental antibody transfer in women living with HIV (WLWH) may contribute to HEU infection risk and has implications for maternal and infant vaccination strategies. We used a systems serology approach to define features of transplacental antibody transfer in maternal-umbilical cord pairs from 176 WLWH in Uganda and 176 HIV-uninfected comparators. We used multiplexed Luminex assays to quantify antigen-specific antibody subclasses (IgG1-IgG4) and binding to FcγR 2A and 3A for a wide range of vaccine-preventable and common pathogens. We used t-tests to compare antibody transfer ratios and partial least squares discriminant analysis (PLS-DA) to identify correlates of antibody profile differences by maternal HIV serostatus. Compared to HIV-uninfected women, WLWH transferred significantly less IgG1 for

polio, hepatitis A, HSV 1 and 2, and CMV. Transfer of IgG1 for pertussis, RSV, Hib, EBV, measles, mumps, rubella, adenovirus, and tetanus toxoid was not affected by maternal HIV serostatus. Compared to HIV-uninfected women, WLWH transferred significantly more FCγR3A-binding antibodies for measles, but significantly less for CMV. PLS-DA revealed that IgG1 titer, FcγR3A, and FcγR2A binding separated HEU antibody profiles in an antigen-specific manner. Transplacental antibody transfer differs by HIV serostatus and may contribute to HEU immune activation and infection susceptibility. Differences observed by maternal HIV serostatus in the quality of maternal humoral immune profiles suggest these alterations may be related to placental changes among WLWH, even in the presence of effective antiretroviral therapy. Further studies may reveal specific mechanisms leading to altered immunity and novel opportunities to design specific therapeutics and vaccines to selectively enhance immunity in HEU children.

1244

HUMAN MILK OLIGOSACCHARIDES AND GROWTH IN HIV EXPOSED UNINFECTED INFANTS IN KENYA

Christine J. McGrath[1], Judd L. Walson[1], Lars Bode[2], Chloe Yonemitsu[2], Rose Bosire[3], James A. Berkley[4], Dorothy Mbori-Ngacha[5], Grace C. John-Stewart[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*University of California San Diego, San Diego, CA, United States,* [3]*Kenya Medical Research Institute, Nairobi, Kenya,* [4]*KEMRI/Wellcome Trust Collaborative Research Programme, Kilifi, Kenya,* [5]*United Nations Children's Fund (UNICEF), Nairobi, Kenya*

Human milk oligosaccharides (HMOs) are the third largest solid component in breast milk and serve as prebiotics, supporting growth of commensal gut bacteria and influencing the immune system. Recent studies implicate perturbations in the infant gut microbiome as a critical mechanism for increased risk of growth faltering and infectious morbidity in HIV-exposed uninfected (HEU) infants. We investigated the association between HMO composition and growth in HEU infants during the first year of life. Total and specific HMO concentrations were quantified from breast milk samples collected at one month postpartum from a random subset of 124 HIV-infected women enrolled in a pre-antiretroviral therapy cohort in Nairobi, Kenya. Linear mixed effects models were used to determine the influence of specific HMOs on the rate of change in monthly weight-for-age (WAZ), length-for-age (LAZ), weight-for-length (WLZ) z-scores. At 32 weeks' gestation, median maternal age was 24 years (Interquartile range [IQR]=22, 27) and median CD4 count was 471 cells/μL (IQR=316, 664). Of the 124 HEU infants, median birth weight was 3.1 kg (IQR=2.9, 3.4) and median breastfeeding duration was 11.8 months (IQR=7.5, 12.0). Weight remained stable from birth to age 12 months (-0.1 WAZ/mo, 95% confidence interval [CI]= -0.3, 0.01, p=0.32; -0.1 WLZ/mo, CI= -0.03, 0.01, p=0.24), while length gradually declined over time (-0.04 LAZ/mo, CI= -0.06, -0.02, p<0.001). Higher concentrations of sialylated HMOs, 6-sialyllactose and sialyllacto-*N*-tetraose c, were associated with a faster rate of increase in WLZ (0.06 WLZ/mo, CI=0.01, 0.10, p=0.02; and 0.07 WLZ/mo, CI=0.22, 0.11, p=0.004, respectively). There was a trend toward an association between higher lacto-*N*-fucopentaose III concentration and faster declines in weight and length growth (-0.04 LAZ/mo, CI= -0.9, 0.004, p=0.08; -.05 WAZ/mo, CI= -0.10, 0.01, p=0.11). These data suggest a relationship between specific oligosaccharides and postnatal growth in breastfed HEU infants. Understanding the mechanisms by which HMOs and gut microbiota interact is critical to inform interventions to optimize growth in HEU children.

1245

SOCIAL FACTORS ASSOCIATED WITH VIROLOGIC SUPPRESSION IN CHILDREN AND ADOLESCENTS LIVING WITH HIV INITIATED ON ANTIRETROVIRAL THERAPY IN LILONGWE, MALAWI

Bryan J. Vonasek[1], Tsogolo Itaye[2], Joseph Mhango[2], Andrea Dean[1], Peter Kazembe[2]

[1]*Baylor College of Medicine, Houston, TX, United States,* [2]*Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi*

Across a wide range of settings and with many diseases, there are strong links between health outcomes and the circumstances in which people live, known as the social determinants of health (SDH). Especially for children and adolescents living with HIV (CALHIV), there is very little evidence about the impact of SDH on successful virologic suppression upon initiation of antiretroviral therapy (ART). Understanding this dynamic in low resource countries like Malawi is key to achieving the third of the UNAIDS' 90-90-90 goals. This was a retrospective cohort study of subjects less than 20 years old initiating ART at the Baylor College of Medicine Abbott Fund Children's Center of Excellence in Lilongwe, Malawi between January 2016 and January 2018. Clinical and social variables were abstracted from the site's electronic medical record and these were compared to virologic suppression. Virologic suppression was defined as documented viral load less than 1000 copies/mL within 8 months of ART initiation. Over this period, 285 CALHIV were initiated on ART at this site with a median age of 7.5 years and 48% female. Within eight months of ART initiation, 93 subjects (33%) had documented virologic suppression. Social factors that were associated with virologic suppression were living in a home with electricity, living in a home with a refrigerator, and using a personal vehicle to travel to clinic visits. However, with multiple logistic regression, the only social variable associated with virologic suppression was using a personal vehicle to travel to clinic visits (adjusted odds ratio 3.40, 95% confidence interval 1.35-8.55). Initial WHO stage of III or IV was also independently associated with virologic suppression (aOR 0.321, 95% CI 0.128-0.807). This initial analysis shows one social factor, mode of transport to clinic, associated with virologic suppression for this cohort of CALHIV. Ongoing research to further identify key social factors associated with the third of the UNAIDS' 90-90-90 goals will be important for developing interventions to improve rates of virologic suppression for CALHIV.

1246

VIROLOGICAL SUPPRESSION AMONG HIV INFECTED ADOLESCENTS & YOUTHS RECEIVING ART IN THE NATIONAL TEACHING AND REFERRAL HOSPITAL IN KENYA

James M. Kangethe

Kenyatta National National/University of Nairobi, Nairobi, Kenya

Virological suppression among HIV infected adolescents and youths receiving ART in the National teaching and referral hospital in Kenya. HIV virological suppression is poor among the adolescents and youths which may be related to several factors including adherence to antiretroviral therapy. This study aimed to determine the HIV virological response and the associated risk factors among adolescents and youths on ART. This was a cross-sectional study among adolescents and youths aged 10 to 24 years in Kenyatta National Hospital who were on ART for at least six months. Patient characteristics were captured in a questionnaire and viral load was abstracted from electronic medical records. Viral suppression was presented as a proportion based on viral load less than 1000 copies per milliliter of plasma. Viral suppression rate was associated with categorical independent factors using chi square test and means were compared using independent T –test. The mean age was 17 years (SD 4.3 years) and 55.6% were females. The median CD4 count was 573 cells per micro liter of blood (IQR: 344- 1780). A total of 227 (74.2%) HIV infected adolescents and youths were virologically suppressed (viral load less than 1000 copies/ml blood). As compared to children 10-14 years old who had 83.2% suppression rate, adolescents 15-19 years had poorer suppression

rate at 69.6% [OR 0.5 (95% CI 0.2-0.9), P= 0.022]. Similarly youths 20-24 years had a lower suppression rate at 70.8% compared to the children [OR 0.5 (95% CI 0.2-0.9), P= 0.022]. Only 56.2% of the study participants had undetectable HIV viral RNA (as per UNAIDS 90-90-90 strategy). RNA Viral suppression rate was lower among ART defaulters (47.2%), those defaulting clinic appointments (51.7%) and those not honoring ART refill (50%). Majority of the participants (86.3%) were in WHO stage I whereas 2% were in WHO stage IV. Among those with unsuppressed viral loads, 20.7% had been diagnosed with Tuberculosis. None of the study participants had Hepatitis B virus infection. In conclusion, HIV viral suppression among adolescents and youths was low and even much lower among 15 to 24 year-olds.

1247

SERUM VITAMIN D IS DIFFERENTIALLY ASSOCIATED WITH SOCIOEMOTIONAL ADJUSTMENT IN EARLY SCHOOL-AGED UGANDAN CHILDREN ACCORDING TO PERINATAL HIV STATUS AND *IN UTERO* ORPERIPARTUM ANTIRETORIVAL EXPOSURE HISTORY.

Amara E. Ezeamama[1], William Yakah[1], Jenifer Fenton[1], Robert Tuke[1], Sarah K. Zalwango[2], Alla Sikorskii[1], Bruno Giordani[3], Michael J. Boivin[1], Philippa M. Musoke[4]

[1]*Michigan State University, East Lansing, MI, United States,* [2]*Kampala Capital City Authority, Kampala, Uganda,* [3]*University of Michigan, Ann Arbor, MI, United States,* [4]*Makerere University School of Medicine, Kampala, Uganda*

It is unknown whether vitamin-D insufficiency (VDI) is associated with socio-emotional adjustment (SEA) in school-aged children. This study examines the hypothesis that deficits in SEA are related to VDI using longitudinal data from 254 children that are perinatally HIV-infected (PHIV), HIV exposed uninfected (HEU) or HIV-unexposed uninfected (HUU). Four caregiver reported age-and sex-standardized measures of SEA were defined at months 0, 6 and 12 for dependent children aged 6-10 years –externalizing problems (EPSI), internalizing problems (IPSI), behavioral symptoms index (BSI) and adaptive skills index (ASI) - per the Behavior Assessment System for Children. Higher scores reflected worse SEA for all but ASI. Serum vitamin-D was measured and analyzed in quartiles in relation to SEA using linear mixed effects models implemented in statistical analysis software SAS 9.4 . VDI was highly prevalent (74%, n=188), and its association with change in SEA measures (i.e., BSI, IPSI and EPSI) over 12 months varied by HIV-status (VDI*HIV, all p-values <0.03). Among PHIV children, there was no association between VDI and change in any SEA measure. Among HUU, BSI (β=-0.32, 95%CI: -0.50, -0.13), IPSI (β=-0.28, 95%CI: -0.47, -0.09) and EPSI (β=-0.20, 95%CI: -0.37, -0.02) all declined modestly per quartile increment in VD. Among HEU, VD relationship to change in BSI, IPSI and EPSI varied according to whether or not these children were exposed to ART *inutero*/peripartum (*Early* ART*VDI all p<0.02). Specifically, in absence of *Early* ART higher VDI predicted a modest to moderate declines in problematizing SEA domains including EPSI (β=-0.26, 95%CI: -0.51, -0.02). However among HEU with early ART exposure higher VDI predicted elevated problems - BSI (β=0.39, 95%CI: 0.00, 0.78) and IPSI (β=0.48, 95%CI: 0.05, 0.92). VDI may be associated with worse SEA among HUU and HEU without *early* ART exposure. The interaction between VD and *early* ART for SEA outcomes warrants further investigation. Improvement of vitamin D levels may be a possible intervention target to remediate SEA impairments among HUU and HEU Ugandan children.

HIV CARE CASCADE REVIEW: CASE REPORTS FROM KENYA CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE NETWORK (CHAMPS) PROGRAM

Victor Akelo[1], Emily Zielinski-Gutierrez[2], Aggrey Igunza[3], Dickens Onyango[4], Dianna M. Blau[5], Pratima L. Raghunathan[5], Robert F. Breiman[6], Beth A. Tippett Barr[1]

[1]*Centers for Disease Control and Prevention, Kisumu, Kenya,* [2]*Centers for Disease Control and Prevention, Nairobi, Kenya,* [3]*Kenya Medical Research Institute, Kisumu, Kenya,* [4]*Kisumu County Public Health Department, Kisumu, Kenya,* [5]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*Emory Global Health Institute, Emory University, Atlanta, GA, United States*

HIV-associated child mortality remains a major public health concern, the magnitude of which is affected by mother-to-child transmission (MTCT) rates. In Kenya, an estimated 4,800 HIV-infected children (<14 years) died in 2016. CHAMPS is a multi-country surveillance program that systematically tracks causes of under-five mortality from a defined catchment area. Between May 2017 and November 2018, causes of death (COD) were determined by a panel of experts for 103 deceased children 0-59 months in western Kenya using data from post-mortem tissue specimen testing, clinical records and verbal autopsy. HIV status and viral load (VL) were determined from whole blood collected within 24 hours of death. Of 103 child deaths, 21 (20%) were HIV-associated (mother or child was HIV-positive); HIV DNA (by polymerase chain reaction) was detected in 6/103 (5.8%). We reviewed the HIV care continuum for the six HIV-infected child deaths to identify areas for improvements. Three (50%) HIV-infected children had unknown HIV diagnosis before death, 2 had prior diagnosis and were on ART while one HIV diagnosis was made during last hospital admission. In 4 (67%) cases, maternal HIV status was either unknown or undocumented; one case had only one maternal HIV negative test in 2nd trimester (no repeat test); and the other maternal HIV status was positive but ART status was undocumented. Four (67%) children died of pneumonia; etiologies for each case were cytomegalovirus [CMV], respiratory syncytial virus [RSV], Streptococcus spp, and in one case, coinfection with RSV, CMV and Streptococcus was considered to have caused the death. Two children died of cerebral malaria (one with salmonella sepsis co-infection). CHAMPS highlighted gaps including missed child and maternal HIV diagnosis, treatment, and HIV-related conditions. The investigation revealed HIV-associated pediatric deaths that would have otherwise been unreported. Improved, focused antenatal care, a high index of clinical suspicion for HIV infection, and routine clinical audits of the HIV care cascade should be encouraged to eliminate pediatric HIV deaths and improve maternal HIV care

1249

THE SAFETY AND ACTIVITY OF POMALIDOMIDE IN THE TREATMENT OF KAPOSI SARCOMA IN INDIVIDUALS WITH OR WITHOUT HIV: LONG-TERM OUTCOMES

Ramya Ramaswami[1], Mark N. Polizzotto[1], Thomas S. Uldrick[1], Kathryn A. Lurain[1], Anaida Widell[1], Kathleen M. Wyvill[1], Priscila H. Goncalves[1], Vikram Khetani[2], Ken Arakawa[2], Jerome B. Zeldis[2], Robert Yarchoan[1]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*Celgene Corporation, Summit, NJ, United States*

Kaposi sarcoma (KS) is caused by Kaposi sarcoma herpesvirus ((KSHV), also known as human herpesvirus 8 (HHV-8)). Its incidence is markedly increased in HIV-infected persons, but also arises in individuals without HIV. KS is one of the most common tumors in sub-Saharan Africa and is the second most common HIV-associated tumor in the United States. Patients with HIV-associated KS are treated with antiretroviral therapy (ART). Chemotherapy, which is required in severe cases of KS, may be administered intermittently for years, as KS is often a relapsing and remitting condition. However, current agents are limited by toxicities, such as cumulative cardiotoxicity and peripheral neuropathy. In initial

results of a Phase I/II study, we showed that pomalidomide, an oral immunomodulatory derivative of thalidomide, was safe and active in patients with KS. Here, we present complete outcomes including progression free survival data. KS patients with or without HIV were treated with pomalidomide 5mg once daily for 21 days per 28-day cycle with aspirin 81mg once daily was administered for thromboprophylaxis. Patients were treated until complete response, plateau or progression from the best response, defined by a modified version of the AIDS Clinical Trial Group KS criteria. We evaluated adverse events on the study, time to progression from best response and long-term outcomes. Twenty-eight male patients were enrolled. Median age was 53 years, 18 (64%) were HIV-positive, 21 (75%) had advanced (T1) disease and 23 patients had prior treatment for KS excluding antiretroviral therapy. The most common grade 3/4 adverse event attributable to therapy was neutropenia (37 cycles, 14 patients). Twenty patients had a complete or partial response (71%; 95% confidence interval (CI) 51-87%); including 12 of 18 HIV-positive patients (66%; 95% CI: 41-87%) and 8 of 10 HIV-negative patients (80%; 95% CI: 44-97%). The median progression free survival was 10.1 months (95% CI: 7.6-15.8 months). Pomalidomide is a safe and active chemotherapy-sparing agent for the treatment of KS among individuals with or without HIV.

TENSION IN THE RED BLOOD CELL MEMBRANE REGULATES *PLASMODIUM FALCIPARUM* INVASION: FROM SINGLE CELL HOST/PATHOGEN LIVE IMAGING TO RESISTANCE IN HUMAN POPULATIONS

Viola Introini[1], Yen-Chun Lin[1], Silvia N. Kariuki[2], Alejandro Marin-Menendez[3], Jurij Kotar[1], Thomas N. Williams[2], Julian C. Rayner[3], Pietro Cicuta[1]

[1]*University of Cambridge, Cambridge, United Kingdom,* [2]*KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya,* [3]*Wellcome Sanger Institute, Cambridge, United Kingdom*

Live imaging of the invasion of red blood cells by malaria parasites has become possible in the last few years, revealing new detail about the short and complex invasion steps. This process takes place within just a few minutes and is one of the most crucial, yet least understood, stages of malaria infection. Blood stage parasites cause the symptoms of malaria, and are also exposed to the host immune system; they thus represent a target for vaccines and drug development. In our research, we developed biophysical methods to investigate invasion characteristics, and properties of the red blood cells. We considered a novel blood group variant, Dantu, a rare polymorphism found mainly in East Kenya that provides up to 70% protection against severe malaria in homozygous individuals. This is a similar level of protection to sickle cell trait but without negative side-effects. With real-time live microscopy we measured the morphology and kinetics of invasion, and with optical tweezers we measured the parasite-red blood cell attachment force during invasion. By analysing red blood cell membrane fluctuations, we established that the membrane tension of the red blood cell strongly correlates with invasion efficiency, identifying a tension threshold above which invasion does not occur: cells with higher tension are protected from invasion, while cells with lower tension are preferentially parasitized. The Dantu cells have on average a higher tension than non-Dantu cells. Finally, we explored the relation between red blood cell biophysical properties such as bending modulus, tension, radius, and viscosity, and *Plasmodium* invasion in other malaria-protective genetic polymorphisms, such as thalassemia. This observation potentially answers a long-standing mystery in the malaria field, why *Plasmodium* parasites prefer young red blood cells, which are known to have low membrane tension values. This paves the way to a potentially novel therapeutic approach, where manipulation of red cell tension properties could provide malaria protection.

1251

SHED EBA-175 MEDIATES RED BLOOD CELL CLUSTERING THAT ENHANCES MALARIA PARASITE GROWTH AND ENABLES IMMUNE EVASION

Nichole D. Salinas[1], May M. Paing[2], Yvonne Adams[3], Anna Oksman[2], Anja T. Jensen[3], Daniel E. Goldberg[2], Niraj H. Tolia[1]

[1]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States,* [2]*Washington University School of Medicine, St. Louis, MO, United States,* [3]*Centre for Medical Parasitology at Department of Immunology and Microbiology, Faculty of Health and Medical Sciences, University of Copenhagen, Denmark, Copenhagen, Denmark*

Erythrocyte Binding Antigen of 175 kDa (EBA-175) has a well-defined role in binding to glycophorin A (GpA) during *Plasmodium falciparum* invasion of erythrocytes, and cell signaling that leads to rigidity changes within the red blood cell (RBC). However, EBA-175 is shed post invasion and a role for this shed protein has not been defined. We show that EBA-175 shed from parasites promotes clustering of RBCs, and EBA-175-dependent clusters occur in parasite culture. The RBC clustering is dependent on EBA-175 binding to GpA and the Region II of EBA-175 is sufficient for clustering. These clusters are capable of forming under physiological flow conditions, across a range of concentrations. EBA-175-dependent RBC clustering provides daughter merozoites ready access to uninfected RBCs enhancing parasite growth. Clustering also provides a general method to protect the invasion machinery from immune recognition and disruption as exemplified by protection from neutralizing antibodies that target the unrelated invasion proteins AMA-1 and RH5. Cluster formation may sterically block antibody access to antigens or could limit the time that the merozoite is exposed to the immune system. Indeed, severe malaria often results in patient death due to high parasite burdens that are protected from immune recognition. These findings provide a mechanistic framework for the role of shed proteins in RBC clustering, immune evasion, and severe malaria. Defining the role of shed proteins in malaria pathogenesis will open new avenues for intervention and control.

1252

PVDBP AMPLIFICATION PROTECTS *PLASMODIUM VIVAX* AGAINST ANTI-PVDBP HUMORAL IMMUNITY

Jean Popovici[1], Camille Roesch[1], Lenore Carias[2], Nimol Khim[1], Amelie Vantaux[1], Ivo Mueller[3], Chetan Chitnis[3], Christopher L. King[2], Benoit Witkowski[1]

[1]*Institut Pasteur of Cambodia, Phnom Penh, Cambodia,* [2]*Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States,* [3]*Institut Pasteur, Paris, France*

Multiple copies of the gene coding for PvDBP have been observed in clinical isolates from diverse geographic areas. This gene amplification might have evolved to facilitate *Plasmodium vivax* (Pv) invasion of Duffy negative reticulocytes. However, isolates with high PvDBP gene copy number occur in areas without Duffy negative individuals (such as in Cambodia) suggesting that this amplification must have other function for the parasite. Here we examine the hypothesis that PvDBP amplification evolved to circumvent host humoral immune response. First we show that the higher the gene copy number of the parasite, the higher the PvDBP gene expression in mature schizonts. Second, through short-term *in vitro* cultures, we show that human monoclonal antibodies (mabs) that target the PvDBP binding interface with the Duffy receptor on reticulocytes blocked Pv invasion of reticulocyte. However the concentration of mAb required to block invasion by 50% (IC_{50}) was on average > 20-fold higher using Pv isolates with three *pvdbp* copies versus single *pvdbp* copies ($P<0.0001$). Invasion inhibition for isolates with two *pvdbp* copies was intermediate between single copy and three copies parasites. Furthermore, the level of PvDBP RNA expressed in the schizonts used for the assays was significantly related to the level of inhibition by mabs. Third, we screened plasma from 267 individuals with acute vivax malaria (for which we had determined the PvDBP amplification status of the infecting parasites) to

identify eight individuals with high levels of naturally acquired, strain-transcending antibodies that inhibit PvDBP binding to erythrocytes. Seven of eight individuals (88%) were infected with *pvdbp* multi-copy parasite while only one was single copy (P=0.010). One out of 151 (0.66%) patients infected with single-copy parasites had high levels of binding-blocking antibodies to PvDBP while for patients infected by multi-copies parasites, 6% (7/116) had high levels of binding inhibitory antibodies (P=0.023). This work indicates that PvDBP gene amplification evolved, at least in part, to escape host humoral immunity.

MULTIPLE *PLASMODIUM FALCIPARUM* K13 MUTATIONS CONFER ARTEMISININ RESISTANCE AND MODULATE PARASITE FITNESS IN ASIAN AND AFRICAN STRAINS

Barbara H. Stokes[1], Kelly Rubiano[1], Nina F. Gnädig[1], Judith Straimer[1], Tim J. Anderson[2], Frédéric Ariey[3], Didier Ménard[4], Sachel Mok[1], David A. Fidock[5]

[1]*Department of Microbiology and Immunology, Columbia University Medical Center, New York, NY, United States,* [2]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [3]*Cochin Institute, University Paris Descartes, Paris, France,* [4]*Malaria Genetics and Resistance Group, Pasteur Institute, Paris, France,* [5]*Department of Microbiology and Immunology and Division of Infectious Diseases, Department of Medicine, Columbia University Medical Center, New York, NY, United States*

Plasmodium falciparum resistance to the first-line drug artemisinin (ART) has spread at an alarming rate across Southeast Asia since its initial detection in Cambodia a decade ago. Recent reports have suggested *de novo* emergence of ART resistance (ART-R) in South America, India and, of particular concern, Africa, where the disease burden is highest. ART-R results primarily from specific point mutations in the C-terminal propeller of the Kelch protein K13. The most important of these is C580Y, which has reached fixation in much of the Greater Mekong Subregion. To date, only a handful of *K13* alleles have been genetically validated as drivers of ART-R. Several other mutations in K13 have been associated with delayed parasite clearance in ART-treated patients and/or with increased parasite survival in the *in vitro* ring-stage survival assay ($RSA_{0\text{-}3h}$), however these have not been assessed by gene editing. Here we report a novel CRISPR/Cas9-mediated system for *K13* editing, which has allowed us to rapidly and efficiently introduce mutations into distinct parasite genetic backgrounds. Of particular interest is M579I, recently identified in Equatorial Guinea, which we report yields moderate ART-R in lab strains and several African isolates, at levels comparable to C580Y. These results provide evidence that K13 mutations can indeed mediate ART-R in African parasites. *In vitro* co-culture assays show that M579I and C580Y confer a significant fitness cost in all parasite backgrounds tested. This reduced fitness may staunch the spread of ART-R, particularly in high-transmission settings. We also observe very low $RSA_{0\text{-}3h}$ survival rates for parasites bearing the Southeast Asian F446I, P553L, or P574L mutations. Moderate $RSA_{0\text{-}3h}$ survival rates were obtained with the R561H mutation, which was previously prevalent in Thailand. Intriguingly, we find that two clinical isolates bearing the E252Q mutation, which lies outside the K13 propeller region, have elevated survival in the $RSA_{0\text{-}3h}$. However, introducing E252Q into various strains was not sufficient to confer ART-R, strongly suggesting that resistance can be multifactorial and background-dependent.

1254

VESICULAR MECHANISMS PROVIDE PHENOTYPIC ASSAYS OF ARTEMISININ RESISTANCE IN *PLASMODIUM FALCIPARUM* MALARIA

Niraja Suresh[1], **Maisha Khair Nima**[1], Isabelle Coppens[2], Souvik Bhattacharjee[3], Mehdi Ghorbal[1], Kasturi Haldar[1]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*Johns Hopkins University, Baltimore, MD, United States,* [3]*Jawaharlal Nehru University, New Delhi, India*

Artemisinin resistance threatens world-wide malaria control and elimination. Our studies show that *P. falciparum* Kelch13 (K13), a primary marker of artemisinin resistance and mutations in which cause resistance, localizes to vesicles in the parasite's endoplasmic reticulum (ER), as detected by cryo-immunoelectron microscopy. Emerging data from multiple labs suggest additional mechanisms that regulate ER vesiculation and export, independent of K13 mutation, also induce artemisinin resistance. Together these data suggest that ER vesicular dynamics may provide phenotypic markers of resistance in both K13-dependent and independent resistance. But phenotypic assays that may be used to detect K13-dependent and independent pathways of resistance have remained elusive. We integrated findings of proteomic studies with transcriptomic and metabolomics analyses to reveal just two parasite pathways that are selectively refractory to artemisinins in drug-resistant but not sensitive ring-stage parasites, the stage of clinical artemisinin resistance. Validation of the first, an ER proteostatic pathway suggests multiple substrates, whose vesicular dynamics in presence of both mutation as well as drug provide novel phenotypic readouts of resistance that may be deployed without establishing (long or short term) cultures from clinical samples.

1255

STUDY OF BIOLOGICAL MECHANISM OF REDUCED ARTEMISININ SUSCEPTIBILITY IN WEST AFRICAN *PLASMODIUM FALCIPARUM* ISOLATES

Aabha Sharma[1], Allison R. Demas[2], Selina Bopp[1], Sarah V. Volkman[1], Daniel L. Hartl[3], Dyann F. Wirth[1]

[1]*Harvard T. H. Chan School of Public Health, Boston, MA, United States,* [2]*Ragon Institute of Massachusetts General Hospital, Massachusetts Institute of Technology, and Harvard, Cambridge, MA, United States,* [3]*Harvard University, Cambridge, MA, United States*

Current emergence of artemisinin resistance threatens the success achieved by artemisinin combination therapies (ACTs) in battling malaria. If this resistance spreads from Southeast Asia to Africa, the continent with the highest global malaria burden, efforts to control malaria will be in serious jeopardy. We sought to investigate artemisinin resistance in the African context through *in vitro* selection of West African parasites using dihydroartemisinin (DHA) pulses. After thirteen rounds of DHA selection, we obtained two independent artemisinin resistant parasite lines Pikine_R and Thiès_R and identified ten mutations in seven genes by whole genome sequencing. Of the seven genes, mutations found in two *loci* (*pfcoronin Pf3D7_1251200* and a conserved *Plasmodium* gene of unknown function *Pf3D7_1433800*) were shared by both parasites while the rest of the changes were unique for each of the two selected lines. Using CRISPR/Cas9 gene editing, we established that WD-40 propeller domain mutations in *pfcoronin* are sufficient to confer artemisinin resistance measured by *in vitro* Ring-stage Survival Assay (RSA) in West African parasites and the 3D7 laboratory strain. Consistent to the observations in *pfkelch13* mutants, parasite genetic background was crucial to the level of resistance observed in *pfcoronin* mutants. To test the potential resistance contribution of *Pf3D7_1433800,* the other gene of unknown function, we have introduced the mutations (I575M and S1054F) separately into the 3D7 wildtype laboratory strain and are reverting these mutations in both Thiès_R (I575M) and Pikine_R (S1054F). We are currently investigating the *in vitro* artemisinin resistance level of *Pf3D7_1433800* revertant parasites and 3D7 mutants by RSA. Additionally, we are testing the potential synergy between *pfkelch13* and *pfcoronin* by introducing

the *pfkelch13* mutation (C580Y) into the *pfcoronin* mutant (R100K & E107V) background, with phenotypic evaluation by RSA. Investigation of *pfkelch13*-independent biological mechanisms of artemisinin resistance will make significant contributions to our currently limited understanding of artemisinin resistance.

1256

HIDDEN SPECIES BOUNDARIES AMONG MOSQUITOES OF THE MALARIA-TRANSMITTING *ANOPHELES GAMBIAE* COMPLEX FROM BURKINA FASO

Jacob A. Tennessen[1], Victoria A. Ingham[2], Hyacinthe K. Toé[3], N'Falé Sagnon[3], Hilary Ranson[2], Daniel E. Neafsey[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso*

The *Anopheles gambiae* complex consists of several morphologically indistinguishable mosquito species representing the most important vectors of the malaria parasite *Plasmodium falciparum* in sub-Saharan Africa. Continued exploration of this diverse clade has included the discovery of the cryptic taxon GOUNDRY in eastern Burkina Faso in 2011, along with other newly described species. The ecological, immunological, and reproductive differences among these species are essential to understand, as they will critically impact population responses to intervention strategies and environmental changes. Recently, we examined whole-genome sequencing data from a longitudinal study of putative *A. coluzzii* in western Burkina Faso, with the goal of detecting evolutionary changes associated with insecticide resistance. Surprisingly, we discovered that many of our samples are genetically divergent from *A. coluzzii* and all other Anopheles taxa. Population genetic analysis suggests that GOUNDRY sensu stricto represents an admixed population descended from both *A. coluzzii* and this new taxon. Thus, a cryptic anopheline species inhabits Burkina Faso and is both more geographically widespread, and more evolutionarily distant from other species, than suggested by the original GOUNDRY discovery. Misidentified cryptic taxa could seriously confound the various extensive ongoing studies of Anopheles ecology and evolution in western Africa. Reproductive barriers between cryptic species may also complicate efforts at vector control, for example via gene drives, and thwart predictions about disease epidemiology and the spread of insecticide resistance.

1257

ENGINEERED RESISTANCE TO DENGUE AND ZIKA VIRUSES IN TRANSGENIC *AEDES* OVER-EXPRESSING RNAI PATHWAY

Yuemei Dong, Shengzhang Dong, Nahid Borhani Dizaji, Natalie Rutkowski, Mary Gebhardt, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

Mosquito transmitted arboviruses have become the most important causes of reemerging epidemic disease worldwide. The spread of insecticide resistance, lack of drugs and limited availability of licensed vaccines, has accentuated the need for the development of novel control strategies that can prevent arbovirus transmission. Similar to other insects, mosquitoes use their innate immune systems, especially the RNA interference (RNAi) antiviral pathway to control arboviral infection and transmission. We have developed genetically modified *Ae. aegypti* mosquitoes that activate the antiviral RNAi pathway in the midgut, by over-expressing RNAi pathway factors Dicer2 or R2D2 by the blood meal inducible carboxypeptidase A (*AeCpA*) promoter. Transgenic over-expression of *Dicer2* and *R2D2* inhibits both Dengue virus serotype 2 (DENV2) and Zika virus (ZIKV) significantly in the midguts, as well as systemically and in the salivary glands. Transient activation of *Dicer2* and *R2D2* in the gut tissue has only a minimal impact on key fitness parameters under laboratory conditions. RNA-seq based full genome transcriptomic analysis showed broad transcriptome regulation in the midgut tissue upon *Dicer2*- and *R2D2* over-expression, and a significant elevated expression of antimicrobial peptides (AMP) genes, suggesting a cross-talk between the RNAi pathway and other immune pathways including Toll and IMD pathways. Over-expression of *Dicer2* and *R2D2* in the midgut tissue in these transgenic mosquitoes also limited the proliferation of the midgut microbial flora, and increased mosquitoes' resistance to systemic bacterial challenges. The midgut-specific activation of the RNAi pathway resulted in a significant resistance to both DENV2 and ZIKV infection, thereby indicating a broad-spectrum antiviral role of RNAi pathway.

1258

20-HYDROXYECDYSONE (20E) PRIMES *ANOPHELES GAMBIAE* INNATE IMMUNE RESPONSE TO BACTERIA AND MALARIA PARASITES

Rebekah Reynolds, Hyeogsun Kwon, Ryan Smith

Iowa State University, Ames, IA, United States

Mosquito blood feeding is driven by the requirement of a nutrient-rich blood meal for egg development, which as a result, can potentially expose mosquitoes to blood-borne pathogens. Shortly after a blood meal, levels of the hormone 20-hydroxyecdysone (20E) increase stimulating yolk protein production in a process known as vitellogenesis. 20E reaches peak levels ~24 hours after blood feeding, coinciding with the timing of malaria parasite invasion. While well-studied with respect to insect development, mating, and reproduction, little is known about the influence of 20E on mosquito immune responses. Here we report the effects of 20E on the innate immune system of *Anopheles gambiae*, further defining the role of 20E in priming mosquito immunity for pathogen challenge. In addition to its influence on phagocytosis, RNA-seq analysis identified that 20E application upregulated expression of antimicrobial peptides, suggesting that 20E influences anti-bacterial immunity. We demonstrate that blood feeding can reduce *E. coli* survival, an effect reconstituted by 20E priming. Similarly, 20E priming also significantly reduces *Plasmodium berghei* survival. We demonstrate that the regulation of the anti-microbial peptide (AMP) cecropin 3 is induced following 20E priming and contributes to both anti-bacterial and anti-*Plasmodium* immunity, offering a potential mechanism for how 20E stimulates mosquito innate immunity. Together, these results suggest that the increased levels of 20E following a blood meal stimulate antimicrobial peptide production and prime mosquito immunity to prevent development of pathogens present in the blood meal. Current experiments are underway to investigate the effect of disrupting 20E synthesis on *Plasmodium* survival. With potential translational applications to reduce malaria transmission, these studies offer important insights into the contributions of mosquito hormones in shaping vector competence.

1259

IR8A MUTANT MOSQUITOES LOSE STRONG ATTRACTION TO HUMANS

Joshua Raji

Florida International University, Miami, FL, United States

Mosquitoes use olfaction as a primary means of detecting their hosts. Previously, the functional ablation of a family of *Aedes aegypti* olfactory receptors, the Odorant Receptors (ORs), was not sufficient to reduce host-seeking in the presence of carbon dioxide (CO_2). This suggests the olfactory receptors that remain, such as the Ionotropic Receptors (IRs), could play a significant role in host detection. To test this, we disrupted the Ir8a co-receptor in *Ae. aegypti* using CRISPR/Cas9. *Ir8a* mutant female mosquitoes are not attracted to lactic acid, a behaviorally active component of human odor, and lack odor-evoked responses to acidic volatiles. The loss of Ir8a reduces mosquito attraction to humans and their odor. We show that the CO_2-detection pathway is necessary but not sufficient for IR8a to detect human odor. Our study reveals that the IR8a pathway is crucial for an anthropophilic vector mosquito to effectively seek hosts.

1260

SEX-SPECIFIC YEAST INTERFERING RNA LARVICIDES FOR EFFECTIVE SORTING OF MALE DISEASE VECTOR MOSQUITOES

Molly Duman-Scheel, Longhua Sun, Ping Li, Joseph Roethele, Limb K. Hapairai, Keshava Mysore

Indiana University School of Medicine, South Bend, IN, United States

Efficient means of sex-sorting prior to mass release of male mosquitoes is critical for a number of mosquito control technologies. However, effective and affordable sex-sorting methods that can be readily employed for mass rearing of mosquitoes at remote or resource-limited locations have not yet been established. We performed a small interfering RNA (siRNA) larval soaking screen that uncovered >30 previously uncharacterized putative female-specific larval lethal genes in *Aedes aegypti. Saccharomyces cerevisiae* shRNA expression strains corresponding to these siRNAs were developed to functionally assess the hypothesis that yeast-mediated RNAi silencing can be employed for simple, effective, affordable, and scalable sex-sorting of male larvae. Use of the yeast system also facilitated down-selection of screen hits to be characterized in further detail. These studies revealed several high-priority target genes that encode long non-coding RNA (lncRNA). Use of yeast interfering RNA larvicide technology revealed that silencing these *lncRNA* genes, including one that will be presented in more detail here, result in female larval mortality without impacting the fertility or fecundity of adult male survivors. The yeast larvicide studies also revealed a high priority protein-encoding target gene that is conserved in multiple species of disease vector mosquitoes. Silencing this gene in *A. aegypti* also resulted in mortality of female larvae without impacting the fertility or fecundity of male survivors. RNAi silencing of the orthologs of this gene in other mosquito species indicated that this strategy can facilitate male sex-sorting in other vector insects. In addition to functionally validating *lncRNAs* as a new class of genes that regulate sex-specific development in mosquitoes, the results of this investigation indicate that yeast-based RNAi larvicides may represent an affordable, effective, and scalable technology that could facilitate mass-rearing of multiple species of male mosquitoes in remote and resource-limited regions throughout the world.

1261

CIRCADIAN GENE KNOCKOUT REDUCES FITNESS AND ALTERS BEHAVIOR IN *AEDES AEGYPTI*

Jacob I. Meyers, Michel A. Slotman

Texas A&M University, College Station, TX, United States

The circadian activity of mosquito disease vectors is well-documented and much of the behavior, physiology and a considerable amount of gene expression of *Aedes aegypti* follows 24-hour cycles. *Aedes aegypti* mosquitoes are active diurnally, with peaks of activity at the beginning and end of the light phase. We hypothesized that these circadian peaks in activity rely on the circadian molecular clock and that disrupting this clock will reduce behavioral activity and overall mosquito fitness. The circadian gene *cycle*, along with its partner *clock*, encode proteins that dimerize to function as a transcription factor which drives circadian gene expression. In *Drosophila*, knocking out *cycle* disrupts circadian clock gene expression causing arrhythmic activity, behavior and reduced fitness. To determine the impact of the circadian clock on *Ae. aegypti* behavior and fitness, we used CRISPR/Cas9 mutagenesis to create a 10bp deletion within the coding sequence of *cycle*, resulting in a premature STOP codon and defective protein product. We used qRT-PCR to measure gene expression of seven circadian genes across the day/night cycle. Surprisingly, *cyc-/-* mutants still had rhythmic expression of clock genes, albeit with a different pattern and intensity. None-the-less, *cyc-/-* mutants have altered flight activity and lack the characteristic activity peaks at the start and end of the light phase, indicating a dysfunctional circadian clock. The effect of a dysfunctional clock on host-seeking activity was measured across the light/dark cycle using an olfactometer. Initial results show that *cyc-/-* mutants display significantly reduced host-seeking activity during end of the light phase, when this mosquito typically host-seeks. We also examined *cycle-/-* mutant fitness by measuring developmental success and rates, as well as adult survivorship. *Cyc-/-* mutants have reduced developmental rates and survival from egg to adult. Additionally, *cyc-/-* mutants have reduced adult survivorship. Our results show that knocking out *cycle* disrupts the circadian clock in *Ae. aegypti* and strongly affects mosquito behavior and fitness.

1262

USING EVOLUTIONARY APPROACHES TO DISSECT THE GENETIC BASIS OF *WOLBACHIA*-MEDIATED BLOCKING OF DENGUE VIRUS IN *AEDES AEGYPTI*

Suzanne Ford[1], Scott Allen[2], Aswathy Sebastian[1], Istvan Albert[1], Stephen Chenoweth[2], **Elizabeth McGraw**[1]

[1]*Pennsylvania State University, University Park, PA, United States,* [2]*The University of Queensland, Brisbane, Australia*

Wolbachia is an intracellular bacterium that blocks virus replication in insects and that has been introduced into the mosquito, *Aedes aegypti* for biocontrol of the viruses: dengue, Zika and chikungunya. In field-releases, *Wolbachia* has reduced the local incidence of dengue fever in humans, however it is unknown if blocking will remain stable, or if resistance will evolve. The mechanism of *Wolbachia*-mediated viral blocking is yet to be fully elucidated. Here we carry out artificial selection upon natural variation in *Wolbachia*-mediated dengue blocking in *A. aegypti* and demonstrate a 45% reduction. We find evidence that stronger blocking genotypes are maintained at high frequencies and have an inherently faster population growth rate and so may be maintained by natural selection. Using genome wide association, we dissect the genetic basis of the changes in blocking phenotype and reveal novel candidate pathways for the basis of blocking, that include aspects of immunity.

1263

GENOME-WIDE ASSOCIATION STUDY OF CRYPTOSPORIDIOSIS IN BANGLADESHI INFANTS REVEALS ROLE FOR *PKRCA*

Genevieve Wojcik[1], Poonum Korpe[2], Chelsea Marie[3], Beth D. Kirkpatrick[4], Rashidul Haque[5], William A. Petri[3], Priya Duggal[2]

[1]*Stanford University School of Medicine, Stanford, CA, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*University of Virginia School of Medicine, Charlottesville, VA, United States,* [4]*University of Vermont Larner College of Medicine, Burlington, VT, United States,* [5]*International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh*

Cryptosporidiosis is a leading cause of diarrhea and is responsible for greater than 200,000 deaths in young children in South Asia and Sub-Saharan Africa each year. The majority of human infectious are caused by *Cryptosporidium hominis* and *C. parvum*, with disease sequelae including morbidity, linear growth faltering, and cognitive defects. To investigate the role of human genetics in cryptosporidiosis, we conducted a genome-wide association study of symptomatic cryptosporidiosis within the first year of life among 873 Bangladeshi infants in three independent birth cohorts. Cases were defined as children with at least one diarrheal episode positive for cryptosporidium within the first year of life (N=183), while controls were children without any positive stool samples (N=690). A total of 6.5 million single nucleotide polymorphisms (SNPs) were evaluated for association with cryptosporidiosis, controlling for, height-for-age Z-score (HAZ_{12}) at 12 months of age, sex, and population substructure by including the first two principal components. We identified a significant association on chromosome 17 within the gene *PRKCA* (protein kinase C alpha) at rs58296998 ($P=3.78x10^{-8}$), with each additional T allele conferring 2.4 times the odds of cryptosporidiosis. We observe consistent effects across all three studies ($P_{het}=0.11$). The Gene-Tissue Expression (GTEx) project, a publicly available resource, previously identified this SNP as being associated with PRKCA expression. When coupled with our results, the direction of effects indicated decreased expression of PRKCA

to be correlated with increased risk of cryptosporidiosis. Genetic variants in *PRKCA* have previously been found to be associated with other infections, including *Staphylococcus aureus*, progression of sepsis, toxoplasmosis, *Burkholderia cenocepacia* in cystic fibrosis patients, and hepatitis E virus replication. Our results further suggest a role for *PRKCA* in the immune system's defense against pathogens, specifically cryptosporidiosis. Future work is needed to better understand the biological mechanism of this gene in intestinal infection.

1264

GIARDIA DUODENALIS INFECTIONS IN THE CONTEXT OF A WASH AND DEWORMING TRIAL IN TIMOR-LESTE

Naomi E. Clarke[1], Jessica Aw[2], James S. McCarthy[3], Rebecca J. Traub[4], Archie C. Clements[5], **Susana Vaz Nery**[1]

[1]*University of New South Wales, Kensington NSW, Australia,* [2]*Australian National University, Canberra ACT, Australia,* [3]*QIMR Berghofer Medical Research Institute, Brisbane QLD, Australia,* [4]*University of Melbourne, Parkville VIC, Australia,* [5]*Curtin University, Perth WA, Australia*

Giardiasis - caused by the protozoon *Giardia duodenalis* - represents one of the most prevalent intestinal protozoon infections worldwide. It is transmitted through the faecal-oral route and is therefore prevalent in low-income countries with poor access to safe water, sanitation and hygiene (WASH), where other neglected tropical diseases (NTDs) are frequently co-endemic. However, there is limited experimental evidence of the impact of community-based WASH interventions on *G. duodenalis* infections. Furthermore, there is limited evidence regarding the impact of regular periodic deworming with albendazole on *G. duodenalis* infections, despite such treatment being regularly delivered in low-income countries for control of other NTDs, such as soil-transmitted helminths and lymphatic filariasis. In the WASH for WORMS cluster-randomized controlled trial, rural communities in Timor-Leste were randomly allocated to receive either a community-based WASH and deworming intervention, or community-based deworming alone. All community members in both study arms received a single dose of albendazole, every six months for two years. We collected stool samples from all willing community members every six months for two years, and diagnosed *G. duodenalis* infections using quantitative PCR. Among 1971 participants at study baseline, the prevalence of *G. duodenalis* infections was 13.1% (95% CI 10.9-16.0), with highest prevalence among those aged 1-5 years (26.4%, 95% CI 20.4-33.5). After four rounds of deworming at six-monthly intervals, *G. duodenalis* prevalence was 15.6% (95% CI 12.8-18.9), not significantly different from baseline prevalence (p=0.165). Compared to deworming alone, the combined WASH and deworming intervention had no impact on *G. duodenalis* infections over a two-year-period (RR 1.18, 95% CI 0.79-1.75, p=0.413). Our findings suggest that periodic deworming has no impact on *G. duodenalis* prevalence and highlights the ongoing high burden of this protozoon in Timor-Leste, particularly among young children. WASH interventions may require higher coverage and adherence to reduce the burden of *G. duodenalis* infection.

1265

TRANSMISSION OF *CRYPTOSPORIDIUM* SPP. IN CONTACT NETWORKS IN SUB-SAHARAN AFRICA

Daniel Eibach[1], Ralf Krumkamp[1], Simone Caccio[2], Akim Adegnika[3], John Amuasi[4], John Lusingu[5], Raphael Rakotozandrindrainy[6], Jürgen May[1]

[1]*Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany,* [2]*Istituto Superiore di Sanità, Rome, Italy,* [3]*Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon,* [4]*Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana,* [5]*National Institute for Medical Research, Korogwe, United Republic of Tanzania,* [6]*Université d'Antananarivo, Antananarivo, Madagascar*

High prevalence and mortality from Cryptosporidiosis among children in sub-Saharan Africa has been shown in recent years, however transmission dynamics and reservoirs are yet to be investigated. This multicentre study traces back *Cryptosporidium* positive children to their close human and animal contacts in order to identify transmission networks and reservoirs. Stool samples from children below 5 years with diarrhoea were collected at hospitals in Gabon, Ghana, Madagascar and Tanzania. *Cryptosporidium* positive and negative initial children were followed to the community, where stool samples from all household members, neighbouring children (<5 years) and animal contacts were obtained. Samples were screened for *Cryptosporidium spp*. by PCR-RFLP analysis and sequence analysis of the 60 kDa glycoprotein gene for *C. hominis* and *C. parvum*. Contact networks were identified and rate ratios (RR) calculated. Among 1,363 initial children 44 (20%), 47 (11%), 25 (11%) and 68 (14%) were diagnosed with *Cryptosporidium* spp. in Gabon, Ghana, Madagascar and Tanzania, respectively. Most frequently *C. hominis* (n=144; 79%), *C. parvum* (n=26; 14%) and *C. meleagridis* (n=10; 5%) were detected. Among 108 contact networks *gp*60 subtyping established 37 clusters, which contained 49% and 54% of *Cryptosporidium* positive household members and neighbours, respectively, but only 18% of *Cryptosporidium* positive animals. In comparison to *Cryptosporidium* negative initial children, positive initial children had an increased risk of having positive household members (RR = 2.5; 95%-Confidence Interval (CI): 1.5–5.2) or positive neighbouring children (RR = 2.7; 95%-CI: 1.6–4.8), but no risk of having positive animals (RR = 1.3; 95%-CI: 0.8–2.1) in their contact network. In conclusion, Cryptosporidiosis in rural sub-Saharan Africa is characterized by clusters among human contacts, to which zoonotic transmission seems to contribute only marginally. Public health programmes need to focus on improving hygiene and sanitation practices, particularly in the context of infant and childcare.

1266

THE EPIDEMIOLOGY AND IMPACT OF *ENTEROCYTOZOON BIENEUSI* AND *ENCEPHALITOZOON INTESTINALIS* INFECTIONS AMONG CHILDREN FROM LOW RESOURCES SETTINGS IN THE MALED COHORT

Amidou Samie[1], Elizabeth Rowgoskii[2], Mal-ed Network Investigators[1]

[1]*University of Venda for Science and Technology, Thohoyandou, South Africa,* [2]*University of Virginia, Charlottesville, VA, United States*

Microsporidia are fungal pathogens though originally known as protozoan parasites. They are responsible for chronic diarrhea among HIV as well as non HIV patients. However, there is a dearth of information on their occurrence and impact on child grow in community settings. In the present study we used qPCR assays to detect *E. bieneusi* and *E. intestinalis* from 41,327 monthly asymptomatic stools as well as stool collected during diarrheal episodes from 1715 children in the MalEd cohort. Anthropometric data were collected on a monthly basis for up to two years. Descriptive analysis of the data provided the overall distribution of microsporidia. We estimated the effects of microsporidia carriage on linear growth at 2 years of age. We also looked at the impact of other socioeconomic factors on the occurrence and distribution of microsporidia in the study population. The overall prevalence of *E. bieneusi* was 5.9% varying from 0.7% in Brazil to 13% in Tanzania while that of *E. intestinalis* was 0.4% with the highest in India (1%) and lowest in Brazil (0%). *E. bieneusi* was significantly high in Tanzania, Pakistan and Bangladesh (p<0.001) while it was less prevalent in Brazil, India and South Africa. Overall there was a significant difference between the prevalence of *E. bieneusi* in male (5.5%) and females (6.3%) (p<0.001). Children who have taken rotavirus vaccine tended to be protected against *E. bieneusi* (OR=0.694; 95% CI: 0.564 - 0.854). *E. bieneusi* was not associated with diarrhea, dehydration, fever, loss of appetite and vomiting. However, *E. bieneusi* infections were significantly associated with stunting (7.3% vs 4.9%) (p<0.0001; OR=1.524, 95%CI: 1.405 - 1.652), underweight (7.5% vs 5.1%) (p<0.0001; OR=1.429; 95%CI: 1.303 - 1.566) and wasting (6.9% vs 5.8%) (p=0.012; OR=1.209; 95%CI: 1.043 - 1.401). Risk factors for *E. bieneusi* included lower income, poor sanitation, low maternal education, poor floor quality, keeping cattle and chicken in the

household and poor quality of drinking water source. *E. bieneusi* infection was associated with faltering growth and low socio-economic factors encouraged the spread of infections among the children.

GIARDIA DUODENALIS MODULATES IMMUNE RESPONSE TO *TOXOPLASMA GONDII* DURING MURINE CO-INFECTION

Camila H. Coelho[1], Aline Sardinha-Silva[1], Marc Fink[2], Diego L. Costa[1], Pedro Gazzinelli-Guimaraes[1], Michael E. Grigg[1], Steven M. Singer[2]

[1]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States,* [2]*Georgetown University, Department of Biology, Washington, DC, United States*

Enteric infections in the developing world are typically poly-microbial rather than due to a single pathogen. Data from the Global Enteric Multicenter Study (GEMS) suggested that co-infection with Giardia duodenalis reduces the incidence of severe diarrhea due to other pathogens. We have used oral infection with Toxoplasma gondii in mice with prior G. duodenalis infection as a model to understand how these parasites interact with each other and their host. We infected $C^{57}BL/^{6}$ mice with ^{1} million G. duodenalis trophozoites (strain GS, assemblage B) three or seven days prior to oral infection with ^{10} cysts of T. gondii (type II strain ^{76}K GFP-Luciferase). After five days of T. gondii infection, we assessed parasite burden daily by in vivo imaging and qPCR for ^{18}S gene. Nine days post-infection we collected tissue from the duodenum and ileum for analyses. In the duodenum, qPCR and Luminex revealed reduced levels of IL-^{6}, TNF-α, IFN-y and IL-$^{1}\beta$ in the co-infected groups compared to the controls. Flow cytometry of lamina propria cells revealed reduced levels of Tbet expression and the reduction of Treg population usually detected in Toxoplasma-infected mice was prevented by Giardia. Histology analyses demonstrated reduced inflammatory infiltrate in the co-infected group compared to tissues from animals infected only with T. gondii. We also observed an increased burden of T. gondii in mice previously infected with Giardia. Current analyses are being performed to compare weight loss, survival and microbiome changes after co-infection. In conclusion, our preliminary results suggest that prior Giardia infection modulates rodent immune response during acute toxoplasmosis.

HIGH-THROUGHPUT SEQUENCING-BASED ANALYSES OF 3,528 INFANT DIARRHEAL SAMPLES FROM THE GLOBAL ENTERIC MULTICENTER STUDY (GEMS) TO IDENTIFY NOVEL PATHOGENIC VIRUSES AND PARASITES

Matthew V. Cannon, Claudia Perez, Jennifer Jones, GEMS consortium, Sharon M. Tennant, David Serre

University of Maryland, Baltimore, Baltimore, MD, United States

More than 800,000 infants die due to diarrheal diseases every year. Diarrhea results from an intestinal infection that can be caused by a wide variety of pathogens, including bacteria, viruses and eukaryotic parasites. A better and more comprehensive understanding of the pathogens causing these diseases would facilitate targeted treatments and could guide the development of vaccines. Unfortunately, traditional detection approaches have important limitations and, even in very large and well-controlled studies, the cause of most diarrhea cases cannot be explained. Indeed, despite screening for more than 40 putative pathogens in >22,000 individuals, 56% of the moderate-to-severe diarrheal cases in the Global Enteric Multicenter Study (GEMS) could not be attributed to any pathogen. Here, we use a novel high-throughput sequencing approach to analyze 3,528 stool samples from infants under the age of five recruited by the GEMS in Mali, Kenya, Bangladesh and Pakistan. By combining multiplex PCRs with next-generation sequencing, our assay enables the sensitive detection and identification of eukaryotic parasites from a wide range of taxonomic groups - including Amoebas, Apicomplexans, Diplomonads, Kinetoplasts, Parabasalia, Platyhelminthes and Nematodes - as well as adenoviruses. Importantly, since our approach relies on PCR amplification of conserved regions, it enables detection and identification of known and previously uncharacterized organisms from these taxa. The results of this study will provide a global perspective on the adenoviruses and eukaryotic parasites present in the intestinal tract of children from these four countries, while the unique case/control design of the GEMS study will enable a first assessment of the respective contribution of these organisms to gastroenteritis.

DIRECT VALIDATION OF SCREENING HITS IN A CRYPTOSPORIDIOSIS *IN VIVO* EFFICACY MODEL

Dale Robinson[1], Natalie Hawryluk[1], Stacie Canan[1], Joseph Camardo[2], Robert K.M. Choy[3], Eugenio L. de Hostos[3], Wesley C. Van Voorhis[4], Matthew A. Hulverson[4], Ryan Choi[4], Molly C. McCloskey[4], Grant R. Whitman[4], Lynn K. Barrett[4], Samuel L.M. Arnold[4]

[1]*Celgene Global Health, San Diego, CA, United States,* [2]*Celgene Global Health, Summit, NJ, United States,* [3]*PATH, San Francisco, CA, United States,* [4]*Center for Emerging and Re-emerging Infectious Disease, Division of Allergy and Infectious Diseases, Department of Medicine, University of Washington, Seattle, WA, United States*

Cryptosporidiosis is a global diarrheal illness caused by the microscopic parasite, *Cryptosporidium*, and is recognized as one of the most common waterborne diseases in humans and animals. Individuals with weakened immune systems (malnourished children, patients receiving cancer chemotherapy, patients with HIV/AIDS, etc.) can develop serious, life-threatening illness from this infection. *Cryptosporidium* is the second most common pathogen in malnourished 6 to 18 month-old children with severe diarrhea in resource limited environments, is a major cause of diarrhea mortality, and is associated with stunting and poor development. Yet, effective anti-*Cryptosporidium* drugs do not exist for malnourished and immunocompromised individuals. A diverse set of compounds from the Celgene chemical library, selected based on principal component analysis (PCA), were screened directly against the parasite of interest, *Cryptosporidium parvum*. After confirmation of hits and expansion of the structure-activity relationship (SAR) with a selection of near neighbor analogues, three compounds from three distinct series were identified with favorable potency, physiochemical properties, and pharmacokinetic (PK) profiles to move directly into *in vivo* proof-of-concept (POC) studies. All three compounds displayed *in vivo* efficacy in the *C. parvum*-infected interferon-γ knockout mouse model, with two of the compounds outperforming the *in vivo* positive control, BKI-1369. SAR around one of the series is currently being explored with the immediate goal of progressing compounds into a calf model of cryptosporidiosis for further validation in a model that fully recapitulates human clinical symptoms.

1270

ATP-BINDING ABILITY OF RIOK-2 PROTEIN KINASE IS ESSENTIAL FOR *STRONGYLOIDES STERCORALIS* EGG HATCHING

Huan Zhou, Weiqiang Lei, Jinyang Hu, Ying Zhang, Min Hu

Huazhong Agricultural University, Wuhan, China

Parasitic nematodes impose a significant impact on economic development and human welfare and the intensive emergence of drug resistance prompted us to develop new drugs and vaccines to control parasitic diseases, which requires a deep understanding of the key molecules' functions in the biological processes of these parasites. Protein kinases have been reported as potential drug targets in various fields. As an atypical protein kinase, RIOK-2 is a non-ribosomal factor essential for processing the 18S pre-rRNA in both yeast and human cells, and depletion of yeast RIOK-2 resulted in the accelerated mitotic exit. Although RIOK-2 have been studied in yeast and mammalian cells, little is known about

its function in parasites. Our previous work investigated the sequence characteristics and expression profiles of RIOK-2 encoding gene (*Ss-riok-2*) of *Strongyloides stercoralis*, a human and canine parasitic nematode. In the present study, extending from the previous work, the function of this gene has been explored using transgenesis combined with the mutation technique. The tissue expression pattern of *Ss*-RIOK-2 was detected in the intestine, hypodermis and pharynx of larvae, and mainly expressed in the cytoplasm. At the same time, the location was shifted from the intestine to the hypodermis with the development of larvae from the first-stage larvae to the third-stage larvae. Bacterially expressed recombinant *Ss*-RIOK-2 with a mutation at its catalytic site (D288A) or a mutation at its ATP-binding site (K123A) lost the kinase auto-phosphorylation activity *in vitro*. The D288A mutation caused the delayed larval growth and development. Interestingly, the K123A mutation induced the localization of *Ss*-RIOK-2 transferred from the cytoplasm to the nucleus, which caused an egg hatching disorder, and this defect can be effectively rescued by the wild-type *Ss*-RIOK-2. Our findings demonstrated that the ATP-binding ability but not the catalytic activity of *Ss*-RIOK-2 is essential for the egg hatching of *S. stercoralis*.

1271

IDENTIFICATION OF LONG NONCODING RNAS IN *STRONGYLOIDES STERCORALIS*

Ying Zhang, Huan Zhou, Weiqiang Lei, Jinyang Hu, **Min Hu**

Huazhong Agricultural University, Wuhan, China

Long noncoding RNAs (lncRNAs) are transcripts generally longer than 200 nucleotides with no or poor protein coding capability, and most of their functions are poorly characterized. Recently, an increasing number of studies have shown that lncRNAs are involved in various critical biological processes such as organism development and cancer progression. However, little is known about their effects in helminth parasites, such as *Strongyloides stercoralis,* a human and canine parasitic nematode which poses a threat to global health and is a major challenge in terms of diagnosis and clinical management. The present study employed a computational pipeline to identify and characterize lncRNAs from RNA-seq data of *S. stercoralis* infective third-stage larvae (iL3) and parasitic females (pF). In total, 1206 new putative lncRNAs were identified through the utilization of different criteria such as genome localization, exon number, gene length, and expression level, including 635 putative lncRNAs differentially expressed between iL3 and pF worms. The new putative lncRNAs were categorized into four types: 586 antisense, 497 intergenic, 106 sense and 17 intronic lncRNAs. Additionally, the credibility of RNA-seq results were successfully confirmed by real-time PCR analysis of 8 randomly selected lncRNAs. The Gene Ontology and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analyses were performed to predict lncRNAs' co-localized and co-expressed target genes, revealing that they were enriched in several pathways involved in the interaction between host and *S. stercoralis*, eg signal transduction, translation, and metabolism. Our findings demonstrated that these lncRNAs could play important regulatory roles during the infection of *S. stercoralis*.

1272

IL-13RA1 SIGNALING DRIVEN BY ALLERGEN SENSITIZATION TRIGGERS EOSINOPHIL-DEPENDENT LUNG-SPECIFIC ARREST OF HELMINTH DEVELOPMENT

Pedro Gazzinelli-Guimaraes[1], Rafael de Queiroz Prado[1], Alessandra Ricciardi[1], Sandra Bonne-Annee[1], Joshua Sciurba[1], Erik Karmele[1], Ricardo Fujiwara[2], Thomas Nutman[1]

[1]*NAID, National Institutes of Health, Bethesda, MD, United States,* [2]*UFMG, Belo Horizonte, Brazil*

We have previously shown, using a murine model of house dust mite (HDM)-induced allergic asthma inflammation followed by *Ascaris* infection, that pre-existing allergen sensitization markedly limits Ascaris larval development and reduces up to 70% the parasite burden in the lung. This reduction in parasite burden is driven by an eosinophil-dependent pulmonary type-2-immune response (Th2 cells, IL-33, IL-4, IL-13 and mucus). To explore further the role played by IL-13/IL-13R signaling in mediating this eosinophil-dependent phenomenon, we show that in HDM-sensitized-IL-13Ra1 deficient mice, there was a significant reduction in tissue eosinophil number (a reduction similar to that found in HDM-sensitized eosinophil-deficient mice) that, as a consequence, failed to limit parasite development or numbers. RNA-seq analyses of *Ascaris* larvae isolated from the lungs of allergen pre-sensitized mice compared to larvae from non-allergic mice demonstrated marked alterations between in the 2 sets of larvae with 1330 genes being significantly differentially expressed. Using L3 and L4 larval stage-specific signature mRNA profiles, it could be shown that the *Ascaris* larvae recovered in the lungs/airways of non-allergic mice showed a transcriptomic-signature of a larvae transitioning between the L3-lung stage and the L4 intestinal stage whereas the larval stages recovered in the airways of HDM-pre-sensitized mice had a molecular signature of L3-liver stage. Taken together, our data suggest that HDM-induced allergic sensitization drives a response that mimics a primary *Ascaris* infection, such that lung-specific IL-13Ra1 signaling driven by allergen sensitization mediates eosinophil-dependent helminth larval killing in the tissue occurs. This study provides a window through which the mechanisms underlying tissue-specific responses that can drive a protective response against the early stages of helminth parasites can be seen. It also helps identify at a molecular level potential gene products crucial for larval development that could be used as potential targets for the prevention of chronic Ascaris infections in the host.

1273

VACCINATION WITH AN ATTENUATED HOOKWORM VACCINE: PRELIMINARY RESULTS FROM A PHASE 1B CLINICAL TRIAL

Paul R. Chapman[1], Paul Giacomin[2], Peter O'Rourke[1], Stacey Llewellyn[1], Christian Engwerda[1], Alex Loukas[2], James S. McCarthy[1]

[1]*Queensland Institute of Medical Research - Berghofer, Herston, Australia,* [2]*Australian Institute of Tropical Health and Medicine, Cairns, Australia*

Control of human hookworm infection through mass drug administration is impeded by high rates of reinfection, leading to the proposal for a human hookworm vaccine. We hypothesized that percutaneous exposure to *N. americanus* larvae (L_3) attenuated with ultraviolet C (UVC) light would result in protective immunity. We conducted a phase 1b clinical trial using an attenuated L_3 vaccine delivered via dermal application to healthy human volunteers. Immune response and protective efficacy were secondary endpoints. Fifteen healthy, hookworm-naive volunteers were randomized (1:2) to receive placebo (tabasco sauce) or vaccine (50 attenuated L_3) via dermal application. L_3 were attenuated by exposure to 700uJ of UVC. Two cycles of placebo or vaccine were administered 6 weeks apart, followed 6 weeks later by challenge (30 unattenuated L_3). Fecal samples were collected from each subject 10-11 weeks post challenge for larval culture by modified Harada-Mori and for fecal hookworm DNA intensity using qPCR. No serious AEs occurred. Following challenge, dermal erythema at day 3 measured a median of 20mm vs 32.5mm (p=0.007) and persisted for a median of 2.0 days vs 5.5 days (p=0.007) in controls and vaccinated subjects respectively. A significant difference in the median peripheral eosinophil count was observed at day 38, 0.49 vs 1.44 (p=0.008) which persisted until day 71 post challenge, 1.13 vs 2.32 (10^9), (p=0.014), in controls and vaccinated subjects respectively. Dermal application of attenuated L_3 was well tolerated. Vaccinated subjects had more robust dermal reactions and peripheral eosinophilia than control subjects, consistent with immune sensitization following vaccination. Significantly fewer larvae were recovered per gram of cultured feces from vaccinated than control subjects (0.78 vs 10.16; p=0.014). Vaccinated subjects had lower fecal hookworm DNA intensity than control groups (cycle time 18.67 vs 16.63; p=0.87). Serological responses to vaccine and challenge will be presented (analysis pending). Lower fecal hookworm DNA intensity and recovery of significantly fewer larvae are suggestive of a protective effect in this pilot study.

1274

REPEATED CONTROLLED HUMAN HOOKWORM INFECTION IMPROVES VARIABILITY IN EGG EXCRETION: THE ROAD TO TESTING VACCINES

Marie-Astrid Hoogerwerf[1], Jan Pieter Koopman[1], Jacqueline Janse[1], Eric Brienen[1], Marijke Langenberg[1], Yvonne Kruize[1], Luc Coffeng[2], Sake de Vlas[2], Leo Visser[1], Lisette van Lieshout[1], Maria Yazdanbakhsh[1], **Meta Roestenberg**[1]

[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Erasmus Medical Center, Rotterdam, Netherlands*

Hookworm control programs fall short due to high rates of re-infection and insufficient coverage of mass drug administration. A vaccine would aid in bringing the ultimate goal of elimination in sight. However, field testing of potential vaccine candidates is costly and hampered by limited infrastructure and large sample sizes. Experimental infection of humans with hookworm, can provide a more controlled setting for preliminary testing of vaccine efficacy and downselection of the most promising candidates, but egg counts should reflect the natural infection setting. This trial aimed to achieve a stable and high egg secretion in a controlled human hookworm model for future vaccine testing. Twenty-four healthy, male and female volunteers were randomized double blind to receive either one, two or three doses of 50 L3 *Necator americanus* larvae at 2-week intervals divided over four infection sites. Volunteers visited the trial center weekly for twenty weeks after which they were treated with albendazole . Adverse events were collected at each visit, eosinophil counts were measured weekly and faecal samples were collected for Kato-Katz slides and PCR from week 6 onwards. Three volunteers received early treatment because of severe abdominal adverse events. Skin adverse events were extremely mild. There was a trend towards a longer duration of adverse events in the highest dose group which received 150 L3. All volunteers showed patent infection by Kato-Katz 6-9 weeks after first exposure to larvae. At 12 to 16 weeks after first exposure egg counts reached a plateau phase. Median egg count for the group exposed to 50L3 for this plateau was significantly lower (480 epg) than the median count for the 100L3 and 150L3 group (both 1200 epg). Variability in egg excretion was highest in the 50L3 group and lowest in the 150L3 group. Repeated infection reduces the variability in egg excretion without a concomitant increase in adverse events. We conclude that doses of 100 or 150 L3 larvae are well tolerated and result in mild-to-moderate level infections according to WHO criteria, resembling field worm burdens.

1275

A COMPARISON OF QUANTITATIVE PCR, KATO-KATZ TECHNIQUE, AND SODIUM NITRATE FLOTATION FOR THE DIAGNOSIS OF HOOKWORM INFECTIONS IN VIETNAM

Naomi Clarke[1], Dinh Ng-Nguyen[2], Rebecca Traub[3], Archie Clements[4], Roy Anderson[5], Susana Vaz Nery[1]

[1]*University of New South Wales, Kensington NSW, Australia,* [2]*Tay Nguyen University, Dak Lak, Vietnam,* [3]*University of Melbourne, Parkville VIC, Australia,* [4]*Curtin University, Perth WA, Australia,* [5]*Imperial College London, London, United Kingdom*

There are concerted global efforts underway to scale up soil-transmitted helminth control efforts. Accurate diagnostic capabilities are crucial to these efforts. However, the current standard diagnostic test, the Kato-Katz technique, has a number of shortcomings. Quantitative PCR (qPCR) and sodium nitrate flotation represent alternative promising diagnostic techniques. This study aimed to compare the diagnostic sensitivity and infection intensity measurements of three different diagnostic techniques: the Kato-Katz technique, qPCR, and sodium nitrate flotation. We obtained stool samples from 430 schoolchildren, recruited from 13 primary schools in Dak Lak province, Vietnam. Samples were analyzed using the Kato-Katz technique and sodium nitrate flotation, with infection intensity measurements given in eggs per gram (epg) of feces. Samples were also analyzed using qPCR, with infection intensity measurements given in Ct values that were converted to epg. Diagnostic sensitivity of each technique was calculated by considering an individual to be a "true positive" if their stool sample was hookworm-positive using any of the three techniques. The prevalence of hookworm infection among the study population was 13.3% (95%CI 10.4-16.9) by Kato-Katz, 16.3% (12.9-20.3) by sodium nitrate flotation, and 21.3% (17.7-25.5) by qPCR. All qPCR-positive individuals had *Necator americanus*, and 6 of these individuals additionally had *Ancylostoma ceylanicum*. Diagnostic sensitivity of the Kato-Katz technique was 54.8%, sodium nitrate flotation 63.3%, and qPCR 87.5%. Egg counts were typically lowest for sodium nitrate flotation, followed by Kato-Katz, and highest for qPCR. This study confirmed the high diagnostic sensitivity of qPCR compared to microscopy-based techniques, and showed superior diagnostic sensitivity for sodium nitrate flotation compared with the Kato-Katz technique. Fecal egg counts, on the other hand, were higher for the Kato-Katz technique compared with sodium nitrate flotation. Correlations between infection intensity measurements for the three techniques will also be presented.

VALIDATION OF A MULTIPLEX REAL-TIME PCR GASTROINTESTINAL HELMINTH PANEL

Jason Kwan[1], Kimberley Marks-Beaubrun[1], Rachel Lau[2], Filip Ralevski[2], Amanda Wang[2], Ruben Cudiamat[2], Ellen Min Chen[2], Krista Orejana[2], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario, Toronto, ON, Canada*

Microscopy is the conventional method for identification of gastrointestinal parasitic pathogens, however, it requires high technical expertise and prolonged turnaround time. Molecular methods provide higher throughput and potentially higher sensitivity and specificity. We validated a commercial multiplex parasitic real time PCR panel detecting 7 helminths: *Ascaris* spp. *(As)*, *Enterobius vermicularis (Ev)*, *Hymenolepis* spp. *(Hy)*, *Necator americanus (Na)*, *Strongyloides* spp. *(St)*, *Taenia* spp. *(Ta)* and *Trichuris trichiura (Tt)* at Public Health Ontario, Canada. We analyzed 86 banked frozen fecal specimens including: 86 specimens without any pre-treatment and 86 specimens pre-treated with ASL buffer, containing *As* (n=23), *Ev* (n=13), *Hy* (n=1), *Ta* (n=4), St (n=33), *Tt* (n=10), and 3 mixed infections. A panel of protozoa and helminth specimens not covered in these assays was used for cross reactivity evaluation. DNA extraction and PCR were conducted with the Hamilton Starlet automated platform and Seegene's extraction and PCR kits. Microscopy was the reference standard for all organisms. Where fully evaluable due to sufficient numbers, sensitivity, specificity, positive predictive-, and negative predictive values without pre-treatment were: 48%, 100%, 100% and 84% for *As*; 77%, 100%, 100% and 96% for *Ev*; 57%, 98%, 95% and 77% for *St*; and 100%, at all metrics for *Hy* and *Ta*; and with ASL pre-treatment were: 65%, 100%, 100% and 89% for *As*; 100% at all metrics for *Hy* and *Ta*; and 53%, 100%, 100% and 75% for *St*. No cross-reactivity was observed with other protozoa or helminths. The platform had high sensitivity for detection of a small number of *Ta* and *Hy,* but suboptimal sensitivity for *Ev* and *St*. Further validation with greater numbers of specimens is required for performance determination with other helminths and those without sufficient numbers to report in this analysis.

COMPREHENSIVE ANTIBODY PROFILING IN NODDING SYNDROME: CONTINUED ASSOCIATION BETWEEN ONCHOCERCA-INDUCED ANTIBODIES AND CROSS-REACTIVE AUTOANTIBODIES TO HUMAN BRAIN EXPRESSED LEIOMODIN-1 AND DJ-1

Joseph Kubofcik[1], Rodney Ogwang[2], Thomas B. Nutman[1], Richard Idro[2]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*Makerere University College of Health Sciences, Kampala, Uganda*

Although the underlying etiology of the Nodding syndrome (NS) is unknown, the most compelling data suggest an association between antibody responses to the filarial parasite *Onchocerca volvulus*(Ov)that cross-react with the human brain-expressed leiomodin-1 (LMOD-1). To explore more comprehensively the role of cross-reactive autoantibodies, we examined IgG responses in the serum of 240 NS patients and 154 unaffected village controls (UVC) to Ov-16 and Ov-3261, 2 antigens that assess exposure to O. volvulus parasites ,human (Hs) LMOD-1 and DJ-1, the 2 brain expressed antigens previously shown to be higher in NS patients, and their OV homologues, Ov-tropomodulin/helminth tropomyosin and Ov-DJ-1. As shown previously, the antibody responses to Ov-16 and Ov-3261 was significantly elevated in NS patients compared to the UVC. Using ROC-based cutoffs to determine positive responses, more NS patients had positive response to human LMOD 1 than did UVC. The response to HsDJ-1 was equivalent between those with NS and the UVC. By correlation analyses, there was a highly significant correlation between the responses to HsLMOD-1 and the Ov homologue (helminth tropomyosin; p= 1e-9) and between the responses to HsDJ-1 and Ov-DJl (p=0.0007). These data provide corroborating evidence that cross-reactive antibodies driven by Ov exposure/infection underlies some of the pathogenesis of NS. Profiling of the autoantibodies in cerebral spinal fluid is underway, as CSF antibody profiling may provide a more CNS specific understanding of the mechanisms underlying the NS.

1278

A TRIAL OF REPEATED DOSES OF IVERMECTIN VERSUS ALBENDAZOELE PLUS IVERMECTIN FOR TREATMENT OF ONCHOCERCIASIS

Nicholas Opoku[1], Seidu A. Mahmood[2], Simon K. Attah[2], James W. Kazura[3], Katiuscia O'Brian[4], Kerstin Fischer[4], Peter U. Fischer[4], Gary J. Weil[4], Christopher L. King[3]

[1]*University of Health and Allied Sciences, Hohoe, Ghana,* [2]*College of Health Sciences, University of Ghana Medical School, Korle-Bu Accra, Ghana,* [3]*Case Western Reserve University, Cleveland, OH, United States,* [4]*Washington University School of Medicine, St. Louis, MO, United States*

An improved treatment for onchocerciasis is needed to accelerate elimination in Africa. This study examined whether annual or semiannual treatment with ivermectin (IVM) plus albendazole (ALB) is superior to IVM alone in killing and/or sterilizing female adult worms. This trial was performed in the Ghana Volta Region and enrolled 375 microfiladermic (Mf)-positive participants not previously treated with IVM and randomized to 5 treatment arms: annual treatment with IVM (200ug/kg) alone or IVM (200ug/kg) in combination with ALB 800mg at 0, 12, and 24 months, or semiannual treatment with IVM alone, IVM+ALB 400mg or IVM+ALB 800mg at 0, 6, 12, 18 and 24 months. Microfiladermia was tested determined pre-treatment and at 6, 12, 18, 24 and 36 months. The primary outcome was the proportion of fertile and viable female adult worms excised from onchocercomata at 36 months. The proportion of living worms with normal embryogenesis based on nodule histology was similar among treatment arms; 32 of 245 (13.1%) in IVM annual, 43 of 309 (13.9%) in IVM semiannual, 46 of 268 (17.1%) in IVM+ALB 800mg annual, 33 of 260 (12.7%) in IVM+ALB 400mg semiannual and 51 of 264 (19.3%) in IVM+ALB 800mg semiannual groups (p=0.231, chi-square analysis). Proportions of dead worms also did not differ between the 5 groups (p=0.37). There was no difference in the proportion of participants without skin Mf at 36 months among treatment groups; 34 of 69 (49%) after annual IVM, 36 of 68 (53%) after semiannual IVM, 26 of 64 (40%) after IVM+ALB 800mg annually, and 31 of 65 (48%) after semiannual IVM+ALB 400mg, and 26 of 62 (42%) after semiannual IVM+ALB 800mg (P=0.411). Thus the combination treatment with IVM plus ALB was no better than IVM alone for the sterilizing and killing of adult worms or achieving sustained Mf clearance. However, semiannual treatment with either regimen was superior to annual treatment for achieving overall reduction in skin Mf during the course of the study.

1279

DRUG DEVELOPMENT FOR THE TREATMENT AND CONTROL OF ONCHOCERCIASIS: A POPULATION PHARMACOKINETIC ANALYSIS OF EMODEPSIDE (BAY 44-4400) IN HEALTHY VOLUNTEERS

Frauke Assmus[1], Richard M. Hoglund[1], Ivan Scandale[2], Joel Tarning[1]

[1]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*Drugs for Neglected Diseases initiative, Geneva, Switzerland*

Programs for the elimination of onchocerciasis (river blindness) rely on mass drug administration of ivermectin, targeting the larvae (microfilariae) and temporarily sterilizing, but not killing the adult parasite. Hence, repeated (bi)-annual treatment during the reproductive lifespan of the adult worm (more than a decade) is required to stop transmission and halt disease progression. In order to reduce the treatment duration, a short-course macrofilaricidal drug that kills the adult worm is needed urgently. Emodepside has shown macrofilaricidal efficiency against a variety of nematodes. Following a repurposing strategy, the veterinary anthelmintic is currently under clinical development for treatment of onchocerciasis and three Phase I studies have been completed. The aim of this study was to characterize the population pharmacokinetic properties of emodepside in healthy subjects and propose a dosing regimen for a planned phase II clinical trial. Plasma concentration-time data was obtained from 142 subjects enrolled in the three Phase I studies, including a single-dose, and

a multiple-dose, dose-escalation study as well as a relative bioavailability study. All cohorts were pooled (doses: 1mg, 2.5mg, 5mg, 10mg, 20mg, 40mg, formulations: oral solution/two new immediate-release tablet formulations, food: fasted/fed) and analyzed using nonlinear mixed-effects modelling (NONMEM v7.3). Different absorption, disposition, variability and covariate models were evaluated and the final population pharmacokinetic model was used to simulate clinical dosing scenarios. Emodepside pharmacokinetics was well described by a transit-compartment absorption model, followed by a 3-compartment disposition model. Body weight was included as an allometric function and both food state and formulation had a significant impact on absorption rate and relative bioavailability (decreased by food intake and by administration of tablet formulations in comparison to the oral solution). Pharmacokinetic modelling and simulation was used to derive an optimized dosing regimen for a planned Phase II clinical trial in sub-Saharan Africa.

1280

ANTI-*WOLBACHIA* CANDIDATE ABBV-4083: PHASE 1 SAFETY AND PHARMACOKINETICS CLINICAL TRIAL IN HEALTHY ADULTS

Negar Niki Alami, David C. Carter, Nisha V. Kwatra, Weihan Zhao, Linda Snodgrass, Ariel R. Porcalla, Cheri E. Klein, Daniel E. Cohen, Loretta A. Gallenberg, Robert A. Carr, Kennan C. Marsh, Dale J. Kempf

AbbVie, North Chicago, IL, United States

Onchocerciasis is caused by the filarial nematode *Onchocerca volvulus.* Doxycycline has demonstrated efficacy against *O. volvulus* by depleting *Wolbachia*, an endosymbiotic bacterium essential for worm development and fertility. ABBV-4083, a macrolide antibacterial with activity against *Wolbachia*, is intended to sterilize and eliminate *O. volvulus* by a similar mechanism but with a shorter treatment course and improved safety profile vs. doxycycline (pregnancy Category D; contraindicated for age <8; photosensitivity). This First in Human phase 1 trial evaluated the pharmacokinetics, food effect, and safety of escalating single and multiple doses of ABBV-4083 in healthy subjects. Seventy-eight healthy subjects were exposed to ABBV-4083 (36 in single ascending dose at 40, 100, 200, 400 or 1000mg; 12 in Food Effect at 1000mg; and 30 in multiple ascending daily dose at 100mg for 7 days, 200mg for 7 or 14 days, or 400mg for 7 or 14 days). Maximum concentrations (C_{max}) of ABBV-4083 were achieved around 1-2 hours, with a half-life less than 4 hours at doses ≤ 400 mg. C_{max} and AUC increased predictably in a slightly more than dose-proportional manner, with similar exposures after multiple dose administration. The mean fractions of ABBV4083 doses recovered in urine were < 1% for a 24-hour collection interval. The most common adverse events (AEs) reported were nausea (8/78, 10%) and headache (6/78, 8%). Two subjects given a single dose of ABBV-4083 1000mg in the food effect portion experienced asymptomatic and reversible ALT and AST elevations (Grade 2 in one and Grade 4 in the other), without bilirubin elevations, deemed related to study drug. The effect of food on exposure parameters was minimal. No treatment-related serious AEs were reported. ABBV-4083 400mg was well tolerated in this Phase 1 study in healthy adults. Based on preclinical pharmacokinetic/pharmacodynamic modeling, ABBV-4083 400mg daily for 7 or 14 days is expected to be an efficacious dose. A Phase 2 proof of concept study with ABBV-4083 will be conducted in Africa by Drugs for Neglected Diseases *initiative*.

1281

PRECLINICAL EFFICACY OF THE NOVEL MACROFILARICIDAL DRUG CANDIDATE ABBV-4083

Marc P. Hübner[1], Thomas W. von Gedern[2], Kennan Marsh[2], Sabine Specht[1], Marianne Koschel[1], Alexandra Ehrens[1], Stefan J. Frohberger[1], Emma Gunderson[3], Christina Bulman[3], KC Lim[3], Mark J. Taylor[4], Joseph D. Turner[4], Stephen A. Ward[4], Judy Sakanari[3], Dale Kempf[2], Achim Hoerauf[1]

[1]*University Hospital Bonn, Bonn, Germany,* [2]*AbbVie, North Chicago, IL, United States,* [3]*University of California San Francisco, San Francisco, CA, United States,* [4]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

The tylosin analogue ABBV-4083 represents a novel drug candidate that is currently considered for phase 2 clinical trials for the treatment of onchocerciasis and lymphatic filariasis. ABBV-4083 targets the *Wolbachia* endosymbionts of filariae. Depletion of *Wolbachia* by the present gold standard doxycycline leads after 4-5 weeks of daily treatment to permanent sterilization and long-term death of adult filariae causing onchocerciasis and lymphatic filariasis. Oral treatment of *L. sigmodontis*-infected mice with ABBV-4083 reduced the *Wolbachia* in female adult worms as soon as three days after treatment start with continued declining *Wolbachia* levels throughout a 3-week washout phase. Two weeks of ABBV-4083 treatment in patently *L. sigmodontis*-infected jirds led to a >99.9% *Wolbachia* depletion in female adult worms, the inhibition of filarial embryogenesis and clearance of peripheral microfilaremia. Furthermore, *Wolbachia* reduction in microfilariae coincided with the *Wolbachia* reduction in adult worms, indicating that *Wolbachia* depletion in microfilariae represents a potential surrogate marker for efficacy in upcoming phase 2 clinical studies. Importantly, continuous daily treatment with ABBV-4083 was not required, as subsequent completion of missed treatments did not impair the *Wolbachia* depletion efficacy. Combination of ABBV-4083 with albendazole allowed lower doses of ABBV-4083 and shorter treatment regimens of 7 days, leading to an improved *Wolbachia* depletion and maintained clearance of peripheral microfilaremia compared to treatments with ABBV-4083 or albendazole alone. Ongoing experiments are now evaluating the number of albendazole treatments required to boost ABBV-4083 efficacy. Confirmation of the *Wolbachia* depletion in adult worms, the inhibitory effect on filarial embryogenesis and the synergistic effect with albendazole by ABBV-4083 treatment was further obtained in *Brugia pahangi*-infected jirds. Thus, ABBV-4083 represents a promising anti-*Wolbachia* candidate that is efficacious in animal models of onchocerciasis and was recently tested in a phase 1 clinical trial.

1282

MANSONELLA PERSTANS IN LYMPHATIC FILARIASIS HOTSPOTS IN SIERRA LEONE

Yakuba M. Bah[1], Mustapha Sonnie[2], Abdulai Conteh[1], Victoria Sawyerr[1], Alhassan Konneh[2], Amy Veinoglou[3], **Mary Hodges**[2], Yaobi Zhang[4]

[1]*Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone,* [2]*Helen Keller International, Freetown, Sierra Leone,* [3]*Helen Keller International, New York City, NY, United States,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Sierra Leone is endemic for lymphatic filariasis (LF) in all 14 districts, with prevalence of antigenemia by immunochromatographic test cards from 3.1% to 52% in 2005. The highest was in Bombali (52%), Koinadugu (46%), Kono (30%), Port Loko (20.5%) and Kailahun (19.1%). It is known that *Mansonella perstans* is also present in Sierra Leone. After a minimum of five rounds of mass drug administrations (MDA) with ivermectin and albendazole, nine districts successfully reached the criteria of stopping MDA in 2017/18. However, four districts failed to pass the pre-transmission assessment survey (pre-TAS) with microfilaremia (mf) prevalence >1% in 2013 in at least one site: Bombali, Koinadugu, Kailahun and Kenema districts. After a further three rounds of MDA, a re-pre-TAS was conducted in these four districts with one sentinel and one

spot check site per district (2 spot checks in Bombali) in 300-350 persons aged ≥5 years per site using Filariasis Test Strips (FTS). All positive results were confirmed by a second FTS test. Antigenemia prevalence by site was 9.1%, 16.7% and 25.9% in Bombali, 7.5% and 19.4% in Koinadugu, 6.1% and 2.9% in Kailahun, and 1.3% and 2.3% in Kenema. In order to investigate potential interference of *M. perstans* infections on FTS tests, a follow-up study was conducted before the next MDA by tracing the 296 FTS positive cases. Among these, 236 provided a midnight blood sample and 232 provided a midday blood sample (80% response rate). Microscopy was performed in the field and all slides double checked by a senior technician from Ghana. Nine persons were positive for *W. bancrofti* mf (2 each in Bombali and Kailahun and 5 in Koinadugu) and 13 persons were positive for *M. perstans* (Bombali 4, Koinadugu 7 and Kailahun 2). This follow-up study suggested that the presence of *M. perstans* may have interfered with the FTS tests, however further study is needed to investigate the use of FTS in the presence of *M. perstans.*

MORBIDITY MANAGEMENT AND SURVEILLANCE OF LYMPHATIC FILARIASIS PATHOLOGY AND ACUTE DERMATOLYMPHANGIOADENITIS (ADLA) ATTACKS USING A MOBILE PHONE-BASED TOOL BY COMMUNITY HEALTH VOLUNTEERS IN GHANA

Linda Batsa Debrah[1], Jubin Osei-Mensah[2], Yusif Mubarik[2], Aliyu Mohammed[3], Olivia Agbenyega[4], Nana Kwame Ayisi-Boateng[1], Janina M. Kuehlwein[5], Ute Klarmann-Schulz[5], Achim Hoerauf[5], Alexander Yaw Debrah[6]

[1]*School of Medical Sciences, Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana,* [2]*Kumasi Centre for Collaborative Research in Tropical Medicine (KCCR), Kumasi, Ghana,* [3]*School of Public Health, Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana,* [4]*Faculty of Renewable Natural Resources, Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana,* [5]*Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn, Bonn, Germany,* [6]*Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ghana*

Health surveillance using mobile phone technology is a burgeoning area in both infectious and non-infectious diseases. Current programmes to control lymphatic filariasis and onchocerciasis rely on sustained delivery of standard anti-filarial drugs to affected communities via mass drug administration (MDA). MDA uses a community-directed treatment strategy where community members with varying backgrounds are trained to distribute drugs. The success of this strategy rests on the resourcefulness of community health volunteers (CHVs). Previous pilot studies in Ghana and Tanzania which tested a short messaging service (SMS) tool that enabled CHVs to report basic information on identified lymphedema (LE) and hydrocele cases, such as village, age, sex, condition and severity, proved to be more efficient than the traditional way of reporting. However, because of high illiteracy rates in Ghana and other African countries, illiterate CHVs could not use the SMS tool. We therefore decided to explore the use of mobile phone voice messaging to overcome this challenge. This mobile phone surveillance uses a simple algorithm. It is designed using an Interactive Voice Response (IVR) system, an automated mobile telephony with the capacity to provide two-way voice communication. The system gives instructions in either English or Twi (a local dialect). The CHVs provide responses by pressing the mobile phone keypad numbers. The pre-coded responses provided by the CHVs are automatically stored on a secured server and extracted in csv format for further analysis. In our ongoing pilot study in Ghana, which is one of the workpackages of the TAKeOFF consortium, CHVs have been engaged to report LE and hydrocele cases as well as ADLA using the IVR. This study has reported 384 pathology cases and 174 ADLA within 6 weeks by both illiterate and literate CHVs. The system, when fully developed, will overcome underreporting of pathology cases and ADLA in endemic communities and people with ADLA could get immediate help from the drone services being introduced in Ghana now. The system has the potential to be further expanded to other communicable or non-communicable diseases.

Mass drug administrations (MDAs) are the main intervention in the control and elimination of preventable chemotherapy neglected tropical diseases (NTDs), specifically lymphatic filariasis (LF), trachoma, onchocerciasis, schistosomiasis and soil transmitted helminths. MDA treatment coverage is used to identify where modifications to the MDA approach are necessary, and is a main criterion for determining when to conduct impact surveys to assess whether MDAs can be stopped. Coverage can be measured through routinely reported programmatic data or population-based coverage evaluation surveys. Reported coverage is often the easiest and least expensive way to estimate coverage, by utilizing NTD program systems and staff at national, district and subdistrict levels; however, it is prone to inaccuracies due to errors in data compilation by persons often with low levels of education, imprecise denominators, and in some cases actually measures treatments offered as opposed to treatments swallowed. We compared data from coverage surveys implemented in 15 countries between 2008–2017 and compared these results to routinely reported coverage for 222 LF, trachoma, onchocerciasis, schistosomiasis and soil transmitted helminths MDAs. Each of these diseases has a minimum coverage threshold. Coverage estimates using routine reports and surveys gave the same result in terms of whether the minimum threshold was reached 70% of the time in the Africa region and 52% in Asia region. The median absolute difference between coverage point estimates using the two data sources was 14 percentage points (IQR 6–25 percentage points). We conclude that in many cases, based on the concordance with respect to reaching the minimum threshold coverage, routinely reported data

should continue to be used for decision-making, while working to improve the quality of these data. Coverage evaluation surveys are a useful tool and should be systematically used to periodically assess the accuracy of routinely reported data.

1285

ASSESSING THE RESILIENCE OF COMMUNITY DRUG DISTRIBUTORS (CDDS) CONDUCTING MASS DRUG ADMINISTRATION (MDA) FOR LYMPHATIC FILARIASIS AND ONCHOCERCIASIS IN CÔTE D'IVOIRE

Daniel Dilliott[1], David Addiss[2], Margaret Gyapong[3], Deborah McFarland[4], Mary Amuyunzu-Nyamongo[5], Esther Comoe[6], Adam Mama Djima[6], Amos Wung Buh[1], Alison Krentel[1]

[1]*Bruyère Research Institute, Ottawa, ON, Canada,* [2]*The Task Force for Global Health, Decatur, GA, United States,* [3]*University of Health and Allied Sciences, Ho, Ghana,* [4]*Rollins School of Public Health, Emory University, Atlanta, GA, United States,* [5]*African Institute for Health and Development, Nairobi, Kenya,* [6]*Ministère de la Santé et de l'Hygiène Publique, Abidjan, Côte D'Ivoire*

Volunteer community drug distributors (CDDs) are pivotal to the success of national neglected tropical disease (NTD) elimination programs. Through mass drug administration (MDA), they distribute millions of preventive chemotherapy treatments to endemic communities. However, CDDs can encounter considerable challenges during MDA, such as massive workload and uncooperative community members. CDDs must be resilient to overcome these challenges and meet NTD elimination and control goals, yet little is known about CDD resiliency. The purpose of this study was to assess resilience among CDDs conducting MDA in Côte d'Ivoire using an international standardized tool and compare their resilience to that of frontline health workers (FLHWs). Samples of CDDs (N=133; 63.9% male, 36.1% female) and FLHWs (N=21) involved in the 2018 MDA in the Abidjan and N'zi Iffou regions were purposively selected. A survey was administered following the MDA to assess participants' demographics and experiences during MDA; resilience was assessed using the Connor-Davidson Resilience Scale 25 (CD-RISC-25). Mean CD-RISC-25 scores were calculated based on 25 self-assessed indicators. Variables individually associated with mean CD-RISC-25 score ($p<0.25$) were included in a multiple regression model. CDDs were found to have lower mean resilience scores than their FLHW counterparts in both Abidjan (73.5 to 86.5, $p<0.05$) and N'zi Iffou (71.2 to 81.1, $p<0.05$). The multivariable regression model revealed that CDDs who reported having an easy relationship with their community were significantly more resilient than those who did not ($p<0.05$). Mean resilience scores were unaffected by variations in district, age, gender, and length of involvement with the NTD program. This study establishes the CD-RISC-25 as a useful tool for assessing the resilience of NTD program volunteers and will assist Ivorian NTD program managers in augmenting CDD training modules and developing interventions to improve CDD-community relationships. Further research is needed to understand, promote, and support the resilience of this valuable health workforce, upon which NTD programs depend.

EVALUATING THE IMPACT OF INTERVENTIONS ON SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHS IN NORTH-CENTRAL NIGERIA

Emily Griswold[1], Abel Eigege[2], John Umaru[2], Solomon Adelamo[2], Bulus Mancha[2], Andrew Nute[1], Obiageli Nebe[3], Chukwuma Anyaike[3], Evelyn Ngige[3], Jonathan Kadimbo[4], Jacob Danboyi[5], Emmanuel Miri[2], Frank Richards[1]

[1]*The Carter Center, Atlanta, GA, United States,* [2]*The Carter Center, Jos, Nigeria,* [3]*Federal Ministry of Health, Abuja, Nigeria,* [4]*Plateau State Ministry of Health, Jos, Nigeria,* [5]*Nasarawa State Ministry of Health, Lafia, Nigeria*

Statewide mapping surveys of schistosomiasis (SCH) and soil-transmitted helminths (STH) were conducted in 2013 in Nasarawa and Plateau states of north-central Nigeria, sampling 11,332 children. Varying combinations of mass drug administration for school-aged children followed for the next five years. We repeated these assessments in 2018 in the same schools, sampling 9,660 children aged 6 to 14 from 202 schools. We analyzed overall parasite prevalence and intensity, as well as any associations with gender, age, behaviors, water and sanitation, and treatment history. Schistosomiasis (*S. haematobium* or *S. mansoni*) prevalence was 15.0% (95% CI: 12.0% - 18.6%) in 2013 in Nasarawa state, and 11.3% (9.5% - 13.4%) in Plateau state. Prevalence in 2018 was 6.5% (4.6% - 9.0%) in Nasarawa and 6.3% (4.6% - 8.6%) in Plateau. Six districts saw significant changes in prevalence of *S. mansoni,* while 11 saw significant changes in *S. haematobium.* Stool samples were also analyzed for presence of *A. lumbricoides, T. trichiura,* and hookworm. The 2013 prevalence of any infection was 14.5% (11.8% - 17.8%) in Nasarawa and 8.0% (6.6% - 9.7%) in Plateau. In 2018, prevalence in Nasarawa was 11.2% (9.1% - 13.6%), whereas it was 8.2% (6.4% - 10.4%) in Plateau. In contrast to SCH, only one district saw a statistically significant changes. Intensity (measured as mean eggs per gram of stool) was measured at both timepoints in stool samples only; egg counts in urine were only done in 2018. Of children infected with *S. mansoni*, heavy infections were found in 2013/2018 in 17.0% (9.9% - 27.7%)/8.1% (3.8% - 16.3%). Of children with *S. haematobium* (2.5% [1.8% - 3.5%] in 2018), 21.3% (13.7% - 31.7%) had heavy infections. Heavy intensity infections were found in <1% of children with hookworm, and none were found in children with *A. lumbricoides* or *T. trichiura* in either study. Water and sanitation data were only available in 2018; latrine coverage was poor: less than half (43.6%) of schools had a latrine and only 14.4% had handwashing facilities. Although progress is evident, heavy schistosomiasis infections remain in Nasarawa and Plateau state.

1287

TREND ANALYSIS OF SOIL TRANSMITTED HELMINTHS AND SCHISTOSOME INFECTIONS PREVALENCE OVERLAID WITH PROGRAMMATIC TREATMENT COVERAGE STRATIFIED BY COUNTIES IN KENYA: LONGITUDINAL STUDY DESIGN

Collins Okoyo[1], Suzy J. Campbell[2], Sammy Njenga[1], Simon J. Brooker[3], Charles Mwandawiro[1]

[1]*Kenya Medical Research Institute, Nairobi, Kenya,* [2]*Evidence Action, Washington, DC, United States,* [3]*London School of Hygiene and Tropical Medical Medicine, London, United Kingdom*

Kenya's national school-based deworming programme began in 2012 and aimed at reducing infection and morbidity associated with soil-transmitted helminth (STH) and schistosome infections. It has rich dataset from its monitoring and evaluation arm conducted during baseline, midterm, endline and sixth year evaluation surveys in 20 counties over the last six years. We conducted trend analysis using six years secondary data collected between 2012 and 2018 from this programme to understand the associations between prevalence of infection and the treatment coverage, by county, over time. The surveys utilized a series of pre- and post-MDA intervention, repeat cross-sectional surveys in a representative, stratified, two-stage sample of 200 schools in 20 counties. In overall, prevalence of 32.3% and 12.9% were observed for the undifferentiated STH infections during baseline and year six evaluation surveys respectively, translating into a significant decline in the prevalence (RR = 60.2%, $p<0.001$). Differentiated STH infections reductions were at differing rates; hookworms (RR = 93.6%, $p<0.001$), *Ascaris lumbricoides* (RR = 46.1%, $p<0.001$) and *Trichuris trichiura* (RR = 45.5, $p<0.001$). For schistosomes, prevalence reduction was observed for *Schistosoma haematobium* (RR = 97.8, $p<0.001$) but not for *Schistosoma mansoni*. Overall significant association between undifferentiated STH prevalence and coverage (Fisher's exact test, $p=0.032$) was observed, however, no significant associations were observed for each of the differentiated STH species as well as for schistosome species. High treatment coverage was seen to be nonsignificantly correlated with low *S. haematobium* infection ($r = -0.1498$, $p=0.7486$). Heterogeneity in county-level associations between prevalence and coverage was observed. The findings of this secondary

analysis will allow the national control programme to make informed decisions regarding maintaining high level treatment coverage as the country rallies towards elimination of these infections.

SUCCESSFUL INTEGRATION OF STH SURVEY WITH LF TRANSMISSION ASSESSMENT SURVEYS IN TEN EVALUATION UNITS IN MALI

Massitan Dembélé[1], Mahamadou Traoré[1], Benoit Dembélé[2], Boubacar Guindo[2], Mama Niélé Doumbia[2], Seydou Goita[2], Modibo Keita[2], Yaya I Coulibaly[3], Salif S Doumbia[3], Moussa Sacko[4], Renion Saye[4], Abdoulaye Guindo[1], Abdoul Karim Sidibé[1], Steven Reid[5], Fama Kondo[2], Mohamed Lamine Yattara[2], Yaobi Zhang[6]

[1]*Directorate General of Health, Ministry of Health and Public Hygiene, Bamako, Mali,* [2]*Helen Keller International, Bamako, Mali,* [3]*Filariasis Unit, International Center of Excellence in Research, Faculty of Medicine and Odontostomatology, Point G, Bamako, Mali,* [4]*Institut National de Recherche en Santé publique, Bamako, Mali,* [5]*Helen Keller International, New York, NY, United States,* [6]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Mass drug administration (MDA) for lymphatic filariasis (LF) with ivermectin and albendazole has also targeted soil-transmitted helminths (STH) in Mali. As recommended by WHO, after a minimum of five years of effective MDA, a series of transmission assessment surveys (TAS) is conducted and the national NTD program should also collect data on STH when a TAS is conducted to inform STH program decision-making. In 2018, Mali combined the TAS2 and STH assessments in 10 evaluation units (EUs), consisting of 27 HDs, according to the WHO guidelines. The Survey Sample Builder (SSB) was used to determine the minimum sample size (for TAS 759-1692 and for STH 332) and to generate the A and B random lists for sample selection in the field. The maximum positive case threshold (critical cut-off) was also determined by the SSB for LF. The target population was based on the type of survey: for STH assessments it was children aged 8-10 years in school and 6-7 years in households, while for LF, the target was children aged 6-7 years. A joint team of surveyors and technicians from two national programs conducted the field assessments. Filaria Test Strips (FTS) for LF and Kato-Katz thick smears for STH were used as the diagnostic tests. Three EUs were surveyed in schools and seven EUs were in communities. In total, 17,263 children were tested for TAS and 3,468 for STH in the 10 EUs. All the EUs evaluated for LF passed TAS2 with the number of positive cases ranging from 1 to 3 in each EU, below the critical cut-off of either 18 or 20 positive results. One or two positive children for STH were diagnosed in 3 EUs (all in community-based surveys), giving an STH prevalence of between 2% and 10% (according to WHO guidance on TAS-STH results). No positive cases for STH were found in the other 7 EUs, indicating that these EUs have an STH prevalence of <2%. These results confirmed the low prevalence of STH in Mali found by sentinel site assessments integrated with schistosomiasis surveys previously. These TAS-STH results indicate the continued success of the Malian LF program and the reduction in STH prevalence and the results show that MDA for STH may no longer be required in these HDs.

1289

COMMUNITY EFFECTIVENESS AND INDIVIDUAL EFFICACY OF IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS, SCABIES AND SOIL TRANSMITTED HELMINTHS IN FIJI

Myra Hardy[1], Josaia Samuela[2], Mike Kama[2], Meciusela Tuicakau[2], Lucia Romani[3], Margot Whitfeld[3], John Kaldor[3], Leanne J. Robinson[4], Andrew Steer[1]

[1]*Murdoch Children's Research Institute, Melbourne, Australia,* [2]*Ministry of Health and Medical Services, Suva, Fiji,* [3]*Kirby Institute, Sydney, Australia,* [4]*Burnet Institute, Melbourne, Australia*

Despite repeated rounds of mass drug administration (MDA) using diethylcarbamazine and albendazole (DA), lymphatic filariasis (LF) remains a public health problem in many parts of Fiji, where scabies and soil-transmitted helminths are also co-endemic. Based upon evidence from other settings, the addition of ivermectin to DA (IDA) was hypothesised to be more effective at eliminating *W. bancrofti* and scabies. A trial conducted in 2017 randomized 35 villages from two Fijian islands, Rotuma and Gau, to receive DA (n=1216) or IDA (n=2396) in a 1:2 ratio, confirming that IDA has an acceptable safety profile in Fiji. Permethrin as scabies treatment was given to 513 in the DA group, and as an ivermectin MDA alternative to 236 in the IDA group. The impact on community prevalence of LF microfilaremia and antigenemia, scabies and soil transmitted helminths (STH) was assessed at 12 months, as well as clearance of microfilaremia in infected individuals from baseline. At 12 months, 2942 participants were re-enrolled, 870 were lost to follow up, and 961 were new residents, resulting in a total of 3903 participants. From baseline to 12 months the prevalence of LF microfilaremia declined from 3.8% to 1.9% (absolute reduction (AR) of 1.9%) in DA and 3.9% to 1.9% (AR 2%) in IDA group. Scabies prevalence declined from 13.6% to 1.1% (AR 12.5%) in DA and 13.4% to 1.9% (AR 11.4%) in IDA group. STH prevalence declined from 13.1% to 4.6% (AR 8.4%) in DA and 21% to 16% (AR 5%) in IDA group. In those individuals who were infected with LF at baseline, clearance of microfilaremia at 12 months was 67.5% in DA versus 62.5% in IDA arm. However this varied between island groups: for DA, clearance in Rotuma was 60% and in Gau 80%; and for IDA, clearance in Rotuma was 57.8% and in Gau 100%. There was a reduction in community prevalence of all three neglected tropical diseases 12 months following MDA of either DA or IDA. However, there was no additional reduction by adding ivermectin to the standard DA MDA for community burden of disease or for clearance of LF microfilaremia in infected individuals. Further analysis is ongoing to understand these findings.

PHARMACOKINETIC STUDY OF YAWS AND LYMPHATIC FILARIASIS DRUGS INTERACTIONS

Lucy Ninmongo John[1], Catherine Bjerum[2], Christopher King[2], Darryl Murry[3], Oriol Mitja[4], Michael Marks[5]

[1]*National Department of Health, Port Moresby, Papua New Guinea,* [2]*Case Western Reserve University, Cleveland, OH, United States,* [3]*Nebraska University Medical Centre, Omaha, NE, United States,* [4]*University of Barcelona, Barcelona, Spain,* [5]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Pharmacokinetic data are a pre-requisite to the integrated implementation of large-scale mass drug administration (MDA) of medicines for neglected tropical diseases (NTDs). We investigated the safety and drug interactions of integration of azithromycin (AZI), targeting yaws, with the newly approved Ivermectin, Albendazole, Diethylcarbamazine (IDA) regime for LF. A small, randomized, 3-arm (12 subjects per arm) pharmacokinetic interaction study in adult volunteers with equal gender participation was carried out in Lihir Island, Papua New Guinea in September 2018. Healthy adult participants were recruited and randomized to (1) IDA alone (2) AZI alone, and (3) IDA combined with AZI. The primary outcomes were safety (i.e. differences in adverse events (AE)) and drug interactions (i.e. differences in area under the curve (AUC)). Thirty-seven (37) participants were randomized and completed the study. There was no significant difference in the frequency of AEs across study arms (AZI and IDA alone arms 9/12 (75%), co-administration arm 12/13 (92%); p = 0.44). All adverse events were grade 1 and self-limiting. There were no significant drug-drug interactions between the study arms. The mean AUC0-∞ adjusted to dose (hr*ng/mL) in the separate compared to co-administration arms were: Albendazole 273.7 vs 257.4 (difference 16.3, 95%CI -199.7 to 232.3); DEC 25332.4 vs 22477.3 (diff 2855.1, -3872.2 to 9582.3); Ivermectin 2348.7 vs 2009.5 (diff 339.2; -359.1 to 1037.5) and AZI 14820.6 vs 16024.0 (diff -1203.4, -5432.1 to 3025.3). There were no serious adverse events in any of the study arms. Co-administration of AZI with IDA did not show evidence of significant drug-interactions. Our data support the need for a larger field-study on the safety of integrated MDA for the control of NTDs.

1291

A RANDOMIZED CLINICAL TRIAL OF THE SAFETY AND IMMUNOGENICITY OF A 2-DOSE HETEROLOGOUS EBOLA VACCINE REGIMEN WITH AD26.ZEBOV AND MVA-BN®-FILO IN HEALTHY AND HIV+ AFRICAN ADULTS

Houreratou Barry[1], Gaudensia Mutua[2], Hannah Kibuuka[3], Zacchaeus Anywaine[4], Jennifer Serwanga[4], Joseph Blehou[5], Christine Bétard[6], Laura Richert[6], Georgi Shukarev[7], Cynthia Robinson[7], Auguste Gaddah[8], Dirk Heerwegh[8], Viki Bockstal[7], Kerstin Luhn[7], Maarten Leyssen[7], Sirima Sodiomon[9], Omu Anzala[2], Salim Wakabi[3], Nicolas Meda[1], Serge Eholie[9], Macaya Douoguih[8], Rodolphe Thiebaut[6]

The West African 2014-16 Ebola epidemic and current outbreaks in DRC highlight the need for safe and effective Ebola vaccines. A 2-dose prophylactic Ebola vaccine regimen based on Ad26.ZEBOV (Ad26) and MVA-BN®-Filo (MVA) is in late stage clinical development. We report a Phase 2, randomized clinical trial of safety and immunogenicity (EBL2002) conducted in Burkina Faso, Côte d'Ivoire, Kenya and Uganda. Healthy and HIV-infected adults were vaccinated with Ad26 (dose 1) on Day 1 followed by MVA (dose 2) on Day 29 (Group 1), Day 57 (Group 2) or Day 85 (Group 3, healthy adults only). Serious adverse events (AEs) were assessed until study end, AEs until 28 days post-dose and solicited AEs until 7 days post-dose. Binding antibody responses were evaluated by EBOV GP FANG ELISA at baseline, pre-dose 2, 21 days post-dose 2 and 1 year post-dose 1. A total of 668 healthy adults (cohort 1) and 142 HIV-infected adults (cohort 2) were enrolled to receive Ad26, MVA (N=559; N=118, respectively) or placebo (N=109; N=24). All Ad26, MVA regimens were well-tolerated with no significant safety signals. In both cohorts, most solicited AEs were mild to moderate. Serious AEs were considered unrelated to study vaccination. A robust humoral immune response was observed in all healthy adults, with 77-81% responders (defined as >2.5x over positive baseline or >2.5x over LLOQ) post-dose 1 and 98-100% responders post-dose 2. Geometric mean binding antibody concentrations (GMC) at 21 days post-dose 2 ranged from 3085 EU/mL (group 1) to 7518 EU/mL (group 2) and 7300 EU/mL (group 3). In HIV-infected adults, 81-88% responders were detected post-dose 1 and 100% post-dose 2. The GMCs at 21 days post-dose 2 were 4207 EU/mL in group 1 and 5283 in group 2. Binding antibody responses persisted in at least 78% of the healthy and 86% of the HIV-infected adults up to at least 1 year post-dose 1. Ad26, MVA regimens were safe, well tolerated and induced robust immune responses in healthy and HIV+ adults. Humoral responses persisted at least up to 1 year post-vaccination in the majority of participants. Ad26, MVA vaccine regimens may be suitable for vaccination strategies in healthy and HIV-infected individuals.

1292

RVSVΔG-ZEBOV-GP EBOLA VACCINE (MERCK & CO., INC., KENILWORTH, NJ, USA): UPDATED SAFETY, IMMUNOGENICITY, AND EFFICACY

Jakub Simon, Matthew Onorato, Kenneth Liu, Rebecca Grant-Klein, Sheri Dubey, Melissa Hughes, Sharon Rudo, Jayanthi Wolf, Beeth-Ann Coller

Merck & Co., Inc., Kenilworth, NJ, United States

Ebola continues to cause significant morbidity and mortality in regions of the world where the provision of healthcare and vaccine are difficult. The vaccine from Merck & Co., Inc., Kenilworth, NJ, USA is a live recombinant vesicular stomatitis virus (VSV) containing the Zaire Ebola virus glycoprotein (GP) in place of the VSV GP (rVSVΔG-ZEBOV-GP). Vaccine safety, efficacy, or immunogenicity have been evaluated in 13 Phase 1-3 clinical trials, 4 additional Phase 2 clinical trials are planned or ongoing; and expanded access protocols allow for the delivery of vaccine in outbreak situations before licensure. More than 90,000 subjects have received rVSVΔG-ZEBOV-GP vaccine in these clinical trials as of 26 Feb 2019 (time of abstract preparation). Common adverse events included injection-site reactions, fever, fatigue, myalgia, arthralgia, and headache, which were mostly mild to moderate in intensity and of short duration. Arthritis, which was also generally mild to moderate in intensity, has been reported at frequencies <5% in most trials. Immune responses, based on GP antibodies detected by GP-ELISA and neutralizing antibodies detected by plaque reduction neutralization test (PRNT), were detectable at 14 days in most vaccinated subjects, with a high proportion of subjects demonstrating a seroresponse by 28 days. Durability of the anti-GP antibody responses was demonstrated through 24 months. Updated safety, immunogenicity, and efficacy data from across the program will be discussed as well as the use of the vaccine in the context of outbreak response.

1293

SAFETY AND IMMUNOGENICITY OF A 2-DOSE HETEROLOGOUS VACCINE AGAINST EBOLA IN AFRICAN CHILDREN AND ADOLESCENTS

Muhammed Afolabi[1], Gaudensia Mutua[2], Zacchaeus Anywaine[3], Hannah Kibuuka[4], David Ishola[1], Bailah Leigh[5], Frank Baiden[1], Kwabena Owusu-Kyei[1], Omu Anzala[2], Mohamed Samai[1], Joseph Blehou[6], Brian Greenwood[7], Daniela Manno[1], Viki Bockstal[8], Auguste Gaddah[9], Dirk Heerwegh[9], Georgi Shukarev[8], Babajide Keshinro[8], Kerstin Luhn[8], Maarten Leyssen[8], Cynthia Robinson[8], Debby-Watson Jones[1], Rodolphe Thiebaut[10], Macaya Douoguih[9], Houreratou Barry[11]

The West African 2014 Ebola epidemic and the recent outbreaks in DRC highlight the need for safe and effective Ebola vaccines. A heterologous 2-dose prophylactic Ebola vaccination regimen consisting of Ad26.ZEBOV (Ad26) followed by MVA-BN®-Filo (MVA) is now in Phase 3 development. In EBL2002 (Burkina Faso, Cote D'Ivoire, Uganda, Kenya) and EBL3001 (Sierra Leone) studies, three age cohorts (adolescents [12-17 years], children [4-11 years] and toddlers [1-3 years]) were vaccinated with Ad26 or placebo (dose 1) followed by MVA or placebo (dose 2), 28 or 56 days

later (EBL2002) or 56 days later only (EBL3001). Placebo was inactive apart from dose 1 EBL3001 where MenACWY was used. Serious adverse events (SAEs) were assessed until end of study, unsolicited and solicited AEs were assessed until 28 and 7 days post-dose, respectively. Overall, 838 participants (adolescents: 322, children: 324, toddlers: 192, Burkina Faso: 121, Cote D'Ivoire: 30, Uganda: 70, Kenya: 42, Sierra Leone: 575) were enrolled. The Ad26, MVA regimen was well tolerated and no safety signals were identified. Most solicited AEs were mild to moderate. One vaccine-related (active or MenACWY) SAE was reported. In toddlers, the frequency of any febrile response was similar between the Ad26, MVA regimen and the control regimen (range 16.7-22.9%, respectively). In children, the frequency of any fever was 14.7% and 5.6% for active or control, respectively. Overall, frequency of grade 3 fever was <2%. Robust humoral immune responses were observed in all age cohorts. The geometric mean binding antibody concentration (GMC) at day 21 post dose 2 was 22452 EU/mL in toddlers, 10212, 7735 and 17388 EU/mL in children (EBL3001, EBL2002 0,28 and 0,56, respectively), and 9929, 7022 and 13532 EU/mL in adolescents (EBL3001, EBL2002 0,28 and 0,56, respectively). Antibody levels were shown to persist up to 6 months post-MVA in children and adolescents. These data indicate that the Ad26, MVA vaccination regimen is well tolerated and produced robust vaccine-induced immune responses and may be suitable for pediatric populations.

1294

AD26.ZEBOV EBOLA BOOSTER VACCINATION INDUCES A STRONG ANAMNESTIC RESPONSE IN PREVIOUSLY VACCINATED PEOPLE AND PROVIDES RAPID PROTECTION AGAINST LETHAL EBOLA VIRUS CHALLENGE IN NHP

Viki Bockstal[1], Ramon Roozendaal[1], Daniela Manno[2], Zacchaeus Anywaine[3], Muhammed Afolabi[2], Gaudensia Mutua[4], Frank Baiden[2], Houreratou Barry[5], Kwabena Owusu-Kyei[2], David Ishola[2], Brian Greenwood[6], Bailah Leigh[7], Mohamed Samai[7], Omu Anzala[4], Brett Lowe[8], Sodiomon Sirima[9], Cynthia Robinson[1], Auguste Gaddah[10], Dirk Heewegh[10], Laura Solforosi[1], Jenny Hendriks[1], Roland Zahn[1], Kerstin Luhn[1], Rodolphe Thiebaut[11], Deborah Watson-Jones[2], Maarten Leyssen[1], Macaya Douoguih[1]

[1]*Janssen Vaccines & Prevention, Leiden, Netherlands,* [2]*Clinical Research Department, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Medical Research Council/Uganda Virus Research Institute and London School of Hygiene & Tropical Medicine Uganda Research Unit, Entebbe, Uganda,* [4]*KAVI-Institute of Clinical Research University of Nairobi, Nairobi, Kenya,* [5]*Centre MURAZ, Bobo-Dioulasso Dioulasso, Burkina Faso,* [6]*Department of Disease Control, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [7]*College of Medicine and Allied Health Sciences (COMAHS), COMAHS Secretariat, New England, Freetown, Sierra Leone,* [8]*University of Oxford, Oxford, United Kingdom,* [9]*Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Unité de Recherche Clinique de Banfora, Ouagadougou, Burkina Faso,* [10]*Janssen Research & Development, Beerse, Belgium,* [11]*INSERM, U*[1219] *Bordeaux Population Health research centre, and Euclid/F-CRIN Clinical Trials Platform, University Bordeaux, Bordeaux, France*

The heterologous 2-dose vaccine regimen of Ad26.ZEBOV (Ad26), MVA-BN®-Filo (MVA) is well tolerated, induces robust immune responses, persisting antibodies, and protection in NHP against lethal EBOV challenge. As the duration of protection is unknown, the potential benefit of a 'pre-exposure' Ad26 booster vaccination was evaluated in adults who received the 2-dose regimen. We describe human clinical data with immunogenicity and efficacy data obtained in NHP challenge studies. Study EBL2002 took place in Burkina Faso, Côte d'Ivoire, Kenya & Uganda and EBL3001 in Sierra Leone. Healthy adults (N=102) were vaccinated with Ad26 (dose 1) on Day 1 followed by MVA (dose 2) on Day 57 (EBL2002 and 3001), or Day 29 in EBL2002. An Ad26 booster vaccination was given 1 year (EBL2002) or 2 years (EBL3001) post-dose 1. Binding antibody responses were assessed via EBOV GP FANG ELISA at baseline and post vaccination. 21 days post-MVA, binding antibody responses were observed in 98-99% of subjects with geometric mean binding antibody concentrations of 3810 EU/ml (EBL3001) to 7518 EU/ml (EBL2002). Binding antibody responses persisted to 1 year (EBL2002) and 2 years (EBL3001) post-dose 1 with pre-booster GMCs ranging from 279 (EBL3001) to 366 EU/ml (EBL2002). Booster vaccination with Ad26.ZEBOV induced ~40-fold increase in binding antibody levels within 7 days. 21 days post-booster dose, binding antibody levels were ~10-fold greater than peak post-MVA levels (GMC: 29238 EU/ml [EBL3001] and 41643 EU/ml [EBL2002]). To test Ad26 booster vaccination protection against Ebola challenge, NHP were boosted at 17 months post-dose 2, 3 or 7 days before EBOV Kikwit infection (IM, 100 pfu). All NHP boosted with Ad26 3 or 7 days prior to EBOV challenge survived. Both in people and NHP, the 2-dose heterologous Ad26, MVA vaccine regimen induces a strong and lasting memory response that is rapidly re-activated by a booster of Ad26. Exposure to EBOV GP in the context of EBOV infection may lead to a similarly strong anamnestic response. The data also suggest that a booster with Ad26 could be considered for individuals at imminent risk of exposure who previously received the 2-dose regimen.

THE EFFECT OF INTENSIVE CARE TREATMENT BUNDLE ON SERUM CYTOKINES AND VIRAL LOAD DURING EBOLA VIRUS (ZAIRE) INFECTION

Paul W. Blair[1], Karen A. Martins[2], Mark G. Kortepeter[3], Michael W. Keebaugh[2], Isaac L. Downs[2], Anthony P. Cardile[2]

[1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [2]*United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Fort Detrick, MD, United States,* [3]*University of Nebraska College of Public Health, Omaha, NE, United States*

Intensive care treatment bundles (ICTBs) are thought to improve survival from Ebola virus disease (EVD). However, the effects of ICTBs on EVD immunopathogenesis are unknown. Therefore, we sought to evaluate the effects of an ICTB on select cytokine levels and serum viral load in a non-human primate (NHP) model. This post-hoc analysis included an ICTB group (N=5), a levofloxacin plus intravenous fluids group (N=2), and a control group (N=4) of rhesus macaques. NHPs were inoculated intramuscularly with a target dose of 1000 PFU *Zaire ebolavirus* (Kikwit). The ICTB group received intravenous fluids, levofloxacin, acetaminophen, norepinephrine, and hydrocortisone following the onset of fever based on a clinical algorithm. We measured serum IL-6, IL-10, GM-CSF, MCP1, MIP1β, IFNγ, and TNFα levels with a Luminex MAGPIX cytokine panel at baseline and daily starting day 3 post-exposure until euthanasia. Linear mixed effects regression models were selected with random slopes and intercepts, using Akaike information criterion, to evaluate the effects of ICTB on serum $\log_{10}$ viral load and serum $\log_{10}$ cytokine levels. These models included an interaction term between days post-fever and treatment group, and models were adjusted for days post-fever and baseline dependent variable values. When evaluating the effect of a supportive care treatment bundle, there were decreases in IL-6 -0.44 $\log_{10}$ pg/mL per day (95% CI: -0.77, -0.10; p-value = 0.01), IFNγ -0.20 $\log_{10}$ pg/mL per day (p-value = 0.005), MCP1 -0.19 $\log_{10}$ pg/mL per day (p-value = 0.006) and GM-CSF -0.11 $\log_{10}$ pg/mL per day (95% CI: -0.19, -0.02; p-value = 0.01) compared to controls. Surprisingly, viral load was observed to decrease at a rate of -1.16 $\log_{10}$ GE/mL per day (95% CI: -1.80, -0.51; p-value < 0.001) in the supportive care group compared to controls. Further research is needed to evaluate the effect of immunomodulating therapies on viral dissemination during EVD.

1296

EBOLA EDUCATIONAL OUTREACH LED BY LOCAL MEDICAL STUDENTS IN EASTERN DEMOCRATIC REPUBLIC OF CONGO

Michael T. Hawkes[1], Kasereka Masumbuko Claude[2]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Université Catholique du Graben, Butembo, Democratic Republic of the Congo*

The second largest outbreak of Ebolavirus is currently ongoing in Eastern DRC. The epidemic is characterized by social resistance to foreign-led response teams. Trusted local health practitioners, including medical

students, may be valuable social mobilizers in this challenging context. We report on a student-led educational campaign to increase community awareness & engagement in EVD control efforts. We evaluated student and community participant satisfaction using standardized questionnaires. The outreach was conducted in November 2018, involving 600 students and reaching 5-10,000 community members with parades, speeches, branded banners and T-shirts, and interpersonal interactions in public spaces. Key messages, linked to previously identified resistant attitudes, included: "Ebola exists in Butembo," "Bring infected family members to the Ebola Treatment Unit," and "Leave burials to the official team." Medical students (n=355) and community participants (n=319) evaluated the outreach campaign. Satisfaction was high: 320 (90%) students agreed that medical students could contribute to the EVD response effort, and 233 (73%) community members agreed that the students had helped them understand Ebola in the area. Lower satisfaction scores were associated with self-reported "resistant" attitudes (e.g., intention to hide infected family member from authorities, ρ=-0.25, p<0.0001), denial of the existence of Ebola in the area (ρ=-0.17, p=0.0018), and mistrust of the foreign response team (e.g., belief in mercenary motive, ρ=-0.11, p=0.042). Higher satisfaction scores were associated with the view that local engagement was critical to ending the epidemic (ρ=+0.13, p=0.017). Both students (77%) and community members (71%) agreed that they were more motivated to combat Ebola as a result of the outreach, suggesting that the activities fostered empowerment. Medical students can lead satisfactory community engagement and educational activities during an EVD epidemic. As trusted local health agents, medical students may be valuable allies in building public trust and cooperation in this epidemic complicated by social resistance.

1297

FINDINGS FROM POST EBOLA SURVEILLANCE: ACUTE FEBRILE ILLNESS IN TWO HIGH VOLUME HEALTHCARE FACILITIES IN MONROVIA, LIBERIA, 2019

Lekilay Tehmeh[1], Elijah Paa Edu-Quansah[2], Terrence Lo[3], Daniel Martin[3], Jolie Dennis[4], Gulu Gwesa[4], John Dogba[5], April Baller[6], Eric Houpt[7], Jie Liu[7], Darwin Operario[7], Maame Pokuah Amo-Addae[2], Davis Ashaba[2], Barry Fields[3], Mosoka Fallah[5], Desmond Williams[4]

[1]*Ministry of Health, Monrovia, Liberia,* [2]*African Field Epidemiology Network, Monrovia, Liberia,* [3]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Centers for Disease Control and Prevention, Monrovia, Liberia,* [5]*National Public Health Institute of Liberia, Monrovia, Liberia,* [6]*World Health Organization, Monrovia, Liberia,* [7]*University of Virginia, Charlottesville, VA, United States*

Clinical diagnoses for fever-causing diseases in Liberia have been limited to malaria and typhoid fever. With the recent emergence of Ebola, there is a need to expand the search for other known and unknown fever-causing pathogens, particularly for those with epidemic and high consequence potential, that may be circulating in Liberia. We report here our findings from acute febrile illness (AFI) surveillance from a hospital and health center in urban Monrovia that both saw Ebola patients in the 2014 epidemic. From December 2018 through March 2019, outpatients and inpatients ≥2 years with documented temperatures ≥37.5 °C or a history of fever within the previous 7 days were enrolled from two high volume health facilities. Blood samples were collected and tested at the National Reference Laboratory using PCR-based TaqMan Array Cards (TAC) with AFI assays to detect 27 pathogens. Demographics and exposure data were collected from participants. Among the 257 enrolled participants, the median age was 16 years (range: 2-83 years), 176 (68%) were female, of which 77 (44%) were pregnant. Preliminary results from 257 samples yielded 41% positivity on at least one target. Malaria was most commonly detected: 97 (38%) were *Plasmodium spp.* with 84 (33%) *Plasmodium falciparum*. Malaria cases were primarily female [n=74 (76%)] with 48 (65%) of them pregnant. Other pathogens detected included 5 (2%) rickettsia, 6 (2%) dengue, 2 (1%) *Streptococcus pneumoniae*, and 2 (1%) Lassa fever. Co-infections with malaria were found among 5 (2%) cases. One Lassa fever case presented without hemorrhagic symptoms and would not have been otherwise suspected. The most common AFI pathogens detected were malaria, but dengue and rickettsia also were detected: pathogens that are newly identified in Liberia. This suggests a need for increased focus on these pathogens. Patient management also should consider possible co-infections with malaria. As Liberia continues to recover post-Ebola, early detection of febrile illness causing pathogens is critical and addressing public health threats must remain a priority.

1298

MODELING AND MAPPING PATHOGEN-SPECIFIC ENTERIC INFECTIOUS DISEASE RISK USING EARTH OBSERVATION-DERIVED AND HOUSEHOLD-LEVEL COVARIATES

Despite considerable progress in recent years, diarrheal disease remains a major cause of mortality and morbidity in childhood and its sequelae lead to poor health and economic outcomes in adulthood. New diagnostic methods, as well a number of ambitious multi-site, population-based studies have started to shed light on the pathogen-specific etiologies of diarreal disease, revealing a complex picture. Numerous microbial agents each with distinct biologies that interact with host factors and environmental and meteorological risk factors cause enteric infections which may be symptomatic or sub-clinical. Under a NASA-funded collaboration, data from multiple multi-site studies have been compiled into a dataset consisting of results from around 90,000 stool samples from 33,000 infants in 28 different locations around the world. Presence of specific enteric pathogens in stool samples was ascertained by multiple diagnostic methods, and samples were matched by date and location to earth observation-derived estimates of hydrometeorological parameters extracted from global models. These along with individual- and household-level covariates were used with modified Poisson regression to model their associations with symptomatic and asymptomatic infections with specific enteric pathogens. This approach is able to explain up to 22% of the variability in a single outcome (rotavirus). The results are being used to create high resolution maps of pathogen-specific enteric disease transmission risk, which will be made available through an online platform for use in programmatic and policy decision-making.

THE GEOGRAPHIC DISTRIBUTION OF CHOLERA IN BANGLADESH

Sonia T. Hegde[1], Ashraf Khan[2], Fahima Chowdhury[2], Md. Taufiqul Islam[2], Joshua Kaminsky[1], Emily S. Gurley[1], Justin Lessler[1], Firdausi Qadri[2], Andrew Azman[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh*

Meeting the ambitious WHO-backed target of reducing cholera as a public health threat by 2030 will require significant reductions in cholera incidence in hyper endemic countries like Bangladesh. Despite years of research on cholera, we know little about the incidence and variability of cholera across the country. Most data informing cholera burden estimates

are based on passive surveillance of acute watery diarrhea cases, which are rarely laboratory confirmed. Using detailed data from systematic laboratory confirmation of acute watery diarrhea cases at 22 sentinel surveillance hospitals across Bangladesh from 2014-2018 with data on acute watery diarrhea visits from all 64 district Ministry of Health facilities from 2014-2018, we sought to estimate cholera incidence to better characterize the geographic distribution of disease and provide critical information for the development of the national cholera control strategy in Bangladesh. We estimated country-wide annual incidence and incidence at a 7 x 7 km grid cell level using generalized additive models in a Bayesian framework with spatially correlated errors, and identified priority areas for future surveillance efforts where both incidence estimates and their degree of statistical uncertainty are high. Considering an incidence of ≥ 1.5 per 1,000 as high risk, preliminary estimates 23.1 million (14.3%) of the Bangladesh population live in high risk cholera areas, while 68.9 million (42.8%) live in moderate risk cholera areas (incidence of ≥ 0.5 to 1.5 per 1,000). We identified high-risk areas in Central (south of Dhaka), Western (near Rajshahi district), and Southeastern (near Chittagong district) Bangladesh. This fine-scale incidence mapping provides a new framework for combining detailed sentinel surveillance data with national datasets on diarrhea and can lead to efficient targeting of oral cholera vaccine, water, sanitation, and hygiene interventions. Only with continued surveillance can we improve our understanding of high-burden cholera hotspots, track changes in incidence and further improve the efficiency of cholera interventions.

GEOGRAPHIC VARIATION IN ORAL REHYDRATION THERAPY COVERAGE IN LOW- AND MIDDLE-INCOME COUNTRIES, 2000—2017

Kirsten E. Wiens, Paulina Lindstedt, Mathew Baumann, Brigette Blacker, Aniruddha Deshpande, Simon I. Hay, Robert C. Reiner, Jr

University of Washington, Seattle, WA, United States

Oral rehydration solution (ORS) is a treatment for diarrhea with the potential to dramatically reduce child mortality, yet less than half of children with diarrhea in low- and middle-income countries (LMICs) received ORS in 2017. Recommended home fluids (RHF) are an alternative to ORS; however, it is unclear whether RHF prevent child mortality. Previous studies have shown considerable variation between countries in ORS and RHF use, but subnational distribution patterns of ORS and RHF coverage are unknown. The aim of this study was to produce the first high-resolution geospatial estimates of oral rehydration therapy (ORT) coverage (use of ORS and/or RHF) in LMICs. We used Bayesian geostatistical modeling techniques and an extensive geolocated dataset to estimate the proportion of children under 5 with diarrhea who received ORS or RHF in LMICs from 2000 to 2017. Wherever possible, we tailored these methods to take into account factors that may contribute to variation in ORT coverage, using spatially-resolved covariates to estimate for areas with sparse data. These techniques produced estimates on continuous continent-wide surfaces, which we aggregated to policy-relevant administrative units. We found that, while ORS use among children with diarrhea increased in most locations, coverage remained below 50% in many administrative units. We identified various countries with even subnational distributions of ORS and RHF; however, we also identified countries with broad inequalities across geographic subdivisions, including countries such as Nigeria, Sudan, and Afghanistan where diarrhea mortality rates remain high. Moreover, increases in ORS coverage over time were correlated with declines in RHF coverage and declines in diarrheal mortality in the majority of administrative units. These results, combined with detailed subnational estimates of diarrheal mortality, can assist in determining where new or increased efforts to improve ORS coverage are needed. Over 50 years after the discovery that led to this simplest of therapies, large gains in reducing mortality could be made by reducing geographic inequalities in ORS coverage.

THE PERSISTENT IMPACT OF THE EBOLA EPIDEMIC ON HEALTH SEEKING BEHAVIOR IN KENEMA, SIERRA LEONE

Mikaela R. Koch[1], Lansana Kanneh[2], Foday Alhasan[2], Robert F. Garry[3], Jeffrey G. Shaffer[3], John S. Schieffelin[3], Donald S. Grant[4]

[1]*Stanford University, Stanford, CA, United States,* [2]*Viral Hemorrhagic Fever Program, Kenema Government Hospital, Kenema, Sierra Leone,* [3]*Tulane University, New Orleans, LA, United States,* [4]*Ministry of Health and Sanitation, Freetown, Sierra Leone*

The West African Ebola epidemic of 2014-2015 killed over 11,000 people and devastated healthcare infrastructure in Liberia, Guinea, and Sierra Leone. Whether, and how, the epidemic impacted health-seeking behavior (HSB) among citizens in these Lassa fever (LF) endemic areas is unknown. Kenema Government Hospital (KGH) is located in the Eastern Province of Sierra Leone, a region considered to have the highest per capita incidence of LF in the world. An advanced clinical and laboratory research infrastructure has been established at KGH, which serves as the primary referral hospital for LF cases in the region. KGH was also an early epicenter of the Ebola outbreak. The numbers of LF patients presenting to KGH was similar from 2008-2012. A retrospective review of KGH records from 2012-2017, analyzed the number of suspected LF patients, number admitted, and noted age, sex, outcome, and district of residence. Trend and proportion analysis showed a statistically significant decrease in suspected Lassa cases presenting to KGH from pre- to post- 2014/2015 Ebola epidemic (2012-2013 vs 2016-2017, with Pearson Correlation -.934 (CI -.9460 to -.9406). The decline pre- vs post- Ebola was statistically significant across all age groups. Furthermore, to assess attitudes of HSB in the region, a validated HSB questionnaire was adapted and delivered to 194 residents from 8 villages in Kenema District living within 32 miles of KGH. 78% of respondents stated they felt hospitals were safer post Ebola with no meaningful difference between religious background, age, gender or education. An accurate assessment of HSB can influence how local health care systems provide care, and, in turn, improve health care delivery and hospital experiences. Post Ebola epidemic, HSB as measured by admissions to the LF ward declined and overall confidence was low. To improve the care in regions confronted with highly pathogenic hemorrhagic fevers, re-establishing trust in health care services will require efforts beyond rebuilding infrastructure/personnel and require concerted efforts to rebuild the trust of local residents who may be wary of seeking care post epidemic.

BEHAVIORAL, ECOLOGICAL AND SOCIO-DEMOGRAPHIC CORRELATES FOR VISCERAL LEISHMANIASIS TRANSMISSION IN BARINGO, KENYA

Hellen Nyakundi[1], Mwatela Kitondo[1], Moses Atuko[2], Elijah Elijah[2], Joseph K. Wang'ombe[1], Damaris Matoke[3], Daniel Masiga[4], Richard Wamai[5]

[1]*School of Public Health, University of Nairobi, Nairobi, Kenya,* [2]*Kaperur Community-Based Organization, Chemolingot, Kenya,* [3]*Kenya Medical Research Institute, Nairobi, Kenya,* [4]*International Centre of Insect Physiology and Ecology, Nairobi, Kenya,* [5]*Northeastern University, Boston, MA, United States*

Visceral leishmaniasis (VL) or Kala-azar is among the neglected tropical diseases (NTDs) endemic in Kenya. The 2015-2020 national NTD program identifies a critical need to determine behavioral correlates of VL and its clinical, epidemiological, entomological and health systems statuses to drive control interventions in the country. Our study sought to determine the behavioral, ecological and socio-economic characteristics of household members in VL endemic remote rural villages in East Pokot Baringo. We used a cross-sectional design to select four high-burden village clusters from a list of hospital records of all villages with diagnosed and treated cases of VL in year 2017-2018. The study sites were assumed to have the greatest transmission risk and increased potential to benefit from control strategies. A knowledge, attitudes and practices (KAP) survey was

implemented using a standard household questionnaire, key informant interviews and focus group discussions. Data analysis was with Epi-Info and excel spreadsheets. A total of 139 households participated in the KAP survey with a slightly larger female representation (72 /52%). Most respondents (84%) were living below the national poverty line and were illiterate (116/83.4%). Most (129/93%) were aware of Kala-azar and of these 110 (79%) knew of someone who had the disease and 8 (5.8%) knew of someone who had died as a result. A large majority (101/73%) knew there is a cure and also knew where to seek treatment. What worried respondents most about Kala-azar is fear of death (28/20%) and challenges of accessing treatment due to distance and cost of transport (44/32%). A socio-ecological observation reveals most houses (82%) had stick walls and grass-thatched roofs. Termite mounds were present in all households. Acacia trees are the main vegetation. These factors make this semi-arid area conducive for sandfly vector breeding and human contact. In conclusion: KAP studies are important determinants of community participation in the control of Kala-azar. An integrated control and prevention strategy using household dynamics will have the greatest impact.

1303

DECLINING MASS DRUG ADMINISTRATION COVERAGE FOR LYMPHATIC FILARIASIS IN PORT-AU-PRINCE, HAITI: A PROGRAMMATIC CASE STUDY AND RECOMMENDATIONS

Breanna K. Wodnik[1], Didié H. Louis[2], Michel Joseph[3], Lee T. Wilkers[1], Susan D. Landskroener[1], Jean F. Lemoine[2], James V. Lavery[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Ministry of Public Health and Population, Port-au-Prince, Haiti,* [3]*Radio Caraibes, Port-au-Prince, Haiti*

The World Health Organization (WHO) defines an effective round of mass drug administration (MDA) for lymphatic filariasis (LF) as one that reaches at least 65% of the target population. In its first round of MDA in 2011-2012, the National Program to Eliminate LF in Haiti achieved a 79% epidemiological coverage in urban Port-au-Prince. In 2013, coverage dropped below the WHO threshold and has declined year-over-year to a low of 41% in 2017. We conducted a retrospective qualitative case study to identify key factors behind the year-over-year decline in coverage in Port-au-Prince and ways to address them. Our findings suggest that the main contributors to the decline in MDA coverage, year-over-year, appear to be the absence of effective documentation of practices, reporting, analysis, and program quality improvement—i.e., learning mechanisms—within the program's design and implementation strategy. In particular, the lack of capacity to identify and resolve challenges for MDA drug distribution teams, and to address aspects of the program that had a significant negative influence on prospective participants' experience of the program, makes the progressive decline in coverage seem almost inevitable. In addition to their contribution to the program's failure to meet its coverage targets, these deficits have resulted in a high cost for the program in both lost momentum and depleted morale. Through a proposed operating logic model, we explore how the pathway from program inputs to outcomes is influenced by a wide array of mediating factors, which shape potential participants' experience of the program and, in turn, influence their reasoning and decisions to take, or not take, the pills. Our model suggests that the decisions and behavior of individuals are a reflection of their overall experience of the program itself, mediated through a host of contextual factors, and not simply the expression of a fixed choice or preference. This holistic approach offers a novel and potentially valuable framing for the planning and evaluation of MDA strategies for LF and other diseases, and may be applicable in a variety of global health programs.

1304

GENDER EQUITY IN MASS DRUG ADMINISTRATION CAMPAIGN FOR NEGLECTED TROPICAL DISEASES (NTDS) IN MALI

Mahamadou Traoré[1], Massitan Dembélé[1], Benoit Dembele[2], Boubacar Guindo[2], Mama Niélé Doumbia[2], Seydou Goita[2], Modibo Keita[2], Abdoulaye Guindo[1], Adboul Karim Sidibé[1], Steven D. Reid[3], Fama Kondo[2], Mohamed Lamine Yattara[2], Yaobi Zhang[4]

[1]*National Direction of Health, Ministry of Health and Public Hygiene, Bamako, Mali,* [2]*Helen Keller International, Bamako, Mali,* [3]*Helen Keller International, New York, NY, United States,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Mali has made significant progress in the control and elimination of NTDs through mass drug administration (MDA). Mali adopted community-based and school-based platforms for delivering treatments to eligible populations in endemic health districts (HDs). MDAs target the minimum required treatment coverage for each NTD in the general population without a specific emphasis on gender. To understand gender equity during MDA in Mali, we analyzed the reported MDA data in 2016, which had the most complete integrated MDA data for lymphatic filariasis (LF), onchocerciasis and soil transmitted helminths and MDA for schistosomiasis (SCH) since 2012. District-level coverage data were analyzed in 61 districts (HDs) for LF MDA and 47 HDs for SCH MDA and overall, in urban vs rural areas and secure vs unsecure areas. The Kruskal Wallis test was used to compare MDA coverage. For LF MDA in 61 HDs, the median coverage for females was 77% (range: 5-100%), which was higher than the 74% coverage (range: 6-98%) reported for males ($p<0.01$). For SCH MDA the median coverage was 91% (range: 36-229%) for girls and 90% (range: 34-253%) for boys ($p>0.05$). In urban areas, the LF median coverage was 79% (range: 37-100%) for females and 79% (range: 23-98%) for males and in rural areas, 75% (range: 5-91%) for females and 71% (range: 6-90%) for males (both $p>0.05$). For SCH MDA, the median coverage was 98% (range: 71-229%) for females and 92% (range: 65-253%) for males in urban areas, and 90% (range: 36-123%) for females and 84% (range: 34-125%) for males in rural areas (both $p>0.05$). There was also no statistical difference in coverage between females and males in secure and insecure HDs: LF females 79% (range: 37-100%) and males 76% (range: 23-98%) in secure areas and females 66% (range: 5-100%) and males 64% (range: 6-86%) in insecure areas, and SCH females 94% (range: 36-130%) and males 92% (range: 34-132%) in secure areas and females 84% (range: 40-229%) and males 81.5% (range: 60-253%) in insecure areas. The results indicate that current MDA strategies in Mali successfully reached both males and females in the eligible populations and there is no major gender imbalance during MDA intervention.

1305

ESTIMATION OF INCIDENCE RATE OF MORTALITY FOR ANTILEISHMANIAL THERAPIES: A SYSTEMATIC REVIEW OF PUBLISHED LITERATURE FROM 1980 TO 2018

Sauman Singh[1], Prabin Dahal[1], Roland Ngu[1], Brittany Maguire[1], Piero Olliaro[1], Kasia Stepniewska[1], Christine Halleux[2], Fabiana Alves[3]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*World Health Organization, Geneva, Switzerland,* [3]*DNDi, Geneva, Switzerland*

The safety of antileishmanial chemotherapies is not well characterised and reported, despite historical records of poor tolerability and serious adverse events. This systematic review aimed to estimate the incidence rate of mortality in patients treated with antileishmanial therapies within 30 days of commencing therapy. We identified therapeutic clinical trials for visceral leishmaniasis published between 1980 and 2018 by searching four databases: clinicaltrials.gov, WHO ICTRP, Cochrane Library, and PubMed. We estimated the incidence rate of death within the first 30 days of treatment initiation for each of the study regimen with confidence interval using exact Poisson method. The pooled incidence rate, expressed per 1,000 person-days, was derived from random effects

meta-analysis after applying continuity corrections to handle structural zeros. We identified 152 published studies (1980 to 2018) enrolling 28,593 patients in 339 treatment arms. Amphotericin B formulations were administered in 147 (43.4%) arms (10,544 patients), pentavalent antimonial in 73 (21.5%, 7,054 patients), and combination therapies in 35 (10.3%, 2,609 patients). In all, 382 deaths were reported during treatment and follow-up, of which 212 (55.5%) occurred during the first 30 days of starting treatment. The overall expected incidence rate of death regardless of the treatment regimen was estimated at 0.656 [95% CI: 0.550 - 0.783] per 1,000 person-days from 291 arms which excluded (or did not describe) HIV patients. This was 2-fold higher in study arms with HIV patients: 1.494 [95% CI: 0.793-2.812] from 13 arms. The incidence rates were comparable between treatment arms: 0.593 [95% CI: 0.489 - 0.719] for Amphotericin B formulations, 0.813 [95% CI: 0.540 - 1.224] for pentavalent antimonial, and 0.630 [95% CI: 0.415 - 0.956] for the combination therapies. This comprehensive review allowed estimating the incidence rate of mortality in VL patients treated with a range of therapies while highlighting the heterogeneity in reporting death post treatment under trial settings and the need for more systematic pharmacovigilance reporting.

1306

LOCAL AND REGIONAL TRANSMISSION DYNAMICS OF VISCERAL LEISHMANIASIS AND INDICATORS OF ONGOING TRANSMISSION

Luc E. Coffeng, Johanna Munoz, Epke A. Le Rutte, Sake J. De Vlas

Erasmus MC, University Medical Center, Rotterdam, Netherlands

Visceral leishmaniasis (VL) is currently targeted to be eliminated as a public health problem on the Indian subcontinent (ISC), which is defined as less than 1 reported case per 10,000 capita per year at sub-district level. However, it is not well understood whether and how VL transmission on the ISC will continue once this target is reached. Mathematical models have highlighted how VL transmission on the ISC may continue in the presence of potential reservoirs of infection such as 1) cases of post-kala-azar dermal leishmaniasis (PKDL), who have been shown to be infective towards sandflies, and 2) asymptomatically infected individuals (if infectious towards sandflies). However, the main limitation of current mathematical models is that they do not yet correctly capture VL transmission dynamics in finite populations and/or when the number of cases is low. Therefore, to investigate the stability of VL transmission in finite populations, we developed a stochastic model for transmission and control of VL. Using the model, we simulated VL transmission dynamics under various assumptions about transmission conditions, human mobility between villages in a region, the risk of developing PKDL, and infectiousness of asymptomatic cases. We then assessed to what extent reported numbers of cases and prevalence of DAT and PCR positivity are indicative of ongoing transmission. Model predictions suggest that with intervention strategies as currently recommended by the World Health Organization, VL transmission may be sustained at levels below the current target (i.e. with few or no reported clinical cases), with small local outbreaks that move around a larger region over the course of years. Model results further suggest that the combination of time since last VL case combined with current prevalence of DAT or PCR positivity is predictive of ongoing transmission. If PKDL is the only reservoir of infection outside of VL cases, intervention strategies targeting the identification and treatment of PKDL cases would significantly increase the chance of interrupting VL transmission.

1307

DEEP SEQUENCING TO EXPLORE CONGENITAL TRANSMISSION OF CHAGAS DISEASE

Natalie M. Bowman[1], Freddy Tinajeros[2], Oksana Kharabora[1], Edith Malaga Machaca[3], Manuela Verastegui[3], Nery Tirabante[3], Maria del Carmen Meduina[4], Billy Scola[2], Cristian Roca[3], Edward Valencia Ayala[3], Steven R. Meshnick[1], Jonathan J. Juliano[1], Robert H. Gilman[5]

Nearly 6 million people remain infected with *Trypanosoma cruzi*, the agent of Chagas disease, and thousands of infected infants may be born each year. The pathogenesis of congenital Chagas disease is not well understood, and clinicians remain unable to predict which ~5% of infected women will vertically transmit the parasite to their newborns. Since May 2016, our group has screened all consenting women delivering at Hospital Maternidad in Santa Cruz, Bolivia for Chagas disease with a rapid serological test (InBios), with positive tests confirmed by IHA and/or ELISA. Infants of *T. cruzi*-infected women provided samples of umbilical cord blood and peripheral blood at 1, 3, 9, and 12 months. Infant samples were tested by micromethod, quantitative polymerase chain reaction (qPCR), and serology. *T. cruzi* DNA was extracted from blood clot and quantified by qPCR using Cruzi 1 and 2 primers and Cruzi 3 probe. From selected parasitemic maternal and infant samples, we amplified the single-copy nuclear gene *tcsc5d*; amplicons of 684 bp were barcoded and purified then sequenced (2x300) on Illumina MiSeq. Sequences were clustered into haplotypes using a heuristic clustering algorithm in the software SeekDeep. Alpha and beta diversity metrics were calculated with EstimateS. More than 5000 women have been enrolled, and 21.5% were seropositive for *T. cruzi*. 58 infants were confirmed infected; these were offered treatment with benznidazole, and qPCR was used to assess for cure. Infected women were 3 times more likely to transmit to twins than to singletons. We sequenced 74 samples from 32 live infants (19 male, 13 female) including 5 sets of twins, 23 mother-infant pairs, and 14 infants with longitudinal samples. Mean age of mothers was 28 years (range 15-40) and only one had been treated for Chagas disease. In one infant, we found evidence of reinfection by a different strain of *T. cruzi* several months after successful treatment, indicating ongoing vector-borne transmission. We have sequenced the largest sample of mother-infant dyads of which we are aware, and our study is unique in its application of sequencing to evaluate *T. cruzi* transmission in multiple sets of twins.

SEQUENCE HETEROGENEITY IN *LEISHMANIA* RNA VIRUS-1 (LRV-1) DETECTED IN STRAINS OF LEISHMANIA VIANNIA SPP.

Ruwandi Kariyawasam[1], Rachel Lau[2], Eric Shao[3], Braulio M. Valencia[4], Alejandro Llanos-Cuentas[5], Andrea Boggild[3]

[1]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario Laboratories, Toronto, ON, Canada,* [3]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [4]*Kirby Institute, University of New South Wales, Sydney, Australia,* [5]*Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru*

Leishmania RNA Virus (LRV) is classified as a Group III dsRNA virus belonging to the family *Totiviridae,* containing a 5284 nucleotide sequence. LRV-1 in the New World has 14 subtypes (LRV-1-1 - LRV-1-14) predominantly isolated from the Amazon basin. Since the detection of LRV-1 in a patient with cutaneous satellite lesions and lymphatic involvement after visiting Suriname, the notion that LRV-1 in the parasite might be causing more severe disease has been the focus of evaluation over the past few decades. We wanted to understand whether sequence heterogeneity within the LRV-1 virus could contribute to the severe

phenotype observed in some patients infected by the *Leishmania Viannia* spp. Nucleic acid was extracted from clinical cultured cells for species identification and LRV-1 detection using quantitative real-time PCR (qPCR). Cultures positive by qPCR were confirmed by end-point PCR and Sanger Sequencing using primers targeting LRV-1-1 and LRV-1-4 subtypes primarily known to circulate in Latin America. Of 109 available clinical cultures, 32 were positive by qPCR. To date, 3/32 (9.4%) LRV-1 positive clinical cultures have been confirmed by end-point PCR with sufficient sequence product. The following species were identified: 2/3 (67%) *L. V. braziliensis* and 1/3 (33%) *L. V. panamensis*. A phylogenetic molecular analysis was performed using the Maximum Likelihood method (BioEdit version 7.2.5) post ClustalW Multiple alignment using the three previously mentioned clinical cultures, ATCC© 50126 *L. V. guyanensis* and NCBI reference genomes: NC002063.1 and NC00306.1. An unrooted tree was produced 2 distinct clusters whereby the 2 LRV-1 positive *L. V. braziliensis* and 1 ATCC© 50126 *L. V. guyanensis* strains were branched from the same node (length = 0.08639, $p < 0.01$) while the LRV-1 positive *L. V. panamensis,* NC00306.4 and NC002063.1 strains branched from an unrelated node (length = 1.23789, $p < 0.01$). Further analysis of the remaining LRV-1 positive cultures will provide more insight into the divergence of LRV-1 between species as well as implications into the severity of disease in ATL.

TRANSMISSION DYNAMICS OF VISCERAL LEISHMANIASIS IN INDIA: ROLE OF ASYMPTOMATICALLY INFECTED INDIVIDUALS

Shyam Sundar

Institute of Medical Sciences, Banaras Hindu University, Varanasi, India

Visceral leishmaniasis (VL) is the most fatal form of leishmaniasis caused by protozoan parasite *Leishmania donovani* complex and transmitted by the bites of blood sucking vector sand fly *Phlebotomous argentipes*. Contribution of the various subsets of infected individuals in propagating disease transmission, especially those without clinical illness, is unknown. In the present study we investigated the role of *L. donovani* exposed individuals from across the infection spectrum in driving the transmission in an endemic area for VL. Direct xenodiagnosis using 10 male and 30 female *P. argentipes* sand flies was performed on each of the active VL patients (n=74), before and after successful treatment, Asymptomatic (with high antibody titres) individuals (n=183) and Post Kala-azar Dermal Leishmaniasis (PKDL) patients (n=26). After 60 hours of blood meal, flies were dissected and infections in sand flies was evaluated by microscopy. We found that sand fly infection positively correlated with severity of disease in VL patients, ranging from 0.4 % (95% CI 0.14-1.44) to 24.02 % (95% CI 3.76- 71.92) in splenic scores 1+ to 5+, respectively. After 30 days of successful treatment with a single dose (10 mg/kg) of liposomal amphotericin B, none of these patients were able to transmit infection to the sand flies. PKDL patients were infective to sand flies, however, nodular PKDL forms are more infective to sand flies (56.3% p=0.031, two sided) than macular forms (p=0.5, two sided). None (of 183) of the asymptomatic subjects transmitted infection to sand flies, and assuming that if we had fed more flies on the subjects they still would not have transmitted, then the estimated probability that an asymptomatic subject can transmit is 0 with 95% CI (0-0.023). Results of this study confirms that while active VL and PKDL patients transmit infection in the vector, asymptomatic individuals play little role in disease transmission.

1310

NOVEL DETECTION OF *LEISHMANIA* RNA VIRUS-1 (LRV-1) IN *LEISHMANIA VIANNIA PANAMENSIS* CLINICAL ISOLATES

Ruwandi Kariyawasam[1], Rachel Lau[2], Braulio M. Valencia[3], Alejandro Llanos-Cuentas[4], Andrea Boggild[5]

[1]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario Laboratories, Toronto, ON, Canada,* [3]*Kirby Institute, University of New South Wales, Sydney, Australia,* [4]*Instituto de Medicina Tropical "Alexander von Humboldt", Lima, Peru,* [5]*Tropical Disease Unit, Toronto General Hospital, Toronto, ON, Canada*

American tegumentary leishmaniasis (ATL) comprises a discrete set of clinical presentations of leishmaniasis endemic to Central and South America. *Leishmania*RNA virus-1 (LRV-1) is a double stranded RNA virus identified in 20-25% of the *Leishmania Viannia*braziliensis and *L. V. guyanensis,* and is believed to be a predictive biomarker of severe ATL. We describe the novel detection of LRV-1 in *L. V. panamensis*and its associations with clinical phenotypes of ATL. Clinical isolates were identified from Public Health Ontario Laboratory (PHOL) and the *Leishmania* Clinic of the Instituto de Medicina Tropical "Alexander von Humboldt" between 2012 and 2018. Banked clinical isolates were species identified by PCR, RFLP analysis, and Sanger sequencing. Clinical isolates identified as *L. V. panamensis*were screened for LRV-1 by real-time PCR. Patient isolates were stratified according to clinical phenotype: localized cutaneous leishmaniasis (LCL) was defined as "non-severe" ATL, whereas "severe ATL" was defined as mucosal or mucocutaneous leishmaniasis (ML/MCL); erythematous, purulent, or painful ulcers and/or lymphatic involvement (inflammatory ulcers); or multifocal/disseminated ulcers (≥ 4 in ≥2 anatomic sites). Of 22 patients with confirmed *L. V. panamensis*, 9 (41%), 7 (32%), 5 (23%), and 1 (0.5%) had travel history to or resided in: Peru, Costa Rica, Ecuador and Panama, respectively. Nine (41%) patients had the severe phenotype while 13 (59%) had a non-severe phenotype. Three (33%) of 9 severe cases and 4 (31%) of 13 non-severe cases were positive for LRV-1, respectively (p=0.90). Median age of patients did not differ by clinical phenotype (median age 45.8 years in severe ATL vs. 31.9 years in non-severe ATL, p=0.09), or LRV-1 status (median age 34.1 years in LRV-1 positive patients vs. 38.3 years in LRV-1 negative patients, p=0.64). No differences in sex were observed for clinical phenotype (p=0.60) and LRV-1 status (p=0.52). We describe the novel detection of LRV-1 in*L. V. panamensis,* a species that has been documented predominantly in Central America.

PREVALENCE OF CHRONIC CO-MORBIDITIES AMONG PEOPLE WITH CHAGAS DISEASE IN LOS ANGELES, CALIFORNIA

Salvador Hernandez, Colin J. Forsyth, Gisele Munoz, José Amadeo Flores, Michelle Toruno Alonso, Lesner Suncin Rivas, Sheba K. Meymandi

Center of Excellence for Chagas Disease, Sylmar, CA, United States

Estimates suggest over 300,000 people with Chagas disease (CD) live in the United States, with 30-45,000 suffering from Chagas cardiomyopathy. In Los Angeles, the prevalence of CD in the Latin America-born population was found to be 1.24% in a large-scale screening study of 4,755 individuals, and was 19% in a separate study of individuals with nonischemic cardiomyopathy. However, little is known about the prevalence of co-morbidities in this population. In this study, via chart review, we assessed the prevalence of seven chronic co-morbidities in a convenience sample of 216 patients with CD at the Center of Excellence for Chagas Disease (CECD) at Olive View-UCLA Medical Center in Los Angeles. Over half the sample (57.4%) was female; the most frequent countries of origin were El Salvador (49.5%) and Mexico (28.2%). Mean age at diagnosis was 50.5. Three in ten patients had developed chronic Chagas cardiomyopathy. The most common co-morbidities were hypertension (40.2%), obesity (32.3%), hyperlipidemia (31.0%), and diabetes mellitus (19.1%). Over 70% of the sample had been diagnosed with at least one co-morbidity, while 35.2% had three or more. Patients with cardiomyopathy had a mean of 3.6 co-morbidities, compared to 1.5 among patients without cardiomyopathy ($p<0.001$). Males also exhibited more co-morbidities than females (2.6 vs 1.8, p=0.007). The number of co-morbidities was significantly correlated with age ($p<0.001$), and individuals over 70 had an average of 3.1 comorbidities, compared to 0.6 in individuals under 40. In a multivariable linear regression, age and presence of Chagas cardiomyopathy were significantly associated with the number of comorbidities. Rates of alcohol (4.3%), tobacco (6.2%),

and illicit drug use (2.4%) were low. Patients with CD in Los Angeles face a significant burden of chronic comorbidities, which are more frequent in older individuals and those who have CD cardiomyopathy. This points to an urgent need for comprehensive care of these patients and for earlier, more proactive screening and treatment of this largely hidden disease.

1312

EXTENSIVE PHENOTYPIC DIVERSITY OF NORTH AMERICAN POWASSAN VIRUS

Bekah McMinn[1], Erica Normandin[2], Sam R. Telford[3], Anne Piantadosi[2], Gregory D. Ebel[1]

[1]*Colorado State University, Fort Collins, CO, United States,* [2]*Broad Institute, Cambridge, MA, United States,* [3]*Tufts University, N. Grafton, MA, United States*

Powassan virus (POWV) is a neuroinvasive tick-borne flavivirus that is maintained in nature by Ixodid ticks. Over the past decade, the number of human cases has quadrupled, and wildlife studies suggest that the intensity of enzootic transmission is also increasing. POWV is marked by diverse transmission cycles and disease outcomes. The virus consists of two distinct phylogenetic clades, and evidence of infection has been observed in several tick and vertebrate species. POWV infection in humans results in variable clinical symptoms, ranging from asymptomatic to severe encephalitis and death, with no apparent correlation to age or co-morbidity. Experimental studies of the relationships between POWV genetic diversity, vector competence, and disease outcome are currently lacking. Therefore, we sequenced several low-passage POWV isolates using NGS and evaluated their ability to replicate in well-characterized mammalian cell lines (Vero and BHK), as well as a human neuronal cell line (SH-SY5Y). Genetically similar POWV isolates vary significantly in *in vitro* replication, though these differences do not correlate with geographical or temporal characteristics. In human neuronal cells, peak titers ranged from 10^5 to 10^8 PFU/mL, the day of peak titer ranged from 4 to 10 dpi, and the degree of cytopathic effects in the monolayers was similarly variable. These results support the observation that the North American POWV population may be highly genetically and phenotypically diverse. The degree to which *in vitro* phenotype reflects transmission and pathogenesis remains to be determined.

1313

WITHIN-SITE HETEROGENEITY OF LARVAL BLOODMEAL SOURCES FOR NYMPHAL DEER TICKS

Heidi Goethert, Sam Telford

Tufts Cummings School of Veterinary Medicine, N. Grafton, MA, United States

Mouse targeted interventions to reduce the risk of Lyme disease have yielded mixed results, likely because of site specific differences for reservoir hosts . We determined the larval bloodmeal hosts for questing nymphal deer ticks within two sampling transects (brush edge and within thickets) 350m apart on the Nantucket Field Station site. Other than edge vs. within thicket, the habitat was physiographically identical. DNA from ticks was extracted by alkaline lysis and the larval blood meal remnants identified by real time PCR targeting host-specific retrotransposons. Retrotransposons are transposable elements that are represented by many thousands of copies in mammalian genomes making them uniquely suited for targets of the very sparse blood meal remnant. Ticks were also tested by PCR for evidence of infection by *Borrelia burgdorferi, Babesia microti* and *Anaplasma phagocytophilum*. Although white footed mouse was the most common host for both sets of ticks, their relative contribution differed between these two transects (P<0.001). In the edge transect, 89% (95% CI=79-95) had fed on mice. The only other major host was shrews (8%). In contrast, within the thicket transect, only 52% (95% CI=39-64) of ticks had fed on mice, with the other major hosts being deer (19%), birds (6%) and unknown (16%). The prevalence of *B. burgdorferi* and *B. microti* combined were generally greater in the edge-collected ticks (26%) that had focused their bites on mice or shrews than thicket ticks (13%) where hosts were more diverse (P=0.07). The prevalence of *Anaplasma* was slightly greater in ticks from the brush transect (22% vs 18%). Bloodmeal sources for larval deer ticks differed at a small habitat scale within what would otherwise be considered a single sampling site. Environmental interventions to reduce the risk of Lyme disease may have to account for microscale habitat heterogeneity of potential reservoir hosts.

1314

VECTOR COMPETENCE OF THE HUMAN FLEA *PULEX IRRITANS* TO TRANSMIT *YESINIA PESTIS*

Adelaide Miarinjara, David M. Bland, Joseph B. Hinnebusch

Laboratory of Bacteriology, Rocky Mountain Laboratories, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Hamilton, MT, United States

Pulex irritans is closely associated with human environments, prevalent in plague endemic regions, and *P. irritans* infected with *Yesinia pestis* have been detected during epidemics. Despite these facts, *P. irritans* is generally considered to be a poor vector and receives very little attention from public health policy makers. However, systematic studies evaluating its ability to transmit *Y. pestis* are needed to establish its potential role in plague epidemiology. We evaluated the vector competence of *P. irritans* collected from foxes and owls in Montana and Idaho. Wild-caught fleas were maintained in laboratory and infected with either human or rat blood containing ~1 x10^8 to 7x10^8 *Y. pestis* CFU/ml, using an artificial feeding system. Infected fleas were allowed to feed on sterile blood every 1-3 days and monitored for mortality rate, feeding rate, infection rate, bacterial load per flea, biofilm formation in the foregut (proventricular blockage), and transmission efficiency. Overall, *P. irritans* was challenging to maintain in laboratory conditions, but uninfected control groups survived longer than the infected fleas. *P. irritans* was susceptible to infection, with > 50% infection rates and high bacterial loads for up to 15 days post infection (dpi). Infected *P. irritans* transmitted *Y. pestis* as early as 3 dpi and proventricular blockage was observed in some fleas by 6 dpi. However, transmission efficiency was influenced by host blood source and feeding frequency, as observed in other flea species. *P. irritans* infected and then fed daily (its natural feeding behavior) using human blood transmitted bacteria less efficiently than those fleas which were infected and fed using rat blood. Higher blockage rates and greater numbers of CFUs transmitted per flea were recorded in groups fed intermittently with rat blood. Our results indicate *P. irritans* is a competent vector, but its role in plague epidemics or epizootics likely depends on host species selection and availability.

1315

DIFFERENTIAL EXPRESSION OF *IXODES SCAPULARIS* SALIVARY FACTORS DURING POWASSAN VIRUS-INFECTED TICK FEEDING

Meghan Hermance[1], Jose M. Ribeiro[2], Steven G. Widen[3], Saravanan Thangamani[1]

[1]*SUNY Upstate Medical University, Syracuse, NY, United States,* [2]*National Institute of Allergy and Infectious Diseases, Rockville, MD, United States,* [3]*The University of Texas Medical Branch, Galveston, TX, United States*

Powassan virus (POWV) is a North American flavivirus transmitted by the Lyme Disease vector, *Ixodes scapularis*. It is the causative agent of a severe neuroinvasive disease with neurological sequelae displayed in over 50% of survivors. In recent years, an expanded geographic range of *Ixodes* ticks has been documented in the United States, coupled with an increase in reported POWV human cases. Transmission of POWV to a host can occur within 3 hours of *I. scapularis* feeding. Through a process known as saliva-assisted transmission, pharmacologically-active tick saliva factors modulate the host environment making it more favorable for the transmission and establishment of a pathogen. In a previous study, *I. scapularis* saliva was shown to facilitate POWV infection and influence disease outcome in mice inoculated with a low dose of POWV. The objective of this study was to characterize the *I. scapularis* microRNAs (miRNAs) and messenger RNAs

expressed during the first 6 hours of POWV-infected tick feeding. POWV-infected and uninfected *I. scapularis* females were fed on naïve mice for 1, 3, and 6 hours, and Illumina next generation sequencing was used to examine miRNA and messenger RNA profiles of POWV-infected versus uninfected ticks. 78 salivary gland miRNAs were significantly up-regulated and 46 miRNAs were significantly down-regulated in response to POWV infection. The majority of significantly modulated miRNAs were unique to each time point and not shared between time points. To investigate the potential role of salivary gland miRNAs in POWV replication, miRNA inhibitors were transfected into VeroE6 cells to profile POWV replication in mammalian cells over time. *In vitro* data from testing 9 miRNA inhibitors demonstrated their role in regulating POWV infection. *In-silico* analysis revealed potential mechanisms by which the tick salivary miRNAs modulate POWV infection during blood feeding. Concurrently, we are analyzing the differential expression of messenger RNAs and the outcome of this study will lead to identification of salivary factor/s with the potential to enhance/regulate POWV transmission to a mammalian host.

1316

SCRUB TYPHUS PROTOTYPE STRAINS OF *ORIENTIA TSUTSUGAMUSHI*: CURRENT STATUS AND THEIR RELATIONSHIP TO RECENT ISOLATES

Allen L. Richards[1], Daryl J. Kelly[2], Paul A. Fuerst[2]

[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*Ohio State University, Columbus, OH, United States*

Scrub typhus, a mite-borne febrile illness, due to infection with the obligate intracellular bacterium *Orientia tsutsugamushi,* occurs primarily in countries of the Asia-Pacific and islands of the Western Pacific and Indian Ocean. Research on scrub typhus has relied on the availability of several prototype strains of*O. tsutsugamushi*, which were isolated from human cases in the 1940´s and 1950´s. We present the history, current status and relationship to recent *Orientia*isolates of the three original, and most important, prototype strains, Gilliam, Karp and Kato, including information on their isolation, their culture history, their clinical characteristics, their importance within the research literature on scrub typhus, and recent advances in elucidating their molecular genomics. The importance of these strains to the researchand development of clinical tools related to scrub typhus will also be presented. We finally examine whether the strains have been genetically stable since their isolation, and examine by DNA comparisons whether the alternative duplicate samples of prototype strains used by different laboratories are actually equivalent. By using genetic information archived in the international DNA databases, we show that the prototype strains used by different laboratories are essentially identical, and that the strains have retained their genetic integrity at least back to the 1950's.

1317

TICK GUT MICROBIOTA-GATEWAYS OR GATE KEEPERS?

Sukanya Narasimhan, Rajeevan Nallakkandi, Ming-Jie Wu, Kathleen DePonte, Morven Graham, Erol Fikrig

Yale University, New Haven, CT, United States

Ixodes scapularis, an obligate hematophagous arthropod transmits bacterial, viral and protozoan parasites, including *Borrelia burgdorferi*, the agent of Lyme disease to the mammalian host. There is no vaccine against these tick-borne pathogens. My presentation will focus on the vector-host-pathogen interface that is generated in the tick gut when the tick takes a bloodmeal. This represents a pivotal interface in the vector-pathogen life cycle and present opportunities to interrupt the life cycles of the vector and consequently of the pathogen. A less understood player at this interface is the resident bacterial microflora and their impact on the process of *Borrelia* colonization, growth and migration in the tick gut. Our work suggests that resident tick gut microbiota modulate the integrity of the glycan-rich peritrophic matrix (PM), a mucus-like layer that separates the gut lumen from the epithelium, and that likely presents a critical bottleneck in pathogen colonization. Our work also suggests that tick gut microbiota is actively managed by the tick innate immune responses. Whether tick gut microbiota also modulate transmission is not known, and our ongoing efforts to elucidate this is briefly summarized.

1318

PREDICTING THE EXPANSION OF LYME DISEASE TO IDENTIFY GAPS IN CASE REPORTING IN NORTHEASTERN U.S.

Donal Bisanzio[1], **Maria P. Fernandez**[2], Elisa Martello[3], Richard Reithinger[1], Maria Diuk-Wasser[2]

[1]*RTI International, Washington, DC, United States,* [2]*Columbia University, New York, NY, United States,* [3]*Independent researcher, Beeston, United Kingdom*

In this study, we modeled the spatio-temporal expansion of LD case reporting at a county level from 2000-2017 in northeastern and Upper midwestern U.S., by combining county-level environmental factors associated with tick presence and the spatial relationship between counties. The main goal was to predict the probability of reporting a LD case in counties not reporting LD in 2000, and derive the direction and spread ve*loci*ty of LD by 2017. We performed a two-step modeling approach, where we used a logistic regression model to identify the relevant explanatory variables and then used them in a stochastic spatially-explicit diffusion model. Reporting a first case of LD was associated with a county's and neighbors' forest cover, elevation, percentage of population living in wildland-urban interface, tick presence, county's population, and proportion of neighbors reporting cases and neighbors' years since first reporting. The LD spread simulated by the model showed high similarity to the observed data, but 30.1% of not reporting counties by 2017 had a high probability to report according to the model. The model also showed a more rapid temporal diffusion, with the first case of LD predicted to occur 5.5 years earlier on average compared to the observed data. The mean spread ve*loci*ty of LD was 27.4 km year^{-1}, spreading faster in South-eastern counties than in the upper Midwest counties. Variations in case reporting might explain the mismatch between the model predictions and observed data in some counties. If updated regularly and expanded geographically, this predictive model can serve as a public health tool to guide LD surveillance efforts by identifying potential gaps in reporting in those counties that are predicted to report LD in the near future.

1319

PRIOR DENGUE VIRUS INFECTION IS ASSOCIATED WITH INCREASED VIRAL LOAD IN PATIENTS INFECTED WITH DENGUE BUT NOT ZIKA VIRUS

Tyler M. Sharp[1], Gilberto Santiago[1], Eli Rosenberg[2], Iris I. Sosa Cardona[1], Luisa Alvarado[3], Gabriela Paz-Bailey[1], Jorge L. Munoz-Jordan[1]

[1]*Centers for Disease Control and Prevention, San Juan, PR, United States,* [2]*University at Albany School of Public Health, Department of Epidemiology and Biostatistics, Rensselear, NY, United States,* [3]*San Lucas Episcopal Hospital, Ponce, PR, United States*

Antibody dependent enhancement (ADE) is a proposed mechanism whereby dengue virus (DENV) infection in an individual previously infected with a heterologous DENV results in increased viral load, immune response, and disease severity. Multiple *in vitro* studies as well as findings from immunocompromised mouse models have suggested that circulating antibodies against DENV can enhance Zika virus (ZIKV) infection. To evaluate potential ADE of ZIKV among patients with prior DENV infection, we compared viral loads and disease severity among patients who tested positive by RT-PCR for infection with ZIKV (n=1,070) in 2016, or DENV-2 (n=312) or DENV-3 (n=260) in 2005-6, and had defined status of primary vs. secondary flavivirus infection (i.e., serostatus). Whereas most patients infected with ZIKV (87%) or DENV-2 (88%) were experiencing secondary infection, frequency of secondary infection was less common among those infected with DENV-3 (55%). Patients with secondary DENV-2 infection were hospitalized more frequently than patients with primary DENV-2 infection (53.3% vs. 31.6%, respectively; p = 0.01), whereas

frequency of hospitalization among patients infected with DENV-3 did not differ significantly by serostatus (39.6% vs. 49.1%, respectively; p = 0.13). Frequency of hospitalization was not different among patients with primary vs. secondary ZIKV infection (1.4% vs. 2.0%, respectively; p = 0.62). Compared to patients without prior DENV infection, patients with prior DENV infection had significantly higher mean viral loads for DENV-2 (10.6 vs. 11.6 $\log_{10}$ GCE/mL, respectively; $p < 0.0001$) and DENV-3 (10.3 vs. 10.9 $\log_{10}$ GCE/mL; $p < 0.0001$), but not ZIKV (4.7 vs. 4.7 $\log_{10}$ GCE/mL; p = 0.959). In a multivariable model of viral load, day post-illness onset of specimen collection, infecting virus, and serostatus were significantly associated with viral load, indicating virus- and serostatus-specific effects on viral load over time. In summary, although viral load was higher among dengue patients with prior DENV infection, similar findings were not observed for ZIKV, arguing against *in vivo* enhancement of ZIKV by anti-DENV antibodies.

1320

FLAVIVIRUS NS1 PROTEINS FACILITATE VIRUS DISSEMINATION THROUGH ENDOTHELIAL CELLS AND ENHANCE VIRUS INFECTION

Scott B. Biering[1], Henry Puerta-Guardo[1], Michael J. DiBiasio-White[2], Chunling Wang[1], Thu Cao[2], Diego A. Espinosa[1], Dustin R. Glasner[1], Richard J. Kuhn[2], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Department of Biological Sciences, Purdue University, West Lafayette, IN, United States*

A pathogenic hallmark of severe dengue virus (DENV) infection is vascular leak. Recently, we found that DENV non-structural protein 1 (NS1) directly triggers vascular leak *in vivo* and endothelial hyperpermeability *in vitro*. We further determined that NS1 from multiple flaviviruses trigger vascular leak in a tissue-specific manner reflecting disease tropism. We next explored if and how NS1 might facilitate virus dissemination into target organs. To do this, we first utilized an *in vitro* model consisting of a Transwell system with endothelial cell monolayers derived from different organs seeded above target cells. Here, we demonstrate that NS1 from different flaviviruses (DENV, Zika virus [ZIKV], and West Nile virus) mediates dissemination of DENV, ZIKV, and Kunjin virus across distinct human endothelial cell monolayers and infection of target monocytes or astrocytes on the basolateral side. Intriguingly, we found increased viral infection of cells when evaluating homologous pairs of NS1 and virus, suggesting an interaction between flaviviruses and their homologous NS1 proteins that enhances infectivity. Further, virion attachment to endothelial cells as well as direct interaction of NS1 with virus particles was observed and was enhanced to the greatest degree in the presence of homologous NS1. A single amino acid mutation of NS1 that disrupts interaction of NS1 and the virion but retains its ability to trigger endothelial hyperpermeability ablated enhanced viral infection. Further, a distinct single amino acid mutation that eliminates NS1-triggered endothelial hyperpermeability also eliminated infection of target cells in the basolateral chamber. Thus, NS1-mediated viral dissemination appears to be a combination of non-specific diffusion through disrupted barriers as well as specific interaction between NS1 and the virion. These studies present a proviral explanation for the evolutionary conservation of NS1-mediated endothelial permeability of multiple flaviviruses and highlight the interaction between the flavivirus virion and NS1 as a new target for antiviral therapeutics.

1321

THE WING DOMAIN OF DENGUE VIRUS NON-STRUCTURAL PROTEIN 1 IS REQUIRED FOR BINDING TO ENDOTHELIAL CELLS AND INDUCING HYPERPERMEABILITY

Nicholas T.N. Lo, Chunling Wang, Scott B. Biering, Kendall E. Lee, Mark Patana, Eva Harris

Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States

Vascular leak is a hallmark of severe dengue caused by the positive-sense RNA flavivirus, dengue virus (DENV). DENV non-structural protein 1 (NS1) is a secreted glycoprotein that causes endothelial hyperpermeability directly by disrupting the endothelial glycocalyx-like layer (EGL) *in vitro*, as well as inducing vascular leak *in vivo*. We have shown that NS1 proteins from different flaviviruses bind to human endothelial cells (EC) and induce vascular leak in a tissue-specific manner, consistent with their respective disease tropism. For example, DENV NS1 but not West Nile virus (WNV) NS1 binds to human pulmonary microvascular endothelial cells (HPMEC), as DENV but not WNV induces leakage in the lungs. However, the molecular determinants of NS1 binding to ECs remain unknown. We recently identified immunodominant regions in the "wing" domain of NS1 in human and mouse DENV infections; this domain contains both conserved and variable regions. Using chimeric NS1 proteins, we exchanged a 35-amino acid (aa) section (101-135) within the wing domain of DENV NS1 with that of WNV NS1. This $DENV^{WNV101-135}$ NS1 chimera lost its ability to bind and induce endothelial permeability in HPMEC. We examined this region further, generating another NS1 chimera ($DENV^{WNV110-122}$) that exchanged only the portion containing highly conserved poly-lysines and a conserved 3-aa motif (110-122). The $DENV^{WNV110-122}$ NS1 mutant retained the ability to bind HPMECs. Further, mutation of the 3-aa motif to Ala reduced binding, EGL disruption, and endothelial hyperpermeability. Interestingly, the reverse exchange of the 101-135 region from DENV into WNV NS1 ($WNV^{DENV101-135}$) did not restore NS1 binding to HPMEC, suggesting that specific residues in this 35-aa section are necessary but not sufficient for DENV NS1 binding to HPMEC. These results support the idea that specific residues in the NS1 "wing" region mediate its broad, as well as tissue-specific, EC binding capacity and identify the residues in DENV NS1 that may confer binding to human ECs, which are required for induction of EC hyperpermeability. Further work is underway to elucidate the implications in viral infection.

CAUGHT ON CAMERA: VISUAL AND BIOCHEMICAL EVIDENCE OF ENDOTHELIAL GLYCOCALYX DISRUPTION IN DENGUE AND ASSOCIATION WITH PLASMA LEAK SEVERITY

Lam K. Phung[1], Angela Mcbride[1], Quyen T. Nguyen[1], Duyen T. Huynh[1], Hans Vink[2], Bridget Wills[3], Sophie Yacoub[1]

[1]*Oxford University Clinical Research Unit - HCMC, Ho Chi Minh City, Vietnam,* [2]*Maastricht University, Maastricht, Netherlands,* [3]*University of Oxford, Oxford, United Kingdom*

The endothelial glycocalyx layer lines all microvessels and provides vital barrier functions to capillary networks. In-vitro studies suggest dengue NS1 mediated degradation of this layer may underlie the capillary leak syndrome associated with severe disease, but there are a lack of human studies to support this. We performed an observational study in two hospitals in Vietnam, to evaluate the sublingual microcirculation using sidestream dark field imaging in patients a) presenting early (<72 hours fever) with clinically suspected dengue b) hospitalized with dengue and c) with other febrile illnesses (OFI). The glycocalyx depth was analyzed using the software application: GlycoCheck™. The Perfused Boundary region (PBR High Flow, PBR_HF), which is inversely proportional to the depth of the glycocalyx and corrected for interpatient microvascular flow differences, and the MicroVascular Health Score (MVHS) were measured at three time-points during the illness. Plasma glycocalyx degradation products including syndecan-1 (SDC1) and endocan were measured at the same time-points. Of the 70 patients enrolled, 45 had GlycoCheck

analysis performed. In dengue patients, we found the PBR_HF was increased in patients with severe plasma leakage versus those with no leakage during the critical phase, 1.36μm (1.22, 1.57) vs. 1.96μm (1.90, 1.98) ($p<0.001$), and MVHS was generally lower in patients with more severe plasma leakage ($p<0.001$). Plasma SDC1 levels were raised in patients with the most severe leakage compared to patients with no plasma leakage, particularly during the critical phase (median: 125.9 versus 2613 ng/ml, $P<0.001$). SDC1 levels had a positive correlation with the PBR_HF but this did not reach statistical significance at the 0.01 level. SDC1 levels were higher in the acute phase of dengue compared to OFI, but we found no significant difference in the PBR_HF or MVHS between patients with dengue versus OFI. In summary, we have shown the first human in-vivo evidence of glycocalyx disruption in dengue patients, with a thinner glycocalyx and increased plasma glycocalyx degradation products associated with worse plasma leakage severity.

1323

PRIMARY DENGUE SEROTYPE 2 INFECTION IN HUMANS IMPRINTS A BLOOD TRANSCRIPTOMIC PROFILE AFTER VIRUS CLEARANCE

Sean A. Diehl[1], John Hanley[1], Korin Eckstrom[1], Dorothy M. Dickson[1], Nicholas Selig[1], Stephen S. Whitehead[2], Anna P. Durbin[3], Kristen K. Pierce[1], Beth D. Kirkpatrick[1], Julie Dragon[1], Donna Rizzo[1], Sam V. Scarpino[4]

[1]*University of Vermont, Burlington, VT, United States,* [2]*National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Johns Hopkins University School of Public Health, Baltimore, MD, United States,* [4]*Northeastern University, Boston, MA, United States*

Dengue disease is caused by any of the four dengue virus (DENV) serotypes and severe disease is most often associated with secondary heterotypic infection. Given the impact of primary DENV exposure as a pre-disposing risk factor for secondary disease, it is important to define systems-level impacts of the immune response to infection and through convalescence. To study this, we used genome-wide RNA-Seq to determine the blood transcriptomic profile of 11 healthy flavivirus-naïve adults that were challenged with an underattenuated DENV2 virus. We captured transcriptomics at baseline, during viremia (day 8 after infection) and at convalescence (Day 28) and used a systems approach to assess transcriptional changes associated with infection and resolution thereof in the context of fine-mapped, longitudinal virological, serological, and clinical findings. We leveraged RNA-Seq replicates for each subject to analyze gene regulation on an individual basis. This novel approachyielded a small set of 99 differentially regulated genes (95 up and 4 down) that changed in the same direction in all 11 subjects between baseline and Day 8 after infection, a timepoint which captured all peak viremias within ± 2 days. At day 28 after infection, neutralizing antibodies were generated, all viremia and clinical signs were resolved, and 93 genes were downregulated in all subjects, including 56 that were upregulated during acute infection. Thus, we found a group of 43 genes that, once regulated by acute infection (39 up and 4 down), did not return to baseline in convalescence in any of the subjects, suggesting evidence of systemic imprinting after primary dengue infection. This residually-activated set of genes included myeloid and immune regulation factors. Since leukocyte responses were re-establishing towards baseline shortly after viremia resolved, this suggested an imprinted profile in remaining cells which may reflect a refractory period of immune activation early in convalescence after primary infection.

DENGUE VIRUS 2 GENOTYPIC VARIATION MEDIATES NEUTRALIZATION SENSITIVITY TO HUMAN ANTIBODY RESPONSES

David R. Martinez, Boyd Yount, Ralph S. Baric

University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Dengue virus (DENV) infection incidence rates in humans have increased recently with up to 390,000 new infections each year worldwide. Yet, the only licensed DENV vaccine, Dengvaxia, does not perform equally well against all four Dengue virus serotypes, with particularly poor vaccine efficacy against Dengue virus serotype 2 (DENV2). It is not clear why vaccine-elicited responses against DENV2 provide lower efficacy compared to DENV serotypes 1, 3, and 4. Thus, more studies are needed to better understand dynamics of DENV2 and host immune responses. To begin to answer this question, we used reverse genetics to generate a ten-virus isogenic panel of precursor membrane (prM) and envelope (E) of the distinct DENV2 genotypes, Asian I, Asian II, Asian-American, Cosmopolitan, Sylvatic African, Sylvatic Asian, and grew them in C6/36 insect cells. Interestingly, these DENV2 genotypic variants showed considerable amino acid residue variability within E domain I, II, and III, which are key targets for neutralizing antibodies. We then tested the neutralization sensitivity of these distinct DENV2 genotypic variants to natural infection human sera, NIH monovalent DENV vaccine human sera, tetravalent DENV vaccine human sera, and human monoclonal antibodies in a Vero cell-based microneutralization assay. Interestingly, distinct DENV2 genotypic variants were differentially neutralized by natural infection sera, vaccine-elicited sera, and monoclonal antibodies, suggesting that DENV2 genotypic variation modulates neutralization sensitivity. Our data suggests that amino acid variation within the prM and E of the different DENV2 genotypes mediates differential neutralization by host-elicited antibodies in both the settings of natural infection and vaccination. Our findings also suggest that the poor vaccine efficacy observed against DENV2 may in part be due to the natural genotypic variation within the DENV2 serocomplex. These findings have important implications for ongoing clinical trials testing the efficacy of DENV vaccine candidates and argue for the use of DENV vaccines with improved coverage against the different genotypes.

ANTI-FLAVIVIRUS ANTIBODY DYNAMICS BEFORE, DURING, AND AFTER THE ARRIVAL OF ZIKA IN THE AMERICAS

Leah Katzelnick[1], Damaris Collado[2], Douglas Elizondo[2], Juan Carlos Mercado[3], Lionel Gresh[2], José Victor Zambrana[2], Amy Schiller[4], Sonia Arguello[2], Raquel Burger-Calderon[2], Tatiana Miranda[2], Sergio Ojeda[2], Nery Sanchez[2], Brenda Lopez[2], M. Elizabeth Halloran[5], Josefina Coloma[1], Aubree Gordon[4], Guillermina Kuan[6], Angel Balmaseda[3], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Sustainable Sciences Institute, Managua, Nicaragua,* [3]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua,* [4]*Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States,* [5]*Department of Biostatistics, University of Washington, Seattle, WA, United States,* [6]*Centro de Salud Sócrates Flores Vivas, Ministry of Health, Managua, Nicaragua*

Dengue viruses 1-4 (DENV1-4) were reintroduced to the Americas in the last 50 years and now circulate endemically. A closely related flavivirus, Zika virus (ZIKV), was introduced in 2014 and caused epidemics across the continent. We evaluated how the arrival of ZIKV impacted the immune landscape to flaviviruses in a longitudinal pediatric dengue cohort study (2004-2018) in Nicaragua. Using an Inhibition ELISA, we first measured dynamics of anti-DENV antibodies (DENV-Abs) in participants with different DENV infection histories in the pre-ZIKV era. Mixed-effects generalized additive models revealed that DENV-Abs reached a stable set-point by 1 year after primary (1°) DENV infection but waned rapidly for 2 years

after secondary (2°) DENV infections before reaching a steady state. This finding differs from the long-held hypothesis that waning DENV-Abs explain changes in risk of severe dengue after 1° DENV infection. Instead, individual DENV-Ab set-point titer is important: those with low titers are at elevated risk of severe dengue, whereas those with high titers are protected. When ZIKV arrived, there was concern that DENV-Abs could also enhance Zika disease. However, we find DENV-Abs are protective against uncomplicated Zika. In contrast, the effect of ZIKV infection on dengue risk is unknown. We built mixed-effects linear models of DENV-Ab titers in the first 2 years following ZIKV infection in those with different DENV infection histories. DENV-Abs were higher after 1° DENV than 1° ZIKV infection but both groups showed evidence for a set-point. Large fractions of both groups had titers within the severe dengue risk range. In contrast, those with 2° ZIKV infections (i.e., DENV-ZIKV) had comparably high DENV-Abs titers as those with 2° DENV. Both groups experienced comparable DENV-Ab decay within 2 years of infection. Thus, while DENV-Abs can partially protect against Zika, ZIKV infection may provide protection against future dengue in those with prior DENV infections while placing many previously naïve individuals at elevated risk of severe dengue. Such asymmetric immune interactions may affect efficacy and safety of DENV and ZIKV vaccines.

INTERACTION OF LIVE ATTENUATED *LEISHMANIA* PARASITES INFECTED NEUTROPHILS WITH DENDRITIC CELLS AUGMENTS CD4$^+$TH1 CELL PRIMING IN C57BL/6 MOUSE

Parna Bhattacharya, Nevien Ismail, Subir Karmakar, kazuyo takeda, Ranadhir Dey, Hira L. Nakhasi

Food and Drug Administration, Silver Spring, MD, United States

Visceral leishmaniasis (VL), is a vector-borne disease with no available vaccine. We have previously reported the protective role of live attenuated centrin gene-deleted *L. donovani* (*LdCen-/-*) parasite vaccine in animal models. *LdCen-/-* induces strong innate immunity which leads towards protective Th1 response. Neutrophils are involved in initial steps of most responses to pathogens and can also enhance various T cell responses either directly or indirectly through activation of dendritic cells (DCs). Recently we have demonstrated neutrophil's direct antigen presenting potential in generating early host protective immune response to *LdCen$^{-/-}$*. However, neutrophil mediated immunomodulation of DC function in response to live attenuated *Leishmania* vaccine has not been studied yet. Hence, we evaluated the interaction between neutrophils and DCs during *LdCen-/-* infection and compared with *LdWT* both *in vitro* and *in vivo*. Robust chemo attractive activity for DCs was detected in the supernatants of neutrophils exposed to *LdCen-/-*compared to *LdWT in vitro. Additionally,* uptake of *LdCen-/-mCherry*-infected neutrophils by DCs augmented their expression of costimulatory molecules and heightened CD4$^+$T cell priming in comparison with DCs with *LdWTRFP* infected neutrophils *in vitro*. Intradermal immunization in the ear with *LdCen-/-* induces synchronized higher neutrophil and DC recruitment compared to *LdWT* parasites. Furthermore, to investigate neutrophil-DCs interactions *in vivo*, we evaluated dermal DCs recovered from mice 24h after infection with *LdWTRFP / LdCen-/-mCherry* parasites. We observed, DCs which have *LdCen-/-* parasitized neutrophils have higher CD4$^+$T cell priming capacity thereby promoting heightened Th1 response compared to *LdWT*. Also, depletion of neutrophil significantly abrogates antigen presenting potential of DC in *LdCen$^{-/-}$* infected mice. This study suggests that interaction of infected neutrophils with DCs plays pivotal role in shaping the vaccine induced host protective adaptive immune response.

CHAGAS DISEASE IN THE NEW YORK CITY METROPOLITAN AREA

Crystal Zheng[1], Orlando Quintero[2], Elizabeth K. Revere[3], Michael B. Oey[3], Fabiola Espinoza[4], Yoram A. Puius[2], Diana Ramirez-Baron[5], Carlos R. Salama[6], Luis F. Hidalgo[7], Fabiana S. Machado[8], Omar Saeed[2], Jooyoung Shin[2], Snehal R. Patel[2], Christina M. Coyle[9], Herbert B. Tanowitz[9]

[1]*Tulane University, New Orleans, LA, United States,* [2]*Montefiore Medical Center, Bronx, NY, United States,* [3]*Donald and Barbara Zucker School of Medicine at Hofstra, Manhasset, NY, United States,* [4]*Metro Infectious Diseases Consultants, Burr Ridge, IL, United States,* [5]*Grameen VidaSana Clinic, Queens, NY, United States,* [6]*Icahn School of Medicine at the Mount Sinai Hospital, Queens, NY, United States,* [7]*University of Kentucky College of Medicine, Lexington, KY, United States,* [8]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [9]*Albert Einstein College of Medicine, Bronx, NY, United States*

Chagas disease, caused by the parasite *Trypanosoma cruzi*, once considered a disease confined to Latin America, is now an emerging global public health problem. An estimated 300,000 immigrants in the United States are chronically infected with *T. cruzi*. However, awareness of Chagas disease among the medical community in the United States is poor. We review our experience managing sixty patients with Chagas disease in hospitals throughout the New York City metropolitan area and describe screening, clinical manifestations, electrocardiogram (ECG) findings, imaging, and treatment. The patients were evenly split by sex (30 males, 30 females), with a mean age at diagnosis of 47 years. The most common country of origin was El Salvador (n = 24) and the most common detection method was by routine blood donor screening (n = 21). Screening family members of newly diagnosed patients identified 10 additional cases representing 4 families. Nearly half of the patients were asymptomatic. Of symptomatic patients, 40% had cardiac symptoms and 23% had gastrointestinal symptoms. The most common ECG abnormality was right bundle branch block, and the most common echocardiogram abnormalities were tricuspid regurgitation and ventricular wall motion abnormalities. Twenty-seven patients were treated with either benznidazole or nifurtimox, of whom 7 did not complete therapy due to side effects or were lost to follow up. Six patients underwent heart transplantation, and 2 experienced reactivation after transplant. Based on our experience, we recommend that targeted screening be used to identify at risk, asymptomatic patients before progression to clinical disease. Family members of newly diagnosed patients should be offered screening as well. Evaluation should include an ECG, echocardiogram, and chest x-ray; gastrointestinal imaging can be pursued if relevant symptoms are present. Patients should be treated if appropriate, but providers should monitor for adverse effects that may prevent treatment completion. Patients with advanced heart disease who are not candidates for medical treatment may require advanced therapies or heart transplantation.

1328

THE TRANSCRIPTION FACTORS BLIMP-1 AND HOBIT DETERMINE THE PATHOGENIC PHENOTYPE CD8 T CELLS EXHIBIT IN LEISHMANIAL LESIONS

Fernanda O. Novais, Phillip Scott

University of Pennsylvania, Philadelphia, PA, United States

Leishmaniasis is a disease caused by protozoan parasites of the genus *Leishmania* and the most common form of the disease is cutaneous leishmaniasis (CL). Importantly, treatment for CL is frequently ineffective, in part because the disease is driven not only by the parasite load but also by immunopathologic responses. Therefore, a fundamental question in CL is what regulates the development of severe disease, information that is critical in order to develop host-directed therapies to ameliorate disease. In a series of studies utilizing murine models coupled with analysis of samples from *Leishmania braziliensis*-infected patients, we demonstrated CD8 T cell-dependent cytotoxicity as the main inducer of

immunopathology in CL. This result was unexpected since IFN-γ production by CD8 T cells plays a protective role by promoting pathogen elimination. To resolve this paradox, we studied the CD8 T cells in different anatomic sites, and found that the effector function of CD8 T cells in CL depends on their location: while CD8 T cells are cytotoxic and produce little IFN-γ in leishmanial lesions, CD8 T cells in the draining lymph nodes (dLN) have the opposite profile. Importantly, CD8 T cells in lesions and not dLN express the transcription factor Blimp-1. Our results show that Blimp-1 and Hobit (a homolog of Blimp-1) deficiency reduced the ability of CD8 T cells to express granzyme B in lesions. Importantly, we found that CD8 T cells from Blimp-1 and Hobit deficient mice are unable to cause severe pathology in *L. braziliensis* lesions. Together, our results indicate that Blimp-1 and Hobit are induced in *L. braziliensis* lesions and are required for CD8 T cell-mediated disease.

1329

MARKER FREE LIVE ATTENUATED *LEISHMANIA MAJOR* (*LMCEN-/-*) INDUCES STRONG HOST PROTECTIVE IMMUNE RESPONSE AGAINST VECTOR BITE TRANSMITTED VISCERAL LEISHMANIASIS

Ranadhir Dey[1], Subir Karmakar[1], Nevien Ismail[1], Fabiano Oliveira[2], Wenwei Zhang[3], Shinjiro Hamano[4], Greg Matlashewski[3], Shaden Kamhawi[2], Abhay Satoskar[5], Jesus G. Valenzuela[2], Hira L. Nakhasi[1]

[1]*CBER/Food and Drug Administration, Silver Spring, MD, United States,* [2]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States,* [3]*McGill University, Montreal, QC, Canada,* [4]*Nagasaki University, Nagasaki, Japan,* [5]*Ohio State University, Ohio, MD, United States*

Leishmaniasis are vector-borne parasitic diseases and there is no licensed vaccine available against human leishmaniasis. It has been shown that low dose of dermatotrophic *Leishmania major* infection (leishmanization) confers protection against cutaneous leishmaniasis (CL). However, such a method of immunization is not practical because of the greater risk of infection in a naïve population. Therefore, genetically modified live attenuated parasites that are non-pathogenic might induce the same protective immunity as leishmanization. We have developed centrin-gene deficient *Leishmania major (LmCen-/-)* using CRISPR-Cas methodology and evaluated the safety, immunogenicity as well as cross-protective efficacy against *L. donovani* challenge in hamster model. Although, intradermal immunization of golden Syrian hamsters with *LmCen-/-* did not develop any visible lesion, but it induced a strong pro-inflammatory immune response compared to wild type *L. major* infection as measured by Real time quantitative PCR. Immunized hamsters were challenged with *L. donovani* either by intradermal needle injection or by infected sand flies as natural mode of infection. In both sets of experiments, twelve months post-challenge, non-immunized challenged hamsters developed severe pathology of VL, while immunized hamsters were protected. We also evaluated the cellular immune response in immunized hamsters after challenge with the wild type parasites and compared with non-immunized and challenged hamsters. Spleen cells from *LmCen-/-* immunized and challenged hamsters produced significantly more Th1-associated cytokines including IFN-γ and TNF-α, and significantly reduced expression of the anti-inflammatory cytokines IL-10 and IL-21, compared to non-immunized and challenged animals. The enhanced pro-inflammatory immune response correlates with the control of parasitemia in immunized animals. Our studies demonstrate that the *LmCen-/-* mutant parasite are safe as an immunogen and have potential to be an effective vaccine against VL and can proceed to be tested in humans.

1330

PARASITE LOAD AND HOST CYTOTOXICITY-RELATED GENE EXPRESSION ARE POTENTIAL BIOMARKERS FOR TREATMENT OUTCOME

Camila Farias Amorim[1], Fernanda Novais[1], Ba Nguyen[1], Ana M. Misic[1], Lucas P. Carvalho[2], Edgar M. Carvalho[2], Daniel Beiting[1], Phillip Scott[1]

[1]*University of Pennsylvania, Philadelphia, PA, United States,* [2]*Universidade Federal da Bahia, Salvador, Brazil*

Gene expression in the skin, particularly inflammasome activation and cytotoxicity, drives pathology in cutaneous leishmaniasis (CL), yet the factors that initiate and sustain these programs have yet to be identified. It is unclear whether patients that exhibit stronger induction of these pathways go on to a worst clinical outcome. Here, in an unbiased approach we investigated whether differences in the expression levels of genes that are highly variable in lesions might influence disease outcome. We obtained biopsies of cutaneous lesions from *L. braziliensis* patients prior to drug treatment, and then monitored patients to determine who failed treatment. A set of genes were identified whose expression is highly variable between patients and which were strongly correlated with treatment outcome. Amongst the most variable genes were components of the cytolytic pathway, and expression of these genes appears to be driven by parasite load in the skin. This is the first demonstration that the outcome of disease in patients, in this case treatment failure, can be directly linked to the cytolytic pathway activated during leishmania infection. Using this host-pathogen biomarker profile, we show that treatment outcome can be predicted with high sensitivity and specificity before the start of treatment. These findings raise the possibility of point-of-care diagnostic screening to identify patients at high risk of treatment failure, and provide a rationale for a precision medicine approach to drug selection in cutaneous leishmaniasis.

1331

DISSEMINATED LEISHMANIASIS IS ASSOCIATED WITH THE ABILITY OF *LEISHMANIA BRAZILIENSIS* TO SURVIVE IN NEUTROPHILS AND MONOCYTES AND IN DOWN MODULATE PHAGOCYTES FUNCTION

Edgar M. Carvalho[1], Olívia Bacellar[1], Thiago Marconi[2], Andreza Dórea[1], Walker Nonato[1], Lucas P. Carvalho[1], Albert Schriefer[1], Paulo Machado[1], Luiz Henrique Guimarães[3]

[1]*Federal University of Bahia, Salvador, Brazil,* [2]*Gonçalo Moniz Institute (IGM), Fiocruz, Bahia, Salvador, Brazil,* [3]*Federal University of the South of Bahia, Itabuna, Brazil*

Disseminated leishmaniasis (DL) is an emergent form of *Leishmania braziliensis* infection characterized by 10 up to thousand papular acneiform and ulcerated lesions. There is no impairment in T cell response in DL, but isolates that cause DL are genotypically different from isolates that cause cutaneous leishmaniasis (CL). Soluble leishmania antigen (SLA) from *L. braziliensis* that cause DL induces a higher inflammatory response in comparison with SLA from CL. Here, we evaluate neutrophils and monocytes function after infection with isolates of *L. braziliensis* from DL or CL patients. In all cases DNA of *L. braziliensis* was detected by PCR. Participants were 30 healthy subjects (HS), 12 patients with CL and 12 with DL. *L. braziliensis* isolates from CL or DL were cultivated in Schneider media supplemented with serum. Neutrophils and mononuclear cells were isolated by density gradient and infection was performed at the ratio of 5 parasites:1 cell. The percentage of infected cells and number of amastigotes / 100 cells were measured by optical microscopy. The neutrophils' activation markers were evaluated by flow cytometry (FACS). The respiratory burst and expression of toll like receptors (TLR) in neutrophils and monocytes were evaluated by FACS. The percentage of infected neutrophils and the parasite load of HS polymorph nuclear cells infected with isolates of DL was higher than that observed in cells infected with isolates of CL ($P<0.01$). The expression of dihidrorodhamine (DHR) and CD66b were lower in neutrophils infected with isolates of DL

than CL (P<0.05). Regarding monocytes, while after 2 hours of infection there was no difference in the degree of infection in CL, DL and HS monocytes infected with DL or CL parasites, after 48 hours the number of amastigotes were higher in cells infected with DL isolate in comparison with CL isolate (P<0.01). After infection, the expression of TLR2 and TLR4 were higher in monocytes infected with isolate from DL than CL (P<0.05). These data indicate that evasion from killing mediated by phagocytes and modulation of phagocyte function by isolates from DL patients play a major role in the pathogenesis of DL.

1332

EVALUATION OF PROTECTIVE IMMUNITY INDUCED BY *LDCEN-/-* IN PRESENCE OF PRE-EXISTING *PLASMODIUM YOELII* INFECTION

Visceral leishmaniasis and malaria are two major parasitic diseases with overlapping geographic distribution and may also coexist in the same individuals. Studies of co-infection of virulent *Plasmodium* and *Leishmania* have shown activation of distinct immunological pathways that might lead to either exacerbation or control of pathogenesis depending on the parasite species. Towards developing a prophylactic vaccine against visceral leishmaniasis, we have tested centrin deleted live attenuated *Leishmania donovani* parasites (*LdCen-/-*) as potential vaccines. However, vaccination studies using *LdCen*$^{-/-}$ were performed mainly in naïve rodent models. The immunological correlates of protection thus derived might have limited applicability in conditions where the immunized host has prior exposure to *Plasmodium* infection. In addition, the most likely recipients of the vaccines in *Leishmania* endemic areas are likely to be asymptomatic carriers of *Plasmodium* infection due to co-endemicity of these pathogens. Towards examining the impact of prior exposure to *Plasmodium* on the *LdCen-/-* induced protection, we performed *LdCen-/-* immunization in mice that were infected with PyNL, and following clearance. Results showed that the PyNL infection shows no impact on the *LdCen*$^{-/-}$ specific CD4^{+} T cell responses including memory responses and polyfunctional responses. However, polyfunctional CD8^{+} T cell responses were impaired in presence of PyNL. Upon challenge with virulent *L. donovani*, reduction in splenic parasite burdens was impaired in mice pre-exposed to PyNL compared to those that received *LdCen-/-* alone suggesting that prior exposure to PyNL impacts the protective immunity induced by *LdCen-/-* parasites. Immune mechanisms impacting the protective immunity induced by *LdCen*$^{-/-}$ parasites due to PyNL will be discussed.

THE 'PREMONITION PROVING GROUND': A SIMULATED FIELD ENVIRONMENT FOR DEVELOPING NOVEL MOSQUITO SURVEILLANCE TOOLS

Isaiah Hoyer[1], Michael R. Reddy[1], Douglas E. Norris[2], Nicolas Villar[1], Marcel Gavriliu[1], Ethan K. Jackson[1]

[1]*Microsoft Research, Redmond, WA, United States,* [2]*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States*

Evaluation of novel mosquito surveillance devices in field settings may be hampered by seasonal fluctuations in mosquito abundance, local climatic conditions and other abiotic factors such as light regime that are difficult to control under natural conditions. Although field deployments serve as the ultimate test of surveillance device efficacy, research conducted prior to going to the field may reduce the cost and time of prototype development. Microsoft's Project Premonition has erected a custom instrumented, cloud-connected, ACL-2 compliant laboratory specifically designed to support testing of arthropod surveillance technologies in a simulated field setting. The "Premonition Proving Ground" replicates climate and solar cycles to mimic the temperature, humidity and ambient light characteristics of temperate and tropical venues for any given time of year. For instance, this allowed us to simulate and validate previous field trials showing that robotic collection devices can detect and distinguish wild *Culex* and *Aedes* mosquitoes to genus with 91% and 90% accuracy respectively based on digital phenotypes generated using infrared detection of wing beat frequency. We also used the Proving Ground to generate digital phenotypes from other sensors on wild mosquitoes that were field-collected as eggs and shipped to the Proving Ground for rearing. Adult mosquitoes were morphologically identified to species and a variety of digital phenotypes were recorded, producing a library of signatures used to train prototype devices to recognize and distinguish mosquito species. Flight trajectory data is captured using the Proving Ground's custom video tracking system indicating the willingness of mosquitoes to enter trappable areas. Such high-fidelity data allows us to quickly compare the relative efficacy of different device designs under controlled conditions. This process of controlled testing and evaluation greatly facilitates the training of our algorithms and rapid prototyping before transitioning to more costly field evaluations.

1334

ARBOMAP: SOFTWARE INTEGRATING ENVIRONMENTAL MONITORING WITH PUBLIC HEALTH SURVEILLANCE FOR ARBOVIRUS FORECASTING

Michael C. Wimberly[1], Justin K. Davis[1], Michael C. Hildreth[2], Joshua Clayton[3]

[1]*University of Oklahoma, Norman, OK, United States,* [2]*South Dakota State University, Brookings, SD, United States,* [3]*South Dakota Department of Health, Pierre, SD, United States*

West Nile virus (WNV) remains a persistent public health hazard in many parts of the U.S., and there is need for knowledge of when and where WNV outbreaks will occur to target public health responses. To address this need, we developed and implemented the Arbovirus Monitoring and Prediction (ArboMAP) system in South Dakota, the U.S. state with the highest incidence of WNV. ArboMAP produces weekly, county-level forecasts of WNV risk using remotely-sensed environmental data combined with entomological and epidemiological surveillance data. We made prospective WNV forecasts in South Dakota during the WNV seasons of 2016, 2017, and 2018. ArboMAP uses a data-driven approach in which human WNV cases are modeled as a function of meteorological variables and mosquito infection status. Gridded environmental data, including air temperature, vapor pressure deficit, and precipitation, were derived from NASA's North American Land Data Assimilation System. Mosquito surveillance were obtained from local trapping programs throughout the state and were pooled and tested for the prevalence of WNV on a weekly basis. We used distributed lags to model the delayed effects of environmental fluctuations, and a log-linear function to model growth of the infection rate in the early transmission season. ArboMAP is implemented using the R software environment for data processing, modeling, and reporting combined with a Google Earth Engine application for environmental data access. Forecasts of WNV transmission risk were made on a weekly basis using observed meteorological conditions and mosquito infection status during the current year. We were able to predict interannual variation in the incidence of WNV cases, as well as seasonal shifts in the start of the transmission season. We also predicted a change in the usual geographic pattern of WNV cases that occurred in 2017. These forecasts fill an important information gap in the early season, when vector abundance is not an effective predictor of risk and most human cases are still unreported. Current work on ArboMAP is focused on evaluating the model in new locations with different transmission cycles.

NEW INSIGHTS ON DIAPAUSE CUES: INVASIVE *AEDES ALBOPICTUS* USE A BET-HEDGING STRATEGY ALONG THEIR NORTHEASTERN UNITED STATES EDGE

Talya Shragai, Laura Harrington

Cornell University, Ithaca, NY, United States

Aedes albopictus is an important vector of arboviruses impacting human health and the world's most rapidly invading mosquito. Since a single introduction in Texas, populations have expanded across the eastern United States (US) and established as far north as New York (NY) State and

Connecticut. Temperate *Ae. albopictus* overwinter through egg diapause; adult females lay diapausing eggs primarily in response to decreasing photoperiod and supported by low temperatures. Laboratory studies have shown that beyond a critical photoperiod, *Ae. albopictus* diapause incidence rapidly reaches 100%, and that populations have evolved diapause responses earlier in the season along a US-wide latitudinal cline. Only one published study has characterized diapause in the field and none have tested it across a fine-scale geographic range, making it difficult to accurately predict future invasions and population dynamics. We tested the hypothesis that diapause phenology varies between proximate cities in southern NY based on each site's microclimate. We collected eggs weekly between August and November using ovitraps with temperature loggers, and determined percent in diapause. We confirmed that beyond a threshold photoperiod, diapause incidence increased; however, it did not rapidly reach 100% as expected. Instead, diapause incidence fluctuated across the collection period in response to temperature, increasing as temperatures decreased, and stabilizing around 50% if temperature was sufficiently high. To investigate this further, we conducted a laboratory experiment using low generation *Ae. albopictus* from our NY field sites and more southern US states. Each population was held at a range of temperatures with NY's predicted critical photoperiod and tested for diapause incidence. Our results suggest, for the first time, that *Ae. albopictus* adopt flexible diapause cues and use a bet-hedging strategy in response to an unpredictable environment. This contrasts the current paradigm of diapause induction in *Ae. albopictus* and highlights the need to study disease vectors on regional geographic scales to understand current human transmission risk.

SEASONAL TRANSCRIPTIONAL CHANGES OF *ANOPHELES COLUZZII* MOSQUITOES DURING DRY SEASON AESTIVATION

Benjamin J. Krajacich[1], Adama Dao[2], Alpha Yaro[2], Moussa Diallo[2], Djibril Samake[2], Zana Lamissa[2], Ousmane Yossi[2], Margery Sullivan[1], Roy Faiman[1], Jose Ribeiro[1], Tovi Lehmann[1]

[1]*National Institute of Allergy and Infectious Diseases, Rockville, MD, United States,* [2]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Bamako, Mali*

For *Anopheles* mosquitoes in sub-Saharan Mali, the 7-month dry season poses a significant challenge to survival. Mark-release-recapture studies have shown that mosquitoes transition between relatively short wet seasons that provide ample breeding habitat via aestivation (a dry season hibernation). However, this long-lived state remains poorly characterized, with mechanisms, behavior, and implications towards malaria competence remaining unknown. Using whole-body mosquito transcriptomes from four time points during the year (early/late dry season and early/late wet season), we found unique expression patterns in immunity, longevity, and metabolic gene expression. First, while these were wild caught, whole-body samples, samplings groups clustered closely to each other, indicating homogeneity in mosquito transcriptional state per season, with differences primarily between seasons. Comparing late dry season to early wet season mosquitoes, we see dry season mosquitoes have significantly higher expression of HSP70 and alpha-crystallin beta chain (7.60, 7.48 log2FC, qval < 0.01). These proteins have been shown to increase in diapause (hibernation) in *Culex* mosquitoes and increase survival under dehydration. This may indicate diapause and aestivation have similar stress response mechanisms and could open alternative climatic conditions to induce aestivation in the lab. In contrast to diapause in other insects, we found many mosquito immune genes (TEP1, TEP4, Defensin, CLIP-B3 and A8 serine proteases) were downregulated in dry season samples (Log2 fold changes of: -2.71, -3.10, -2.33, -2.54 and -2.33, q-value < 0.05). This may point to limited blood-feeding or limited pathogen presence during this period. Finally, when comparing KEGG functional pathways, we see differences in fatty acid metabolism and longevity regulating pathways which may be indicative of aestivation mechanisms. Future work will look to correlate genetic background (karyotype) with aestivation phenotype, and to verify if transcriptional profiles of laboratory mosquitoes under known diapause inducing conditions mimic those from wild aestivators.

Mosquitoes are one of the most important insects in terms of public health, with their ability to transmit numerous pathogenic eukaryotic parasites and viruses that are responsible for millions of deaths worldwide. Several studies have shown that the mosquito commensal microbiota can influence parasitic and viral infection of the mosquito as well as impact the mosquito's development and the transmission of pathogens to humans. These discoveries have highlighted the potential of targeting the microbiota for alternative entomological control approaches. However, despite the clear importance of the mosquito-microbiota interactions, little is known about the relative importance of genetic and non-genetic factors in shaping the bacterial communities of mosquitoes. Here, we use a novel genomic assay to comprehensively characterize the bacterial populations, eukaryotic parasites and arboviruses carried by 665 individual *Anopheles* mosquitoes collected in several locations in Guinea and Mali. We identified two Apicomplexan, four Microsporidian and six nematode species as well as two Flaviviruses, infecting in total 127 mosquitoes. In addition, we use our assay to simultaneously characterize each mosquito's species, insecticide resistance alleles and the composition of its blood meal. Overall, we identified that 665 mosquitoes belonged to five *Anopheles* species, harbored varying frequencies of the *kdr-w* mutation, and were able to characterize the source of the blood meal for 133 mosquitoes. We then tested how these factors - geography, mosquito species, insecticide resistance genotypes, presence of pathogens, and mammalian blood-meal diet – influence the composition of the mosquito bacterial microbiota. We show that geographical location is the main driver of the microbial composition and diversity in wild-caught mosquitoes, with other factors having marginal effects. This study offers a comprehensive approach to disentangle the simultaneous influence of multiple factors in shaping the microbiota of *Anopheles* mosquito in nature.

1338

CHARACTERIZING VECTORS OF *PLASMODIUM FALCIPARUM* RESIDUAL TRANSMISSION IN AN ELIMINATION SETTING IN CHOMA DISTRICT, ZAMBIA

Mary E. Gebhardt[1], Kelly M. Searle[2], Tamaki Kobayashi[1], Timothy M. Shields[1], Harry Hamapumbu[3], Limonty Simubali[3], Twig Mudenda[3], Philip E. Thuma[3], Jennifer C. Stevenson[1], William J. Moss[1], Douglas E. Norris[1]

[1]*Johns Hopkins Bloomburg School of Public Health, Baltimore, MD, United States,* [2]*Division of Epidemiology and Community Health, Minneapolis, MN, United States,* [3]*Macha Research Trust, Macha, Zambia*

Macha, in Choma District in southern Zambia, is working toward a national goal to eliminate malaria by 2021. Malaria prevalence in Macha decreased from 9% in 2008 to 1% in 2013 after insecticide-treated bed net (ITN) campaigns, however residual malaria transmission still occurs with yearly infection prevalence from 1-3% under active case surveillance. As vector control strategies are successfully implemented, identification of the vectors of residual transmission remains challenging. While ITNs reduce the threat from predominately endophagic and endophilic vectors, other opportunistic foraging species may contribute as secondary vectors in residual transmission settings. In 2013, the Zambian government implemented a reactive test-and-treat strategy in Choma District to pursue

their goal of elimination. When an index case was identified positive for *P. falciparum* by rapid diagnostic test (RDT) at a local health facility, a healthcare worker visited their household and every household within 140 meters. In this study, the radius was extended to 250 meters and all individuals within the radius were screened for *P. falciparum* using a RDT and treated with ACT if positive. This procedure was repeated 30 and 90 days after the initial visit. At every visit, entomological samples were collected by placing CDC light traps indoors next to a person sleeping under a bed net and outdoors near animal pens in index and neighboring households. Each anopheline was morphologically and molecularly identified to species level by PCR, analyzed for recent blood meal content via PCR, and evaluated for sporozoite prevalence using a *P. falciparum* ELISA. A negative binomial regression will be performed to determine association of anopheline counts with risk factors including roof type, open house eaves, animal pens, and proportion of people sleeping under ITNs. Spatial analyses will also be performed to ascertain if proximity to index households influences the composition of anopheline species present. This study will provide information about vector dynamics in Macha and influence recommendations for future interventions to target residual malaria vectors.

PREDICTING SPILLOVER OF YELLOW FEVER VIRUS TO HUMANS USING VECTOR AND PRIMATE ECOLOGY

Marissa L. Childs, Nicole Nova, Justine Colvin, Erin A. Mordecai

Stanford University, Stanford, CA, United States

Yellow fever is a (re)emerging disease that largely occurs in humans following virus spillover from non-human primates via mosquitoes. To predict spillover and better understand the conditions limiting spillover in the Americas, we develop a model based on the mechanisms of spillover including the ecology of mosquito vectors and non-human primate hosts, human susceptibility, and human density. We estimate four risk metrics based on hypotheses about the factors limiting spillover. We then test these hypotheses by comparing the risk metrics to the spatial and temporal occurrences of human cases of yellow fever in Brazil from 2001 to 2016. We find that environmental risk is the best predictor of spillover independent of human case data. Unexpectedly, incorporating information about human vaccine coverage and density did not improve prediction. This finding suggests that environmental suitability may be more limiting for spillover than availability of susceptible human hosts. More generally, this work points to the potential for ecological interactions to inform prediction of pathogen spillover.

There is a growing body of evidence that immune responses targeting O-specific polysaccharide (OSP) of *Vibrio cholerae* are involved in mediating protection against cholera; however, little is known about this immune response in immunologically naïve humans exposed to *V. cholerae*. To address this, we measured serum anti-OSP (Inaba and Ogawa) antibody responses in adult North American volunteers experimentally challenged with *V. cholerae* O1 Inaba El Tor N16961. We also measured vibriocidal and anti-cholera toxin B subunit (CtxB) responses, and compared responses to those induced in age, gender, blood group, and serotype matched *V. cholerae* O1-infected cholera patients in Dhaka, Bangladesh, an area endemic for cholera. We found that prominent anti-OSP responses develop following initial cholera infection, these response are largely IgM and IgA isotypes, are highest to infecting serotype but have significant cross-serotype reactivity, peak soon after infection but remain elevated over baseline for at least 6 months, correlate with vibriocidal responses, and that anti-OSP IgA responses are lower in blood group O cholera-naïve individuals than in non-O individuals. We also found significant differences in immune responses between naïve and endemic zone cohorts, presumably reflecting previous exposure in the latter.

IMPACT OF BACKGROUND EXPOSURE DOSE ON DIRECT AND INDIRECT EFFECT OF KILLED ORAL CHOLERA VACCINES

Qifang Bi, Andrew S. Azman, Justin Lessler

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Previously published meta-analyses of the direct protection of killed whole-cell oral cholera vaccines (kOCVs) reported lower direct protection to people living in cholera-endemic Asian countries than African countries. Direct protection conferred by kOCV is also lower in children younger than 5 years than in those 5 years or older. Studies in India and Bangladesh showed that kOCVs provided stronger indirect protection to the unvaccinated than the vaccinated; specifically, the incidence among unvaccinated people was greatly reduced as community vaccine coverage increased with almost no corresponding incidence reduction among vaccinated people. Understanding the underlying mechanisms leading to these differences in direct and indirect protection across populations is important for forecasting disease dynamics and designing more effective vaccination strategies. Recently published studies have reported reduced vaccine efficacy at higher exposure dose for a range of pathogens, and these studies have shown that non-linear increase in probability of infection with increasing exposure dose could be an important contributing factor. If similar dose-response relationship is observed for cholera, we hypothesize that this dose-response relationship can explain the differences in the direct and indirect protection across populations. Using mathematical models incorporating dose-response relationships generated from historic human challenge studies of cholera, we show that increases in background exposure dose to *Vibrio cholerae* can lead to decreases in estimated direct vaccine efficacy. We also show that reductions in the bacterial exposure dose in the community as a result of vaccination coverage can explain the stronger indirect protection among unvaccinated compared to vaccinated individuals.

LARGEST PRE-EMPTIVE VACCINATION WITH ORAL CHOLERA VACCINE PREVENTS CHOLERA OUTBREAKS AMONG THE ROHINGYA PEOPLE IN COX'S BAZAR: A 360 DEGREES OF LEARNING

Firdausi Qadri

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Bangladesh, a country with endemic cholera, faced a major challenge of epidemic potential in the middle of 2017 with the influx of 700,000 people from the Rakhine state in Myanmar (referred to as Forcibly Displaced Myanmar Nationals). The prevailing conditions of the stranded people made them prone to high risk for cholera. The Government of Bangladesh together with the support of icddr,b and partner organizations conducted four mass campaigns with the oral cholera vaccine (OCV) between October 2017 to December 2018 in Cox's Bazar in this fragile population. In the campaigns, a single dose of OCV was given to all FDMNs while a second dose was given to ≤5 years in a dose-sparing attempt since OCV was limited in supply. Subsequently, two doses were offered to all of FDMNs including the host population. An important implementation system emerged from the mass vaccination such that in the first 3 rounds, OCV was delivered in a campaign design in 150 vaccination sites, however in the final campaign conducted between November to December 2018, vaccine was delivered through the 780 routine EPI fixed and outreach sites by 65 outreach mobile teams as per national EPI program. In the four campaigns, a total of 2,143,920 OCV doses were administered. In the campaigns, the icddr,b, OCV staff were involved in vaccination at the field and in training, campaign planning, monitoring and problem-solving issues together with the EPI and others heralding another unique strength of icddr,b to partner with the government in this effort. Coverage evaluation was carried out which confirmed high rates of OCV coverage. Along with the campaigns, surveillance for *V. cholerae* is continuing for evaluation of the effectiveness of OCV in this fragile population in a test-negative case-control design and also to develop an early warning system for control of epidemics. Until now, no cholera epidemics have occurred among the FDMNs or host population. The successful OCV campaign in Cox's Bazar has become a showcase for Bangladesh on use of OCV for control of future endemic cholera using the existing EPI system of Bangladesh. Further evaluation of data will be presented.

LONG READ SEQUENCING OF *VIBRIO CHOLERAE* REVEALS REGIONAL TRANSMISSION PATTERNS IN MALAWI

Shirlee Wohl[1], Watipaso Kasambara[2], Innocent Chibwe[2], Amanda Debes[1], David Mohr[3], Justin Lessler[1], Andrew Azman[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Public Health Institute of Malawi, Ministry of Health, Lilongwe, Malawi,* [3]*McKusick Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States*

Whole genome sequencing has recently been used to understand the movement of seventh pandemic El Tor (7PET) *Vibrio cholerae* strains into and out of Africa. However, much remains unknown about the spread and evolution of cholera at the local and regional levels. New highly portable long read sequencing technology (such as Oxford Nanopore (ONT)) has the potential to bring sequencing closer to the places where cholera outbreaks occur, potentially providing near real-time actionable data. Long read sequencing also has the potential to more clearly resolve long repeats and regions with structural variation than sequencing short reads. We performed whole genome sequencing using the ONT platform on cholera isolates collected throughout Malawi between 2015 and 2018 to identify the strains underlying recent outbreaks and to understand cholera dynamics within the region. We performed a phylogenetic analysis of these sequences and identified multiple distinct cholera sublineages within the larger 7PET lineage circulating within Malawi from 2015-2018. Additionally, we found that some, but not all, of the isolates contain a multidrug resistant IncA/C conjugative plasmid, in line with recent studies that identified acquired IncA/C plasmids in certain cholera lineages, including in isolates collected in East and West Africa. We compared these genomes to those sequenced on the Illumina platform (short reads) and to the results of commonly-used typing methods such as multi-locus variant analysis (MLVA). More generally, because of the potential for ONT sequencing to quickly provide genomic data important to a local public health response, we developed and implemented a pipeline for rapid lineage identification and antimicrobial resistance screening of cholera and discuss the potential added value of in-country real-time cholera sequencing during an outbreak.

VIBRIO CHOLERAE TRANSMISSION IN BANGLADESH: INSIGHTS FROM A NATIONAL SEROSURVEY

Andrew S. Azman[1], Justin Lessler[1], Daniel Leung[2], Francisco J. Luquero[3], Jason Harris[4], Stephen Lauer[1], Fatema Khaton[5], Kishor K. Paul[5], Md. Taufiqur Rahman Bhuiyan[5], Henrik Salje[6], Firdausi Qadri[5], Emily S. Gurley[1]

[1]*Johns Hopkins School of Public Health, Baltimore, MD, United States,* [2]*University of Utah, Salt Lake City, UT, United States,* [3]*Epicentre, Paris, France,* [4]*Massachusetts General Hospital, Boston, MA, United States,* [5]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [6]*Institut Pasteur, Paris, France*

Despite years of cholera research in Bangladesh little is known about the geographic distribution and magnitude of pandemic *Vibrio cholerae* O1 (VC) transmission across the country as most surveillance data come from just a few sites. We aim to use recent advances in cholera seroepidemiology to describe cholera infection risk across Bangladesh. We conducted a nationally representative serosurvey across Bangladesh of 2,778 individuals from 70 randomly selected communities and tested serum samples using six assays quantifying different VC-specific antibodies. Using 6 biomarkers (vibriocidal Inaba, vibriocidal Ogawa, anti-CTB IgG, anti-CTB IgA, anti-LPS IgG and anti-LPS IgA), age and sex profiles from participants, we found that 20.7% of the population had evidence of VC infection in the previous year using a recently validated machine learning model (range: 0-73% across communities). We explored a number of potential individual- household- and community level risk factors and found that only age (risk increasing with age) and being female were significantly associated with increased cholera infection risk. We created high-resolution maps of VC infection risk using Bayesian model-based geostatistical methods and found that while the absolute infection risk is generally high throughout Bangladesh, there are clear areas with evidence of elevated transmission ('hotspots') that are qualitatively similar to clinical case maps based national diarrhea data and cholera sentinel surveillance data from the same time period. Our preliminary estimates suggest that as many as 35.4 million infections (95% CrI 29.5-41.5 million) occurred across Bangladesh in the year preceding the survey, although this estimate includes infections across the severity spectrum from asymptomatic to severe cholera gravis.These results illustrate how serosurveillance provides an avenue for identifying areas of high VC transmission and exploring key risk factors for infection across geographic scales. Future work combining serologic studies and estimates of clinical disease rates can help improve the interpretation of cross-sectional serosurvey results.

Norovirus is an important enteric viral agent causing acute gastroenteritis in children worldwide. Using data from Vaccine Impact on Diarrhea in Africa (VIDA), a prospective, health center and community-based case-control study from May 2015 - July 2018, we describe the epidemiology of norovirus among children <5 years old in The Gambia, Kenya, and Mali. An MSD case was defined as a child 0-59 months old, passing ≥3 loose stools in the previous 24 hours with ≥1 of the following: sunken eyes, poor skin turgor, dysentery, IV rehydration, or hospitalization within 7 days of diarrhea onset. Diarrhea-free controls matched for gender, age, time, and community were enrolled at home. Stools collected from cases and matching controls at enrolment were tested for a panel of enteropathogens, including norovirus genotype I (NVI) and II (NVII), using TaqMan Array Card (TAC). A TAC cut-off value of <35 Cq was considered positive. Adjusted attributable fractions (AF) for each pathogen significantly associated with MSD were derived for each site and age stratum using multiple conditional logistic regression (CLR). Using LR, adjusting for age, blood in stool, and study site, we evaluated factors associated with norovirus MSD. VIDA included 4, 779 MSD cases (221 NVI-positive and 550 NVII-positive), and 4750 controls (234 NVI-positive and 513 NVII-positive). Whereas NVI was not significantly associated with MSD, NVII was significantly associated with MSD in all sites in infants 0-11 months old (The Gambia AF 5.0, 95% CI [2.0-9.9]; Mali AF 7.9, 95% CI [3.7-12.4]; and Kenya AF 10.3, 95% CI [6.9-14.7]), and in Kenya among those 12-23 months (AF 5.6; 95% CI [3.0-9.6]). Compared to non-NVII MSD cases, NVII patients were more likely to be infants (284 [51.6%] vs. 1413 [33.4%], aOR 3.09, 95% CI 2.38-4.01) and to present with vomiting (308 [56%] vs. 1927 [45.6%], aOR=1.40, 95% CI 1.16-1.69), but were less likely to present with blood in stool (54 [9.8%] vs. 637 [15.1%], aOR =0.72, 95% CI 0.53-0.98). We found that infants bear the greatest burden of MSD associated with norovirus GII.

1346

USING KERNEL DENSITY ESTIMATES IN LIKELIHOOD RATIOS TO OPTIMIZE ETIOLOGICAL PREDICTIONS OF INFECTIOUS DIARRHEA IN RESOURCE-LIMITED SETTINGS

Benjamin J. Brintz[1], Joel Howard[1], Benjamin Haaland[1], Andrew Pavia[1], Tom Greene[1], Dennis Chao[2], Joshua Proctor[2], Adam Levine[3], Karen Kotloff[4], James Platts-Mills[5], Daniel Leung[1]

[1]*University of Utah, Salt Lake City, UT, United States,* [2]*Institute of Disease Modeling, Seattle, WA, United States,* [3]*Brown University, Providence, RI, United States,* [4]*University of Maryland, College Park, MD, United States,* [5]*University of Virginia, Charlottesville, VA, United States*

Non-laboratory methods to more accurately assess etiology are needed for appropriate management of pediatric diarrhea in low and middle income countries (LMICs). In LMICs, etiological diagnosis is rarely made, and a large number (up to 70%) of diarrheal patients are prescribed antibiotics empirically. Our goal is to build an electronic clinical decision support system (eCDSS) with multiple data sources appropriate for use in LMICs. We use clinical and quantitative molecular etiologic data from the Global Enteric Multicenter Study (GEMS) to develop predictive models for viral-only diarrheal etiology in young children, given the lack of efficacy of antibiotics for viral-only infections. We use the post-test odds (PTO) formulation which allows for prior knowledge as well as flexible inclusion or omission of one or more "tests", or information sources, for evaluating the likelihood of an etiology. In addition to using current patient clinical predictors, other sources of data we consider are clinical data from previous patients and local climate data. For climate, we calculate a rolling weighted average of temperature and rain data from NOAA weather stations in order to capture weather pattern trends, and we calculate a weighted average of recent patient data to account for influxes of a particular etiologies. We build a parsimonious set of prediction variables from the full set of GEMS survey responses via random forest variable importance screening. Variables predictive of viral etiology include age, vomiting, BMI, bloody diarrhea, breastfeeding. We address uncertainty in predictions by constructing Gaussian kernel density estimates of likelihood ratios for each test based on training predictions. Cross-validation shows that use of PTO improves average AUC by up to 0.04 (from 0.81 to 0.85) by including recent weather patterns in addition to clinical predictors. Overall, our post-test odds model's performance suggests that incorporating additional data sources can improve the performance of a clinical prediction rule for etiological prediction of diarrhea in LMICs over what can be achieved with clinical information alone.

of Copenhagen, Copenhagen, Denmark, [7]Institut für Tropenmedizin, Eberhard Karls Universität Tübingen, Tübingen, Germany, [8]European Vaccine Initiative, Heidelberg, Germany

Placental Malaria (PM) pathogenesis is caused by interactions between the parasite protein VAR2CSA and chondroitin sulfate A (CSA) in the human placenta. The PAMVAC vaccine is a VAR2CSA protein-based vaccine, aiming to protect fetus and mother against the adverse effects of PM. After a safe Phase Ib clinical trial conducted in Benin from November 2016 to September 2017, PAMVAC immunogenicity was explored in 21 healthy nulligravid adult females randomized in 3 groups (9 Alhydrogel, 9 GLA-SE, 3 Placebo). They received 3 doses of 50 μg of adjuvanted PAMVAC or Placebo 28 days apart (Day 0, 28 and 56). Plasma samples and PBMC harvested at Days (D) -1, 56, 84, 168, 252 were stored respectively at -20°C and in liquid nitrogen for immunoassays. Memory B cells were quantified by ELISpot and functional antibody properties assessed for Variant Surface Antigen (VSA) recognition and opsonic phagocytosis using FACS. PAMVAC vaccination induced a memory B response that increased noticeably after the 2nd dose of vaccine (D56) and persisted over time at levels substantially higher than those we have previously measured in multigravid Beninese. The frequency of PAMVAC-specific antibody-secreting B cells was notably higher with GLA-SE than with alum, and responses were stable between D56 and D84. PAMVAC-specific B cell responses were undetectable in the Placebo group. PAMVAC immunization also induced antibody-mediated homologous VSA recognition and opsonic phagocytosis activities. IgG1 and IgG3 responses to VSA were higher in both adjuvant groups compared with Placebo, and opsonic phagocytosis of infected red blood cells was observable from D56 in the vaccinated groups. PAMVAC with alum induced stronger opsonic phagocytosis than with GLA-SE. In conclusion, the combination of PAMVAC with GLA-SE rather than alum was associated with the strongest B cell responses, whilst the combination with alum was associated with stronger functional antibody responses in women of childbearing age before their first pregnancy.

HUMAN MAB BLOCKS MALARIA TRANSMISSION IN *PLASMODIUM*-INFECTED MOSQUITOES

Camila H. Coelho[1], Marty Butkhardt[1], Issaka Sagara[2], Jacob D. Galson[3], Thiago A. Silva[4], Justin Taylor[5], Miranda Byrne-Steele[6], Nichole Salinas[1], David Narum[1], Niraj Tolia[1], Jonathan Renn[1], Patrick E. Duffy[1]

[1]*Laboratory of Malaria Immunology and Vaccinology/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [2]University of Bamako, Bamako, Mali, [3]Kymab, UK, United Kingdom, [4]Laboratory of Malaria and Vector Research/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [5]Fred Hutchinson Cancer Research Center, Seattle, WA, United States, [6]iRepertoire, Huntsville, AL, United States*

Malaria transmission blocking vaccines (TBVs) target sexual stage proteins of *Plasmodium falciparum* parasite in the mosquito vector, thereby reducing transmission. To improve the design of transmission-blocking therapeutic approaches, functional antibodies generated against these proteins need to be better characterized. Here, we generated functional human mAbs against the protein Pfs230, a surface antigen of *P. falciparum* gametes. Pfs230-specific single B cells generated by the fourth dose of Pfs230D1-EPA/Alhydrogel® in Malian adults were sorted after labelling with antigen-tetramers, and both heavy and light antibody chains were sequenced. Paired BCR sequences were selected from two vaccinees, based on repeated frequency among sorted cells and high mutation rates, and two BCR sequences were chosen to generate fully human recombinant IgG1 by expression in HEK cells. These antibodies LMIV230-01 and LMIV230-02, bound to Pfs230D1 and to protein extract of female gametocytes. LMIV230-01 and LMIV230-02 demonstrated high and similar binding affinities to recombinant Pfs230D1 antigen. However, only LMIV230-01 strongly bound to the surface of live female gametes while LMIV230-02 reacted minimally. LMIV230-01 also bound to gametocytes and zygotes, but did not bind to ookinetes, as expected. LMIV230-01 reduced *P. falciparum* oocyst burden in mosquitoes by 99% at 1000 μg/mL while LMIV230-02 reduced by 60% at the same concentration, although activity of both antibodies was determined to be complement-dependent. Competition assays suggested that the two antibodies react to different epitopes, and their CDR3 in the heavy chain shares no similarity. These functional mAbs provide the basis for the rational design of an improved Pfs230 vaccine or of antibody-based interventions against mosquito-stage proteins that prevent malaria transmission through parasite neutralization.

The transmission of malaria parasites from humans to the mosquito vector involves relativity small numbers of parasites and has long been viewed as a target for interrupting transmission. With this aim in mind, a number of vaccines are currently under development. We have developed a mathematical description of a vaccine for *Plasmodium falciparum*, targeting antigen *Pfs*230, based on trial data collected in Mali. Incorporating the vaccine into a widely-used model of malaria transmission allows us to estimate the population-level impact of the vaccine, as well as identify the key demographics to target in a vaccination campaign. As transmission-blocking interventions are commonly measured by a standard membrane feeding assay, we consider how best to translate transmission blocking and reducing activities into different measures of efficacy in clinical trial settings. Unlike conventional vaccines, a transmission blocking vaccine confers no direct individual-level protection against bites from infectious Anopheles mosquitoes so vaccine effectiveness will depend on clinical incidence in both vaccinated and unvaccinated individuals and their relative spatial distribution. A high degree of mixing between these sub-populations will lead to the vaccine-derived benefits being shared throughout the entire population. In contrast, in a scenario in which transmission is focal and vaccinated subjects cluster together, the impact will be focused upon the vaccinated population. Such effects, which we estimate with our model, must be appreciated to accurately assess the full impact of transmission blocking interventions.

The *Plasmodium vivax* Duffy binding protein (DBP) is a prime target of the protective immune response and a promising vaccine candidate for *P. vivax* malaria. Naturally acquired immunity (NAI) protects against malaria in adults residing in infection-endemic regions, and the passive transfer of malarial immunity confers protection. A vaccine that replicates NAI will effectively prevent disease. Here, we report the structures of

DBP region II in complex with human-derived, neutralizing monoclonal antibodies obtained from an individual in a malaria-endemic area with naturally acquired immunity. We identified protective epitopes by X-ray crystallography, hydrogen-deuterium exchange mass spectrometry, mutational mapping, and *P. vivax* invasion studies. These approaches reveal that naturally-acquired human antibodies neutralize *P. vivax* by targeting the DARC–binding site and dimer interface of *P. vivax* DBP. Antibody binding is unaffected by polymorphisms in the vicinity of epitopes, suggesting the antibodies have evolved to engage multiple polymorphic variants of DBP. The human antibody epitopes are broadly conserved and are distinct from previously defined epitopes for broadly conserved murine mAbs. A library of globally conserved epitopes of neutralizing human antibodies opens new horizons for rational design of strain-transcending DBP-based vaccines and therapeutics against *P. vivax*.

Malaria could be the first disease against which any subunit vaccine working through $CD8^+$ T cells is licensed. Such a vaccine would need to target the liver-stage malaria parasite. ChAd63 and MVA ME-TRAP, two leading vectored vaccine candidates for this indication, induce high numbers of circulating $CD8^+$ T-cells, but only result in modest (20-25%) sterile efficacy against sporozoite challenge, although a small field trial in Kenya identified higher efficacy in semi-immune adults. Preclinical experiments demonstrated that changing the immunisation regimen, to include a final booster dose intravenously, substantially improved sterile efficacy against transgenic *P. berghei* challenge. Use of such a *prime-target* strategy, in which one or more intramuscular doses of a CD8 T cell-inducing viral vector is followed by an intravenous dose of the same or another viral vector with the same transgene, conferred 100% efficacy for numerous liver-stage antigens in mice. This strategy induces high numbers of antigen- specific tissue-resident memory T-cells (T_{RM}), in the liver, and their causal protective role was demonstrated by adoptive transfer studies. The first Phase I vaccine trial (VAC064) of any intravenous use of vaccine vectors demonstrated adequate safety and strong immunogenicity of single-dose intravenous ChAd63 and MVA ME-TRAP. We have now undertaken a Phase I/IIa (VAC066) CHMI trial to evaluate the *prime-target* strategy for the first time. This trial has enrolled 37 volunteers, 31 of which were vaccinated, according to four different immunization schedules, using ChAd63 and MVA encoding ME-TRAP. Fine needle aspirates of the liver in some volunteers allowed direct measurement of intrahepatic antigen-specific T cells.We will report the safety, immunogenicity and efficacy measured in this first clinical trial of a novel immunisation strategy, which could provide a rapid two-dose approach to inducing liver-stage immunity to malaria.

NOVEL METHODS TO DETERMINE LIVER-STAGE MALARIA VACCINE CORRELATES OF PROTECTION: KINETICS, DEEP IMMUNE PHENOTYPING AND TRANSCRIPTOMICS

Andrés Noé, Duncan Bellamy, Amy Flaxman, Mehreen Datoo, Daniel Jenkin, Ali Husainy, Katie J. Ewer, Adrian V. Hill, Alexandra J. Spencer

The Jenner Institute, University of Oxford, Oxford, United Kingdom

Protection from liver-stage malaria requires high numbers of CD8+ T cells to find and kill *Plasmodium*-infected cells. A new malaria vaccine strategy, Prime-Target Vaccination (PTV), involves sequential viral-vectored vaccination by intramuscular and intravenous routes to target cellular immunity to the liver. The efficacy of leading liver-stage malaria vaccine candidates in mice can be enhanced with this approach from 0-30% to 100%. PTV substantially increases the number of antigen-specific tissue-resident memory CD8+ T cells (TRMs) in the liver of mice. The first human phase I/IIa clinical trial of PTV efficacy against controlled human malaria infection is ongoing. We hypothesise that protection correlates to the magnitude of the TRM response elicited in the liver by vaccination. We have seen that cells with a TRM phenotype transiently appear in the blood of IV vaccinated individuals, which is consistent with data in animal models. Herein, we track the kinetics of these blood-derived TRMs with the expectation of identifying a correlate of vaccine protection against CHMI. Directly sampling the human liver safely is difficult but possible through liver fine needle aspiration (FNA). We safely obtained FNAs from 13 volunteers. Our project is the first-ever to perform deep immune phenotyping and transcriptomic evaluation of the intrahepatic effect of a new and promising liver-stage malaria vaccine strategy. As a means to identify correlates of liver-stage malaria protection, we obtained time-matched PBMC samples from the same volunteers who underwent FNA. We used flow cytometry and single-cell RNA sequencing on lymphocytes from the liver and blood to identify differentially expressed genes. This work provides clinical proof-of-concept of multiple novel methods to investigate pre-erythrocytic malaria vaccines, immunological evaluation of a malaria vaccine strategy by CHMI, and insights into correlates of protection after vaccination. A simple and reproducible correlate of protection would be particularly helpful in trials of liver-stage malaria vaccines as they progress to phase III, large-scale testing in African infants.

Title: Development of multi-strain and multi-strain hybrid *Plasmodium falciparum* sporozoite vaccines. Sanaria® PfSPZ Vaccine is composed of radiation attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ). Based on safety and vaccine efficacy (VE) results, Phase 3 clinical trials are planned for 2020. It has been hypothesized that broader, more potent VE can be obtained by immunizing with PfSPZ from diverse geographic origins. PfSPZ Vaccine is produced from the NF54 strain of Pf, thought to be from West Africa. Pf NF54 is an excellent producer of PfSPZ. On the other hand, PfNHP4026, a Thai isolate (F. Nosten, Thailand), is an exceptionally infectious to hepatocytes. This suggests that this parasite may be a more potent vaccine immunogen than PfNF54, because infection of the liver by the vaccine is a prerequisite for protective T cell responses. We are thus developing PfNHP4026 as a vaccine strain. In order to achieve diversity we used genetic crossing between the two Pf strains to create hybrid progeny

parasite strains that combine Pf antigens from different geographic areas. Use of hybrid Pf strains that produce more PfSPZ/mosquito and are more infectious to hepatocytes than PfNF54 would constitute a simple and elegant solution to increasing and broadening vaccine-induced protection. We have successfully crossed PfNF54 and the Thai isolate, PfNHP4026, and produced F1 progeny (F1 Hybrids). We are developing the F1 Hybrids to select a vaccine candidate. Our selection includes high PfSPZ productivity, high hepatocyte infectivity and high predicted proteomic (T cell epitope) diversity. We will report on optimization of aseptic production of PfSPZ from PfNHP4026 and selected PfHybrids, and characterization of their infectivity to hepatocytes *in vitro* and human liver-chimeric mice *in vivo*.

The Zambian National Malaria Elimination Centre have set ambitious targets for achieving malaria elimination. Key to achieving this is the efficient and optimal deployment of resources to maximize impact. The basis of this "optimal deployment" is multifaceted and will depend on the intervention or combination of interventions under consideration, as well as the epidemiological features of the transmission setting. In this study we develop stratification maps specific for each intervention, whereby targeting is based not only on the level of malaria transmission, but also a range of geospatial covariates including access to treatment based on the travel time to the nearest healthcare provider, level of rurality, duration of malaria transmission season, existing intervention coverage, and population density. The stratification map for each intervention is also tailored to the spatial scale at which the intervention is delivered. Furthermore, we use a range of data sources to track changes in malaria transmission to identify "breakpoints" where the optimal intervention package for a region should change. Traditionally, these decisions have been made using malaria incidence data from routine surveillance. However, improvements in surveillance and response as well as access to treatment have resulted in an increasing number of both passively and proactively identified cases, making interpretation of case totals and thus transmission more difficult. We circumvent this problem by employing a range of data sources, including test positivity rate and the proportion of cases in under-5-year-olds, to better elucidate underlying trends in transmission. Data-driven methods to inform stratification and intervention targeting, and to understand trends in transmission from routine data, have the potential to enhance elimination efforts in Zambia. Here we present an example of this approach and discuss how these methods can be adopted by national malaria control programs.

1355

CHOOSING THE RIGHT TOOL FOR THE JOB: ESTIMATING EFFECT SIZES FOR MULTIPLE OVERLAPPING INTERVENTIONS IN SOUTHERN PROVINCE, ZAMBIA

Joshua G. Suresh[1], Jaline Gerardin[2], John Miller[3], Busiku Haimanza[4], Thom Eisele[5], Edward A. Wenger[1], Caitlin A. Bever[1]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*Northwestern University Feinberg School of Medicine, Chicago, IL, United States,* [3]*PATH, Lusaka, Zambia,* [4]*National Malaria Elimination Centre, Lusaka, Zambia,* [5]*Tulane University, New Orleans, LA, United States*

Modern anti-malarial campaigns often layer multiple interventions, such as indoor residual spraying (IRS), distribution of insecticide-treated bed nets (ITN), mass drug campaigns (MDA), and deployment of community health workers (CHWs). However, when these interventions are implemented together with spatially varying coverages and timings, it can be difficult to disentangle intervention effect sizes and identify which interventions were most impactful in a given region. This issue becomes critical when comparing regions which, on the surface, received the same interventions but arrived at disparate clinical endpoints. Such is the case with the Lake Kariba region of Southern Zambia, an area which has benefited from IRS and ITN campaigns as well as a multi-armed MDA trial and deployment of CHWs from 2014 onwards. The different health facility catchment areas, though receiving similar intervention packages, experienced a wide range of clinical burden reduction levels. We address the question of disparate impact using detailed spatial simulations of the entire MDA trial area, calibrated to all available data sources. Drawing from survey data, we implement the timing and coverage for each intervention on a per-square-kilometer basis. We also implement data-informed migration patterns, treatment-seeking, and reactive case detection. Relative abundances of the two primary vectors, An. arabiensis and An. funestus, are determined by calibrating to observed parasite prevalence and clinical incidence using entomological data as a prior. We are able to attribute effect sizes to each intervention employed in each catchment, and draw systematic conclusions about how intervention impact varies with key environmental covariates. We also explore hypothetical scenarios to identify the optimal package to yield a high probability of interruption in different risk strata, including with new proposed interventions that target outdoor biting such as endectocides and ATSBs. Finally, we introduce a stratification scheme, with optimal intervention packages targeted towards clinical burden reduction suggested for each risk stratum.

1356

MASS DRUG ADMINISTRATION FOR MALARIA: AN UPDATED COCHRANE SYSTEMATIC REVIEW

Monica Shah[1], Jimee Hwang[2], Leslie Choi[3], S. Patrick Kachur[4], Meghna Desai[1]

[1]*Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*U.S. President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention; Global Health Group, University of California San Francisco, San Francisco, CA, United States,* [3]*Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [4]*Malaria Branch, Centers for Disease Control and Prevention, Atlanta, Georgia; Heilbrunn Department of Population and Family Health, Columbia University, Mailman School of Public Health, New York, NY, United States*

There has been renewed interest in mass drug administration (MDA) with antimalarial drugs to accelerate progress towards malaria elimination. We assessed the effect of MDA compared to no MDA on the interruption of transmission in settings of very low-to-low endemicity and on the reduction in malaria transmission in settings of moderate-to-high endemicity. We searched multiple databases for relevant studies comparing the effect of MDA against no MDA on *Plasmodium falciparum* parasitaemia prevalence. Studies with balanced co-interventions across arms and at least two sites per arm were included. For cluster randomized-controlled trials (cRCTs), we estimated risk ratios (RR) and we adjusted 95% confidence intervals (CIs) for clustering. Analyses were stratified by malaria endemicity. We assessed the certainty of evidence using the Grading of Recommendations Assessment, Development and Evaluation approach. Nine cRCTs were included. Two trials in moderate-to-high transmission areas showed that MDA probably leads to little or no reduction in parasitaemia prevalence through 6 months post-MDA (RR 1.76, 95% CI 0.58-5.36 at 1-3 months post-MDA and RR 1.18, 95% CI 0.89-1.56 at 4-6 months; moderate certainty evidence). Due to very low certainty evidence from seven trials in very low-to-low transmission areas, we do not know if MDA has an effect on parasitaemia prevalence within 12 months post-MDA; the effects ranged from RR 0.12 (95% CI 0.03-0.52) at < 1 month post-MDA, RR 0.06 (95% CI 0.01-0.45) to 1.34 (95% CI 0.50-5.92) at 1-3 months, RR 0.07 (95% CI 0-1.31) to 0.89 (95% CI 0.27-2.95) at 4-6 months, and RR 0.08 (95% CI 0-1.36) to 1.55 (95% CI 0.77-3.13) at 7-12 months. In very low-to-low transmission settings, MDA initially had strong but heterogeneous effect on parasitaemia prevalence that waned over time, but we found no evidence of interruption of

transmission. MDA did not reduce malaria transmission in moderate-to-high transmission settings at any post-MDA time point. Additional results from non-randomized studies, for other primary outcomes, and for *P. vivax* will be presented.

1357

RESULTS OF A PILOT OF TARGETED MASS DRUG ADMINISTRATION WITH SULFADOXINE-PYRIMETHAMINE AND PRIMAQUINE AS A COMPONENT OF A MALARIA ELIMINATION PACKAGE IN HAITI

In Haiti, the prevalence of *Plasmodium falciparum (Pf)* malaria is <1%. Malaria Zero, an alliance of partners led by the Haitian National Malaria Control Program, has piloted a package of interventions to accelerate progress toward malaria elimination. The package includes: expanded access to malaria case management (CM), strengthened case-based surveillance (CBS), indoor residual spraying (IRS), and targeted mass drug administration (tMDA). After deploying CM and CBS in 5 pilot communes, we conducted tMDA and IRS in 12 high-transmission malaria *foci* at the start of the rainy season in 2018 (15 October-5 November). For tMDA, sulfadoxine-pyrimethamine (SP) and single low dose primaquine (PQ) were administered with direct observation to all eligible residents during household visits. Pharmacovigilance of adverse events (AEs) from SP/PQ occurred for 30 days following the tMDA campaign; 54 AE reports were completed with 0 reports of clinical hemolysis or Stevens-Johnson Syndrome. The IRS campaign used the insecticide pirimiphos-methyl capsule suspension. A baseline cross-sectional household survey was done prior to the campaign; post-campaign surveys are planned at 10 weeks, 6 and 12 months to assess acceptability and changes in parasite prevalence and serological markers of malaria exposure. The tMDA effective coverage was 89.5% (36,388 people treated of 40,618). Preliminary results from the 10 week post-campaign survey found that among 1,317 respondents, 134 people did not take the tMDA medications; the most common reasons were absenteeism, refusals, and pregnancy (58.0%, 14.2%, and 8.9%, respectively). Of 1,183 respondents who took the tMDA medicines, almost all (99.6%) were willing to take the medicines in future campaigns. *Pf* prevalence measured by a conventional and a highly sensitive rapid diagnostic test was lower at 10 weeks post-campaign (0.95% after rainy season, n=1,365) than at baseline (1.7% pre-rainy season, n=1,196). The pilot demonstrated the feasibility of achieving high coverage for tMDA with SP/PQ in a single round. Additional results for IRS, access to care, and serological changes will be presented.

1358

THE *MAGUDE PROJECT:* DRASTIC REDUCTION OF MALARIA BURDEN AND SUSTAINED GAINS AFTER A MALARIA ELIMINATION PROJECT IN SOUTHERN MOZAMBIQUE

Beatriz Galatas[1], Helena Martí-Soler[1], Caterina Guinovart[1], Lidia Nhamussua[2], Wilson Simone[2], Humberto Munguambe[2], Arlindo Chidimatembue[2], Júlia Montañà[1], Fabião Luis[2], Krijn Paaijmans[1], Quique Bassat[1], Alfredo Mayor[1], Clara Menéndez[1], Baltazar Candrinho[3], Regina Rabinovich[1], Pedro Alonso[1], Francisco Saúte[2], Pedro Aide[2]

[1]*ISGlobal, Barcelona, Spain,* [2]*CISM, Manhiça, Mozambique,* [3]*National Malaria Control Programme, Ministry of Health, Maputo, Mozambique*

The feasibility of malaria elimination using currently available tools in low transmission areas of sub-Saharan Africa remains unknown. A before-after study was conducted in Magude district, southern Mozambique to evaluate the impact of a package of interventions on malaria morbidity and inpatient admissions and deaths. Two years of two mass drug administration (MDA) rounds per year (Phase I, August 2015-17) followed by one year of reactive focal drug administrations (rfMDA) at household level (Phase II, September 2017 to June of 2018) with dihydroartemisinin-piperaquine were deployed in combination with annual rounds of indoor residual spraying (IRS), programmatically distributed bednets and standard case management. Parasite prevalence was monitored through yearly cross-sectional surveys. Routine malaria data were used to depict case incidence and inpatient admissions and mortality trends. An interrupted time series analysis using a generalized estimated equation with Poisson was used to estimate the level and trend change in malaria cases associated with the project interventions, and the number of cases averted. The four MDA rounds covered 58%-72.3% of the population, and annual IRS campaigns covered >70% of households. All-age parasite prevalence by rapid diagnostic test declined from 9.1% (95%CI 7.0-11.8) to 2.6% (95%CI 2.0-3.4) (71% reduction) after phase I, and to 1.5% (95%CI 1.0-2.4) after phase II (83% overall reduction). Case incidence fell from 195 cases per 1000 to 77 cases per 1000 after phase I (65% reduction), and to 31 per 1000 after phase II (84.1% overall reduction). Phase I interventions were associated with a significant level reduction (Adjß=0.31, 95%CI 0.23-0.43), and an estimated 76.7% (95%CI 76.4% -77.1%) of expected cases averted throughout the project. In conclusiom, MDA and vector control served as an accelerator to rapidly reduce malaria transmission, and rfMDA sustained the gains up to one year, but malaria was not eliminated.

1359

A *FOCI* COHORT ANALYSIS TO ASSESS MALARIA ELIMINATION IN THAILAND

Prayuth Sudathip[1], Julien Zwang[2], Rungrawee Tipmontree[1], Suravadee Kitcharkarn[1], Thannikar Thongrad[1], Felicity Young[3], Richard Reithinger[3], Jui A. Shah[2], David Sintasath[4], Preecha Prempree[1], Darin Areechokchai[1], Jersuda Kajanasuwan[1], Cheewanan Lertpiriyasuwat[1]

[1]*Bureau of Vector Borne Diseases, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand,* [2]*Inform Asia: USAID's Health Research Program, RTI International, Bangkok, Thailand,* [3]*RTI International, Washington, DC, United States,* [4]*U.S. President's Malaria Initiative, Regional Development Mission for Asia, United States Agency for International Development, Bangkok, Thailand*

Thailand's malaria elimination strategy is based on the identification and classification of malaria cases, including by place of residence or geographical locality. Active *foci* are geographical localities with ongoing malaria transmission, compared to reverted *foci* that have recorded no malaria cases in the previous 12 months. The objective of this study was to assess the effectiveness of Thailand's *foci*-based malaria elimination strategy by following a cohort of active *foci* from 2014 through 2018. Reversion was assessed by Kaplan-Meier survival analysis, and the predictors of *foci* reversion were measured as adjusted hazard ratios

using Cox regression models. At the start of the study period, 3,425 active *foci* reporting 24,558 malaria cases were identified. From 2014 to 2017, the reactive case detection ratio increased by 73.0%, from 15.2 to 26.3 people screened per case. Foci and case investigation rates remained high, at over 90.0%. Coverage of vector control interventions, including insecticide-treated nets and indoor residual spraying, showed minimal increases. The number of active *foci* dropped to just 435 in 2018, representing an 87.3% decrease during the study period. Similarly, the number of confirmed malaria cases dropped to 3,107 in 2018. Multivariate analysis showed that smaller *foci* (defined as <10 cases per year) were more likely to revert compared to larger *foci* (93.6% versus 50.7%), as well as *foci* with smaller population size (defined as <100 people) and *foci* with a greater proportion of *P. falciparum* cases. Foci located in Sisaket, Tak, and Yala provinces were less likely to revert compared to other provinces. Thailand's *foci*-based malaria strategy, comprising strong national treatment guidelines, high investigation rates, and an increased reactive case detection ratio, is showing success in decreasing active *foci* and cases. Thailand's strategy and these encouraging results may be a useful example for other countries in the Greater Mekong sub-region as they progress towards malaria elimination.

OVERCOMING BARRIERS TO LOW MALARIA TESTING RATES IN AN ELIMINATION CONTEXT: RESULTS FROM MIXED METHODS RESEARCH IN LAO PDR

Samuel Haddad[1], Malaykham Duangdara[1], Rebecca Potter[2], Saysana Phanalasy[1]

[1]*Population Services International, Vientiane, Lao People's Democratic Republic,* [2]*Population Services International, Laos, Lao People's Democratic Republic*

Lao PDR aims to eliminate malaria by 2030; yet, at 4.1%, the annual blood examination rate (ABER) falls short of the 10% benchmark set by WHO. The NMCP revised national treatment guidelines in 2018 with an aim to boost testing rates. PSI Laos supports a network of 525 private sector providers, which detected 15% of the national malaria caseload in 2018. PSI conducted mixed methods research to better understand barriers to malaria testing among private providers. Qualitative and quantitative research was used to generate evidence about provider motivation, and a mystery client survey was conducted to document observations about provider behaviors and adherence to guidelines. These data were used to develop strategies for improving adherence to national guidelines. Routine surveillance data were analyzed pre- and post-intervention to estimate the impact on testing rates. Mystery client survey data showed that ~35% of clients presenting to a private provider with fever symptoms received an RDT, compared to 99% of suspected cases reported to receive RDTs through routine data. Qualitative analysis of provider motivation data revealed that private providers valued professional development opportunities, being part of a community of peers, and contributing to malaria elimination in their communities. These insights were integrated into provider behavior change communication (PBCC) interventions carried out by field officers providing monthly supportive supervision beginning in May 2018. Prior to the roll-out of new testing guidelines and PBCC intervention, private sector providers in PSI's network tested an average of 6.01 clients per month. Post-intervention, providers conducted an average of 10.29 tests per month. Sustaining provider motivation to maintain testing in low-burden environments remains a significant challenge for malaria elimination. Understanding provider motivations and developing strategies based on insights can improve testing rates. Complementary research on provider behaviors in public sector channels is needed to inform national strategies for improving provider adherence to national guidelines.

EVALUATION OF EXTENDED EFFICACY OF TETRAVALENT CHIMERIC YELLOW FEVER-DENGUE (CYD) VACCINE AGAINST SYMPTOMATIC AND SUBCLINICAL DENGUE VIRUS INFECTIONS AMONG FILIPINO CHILDREN

Alan L. Rothman[1], Mary N. Chua[2], Mary T. Alera[3], Henrik Salje[4], Damon Ellison[5], Anon Srikiatkhachorn[1], Richard G. Jarman[5], In-Kyu Yoon[6], Louis R. Macareo[6]

[1]*University of Rhode Island, Providence, RI, United States,* [2]*Chong Hua Hospital, Cebu City, Philippines,* [3]*Philippines-Armed Forces Institute of Medical Sciences Virology Research Unit, Cebu City, Philippines,* [4]*Institut Pasteur, Paris, France,* [5]*Walter Reed Army Institute of Research, Washington, DC, United States,* [6]*Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Dengvaxia, the tetravalent chimeric yellow fever-dengue (CYD) live attenuated virus vaccine, has been licensed for the prevention of symptomatic dengue in several dengue-endemic countries. However, vaccine implementation has been limited due to safety concerns and uncertainty about long-term benefit. In the pivotal phase III trials of CYD, active surveillance for symptomatic dengue was limited to 25 months, and only a subset of the cohort was evaluated for subclinical dengue virus (DENV) infections. We recruited 611 participants in the CYD trial in Cebu, the Philippines, into an ancillary study to further evaluate vaccine immunogenicity and efficacy. Ancillary study subjects were followed by active surveillance for over 5 yrs, with annual blood sampling. Symptomatic DENV infections were detected by RT-PCR and serology on acute/convalescent blood samples from febrile illnesses, and subclinical infections were detected based on a 4-fold or greater rise in neutralizing antibody titer in annual blood samples (from month 25 onward). During the study period, DENV2 was the predominant serotype in placebo recipients, followed by DENV1, DENV3, and DENV4. As observed in the overall trial, CYD vaccine had ~50% efficacy in the ancillary study cohort during the first 2 yr (up to 13 months post-vaccination). From year 3 on, CYD vaccine showed no efficacy against symptomatic dengue. Vaccine efficacy against subclinical infection was ~45% in year 2 but decreased in years 3 and 4. These data suggest that CYD vaccine efficacy may be relatively short-lived, even in a cohort with high baseline DENV seropositivity. The small sample size and predominance of DENV2 limit the interpretation of our data, however. Extended evaluations of the efficacy of this and other dengue vaccines will be important to guide appropriate utilization.

1362

EFFICACY OF A TETRAVALENT DENGUE VACCINE IN HEALTHY 4 TO 16 YEAR-OLD CHILDREN

Shibadas Biswal, TIDES Study Group

Takeda Vaccines Pte Ltd, Singapore, Singapore

Dengue, a mosquito-borne viral disease, is a WHO top ten threat to global health in 2019. There is an important unmet medical need for a safe and effective vaccine, particularly for dengue-naïve individuals. We present key efficacy data from Parts 1 and 2 of an ongoing phase 3 randomized trial of a tetravalent dengue vaccine candidate (TAK-003) in 8 endemic countries of Asia and Latin America. Healthy 4-16 year-old children were randomized 2:1 (stratified by age range and region) to receive two doses of vaccine or placebo three months apart. Participants presenting with febrile illness were tested for virologically-confirmed dengue (VCD) by serotype-specific RT-PCR. The primary endpoint was efficacy in preventing VCD induced by any dengue serotype occurring from 30 days post-second vaccination until the end of Part 1. The secondary efficacy endpoints were efficacy against individual serotypes, by baseline serostatus, and efficacy in prevention of dengue leading to hospitalization and severe dengue after end of Part 2. Part 1 was complete once 120 VCD cases were confirmed for primary endpoint analysis and participants had a minimum follow-up of 12 months post-second vaccination. Part 2 lasted for another 6 months. Of 20,071 children given at least one dose of vaccine or placebo, 19,021

were included in the per protocol analysis. The primary and secondary efficacy endpoints will be presented along with safety and immunogenicity data.

1363

PREEXISTING IMMUNITY ENHANCES RECRUITMENT AND INFECTION OF MYELOID CELLS WITH DENGUE AND ZIKA VIRUSES IN HUMAN SKIN

Priscila Mayrelle da Silva Castanha, Parichat Duangkhae, Geza Erdos, Simon C. Watkins, Louis D. Falo Jr, Ernesto T. Marques Jr, Simon M. Barratt-Boyes

University of Pittsburgh, Pittsburgh, PA, United States

Dengue (DENV) and Zika virus (ZIKV) infections in humans are likely subject to antibody-dependent enhancement (ADE), but the precise mechanism of ADE *in vivo* remains to be determined. Human skin is the primary site of virus replication after inoculation by an infected mosquito, making skin a potentially important site for ADE of infection in immune individuals. We used full-thickness human skin explants to determine whether preexisting immunity to one DENV serotype enhanced infection of a different DENV serotype or ZIKV. Monotypic DENV-immune sera were introduced into skin using microneedle arrays before inoculation with homologous or heterologous DENV or ZIKV. Skin explants were analyzed by confocal microscopy using antibodies to cell-specific markers and NS3 protein. As expected, inoculation of DENV-3 into skin pretreated with DENV-3 immune sera resulted in inhibition of virus replication in epidermis and dermis. In contrast, inoculation of skin with DENV-2 pretreated with DENV-3 immune sera resulted in a dose-dependent increase in infected cells in the dermis, reaching a 3-fold boost at the highest concentration of immune sera. When compared to infection of skin pretreated with naïve sera, 1,000 times more virus was needed to compensate for the effect of immune sera on the density of infected cells in dermis. Real-time quantitative PCR confirmed increased viral RNA copies/mg of tissue in the dermis of skin inoculated in the presence of immune relative to naïve sera. Within the dermis, ADE was mediated by increased recruitment, infection and migration of Langerhans cells, macrophages and dermal dendritic cells. Simultaneous blockage of FcγR CD32 and CD64 inhibited ADE in the dermis. Inoculation of ZIKV into skin pretreated with DENV-3 immune sera also lead to increased virus replication in the dermis, which was primarily mediated by increased infection of Langerhans cells and dermal dendritic cells, with minimal effect of macrophages. Collectively, our findings reveal that ADE readily occurs in human skin, primarily within the dermis, and highlights the importance of this site in initiating and supporting ADE of DENV and ZIKV infection.

1364

PREVIOUS ZIKA EXPOSURE IMPROVES IMMUNE RESPONSE AGAINST DENGUE WITHOUT PATHOGENESIS ENHANCEMENT IN RHESUS MACAQUES

Erick X. Pérez-Guzmán[1], Petraleigh Pantoja[1], Crisanta Serrano-Collazo[1], Mariah A. Hassert[2], Alexandra Ortiz[3], Idia V. Rodriguez[1], Luis Giavedoni[4], Vida Hodara[4], Laura Parodi[4], Lorna Cruz[1], Teresa Arana[1], Laura White[5], Melween I. Martinez[1], Daniela Weiskopf[6], James D. Brien[2], Aravinda de Silva[5], Amelia Pinto[2], Carlos A. Sariol[1]

The role of a previous Zika virus (ZIKV) immunity on subsequent Dengue virus (DENV) infections is poorly understood. This is relevant to anticipate the dynamics of forthcoming DENV epidemics in areas with previous ZIKV exposure. It is still uncertain if the immunity conferred by the recent ZIKV epidemic may contribute to protection or worsening DENV cases severity. To test this, three cohorts of rhesus macaques were infected with DENV-2 after no exposure (naïve group), 2 month (early-convalescence) or 10 month (middle-convalescence) after exposure to different contemporary ZIKV strains. We assessed DENV viremia, cytokine profile, neutralizing antibody response against multiple ZIKV strains and all DENV serotypes, and the activation and polyfunctional response of T cell subpopulations up to 90 days after DENV infection. Our results showed that a subsequent DENV infection in animals with early- and middle-convalescent periods to ZIKV do not promote an increase in DENV viremia nor pro-inflammatory status. We found that previous ZIKV exposure improves the neutralizing antibody and T cell responses against DENV and that the time interval between infections impacts the magnitude and durability—more efficient after longer ZIKV pre-exposure—of the immune response. Furthermore, our data suggest that the elicited immune modulation between both ZIKV-immune groups after DENV infection are more influenced by the time elapsed between ZIKV and DENV infections and the maturation of the cross-reactive immune memory, rather than a possible effect due to ZIKV strain variation. Collectively, our findings provide evidence of a non-detrimental effect of ZIKV immunity in a subsequent DENV infection. This supports the implementation of ZIKV vaccines that could also improve immunity against future DENV epidemics.

1365

CROSSREACTIVITY OF CD8+T CELL RESPONSES AMONG FLAVIVIRUSES AFTER DENV OR YF VACCINATION

Alba Grifoni[1], Hannah Voic[1], Aruna D. de Silva[2], Anna Durbin[3], Stephen Whitehead[4], Sean A. Diehl[5], Eva Harris[6], Alessandro Sette[1], Daniela Weiskopf[1]

[1]*La Jolla Institute for Immunology, La Jolla, CA, United States,* [2]*Kotelawala Defense University, Ratmalana, Sri Lanka,* [3]*Johns Hopkins University, Baltimore, MD, United States,* [4]*National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States,* [5]*University of Vermont, School of Medicine, Burlington, VT, United States,* [6]*University of California, Division of Infectious Diseases and Vaccinology, School of Public Health, Berkeley, CA, United States*

Several flaviviruses, including Dengue Virus (DENV), Zika Virus (ZIKV), Japanese Encephalitis Virus (JEV), West Nile Virus (WNV), and Yellow Fever Virus (YFV), share significant sequence homology and often circulate in the same geographical regions. Significant levels of cross-reactivity could in turn result in pre-existing T cell immunity modulating T cell responses to subsequent flavivirus infections before or after vaccination. Whether and to what extent cross-reactivity at the level of CD8 responses is detected is currently unclear. To address this question, we stimulated PBMC of individuals vaccinated with DENV or YF with designed pools of epitopes and predicted HLA binding peptides derived from the different flavivirus (DENV, ZIKV, JEV, WNV and YFV) to assess their potential to recall antigen specific CD8 memory T cell response in Intracellular Cytokine Staining (ICS) assay. Significant cross-reactivity of CD8 T cell responses against several of the pools was observed both in the case of DENV and YF vaccinees, but the extent of cross-reactivity varied as a function of the flavivirus species considered, and the cross-reactive responses were significantly lower than the responses to the autologous virus. Phenotypic analyses showed a suboptimal expression of activation markers in cross-reactive responses. When the cross-reactive responses are characterized at the single epitope level in monovalent DENV vaccinees, the T cells are able to cross-react mainly across different DENV serotypes (and occasionally ZIKV) but not with other flavivirus included YFV. We are in the process to characterized crossreactivity at the single epitope level in YFV vaccinees, being YFV backbone frequently used to develop novel Flavivirus vaccination. Characterization of the extent and functionality of CD8 cross-reaction across different flaviviruses will contribute to the understanding of immunity in the natural infection, and has particular implications for vaccine design, efficacy and safety in endemic settings.

1366

VACCINATION AND PRIOR DENGUE EXPOSURE CORRELATE WITH VIREMIA LEVEL AMONG SYMPTOMATIC DENGUE 1 AND DENGUE 2 INFECTIONS IN COHORT SUBJECTS IN THE PHILIPPINES

Simon Pollett[1], Maria Alera[2], Wiriya Rutvisuttinunt[1], Anon Srikiatkhachorn[3], Abhinaya Srikanth[1], In-Kyu Yoon[4], Irina Maljkovic Berry[1], Damon Ellison[5], Louis Macareo[5], Alan L. Rothman[3], Richard G. Jarman[1]

The chimeric yellow fever-dengue vaccine (CYD, Dengvaxia) reduces the risk of symptomatic dengue in DENV-experienced hosts, but its effect on breakthrough infection viral load is unclear. We leveraged an ancillary study cohort of 584 subjects from Cebu, the Philippines, who had received placebo or CYD in the phase III CYD vaccine trial. Ancillary study subjects underwent active surveillance for symptomatic dengue for >5 yrs after the first vaccine dose. Confirmed DENV cases underwent viremia quantification by qPCR to determine any association between CYD receipt and DENV viral load. Baseline serostatus was determined by DENV PRNT and/or NS1 ELISA. There were 17 DENV-1, 40 DENV-2, 6 DENV-3, and 6 DENV-4 infections sampled. In the CYD arm there were 10 DENV-1 and 25 DENV-2 confirmed infections, of which 3 and 12 were DENV seropositive at baseline, respectively. In the placebo group there were 7 DENV-1 and 15 DENV-2 infections, of which 6 and 14 were DENV seropositive at baseline, respectively. The remaining DENV-1 and DENV-2 cases were seronegative or seroindeterminate at baseline. CYD receipt was associated with 1.16 log10 GE/mL (p=0.21) and 0.34 log10 GE/mL (p=0.55) lower geometric mean DENV-1 and DENV-2 viremia levels, respectively, when compared to placebo-recipients. Among those with prior dengue exposure, there was a 2.19 log10 GE/mL lower mean DENV-1 viremia level (p=0.19) and a 1.09 log10 GE/mL (p=0.1) lower mean DENV-2 viremia level in CYD vs. placebo recipients. Among CYD-recipients who experienced breakthrough infections, there was a 1.86 log10 GE/mL higher mean DENV-1 viremia level in those with no history of dengue exposure compared to those seropositive at baseline (p = 0.17), and a 1.63 log10 GE/mL higher mean DENV-2 viremia level in subjects with no history of prior DENV exposure compared to those with baseline DENV seropositivity (p = 0.03). Collectively our findings suggest that Dengvaxia receipt may reduce the infecting viral load of breakthrough dengue infections, but that this association is likely modified by host dengue exposure history. These findings prompt further analyses of a larger sample size pending from this cohort.

1367

PRIOR VACCINATION WITH CYD-TDV DID NOT POTENTIATE SYMPTOMATIC ZIKA IN DENGUE ENDEMIC AREAS OF LATIN AMERICA

Betzana Zambrano[1], Doris Maribel Rivera[2], José Luis Arredondo[3], Humberto Reynales[4], Kleber Luz[5], Carmen Deseda[6], Matthew Bonaparte[7], Edith Langevin[8], Yukun Wu[7], Margarita Cortes[9], **Gustavo H. Dayan**[7], Carlos Diaz Granados[7], Stephen Savarino[7], Fernando Noriega[7]

[1]*Sanofi Pasteur, Montevideo, Uruguay,* [2]*Inversiones en Investigación Médica, Tegucigalpa, Honduras,* [3]*Instituto Nacional de Pediatría, Mexico City, Mexico,* [4]*Centro de Atención e Investigación Médica, Bogota, Colombia,* [5]*Universidade Federal do Rio Grande do Norte, Natal, Brazil,* [6]*Caribbean Travel Medicine Clinic, San Juan, Puerto Rico,* [7]*Sanofi Pasteur, Swiftwater, PA, United States,* [8]*Sanofi Pasteur, Marcy L'Etoile, France,* [9]*Sanofi Pasteur, Bogota, Colombia*

An unprecedented Zika outbreak began in Latin America in 2015, including in the countries where Sanofi Pasteur's Phase III Dengue efficacy trial (CYD15, NCT01374516) was being conducted. The current analysis describes data on virologically-confirmed Zika (VCZ) episodes by study group in CYD15. This observational objective, added as an amendment to the CYD15 protocol, assessed the impact of dengue vaccination on the occurrence and clinical features of Zika disease in trial participants aged 9-16 years recruited in Brazil, Puerto Rico, Mexico, Honduras and Colombia and still enrolled in the study over the November 2015-March 2018 period (end of the trial). Acute serum samples from febrile (38°C for 2 consecutive days) subjects that had been collected for Dengue virological confirmation were also tested for Zika RNA (RT-PCR) detection. Dengue Anti-NS1-IgG ELISA was performed in all subjects from a sub-cohort (10% of the entire cohort) and in VCZ cases, 1 month after last trial injection to assess Dengue basal serostatus. Relative risk (RR) was calculated as the ratio of the VCZ episodes between CYD-TDV (Dengvaxia®) and Control groups (randomized in a 2:1 CYD-TDV:placebo ratio). When the analysis was stratified by dengue serostatus, a case-cohort design was used to estimate the Hazard Ratio (HR) from a weighted Cox regression. A total of 10,157 acute febrile samples were tested, 239 (2.4%) samples showed Zika virological-confirmation, 152 (2.3%) episodes from the CYD-TDV group (one subject had 2 episodes) and 87 (2.4%) from the Control group. Results indicated no increased risk in the CYD-TDV group as a whole (RR 0.86 [95%CI 0.65;1.13]). When focusing on Dengue seropositive subjects at baseline, 106 VCZ cases were observed in the CYD-TDV group and 68 in the control group (HR 0.72 [95%CI 0.52;1.00]). Our data indicate that prior vaccination with CYD-TDV does not increase the risk of symptomatic Zika and may protect dengue seropositive vaccinees from subsequent symptomatic Zika infection.

1368

TRACKING MOSQUITOES OVER TIME: TESTING THE ROLE OF AESTIVATION IN DRY SEASON PERSISTENCE

Roy Faiman[1], Adama Dao[2], Alpha S. Yaro[2], Moussa Diallo[2], Djibril Samake[2], Zana L. Sonogo[2], Yossi Ousmane[2], Margery Sullivan[1], Laura Veru[1], Benjamin J. Krajacich[1], Joy Matthews[3], Christine A. France[4], Gabriel Hamer[5], Leland Graber[1], Tovi Lehmann[1]

[1]*National Institutes of Health, Rockville, MD, United States,* [2]*Malaria Research and Training Center, Faculty of Medicine, Bamako, Mali,* [3]*University of California Stable Isotope Facility, Davis, CA, United States,* [4]*Smithsonian Institution Museum Support Center, Suitland, MD, United States,* [5]*Texas A&M University, College Station, TX, United States*

Despite its recognized importance, tracking mosquitos over extended time has been beyond medical entomology's tool kit. Stable isotope enrichment of mosquito breeding sites enables marking of mosquitoes without human handling. Mosquito larvae developing in [^{2}H]- enriched water are structurally marked for life, providing a unique opportunity to test the hypothesis that *Anopheles coluzzii*, but not *A. gambiae* s.s and *A. arabiensis*, locally persists in the Sahel through the dry season via aestivation. A large-scale experiment to test this hypothesis began in September 2017 in two Sahelian villages in Mali. We aimed to estimate the contribution of aestivation to persistence of mosquitoes through the 7-month long dry season by marking at least 50% of the *A. gambiae* s.l. adults by the end of the wet season and assess the proportion of marked adults through the dry season, and immediately after the first rain in June 2018. If aestivation is the only way *A. coluzzii* persists, the frequency of marked mosquitoes should be similar throughout. Finding no marked mosquitoes would be evidence against aestivation. Twenty-four natural larval sites were enriched from late September. The marked adult proportion by the end of the wet season was above 60%. Five months later a similar frequency of marked adults was detected. Notably, after the first rain, nearly 8 months after the onset of the dry season, 6% showed clear enrichment. All the marked mosquitoes detected after the onset of the DS were *A. coluzzii*, in accord with aestivation in this species alone. Because ^{2}H-marking in mosquitoes has steadily weakened over time, we suspect some of the seemingly un-enriched mosquitoes had lost their marking. Accordingly, we find that the distribution of ^{2}H in mosquitoes after the first rain exhibits an exceptionally heavy right tail, indicating that in addition to naturally un-enriched mosquitoes there are many enriched

mosquitoes that lost much of their enrichment but are clumped in that zone. Our results provide, for the first time, hard evidence of population-wide aestivation in *A. coluzzii* alone, supporting annual malaria resurgence shortly after the wet season onset.

1369

INVESTIGATING THE MOLECULAR PLASTICITY OF *AEDES ALBOPICTUS* IN RESPONSE TO ZIKA VIRUS INFECTION UNDER INCREASED TEMPERATURES

Maria G. Onyango, Sean Bialosuknia, Anne Payne, Mathias Nicholas, Lilli Kuo, Alexander Ciota, Laura D. Kramer

Wadsworth Centre, New York State Department of Health, Slingerlands, NY, United States

A rapid and significant range expansion of both Zika virus (ZIKV) and its *Aedes* vector has resultedin the virus being declared a global health threat. In spite of this, significant knowledge gaps exist on the interactions of ZIKV and *Aedes*. Mean temperatures are projected to increase globally, likely resulting in alterations of the transmission potential of mosquito-borne pathogens. Consequently, it is crucial to understand how future increase in temperature will alter ZIKV transmission. To investigate how ZIKV impacts its host physiology, especially under increased heat conditions, cDNA libraries were generated from midguts of ZIKV-infected female *Ae. albopictus*that were hatched and reared at Day 30°C; Night 26°C or Day 28°C; Night 24°C temperature regimes. The libraries were created from individuals held at both temperature regimes for 7 days after infectious or non-infectious blood meals. The resulting Illumina sequence reads were mapped to the *Ae. albopictus*genome, from which we detected the expression of 805 known genes and additional 1263 clusters not located within the predicted genes. Individuals infected with ZIKV presented a strong differential expression in genes and pathways involved in odorant reception [Log fold change 6; FDR P(7.19E-03)], signal transduction [Log fold change -3; FDR P(1.76E-03)] and sex-limited genes [Log fold change 2; FDR P(1.83E-04)] when compared to non-infected insects. Individuals exposed to higher temperatures showed a significant differential expression in genes related to chitin metabolism [Log fold change -8; FDR P(6.09E-12)] when compared to individuals reared at the lower temperatures. Individuals that were exposed to both higher temperatures and ZIKV infection presented a differential expression of genes important for virus transmission and those which are associated with host seeking biology of the mosquito. These gene sets form a relevant pool of candidates that could be further investigated as novel biological control tools.

1370

THERMAL ECOLOGY OF MALARIA TRANSMISSION AND THE POTENTIAL IMPACT OF BEHAVIORAL RESISTANCE

Eunho Suh[1], Marissa K. Grossman[1], Jessica L. Waite[1], Ellie Sherrard-Smith[2], Thomas S. Churcher[2], Matthew B. Thomas[1]

[1]*Pennsylvania State University, University Park, PA, United States,* [2]*Imperial College London, London, United Kingdom*

A number of studies report changes in the biting time of malaria mosquitoes following the introduction of long-lasting insecticide-treated bed nets (LLINs). Here, we explored whether timing of blood feeding interacts with environmental temperature to influence the vector competence of *Anopheles* mosquitoes for the human malaria parasite, *Plasmodium falciparum*. We found no effect of biting time on the proportion of mosquitoes that became infectious at constant temperature. However, the addition of realistic daily temperature fluctuation reduced the vector competence of mosquitoes feeding in the morning and increased the competence of those feeding in the early evening. A transmission dynamics model illustrates that such changes could have important implications for the epidemiological impact of "behavioral resistance". A shift in mosquito biting to the morning could reduce the transmission probability, and so poses little epidemiological risk. However, an increase in early evening biting could increase transmission not only because people are unprotected by bed nets, but also because there is a higher chance of blood-feeding mosquito becoming infectious.

1371

A NEW BIO-ASSAY TO MEASURE MOSQUITO MORTALITY AND OUTDOOR BITE PREVENTION STRATEGIES UNDER SEMI FIELD CONDITIONS

Mgeni M. Tambwe, Sarah Moore, Jason Moore, Hassan Chilumba, Adam Saddler

Ifakara Health Institute, Bagamoyo,Tanzania, United Republic of Tanzania

Aedes aegypti is the primary vector of several Arboviral diseases and is primarily controlled through larval source reduction, and space spraying, which are costly and logistically difficult to implement. Previous studies demonstrated that the volatile pyrethroids transfluthrin and metofluthrin are effective in preventing *Aedes aegypti* bites. We developed a long-acting transfluthrin passive emanator and evaluated its effect to prevent bites and kill *Aedes aegypti* mosquitoes over six months in an outdoor environment. Two evaluations were performed 1) in a large cage semi-field system (SFS) and 2) in the Large Ifakara-Ambient Chamber Test (LI-ACT). Both experiments were conducted for three hours using laboratory-reared *Aedes aegypti*. Two emanators (each treated with 3g of transfluthrin) were placed 6 m apart and human volunteer sat between them. The SFS experiment was conducted at 0, 3 and 6 months in a 21 x 9 x 4.5 m compartment to measure bite prevention by human landing catches (HLC). The LI-ACT measured feeding inhibition and mosquito mortality inside a large 20 x 4 x 4 m contiguous chamber that allows recapture of all released mosquitoes. In this experiment, HLC wasn't performed but a volunteer rested in the chamber. All mosquitoes were recovered scored as alive/dead, fed/unfed after 24 hours holding. In the SFS, significantly fewer *Aedes aegypti* were captured landing in the treatment compared to the control at month 0 and 6. In the LI-ACT, mosquitoes were inhibited from feeding and were more likely to die 24 hours later compared to the control. LI-ACT experiments are ongoing to measure the duration of effect. This is the first time that Transfluthrin passive emanators have been demonstrated to provide both personal and community protection against *Aedes aegypti* mosquitoes for up to six months. The devices reduce the ability of mosquitoes to feed and cause delayed mortality. These devices show promise as a public health intervention for outdoor and day-biting *Aedes aegypti* mosquitoes in the urban environment.

1372

VECTOR CHIP: A MINIATURIZED PLATFORM FOR HIGH-THROUGHPUT INTERROGATION OF MOSQUITO-PATHOGEN DYNAMICS

Shailabh Kumar, Felix Hol, Manu Prakash

Stanford University, Stanford, CA, United States

Curbing the spread of mosquito-borne diseases requires intimate knowledge of the dynamics of mosquitoes and the pathogens they transmit. There is a pressing need to develop field-deployable platforms which can provide this information in a geographical and temporal context in a high-throughput manner. Current laboratory and field approaches to interrogate mosquito-pathogen communities, are severely limited in throughput preventing a detailed understanding of mosquito-borne disease dynamics. To overcome current limitations, we exploit the fact that biting mosquitoes transmit pathogens by expectorating saliva, to autonomously collect saliva droplets resulting from single mosquito bites. We have developed a miniaturized platform which enables on-chip arrayed analysis of individual saliva droplets for high-throughput dissection-free characterization of the genetic make-up of the biting mosquito, and the pathogens it transmits. We demonstrate a lab-based proof of concept to screen populations of *Aedes aegypti* mosquitoes using this strategy, and are currently optimizing the platform to enable large-scale field deployment across several geographical locations. The vector chip

platform holds the potential to reveal yet unknown mosquito-pathogen interactions, serve as a local early warning system for mosquito-borne diseases, and can be optimized for other biting insects.

1373

ACTIVATION OF MOSQUITO IMMUNITY BLOCKS THE DEVELOPMENT OF TRANSMISSION-STAGE FILARIAL NEMATODES

Abigail R. McCrea, Elizabeth B. Edgerton, Corbett T. Berry, Yukwah Kwok, Brittany Watson, Letitia K. Thompson, Thomas J. Nolan, James B. Lok, **Michael Povelones**

University of Pennsylvania, Philadelphia, PA, United States

Mosquito-borne helminth infections are responsible for a significant worldwide disease burden in both humans and animals. Accordingly, development of novel strategies to reduce disease transmission by targeting these pathogens in the vector are of paramount importance. We found that a strain of *Aedes aegypti* that is refractory to infection by *Dirofilaria immitis*, the agent of canine heartworm disease, mounts a stronger immune response during infection than does a susceptible strain. Based on this finding, we hypothesized that activating a stronger immune response in the susceptible strain would render them refractory. Using a novel assay that we developed to measure the number of transmission-stage parasites capable of emerging from individual mosquitoes, we tested the effect of activating the Toll and IMD immune pathways using RNAi silencing of inhibitory proteins. Excitingly, we found that activation of the Toll immune signaling pathway in the susceptible strain arrests larval development, thereby decreasing the number of transmission-stage larvae. Co-silencing Rel1, a transcription factor that mediates Toll signaling, rescued development of transmission-stage larvae showing that the effect was specific. Importantly, this strategy also blocks transmission stage *Brugia malayi*, an agent of human lymphatic filariasis. Our data show that mosquito immunity can play a pivotal role in restricting filarial nematodes and suggest that genetically engineering mosquitoes with enhanced immunity will help reduce disease transmission.

1374

DIFFERENTIAL CONTRIBUTION OF *ANOPHELES* VECTORS TO MALARIA TRANSMISSION IN TWO NEIGHBORING VILLAGES IN THE RURAL COMMUNE OF ANDRIBA, MADAGASCAR

Jessy Marlene Goupeyou-Youmsi[1], Tsiriniaina Rakotondranaivo[2], Mandaniaina Radotiana Andriamiarimanana[2], Tsikiniaina Rasoloharimanana[2], Nicolas Puchot[2], Rado Lalaina Rakotoarison[2], Emma Rakotomalala[2], Romain Girod[2], Mamadou Ousmane Ndiath[2], Ines Vigan-Womas[2], Catherine Bourgouin[3]

[1]*University of Malawi College of Medicine, Blantyre, Malawi,* [2]*Institut Pasteur de Madagascar, Antananarivo, Madagascar,* [3]*Institut Pasteur, Paris, France*

In a region of moderate to high malaria transmission, the prevalence of malaria cases in two nearby villages with apparent similar pattern was significantly different. To try deciphering the reason for this difference, a multidisciplinary study including entomology, parasitology and immunology was conducted. Human and mosquito populations were targeted in order to evaluate *Plasmodium* carriage using real-time PCR. Rapid diagnostic tests (RDTs) and microscopy were also used for rapid assessment of *Plasmodium* carriage in the human population. In addition, prevalence and specificity of antibodies against *Plasmodium* antigens were determined using a multiplex bead-based serological assay. The overall human malaria prevalence among 590 samples was 8.0% by RDT, 4.8% by microscopy and 12.2% by PCR. Malaria infection cases were due to *P. falciparum* (84.3%), *P. vivax* (5.7%) and *P. malariae* (1.4%), with 8.6% of mixed infections. Serological makers for parasite and vector exposure perfectly matched with the human malaria prevalence variations in both villages (no significant difference), with an increase at the middle of the transmission season. Among 1553 anopheline mosquitoes collected by Human Landing Catches, three anopheline species were found carrying *Plasmodium* sporozoites by Taqman qPCR: *An. funestus* (n=3), *An. coustani* (n=7) and *An. arabiensis* (n=3). No significant difference on *Plasmodium* carriage in mosquitoes was observed between the two villages (SI=0.82% in the village of Ambohitromby and SI=1.15% in the village of Miarinarivo). However, the Entomological inoculation rate (EIR) shows that *An. arabiensis* had the major contribution in malaria transmission in Ambohitromby (EIR=0.10 infective bite/man/night), while it was *An. coustani* (EIR=0.17 ib/m/n) that contributed more in Miarinarivo. Different contribution of vectors in malaria transmission between the two villages has been observed despite the similarity of human malaria prevalence. This study demonstrates the variability of *Anopheles* vector dynamics that can be useful to better describe epidemiology and malaria transmission in Madagascar.

Klebsiella pneumoniae (Kp) is as an important cause of nosocomial infections, characterized by increasing antimicrobial resistance and high case fatality. Limited data are available on illness and death due to nosocomial or community-acquired Kp, particularly in resource-poor settings. We analyzed data from the Child Health and Mortality Prevention Surveillance (CHAMPS) in Kenya to characterize child deaths attributed to Kp. CHAMPS actively identifies deaths among children aged <5 years in an urban and rural area in western Kenya. Parents of deceased are interviewed and medical records reviewed. Minimally invasive tissue sampling is conducted, followed by extensive etiologic testing (microbiologic, molecular, and histologic), and review by two pathology teams. Cases are reviewed by an expert panel to determine immediate, comorbid, and underlying causes of death. Among 142 analyzed deaths from 05/2017 to 03/2018, Kp contributed to 21 (15%), including 18 (86%) as the immediate cause of death, and 3 (14%) as comorbid condition; other immediate causes of death were cerebral malaria (n=1), pneumococcal sepsis (n=1) and head injury (n=1). The most common underlying cause in Kp deaths was malnutrition (n=7, 33%). Kp was isolated from blood and/or cerebrospinal fluid of 11 (52%) cases; the remainder had molecular and/or immunohistochemical evidence of infection in tissues. The median age of Kp deaths was 4 months (range 1 day to 31 months), and 36% were male. Death occurred in a health facility for 13 (62%); median duration of admission before death was 5 days (range 0 to 38 days). Among facility deaths, 12 (92%) received antibiotics. Of those, 11 (92%) received penicillin and gentamicin, including 3 who also received a cephalosporin. Among 8 community deaths, none were hospitalized during the course of illness and 5 (62%) had received outpatient care; all received antibiotics (amoxicillin n=4 and cotrimoxazole n=1). Kp plays an important role in child death in Kenya, and infections seem to be both nosocomial and community-acquired. Commonly used antibiotics may not adequately treat Kp; current data on Kp susceptibility in Kenya are urgently needed.

Worldwide, an estimated 500,000 children die annually from pneumococcal disease. Introduction of pneumococcal conjugate vaccine (PCV) into the infant immunization programs in low- and middle-income countries could reduce child mortality. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network aims to improve understanding about causes of child mortality through longitudinal surveillance and etiologic investigation of under-five deaths and stillbirths by combining postmortem minimally invasive tissue sampling (MITS), molecular, microbiologic, and histopathologic testing, clinical records, and verbal autopsy. Such a surveillance provides a platform for more refined population-based estimates of cause-specific mortality fractions in Sub-Saharan Africa (Kenya, Mali, Sierra Leone, Ethiopia, Mozambique, South Africa) and South Asia (Bangladesh). Underlying, co-morbid, and immediate causes of death (causal chain) are ascribed according to ICD-10 guidelines by local panels of experts reviewing all data on each case. Of cases undergoing panel review thus far (n=594), *S. pneumoniae*-associated conditions were listed in the causal chain in 46 (7.7%) of 594 children under 5 years of age, ranging from 1.4 % of neonates, 13.2 % of infants, and 20.2% of children 12 months to 5 years; associated conditions included lower respiratory infections (81.8%), meningitis (15.9%), and sepsis (36.8%). Of the pneumococcal deaths, 12.8% were in HIV-infected children. Preliminary findings support a continued focus on prevention of invasive pneumococcal disease. Next steps are to assess: a) proportion of pneumococcal deaths due to vaccine serotypes; b) PCV coverage rates and occurrence of death among adequately vaccinated children c) and factors for under-immunization.

Bacterial infections are life threatening in fetuses and newborns; timely, appropriate antimicrobial therapy is often pivotal for survival. However, increasing rates of multidrug resistance (MDR) has created therapeutic challenges. Therefore, determining drug susceptibility patterns of local pathogens is a crucial component for appropriate empiric antibacterial treatment. We isolated bacterial pathogens from blood of deceased and ill children in a tertiary care facility in Faridpur, Bangladesh through the Child Health and Mortality Prevention Surveillance (CHAMPS) project. Blood samples were collected from 35 CHAMPS (deceased: 16 stillbirth, 18 neonates and one 1-year-old child) and 41 non-CHAMPS (ill: 36 neonates and five children under 5 years of age) between October 2017 and December 2018. Bacteria were identified by blood culture and susceptibility was tested using the disk diffusion method. MDR was defined as non-susceptibility to at least one agent in three or more antimicrobial categories. Fifty one (67%) specimens were culture positive with lower isolation rate in CHAMPS (57%) than non-CHAMPS (76%) cases although the difference was not statistically significant (p-value= 0.096). Predominant isolates were *Klebsiella* spp. (29%) followed by coagulase-negative Staphylococci (16%), *Acinetobacter* spp. (7%) and *Enterococcus faecalis* (4%). Among 54 bacterial isolates (three cases had two isolates) recovered, 92.5% were categorized as MDR to routinely prescribed antibiotics in Bangladesh for pediatric bacterial infections, such as ampicillin (93%), gentamicin (75%) and cephalosporins (63%). Similar rate in MDR was observed when comparing CHAMPS (93%) and non-CHAMPS (92%) cases. *Klebsiella* spp. showed 67% resistance against carbapenem group antibiotics; susceptibility was greatest to vancomycin (100%), tigecycline (95%) and colistin (78%), thus, a consideration for empiric therapy of severe pediatric infections in this setting. Isolation of MDR bacteria warrants primary infection control strategy as well as proper diagnosis and administering antibiotics appropriately to treat pediatric infections.

In low- and middle-income countries (LMIC), nearly 41% of all under 5 deaths occur in the neonatal period; one third of which are due to infections. As compared to industrialized countries, the rates of neonatal bloodstream infections (BSI) in LMIC are 3-20 times higher. With increasing facility-based deliveries, the risk of hospital-acquired infections rises. We aimed to identify maternal and neonatal risk factors for hospital-associated BSI (HA-BSI) among neonates at a sub-Saharan tertiary care facility. We performed a prospective observational cohort study of neonates admitted to the neonatal intensive care unit (NICU) at the University Teaching Hospital (UTH) Lusaka, Zambia. Blood cultures were performed in neonates with suspected sepsis based on established clinical criteria. Only blood cultures that grew a pathogen were consider positive. Cultures

were designated as either early-onset (EO-BSI) if they occurred within 3 days of birth; otherwise they were designated as late-onset BSI (LO-BSI). Risk factors were compared between newborns with confirmed BSI with those with suspected sepsis that was culture negative or whose culture yielded contaminants. Of the 3316 neonates hospitalized in the NICU, 407 (12%) had at least one BSI, including 228 EO-BSI and 179 LO-BSI. When compared to those who did not have any BSIs with a pathogen, factors associated with EO-BSI were low maternal education, prolonged rupture of membranes, and fewer than two antenatal visits (all p<0.001). Inborn (birth at UTH), maternal HIV infection, and C-section delivery were found to be protective against LO-BSI (p<0.01, p=0.04, p=0.01 respectively). Maternal and neonatal characteristics can increase the risk of pathogen-associated EO- or LO-BSI. Further study is needed to elucidate the impact of HIV status on neonatal BSI. Development and implementation of policies that will improve antenatal visit attendance and female education may help to reduce BSI-associated neonatal morbidity and mortality.

Antimicrobial resistance (AMR) in multidrug resistant Gram negative bacilli (MDR-GNB) is a global public health problem. South Asian countries including Nepal are considered as epicenter for this. The contributory role of neonatal sepsis in overall burden of nosocomial AMR is substantial. The difficulty in its clinical diagnosis and probable serious consequences in case of delayed treatment compel for the empirical use of antimicrobials without microbiological justification. Such increased empirical use of last resort drugs such as extended spectrum Cephalosporins and Carbapenems in neonatal intensive care unit (NICU), contribute in selective evolution of MDR-GNB. A six years (2012-2018) retrospective study on microbiological culture results from Patan hospital, a tertiary government hospital of Nepal, showed that 47%, 1254/2667 of the commonest GNB (*Klebsiella pneumoniae, Enterobacter* sps*, E. coli*, *Acinetobacter* sps) were MDR, 64%, 1381/2153 being ESBL producers and 22%, 474/2153 had reduced susceptibility against Carbapenems. Over half (54%, 372/691) of all inpatients' bacterial isolates were derived just from neonates (NICU and nurseries) with 61% (208/342) of the top four neonatal GNB being MDR, 55% (178/323) being ESBL producers and 34% (109/323) showing resistance against Carbapenems, possessing bla_{NDM-1}, bla_{KPC} or bla_{OXA} genes. Specifically 83% (52/63) of neonatal *Acinetobacter* sps were resistant to Carabapenem, possessing bla_{OXA51} (73%) and bla_{NDM-1} (54%) genes. A prospective NICU cohort study, showing a high incidence of neonatal sepsis (50%,71/141), revealed that 91% (128/141) of the cases received Ampicillin-Amikacin, though only 30% (22/141) yielded positive blood cultures. Over half of cases were given Cephotaxime, a quarter received Carbapenem, 17% had Colistin, all being the last resort drugs. Our study presents an evidence of alarming situation of AMR in nosocomial GNR and increased use of antimicrobials in NICU. Improved diagnostic tools, judicious use of antimicrobials and strong infection control/prevention policies are indispensable for combating this burgeoning problem of AMR.

In endemic regions, clinical malaria frequently presents with concurrent bacteremia in children. Co-infection promotes poor health outcomes; we have previously shown that bacteremic children in rural western Kenya with malaria have higher rates of mortality and severe anemia than non-bacteremic children. High levels of antimicrobial resistance (AMR) further complicate treatment of bacteremia in many parts of sub-Saharan Africa. As such, we examined the prevalence of bacteremia and AMR patterns in children (1-36 months of age; n=1,639) in a *Plasmodium falciparum* holoendemic malaria transmission region of western Kenya (2004-2012). There was a decreasing trend in the prevalence of bacteremia in malaria(+) children over this time period: 9.8% from 2004-2006 versus 4.7% from 2009-2012 (p=0.05). The most common pathogen was non-typhoidal Salmonella (NTS), accounting for 56.8% (2004-2006) and 58.8% (2009-2012) of bacteremia cases, respectively. AMR patterns for NTS remained relatively constant between 2004-2012, except for 3rd generation cephalosporin resistance which increased from 0% (2004-2006) to 15% (2009-2012). A history of antimicrobial administration in the seven days prior to blood culture was observed for 17% of the children with NTS bacteremia and resistance rates for SXT were high (85.7% non-susceptible). However, a history of SXT administration in the past week was not associated with SXT resistant NTS infections. High rates of AMR in NTS to other commonly used antimicrobials were also observed: chloramphenicol (70.1% non-susceptible) and amoxicillin-clavulanic acid (73.2% non-susceptible). Bacteremia was associated with increased mortality: 9.6% in bacteremic children compared to 1.1% in non-bacteremic children (p=0.01). Results here demonstrate a consistently high prevalence of AMR to commonly used antimicrobials in invasive NTS since the early 2000s.

Bacterial infections, including enteropathogens, are a leading cause of morbidity and mortality among pregnant women and their infants, particularly in low-resource countries. Sulfadoxine-pyrimethamine (SP) has been used in intermittent preventive treatment of malaria in pregnancy (IPTp). It has been postulated that, as a combination antibiotic and antifolate, SP may clear other pathogens, and that it may have an effect on the gut microbiota. We assessed whether monthly SP-IPTp has an effect on the carriage of common intestinal pathogens in expectant mothers and whether it associates with changes in the gut microbiome. We used stool specimens from 98 pregnant Malawian women enrolled in a randomized controlled study comparing the efficacy of SP to dihydroartemisinin-piperaquine (DP). Unlike SP, DP is an antimalarial with no known antibacterial effect. We screened for: five *Escherichia coli* strains, *Shigella spp.*,*Vibrio cholerae*, *Salmonella*, *Campylobacter coli/jejuni*, and three protozoa (*Giardia spp.*, *Entamoeba histolytica*, and *Cryptosporidium spp.*). We characterized the gut bacterial microbiota by deep sequencing the 16S ribosomal RNA gene and analyzing the data with the established bioinformatic pipeline QIIME2. Samples were assessed for pathogens and microbiome patterns at enrollment prior to study drug administration and at each subsequent antenatal visit, when study drug was administered. The lab remains blinded to study drug allocation. Initial results show that 51% of expectant mothers in our study (50/98 women) carry at least one gut pathogen prior to first drug dose, with the most common being enteropathogenic and enteroaggregative *E. coli*, detected in 51% and 48% of women, respectively. Evaluation of pathogen carriage rates and microbiome structure in additional samples after receipt of drug is ongoing and data will be analyzed by drug arm. With these results, we will show whether SP has a malaria-independent effect on the gut. We will discuss the significance of our results in the context of proposed discontinuation of SP-IPTp and explore implications the use of SP against other pathogens may have in sub-Saharan Africa.

Plasmodium sporozoites are transmitted from an infected mosquito to mammals in which they infect the liver. The infectivity profile of sporozoites changes as they egress from oocysts on the mosquito midgut into the hemocoel, and then invade the salivary glands, where they maintain a poised and infectious state until transmission occurs. Upon transmission, the sporozoite must then navigate the host skin, vasculature, and liver. All of these feats require distinct repertoires of proteins and capabilities that are coordinated in an appropriate temporal manner. Here, we report the comprehensive and dynamic transcriptomes and proteomes of both oocyst sporozoite and salivary gland sporozoite stages in both rodent-infectious *Plasmodium yoelii* parasites and human-infectious *Plasmodium falciparum* parasites. These data robustly define mRNAs and proteins that are Upregulated in Oocyst Sporozoites (UOS) or Upregulated in Infectious Sporozoites (UIS), which include critical gene products for sporozoite functions, as well as many of unknown importance that are similarly regulated. Moreover, we found that *Plasmodium* uses two overlapping, extensive, and independent programs of translational repression across sporozoite maturation to temporally regulate specific genes necessary to successfully navigate the mosquito vector and mammalian host environments. Finally, gene-specific validation experiments of selected, translationally repressed transcripts in *P. yoelii* confirmed the interpretations of the global transcriptomic and proteomic datasets. Together, these data indicate that two waves of translational repression are implemented and relieved at different times in sporozoite maturation to promote its successful life cycle progression.

1383

PLASMEPSIN V IS ESSENTIAL IN *PLASMODIUM* LIVER STAGES AND DIRECTS EXPORT TO THE INFECTED HEPATOCYTE

Pravin Rajasekaran, Ryan Steel, Matthew O'Neill, Bethany Davey, Annie Yang, Brad Sleebs, Alan Cowman, **Justin Boddey**

Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia

Central to the pathogenesis of malaria is the *Plasmodium* parasite's ability to remodel erythrocytes by exporting hundreds of proteins into the host cell. Export of effector cargo involves proteolytic cleavage of the PEXEL motif by the protease plasmepsin V prior to translocation across the parasitophorous vacuole membrane by the PTEX translocon. Prior to blood stage infection, malaria sporozoites deposited by an infected mosquito home to the liver and invade hepatocytes within a parasitophorous vacuole. The invaded parasites need to evade host innate responses in order to survive and grow. Long-standing questions in the field are whether liver stages export proteins into infected hepatocytes using the PEXEL machinery, and if so, why? Here, we conditionally knockdown Plasmepsin V expression in liver stages using the Flp/FRT site-specific recombination system. Dissection of *Plasmepsin V* knockdown sporozoites from mosquitoes and injection into mice resulted in normal liver infections at early time points but clearance of exoerythrocytic forms from mice by 24 hours, no patent malaria infections and production of protective immunity against challenge with a lethal dose of wild-type sporozoites. Immunofluorescence microscopy reveals that export of a PEXEL-containing effector protein to the hepatocyte is disrupted by plasmepsin V knockdown and immunoblotting reveals accumulation of uncleaved PEXEL precursors in PMV knockdown parasites. This study shows that plasmepsin V is essential in liver stages owing to a conserved role in cleavage of proteins for export to the host cell. Identification of further hepatocyte exported proteins is underway. Plasmepsin V thus represents a multi-stage, pan-*Plasmodium* target for a new class of antimalarial drugs, which are under development in collaboration with Merck and the Wellcome Trust.

1384

PHOSPHORYLATION OF THE VAR2CSA EXTRACELLULAR REGION IS ASSOCIATED WITH ENHANCED ADHESIVE PROPERTIES TO THE PLACENTAL RECEPTOR CSA

Dominique Dorin-Semblat[1], Marilou tetard[1], Aurélie Claës[2], Jean-Philippe Semblat[1], Sébastien Dechavanne[1], Zeineb Fourati[1], Romain Hamelin[3], Florence Armand[3], Graziella Matesic[1], Sofia Nunes-Silva[1], Anand Srivastava[1], Stéphane Gangnard[1], Jose-Juan Lopez-Rubio[4], Marc Moniatte[3], Christian Doerig[5], Artur Scherf[2], **Benoit Gamain**[1]

[1]*INSERM, Paris, France,* [2]*Institut Pasteur, Paris, France,* [3]*EPFL, Lausanne, Switzerland,* [4]*MIVEGEC, Montpellier, France,* [5]*Monash University, Melbourne, Australia*

Plasmodium falciparum is the main cause of disease and death from malaria. *P. falciparum* virulence resides in the ability of infected erythrocytes (IEs) to adhere to specific receptors in various tissues, causing significant clogging of capillaries leading to severe malaria. The parasite adhesion molecule *P. falciparum* erythrocyte membrane protein 1 (PfEMP1), encoded by the *var* gene family, mediates adhesion to various host receptors expressed along blood vessels in different organs. However, tissue adhesion tropism of this pathogen remains poorly understood. Here we investigated the effect of phosphorylation on PfEMP1 adhesive properties on placental sequestration, which is mediated through the interaction between VAR2CSA, a member of the PfEMP1 family, and chondroitin sulfate A (CSA) on the placental syncytium. We show that

phosphatase treatment of intact IEs impairs cytoadhesion to CSA. In line with this observation, we demonstrate that the extracellular region of VAR2CSA is phosphorylated in regions known to interact with CSA. Mass spectrometry analysis of recombinant VAR2CSA phosphosites prior to and after phosphatase treatment, as well as mutation of these phosphoresidues to alanine in recombinant VAR2CSA, identified critical phosphoresidues associated with CSA binding. Furthermore, using CRISPR/Cas9, we generated a parasite line in which a phosphoresidue is changed to alanine and showed that this mutation strongly impairs IEs cytoadhesion to CSA under both static and flow conditions. Taken together, these results inform that phosphorylation plays a major role in infected erythrocytes cytoadhesion to CSA and provide new molecular insights for vaccine and therapeutic strategies aiming to reduce the morbidity and mortality of placental malaria.

1385

IN VITRO AND *IN VIVO* EVIDENCE THAT GDV1 REGULATES SEXUAL DIFFERENTIATION UPSTREAM OF *AP2-G*

Miho Usui[1], Surendra K. Prajapati[1], Ruth Ayanful-Torgby[2], Festus K. Acquah[2], Elizabeth Cudjoe[2], Courage Kakaney[2], Jones A. Amponsah[2], Evans Obboh[3], Deepti K. Reddy[1], Michelle C. The development of sexual stage parasites is critical for malaria transmission, yet much remains unknown about how this process is regulated. Recently, epigenetic repression and expression of the transcription factor AP2-G have been shown to play important roles in sexual commitment. However, the mechanisms that release repression and consequently allow gametocyte production are still a mystery. Our previous work demonstrated that *Pfgdv1* is required for gametocyte production. Here, we assess gametocytogenesis *in vitro* and demonstrate that GDV1 protein expression during schizogony is critical for gametocyte commitment and modulates transcript levels of *ap2-g*, a transcription factor associated with gametocytogenesis, as well as *msrp1*. In the next generation of ring stage parasites, *ap2-g* and *msrp1* RNA levels remain elevated and there is a GDV1-dependent increase in transcript levels of *gexp5*, an *ap2-g* independent gene. Ring stage RNA levels of all three GDV1-regulated genes, *ap2-g, msrp1* and *gexp5* correlated positively with gametocyte differentiation *in vitro* (R^2 = 0.45 to 0.92). Transcript levels for these genes were also significantly higher in field samples collected in Ghana during two malaria seasons, July-August 2016 and 2017, that had high ex-vivo gametocyte conversion rates (GCR) (Day4 GCR > 4.9 %; n=20) than those with low to undetectable ex-vivo GCR (n=20). Interestingly, GDV1 mutant allele (Histidine^{217}) which predominated in an area of limited seasonal malaria in the Gambia, has a high frequency only in high GCR samples (Fisher exact test, p=0.022) while *msp2* alleles are randomly distributed in both groups. Together the data suggests GDV1 acts as a rheostat for sexual differentiation upstream of *ap2-g in vitro* and plays a regulatory role *in vivo*.

GEOGRAPHIC ACCESSIBILITY AND FACILITY-BASED HEALTHCARE IN ZAMBIA: A GEOSTATISTICAL MAPPING STUDY

Roy Burstein[1], Felix Masiye[2], Nancy Fullman[3], Simon Hay[4]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*University of Zambia, Lusaka, Zambia,* [3]*University of Washington, Seattle, WA, United States,* [4]*Institute for Health Metrics and Evaluation, Seattle, WA, United States*

Understanding who accesses healthcare, why, and for what type of services is critical for planning health systems, which ultimately ought to be responsive and available to all potential users. Several studies have attempted to exploit the strong association observed between distance to health services and utilization in order to predict utilization rates across large geographic areas with sparse data. Efforts to quantify the relationship between distance and utilization and then predict utilization rates onto gridded geospatial surfaces have been subject to considerable data and methodological limitations. These include: limited data on health facility locations, 'jittering' of household locations in public datasets, unrealistic simplifying assumptions used in measuring geographic accessibility, focus on only one illness or age group, ignoring model and data uncertainty, and omission of important covariates. In this study, we sought to overcome limitations in accessibility and utilization mapping using a triangulation of health facility, household, and geospatial data sources from Zambia to answer four primary questions: What is the status of geographic accessibility to health facilities in Zambia? How does travel time to nearest health facility affect utilization rates? And finally, can we make a reasonable map of utilization rates using a geostatistical model? How does this approach compare to previous methods? We found that a large proportion of the Zambian population lives relatively close to facility care, but that small differences in travel time within the first hour from a health facility seem to impact utilization rates more than those same differences in distances for households that are further away from health facilities. Our approach showed considerable predictive improvement over existing methods. Furthermore, in accounting for uncertainty we found that spatially resolved estimates of utilization are difficult to achieve with any practical degree of certainty. We conclude that, by ignoring uncertainty, previous spatial utilization studies may have overstated the strength of evidence they produced.

1387

DATA ACCESS COMMITTEES: WHAT SHOULD THEIR ROLES AND RESPONSIBILITIES BE AND WHO SHOULD BE ON THEM?

Phaik Yeong Cheah[1], Jan Piasecki[2]

[1]*Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*Jagiellonian University Medical College, Krakow, Poland*

Sharing individual-level health data has many benefits, however there are also some potential harms, such as misuse of data and breaching of participants' confidentiality. One way to promote benefits of sharing while ameliorating its potential harms is through the adoption of a managed access approach where data requests are channeled through a Data Access Committee (DAC), rather than making data openly available without restrictions. A DAC, a formal or informal group of individuals have the responsibility of reviewing and assessing data access requests. Many individual groups, consortium, and institutional DACs have been set up but there is currently no widely accepted framework for their organization and functioning. Based on literature review, ethical analysis, and three years' experience coordinating a DAC (PYC), we propose that DACs, should have both the role of promotion of data sharing and protection of data subjects, their communities, data producers and their institutions. We suggest that data access should be granted by DACs as long as the data reuse has some potential social value and provided there is low risk of foreseeable harms. To promote data sharing, DACs could encourage secondary uses that are consistent with the interests of primary researchers and their institutions. Given the suggested roles of DACs, there should

be transparent, simple and clear application procedures for data access. DACs should be established within institutional and legal frameworks with clear lines of accountability, terms of reference and membership. In order to fulfill its functions, a DAC should consist of a reasonable number of members, each with multiple relevant areas of expertise. Ideally there should be members representing senior management, data management, ethics, relevant research areas and potentially a data sharing advocate. It is also desirable to have independent members.

1388

BEACON: A TOOL FOR EVALUATING MHEALTH READINESS IN GLOBAL HEALTH

Thomas F. Scherr[1], Carson Moore[1], Saidon Mbambara[2], Philip Thuma[2], David Wright[1]

[1]*Vanderbilt University, Nashville, TN, United States,* [2]*Macha Research Trust, Macha, Zambia*

Mobile health interventions are increasing in popularity, due in part to the ubiquity of mobile phones and data-rich possibilities. The growth of mobile phones has been a global trend, yet uncertainty remains amongst key stakeholders and decision makers that these interventions could successfully be used in global health. These skepticisms may be merited in some cases, however, in others, mHealth could be used to reduce geographic, financial, and social barriers to quality healthcare. Overall, there remains hesitation to use mHealth due to a lack of tools that can effectively evaluate a site's readiness to implement an intervention. This reduces the debate to an argument between empirical observations and dated facts, or worse, opinions. To this end, we have developed Beacon - a tool for evaluating mHealth readiness in global health. Beacon is an automated mobile phone application that repeatedly collects spatiotemporal data on network performance. Each data point is tagged with a timestamp and GPS coordinates, along with ping/download/upload latency and duration. Results can be collected, even in the absence of network connectivity, and uploaded to REDCap (a web-based electronic research database) for further analysis. As a demonstration of its utility, we present results collected in and around Macha, Zambia over a 4-week time period in 2019 (over 10,000 data points). These results show times of day when cellular networks experience a heavy load and slow down, compare performance of different cellular networks, and find geographic "dead zones" with limited or no cellular service. Beacon was developed to measure performance as it relates to our work in disease surveillance through point-of-care diagnostics, but it could be readily tailored to evaluate other mHealth interventions. We envision Beacon as a tool that could be used by 1) organizations that are considering an mHealth intervention in a low- and middle-income country, but are questioning its feasibility - including infrastructure and cost, and 2) organizations that have an existing mHealth intervention and are looking to optimize its delivery with improved logistics management.

TRANSLATING CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) RESULTS INTO ACTION AT THE DISTRICT LEVEL: THE EXPERIENCE OF MOZAMBIQUE

Inaco Mandomando[1], Pio Victorino[1], Saquina Cossa[1], Maria Maixenchs[2], Bento Nhancale[1], Estevao Mucavele[1], Madalena Ripinga[1], Rosauro Varo[2], Jaume Ordi[2], Elizabeth O'Mara[3], John Blevens[3], Navit Salzberg[3], Robert Breiman[3], Dianna Blau[3], Carla Carrilho[4], Quique Bassat[2], Khatia Munguambe[1]

[1]*Manhica Health Research Centre, Maputo, Mozambique,* [2]*ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain,* [3]*Emory Global Health Institute, Atlanta, GA, United States,* [4]*Hospital Central de Maputo, Maputo, Mozambique*

CHAMPS was established in rural Southern Mozambique to ascertain causes of child death (CoD), inform policy and public health action. Minimally Invasive Tissue Sampling (MITS) for histopathology and microbiological CoD assessment, together with a comprehensive demographic surveillance for detecting childhood deaths are on-going at the Manhiça District. Families of deceased under-5 children from the catchment area are approached for consenting to MITS, and individual CoD results returned to the family while aggregate data are fed back to the District authorities. We describe the process of translating CHAMPS results into action at the District level to improve health care quality. From December 2016 to March 2019, 161 (63%) MITS of the 255 approached cases were performed and CoD assigned to the first 100 cases, and results returned to 88 families within ~6 months. CHAMPS results may have a significant impact at the household level, as they entail the possibility of treating conditions (in household members) that have been detected in the deceased case. Clinical follow-up needs were identified for 15 families of which some of their members presented health problems that received additional care at the hospitals in follow-up to the CHAMPS feedback visit (e.g. HIV infected mothers who had abandoned the antiretroviral treatment; syphilis cases and the mother was found pregnant during the feedback results, and she was recommended to promptly attend the antenatal clinic until the successful delivery; mothers with cardiomegaly, endocrine and hematological disorders). While the individual-level tests are critical to timely reporting of communicable emerging diseases or unexpectedly important pathogens (e.g. cytomegalovirus), action was not limited to individual or household level support. Results feedback process triggered immediate action by the District Health Authorities to establish follow up visits for mothers referred by CHAMPS to the referral hospitals. In addition, the community death component has led to transporting, severe patients from the community to the hospital, a service that was previously restricted to pregnant women.

1390

EXPANDING GLOBAL PARTNERSHIPS TO STRENGTHEN PATHOLOGY-BASED MORTALITY SURVEILLANCE

Tia R. Paganelli[1], Norman J. Goco[2], Lindsay M. Parlberg[2], Elizabeth M. McClure[2]

[1]*RTI International, Seattle, WA, United States,* [2]*RTI International, Research Triangle Park, NC, United States*

The Minimally Invasive Tissue Sampling (MITS) Surveillance Alliance is a global, multidisciplinary consortium which aims to improve the quality of global mortality data, specifically cause of death classification through the expansion of the use of the MITS technique. MITS, a less-invasive alternative compared to complete diagnostic autopsies, targets only specific organs and can be performed by pathology technicians with specialized training. Initial studies have shown that MITS can generate high quality mortality data in low- and low-middle-income countries. The MITS Surveillance Alliance provides a forum for knowledge management, standardization of procedures and training, and sharing best practices for tissue processing and cause of death classification. Members include a collaborative body of clinical researchers, epidemiologists, pathologists, microbiologists, social scientists, and specialists interested in, or already implementing MITS. Through the support of the Secretariat the MITS Surveillance Alliance has organized dynamic Communities of Practice which serve as the cornerstone for knowledge sharing. With insight from members of various sized projects and geographic contexts, the Communities of Practice have collaboratively developed several resources; including guidance for introducing and conducting post-mortem research studies in vulnerable populations, tools for ensuring quality control in specimen collection. Additionally, the Communities of Practice have provided input on streamlined guidelines for the minimum data sources required for determining cause of death in different populations. By fostering global partnerships and advocating for high quality data through the expansion of MITS, the MITS Alliance can help governments, institutions, and stakeholders strengthen mortality surveillance and prioritize policies and interventions.

1391

ELECTRONIC DATA MANAGEMENT FOR GLOBAL HEALTH FIELD RESEARCH PROJECTS

Katiuscia K. O'Brian[1], Amy Rigney[2], Gary J. Weil[1]

[1]*Washington University School of Medicine, St Louis, MO, United States,* [2]*SPRI Clinical Trials, Pittsboro, NC, United States*

It can be challenging for global health research projects to collect and store data with tools and systems that are affordable and compliant with global standards. Special approaches are needed for collection of high quality, secure data in resource-poor settings with limited internet connectivity and on-site technical expertise. Electronic data management, coordinated with a strong data management plan (DMP) to ensure high quality data for analysis, is a useful approach. The benefits of electronic data management is the ability to collect data offline in areas with variable internet access, in near real-time, with remote monitoring and management, and producing high data quality. Data management can be all electronic (eSource) or a mixed system that includes both paper and electronic data capture (EDC) systems. DMPs should contain the following components: careful database design and development; data collection and capture procedures; data security; data quality and validation checks; data reporting, database closure, and archiving. It is important for researchers to discover if their projects needs to be 21 CFR Part 11 compliant, as this will dictate which EDC system would be appropriate. Compliance requires software controls including system validations, audit trails, electronic signatures, and documentation for software used to collect and process data in a manner that is trustworthy, reliable, and equivalent to paper records. Additional steps that we suggest for a successful and comprehensive global health data management plan should include: extensive user acceptability testing of EDC system; training teams for site initiation; technology assessment; on-site data manager; and frequent data cleaning during the study period so that errors can be corrected while participants are still available. Our poster will summarize lessons learned in multiple locations previously considered off the digital track using RedCAP (webportal EDC), EpiInfo (EDC App on Android BLU phone device syncing with Azure cloud server), and a proprietary system (EDC App on iOS iPad device syncing with Amazon cloud server) that is 21 CFR Part 11 compliant.

1392

STRENGTHENING THE VACCINE SAFETY SYSTEM IN KENYA: ASSESSMENT OF BEST PRACTICES FOR VACCINE SAFETY AMONG HEALTHCARE WORKERS IN KENYA

Zunera Gilani[1], Dorothy C. Koech[2], Lucy Mecca[3], Christabel Khaemba[4], Martha Mandale[4], Wilbrod Mwanje[5], Laura Conklin[1], Tabu Collins[3], Jane Gidudu[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*African Field Epidemiology Network, Nairobi, Kenya,* [3]*Kenya National Vaccines and Immunization Program, Nairobi, Kenya,* [4]*Kenya Pharmacy and Poisons Board, Nairobi, Kenya,* [5]*African Epidemiology Network, Kampala, Uganda*

A functional vaccine safety system is a key component for sustaining confidence in an immunization program, yet these systems are sub-optimal in many African countries including Kenya. This study's objectives were to: (1) assess healthcare worker (HCW) adverse event following immunization (AEFI) knowledge and practice; and (2) identify gaps, challenges and strategies to improve the AEFI reporting system. We selected 68 health facilities (HF) in six counties in Kenya; 61 were selected randomly and seven purposely as the largest facilities in the county/sub-county. At each HF, HCW that provided vaccination and/or managed AEFI were administered a structured questionnaire. In addition, we conducted key informant interviews (KII) with HCW involved in vaccine safety leadership, monitoring and reporting. Among 72 HCW surveyed, nearly all (n=68; 94.4%) knew the country's AEFI definition and most (n=61; 84.7%) knew the AEFI Reporting Form. Most HCW had not encountered an AEFI in the past two years (n=53; 73.6%). For those that had encountered an AEFI, half (n=7; 50%) believed they did not need to report non-serious AEFI and 57.1 % (n=8) believed they did not need to report AEFI they could manage. Only 63.3% (n=38) of HCW reported having an AEFI Reporting Form at their workstation. Nearly all HCW indicated that they provide AEFI information to caregivers of children they immunize (n=71; 98.6%). Finally, most HCW indicated they had not been trained on AEFI (n=63; 87.5%). Forty-five HCW participated in KII. Gaps and challenges identified centered on capacity, reporting and data. Strategies to address these gaps include: 1) HCW training to improve awareness of reporting processes; 2) improved availability of AEFI reporting forms, 3) development of job aids to encourage reporting all AEFI; and 4) strengthening data use and AEFI data systems. There have been few assessments of HCW vaccine safety knowledge and practice in the African region. Our study is one of the first to utilize a qualitative component. We identified good vaccine safety knowledge and practice, as well as gaps and strategies, with potential for applicability in similar geographical settings.

1393

SOCIAL ACCEPTABILITY OF COMPLETE DIAGNOSTIC AUTOPSY AND MINIMALLY INVASIVE TISSUE SAMPLING IN THE KILIMANJARO REGION OF NORTHERN TANZANIA

Francis P. Karia[1], Martha O. Mwanga[2], Elizabeth F. Msoka[2], Venance P. Maro[1], John A. Crump[3], Matthew P. Rubach[3], Lauren S. Blum[4]

[1]*Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania,* [2]*Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania,* [3]*Division of Infectious Diseases and International Health, Department of Medicine, Duke University Medical Center, Durham, NC, United States,* [4]*Consultant, Duke University, Durham, NC, United States*

Lack of reliable information on cause of death (CoD) in low- and middle-income countries (LMICs) is recognized as a constraint to global health and development. While complete diagnostic autopsy (CDA) is considered the gold standard to determine CoD, researchers often claim that CDA procedures are incongruent with cultural and religious beliefs and therefore less acceptable in LMICs. Minimally invasive tissue sampling (MITS), a useful but less comprehensive means to establish CoD, has been assumed to be more socially acceptable in LMICs. We conducted research from May 2016 through April 2019 to assess autopsy acceptability in two referral hospitals in the Kilimanjaro Region of Tanzania where CDA and MITS are being offered for in-patient febrile deaths. Families approached for authorization were first offered CDA; if they refused, MITS was offered. In-depth interviews were conducted longitudinally across the study time span and involved 24 families who accepted autopsy, including six accepting MITS, and 24 families who refused CDA or MITS to assess reasons for acceptance and refusal. Of 407 families approached, 117 (29%) accepted autopsy procedures including 95 (81.2%) authorizing CDA. Of 312 refusing CDA, 22 (7%) authorized MITS. Reasons for CDA acceptance included uncertainty about CoD, benefits to family and science, and whether witchcraft contributed to the CoD. Reasons families accepted MITS were that it is less invasive and to conceal procedures from other members. Reasons for refusal of autopsy procedures included the CoD had already been determined, results would not benefit the deceased, inadequate information, or inappropriate timing of authorization. Reluctance to have the body cut was reported by comparatively fewer families. Results show that acceptance and refusal of autopsy is primarily related to the perceived benefits of learning the CoD and conduct of authorization, and less about the type of procedure. In northern Tanzania, families desiring to learn the CoD will choose CDA. Counter to assumptions about CDA acceptability in LMICs, CDA acceptance was relatively high and uptake of MITS by families who refused CDA marginal.

1394

THE ROLE OF TRUST IN EMERGENCY PREPAREDNESS: INSIGHTS FROM A QUALITATIVE STUDY ON ZOONOTIC DISEASES IN CÔTE D'IVOIRE

Natalie Tibbels[1], Danielle Naugle[1], Abdul Dosso[2], William Benié[2], Walter Kra[3], Corinne Fordham[1], Mieko McKay[2], Valère Konan[4], Jeanne Brou[5], Jocelyne Nebre[5], Adaman Kouadio[4], Zandra Andre[6], Diarra Kamara[2], Stella Babalola[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Johns Hopkins University, Abidjan, Côte D'Ivoire,* [3]*Alassane Ouattara University, Bouaké, Côte D'Ivoire,* [4]*Department of Veterinarian Services Ministry of Animal Ressources and Fisheries, Abidjan, Côte D'Ivoire,* [5]*National Institute of Public Hygiene, Abidjan, Côte D'Ivoire,* [6]*U.S. Agency for International Development, Abidjan, Côte D'Ivoire*

Recent outbreaks of zoonotic diseases in West Africa, such as the 2014-2016 Ebola epidemic, have drawn attention to the need for stronger trust between communities and the health system. Trust has been linked to increased healthcare-seeking practices, and lack of trust can hinder compliance with emergency response efforts. Previous research has identified specific types of trust that operate in a health systems setting (e.g. interpersonal, institutional), as well as determinants (such as perceived competence or honesty of the provider or agency). However, gaps remain in our understanding of public trust during zoonotic epidemics. A qualitative study was implemented in early 2019 to understand individual, social, and cultural determinants of risk, prevention, and response behaviors related to five priority zoonotic disease groups in Côte d'Ivoire. The study involved 32 focus group discussions, 33 in-depth interviews, 20 observations, and 20 community mapping activities engaging a total of 234 adult men and women across four urban sites. The salience of trust was a key finding from the study. Trust was linked to relational proximity, with peers and local leaders more trusted than actors operating outside of or above the local level. Participants at times questioned even the existence of zoonotic diseases and described suspicions related to specific authorities, such as veterinarians, health providers, public officials, and international entities. Participants who engaged in animal husbandry as their main economic activity expressed distrust of authorities due to an insufficient compensation system for slaughtered sick animals. Fear of losing their animals and livelihoods fostered distrust and impeded open and expedient communication with authorities concerning sick animals. Herders and poultrymen described high risk behaviors that may lead to zoonotic outbreaks. These findings point to the need for community engagement around livelihood protection and prevention of zoonotic disease transmission as well as programs that fairly compensate animal husbandry workers, to build trust toward epidemic prevention and response.

1395

IMPLEMENTATION OF THE SMITHSONIAN'S *OUTBREAK DIY* TOOLKIT FOR LOCAL COMMUNITIES OF LAIKIPIA, KENYA: SUCCESSES, CHALLENGES AND LESSONS LEARNED

Jennifer H. Yu[1], Sabrina Sholts[2], Dawn Zimmerman[1], Joseph Kamau[3], Elizabeth Ashby[1], Dino Martins[4], Fardosa Hassan[4], Suzan Murray[1], Kerri Dean[5]

[1]*Global Health Program, Smithsonian's National Zoo and Conservation Biology Institute, Washington, DC, United States,* [2]*Department of Anthropology, Smithsonian National Museum of Natural History, Washington, DC, United States,* [3]*Molecular Biology Unit, Institute of Primate Research, Karen-Nairobi, Kenya,* [4]*Mpala Research Centre and Wildlife Foundation, Laikipia, Kenya,* [5]*Department of Exhibitions, Smithsonian National Museum of Natural History, Washington, DC, United States*

In 2018, the Smithsonian's National Museum of Natural History launched *Outbreak DIY*, a free, multilingual, and customizable toolkit for public health education in communities worldwide. Intended to generate discussion and raise public awareness about zoonotic threats, the *Outbreak DIY* materials include digital files for panels, videos, and games that communicate the role of animals in public health, anthropogenic factors that drive their emergence, and risk mitigation strategies. While the *Outbreak DIY* toolkit has been used more than 85 times in 29 countries to date, here we present its use for public displays in Kenya as part of the larger USAID Emerging Pandemic Threats PREDICT project, with overall goals of strengthening health security as part of the Global Health Security Agenda. In addition to emphasizing the overarching message of the benefits of the One Health perspective, panels were customized to: 1) target regional priority diseases; 2) depict endemic and regional species of interest; 3) emphasize country-specific One Health policy, institutional bodies, and interventions; and 4) highlight key individuals and partners working in One Health. In communities of Laikipia, Kenya, *Outbreak DIY* achieved some initial objectives of its users, improving knowledge of the role animals play in disease transmission and ways to live safely with wildlife. The display prompted discussion of diseases, associated clinical signs, species that carry them, and behavioral practices that increase risk. Another success was the engagement of Kenyan graduate students in the communication of the exhibit's content, allowing for further tailoring of the subject matter to community contexts. These experiences show that the *Outbreak DIY* toolkit can be easily adapted for local communities, but to maximize its educational value, further consideration of additional concerns is recommended by its users, including: 1) facilitating engagement of local actors and health workers in the presentation; 2) further customization of the content to local communities for context on a finer scale; and 3) consideration of diverse or varied audiences in messaging.

1396

IMPACT OF A FACILITY-BASED INTERVENTION ON PROVIDERS' CASE-MANAGEMENT SKILLS RELATED TO CHILDHOOD DIARRHEA: LEARNING FROM A QUASI-EXPERIMENTAL STUDY CONDUCTED IN UTTAR PRADESH, INDIA

Lopamudra Ray Saraswati, Prince Bhandari, Animesh Rai, Ambrish Chandan, Ashutosh Mishra

RTI International India, New Delhi, India

Globally, India ranks first in terms of childhood diarrheal deaths, most of which are preventable with correct diagnosis and treatment. We conducted a quasi-experimental study to assess the effectiveness of an intervention aimed at reducing child mortality through capacity building of facility-based health providers toward appropriate case management of childhood diarrhea. This paper measures the impact of intervention using difference-in-differences (DID) analysis. We observed 331 suspected diarrhea cases (treatment: 191; comparison: 140) pre-intervention, and 306 cases (treatment: 160; comparison: 146) post-intervention, receiving care at the facilities in three intervention and three comparison districts. Appropriate case management was defined as the suspected diarrhea cases being diagnosed with diarrhea, assessment being done using World Health Organization's facility-based integrated management of neonatal and childhood illnesses (F-IMNCI) checklist, and prescription of correct treatment, that is ORS and Zinc for diarrhea with no or some dehydration, intravenous fluids for diarrhea with severe dehydration, and Ciprofloxacin or Ceftriaxone for dysentery. The intervention proved to be effective in strengthening providers' skills of diagnosis [DID coefficient: 0.26; 95% confidence interval (CI): 0.10 - 0.41] and treatment [DID: 0.17; 95%CI: 0.07 - 0.26]. However, it remained ineffective in improving their adherence to F-IMNCI guidelines for assessment, an important component of fidelity to evidence-based clinical practice. These findings indicate that interventions adopting a conventional approach can only partially improve the case management skills of providers and fails to make an impact on their practicing skill which is associated with attitudes and beliefs. Hence future child survival programs should focus on providers' behavioral aspect and explore innovative strategies to improve their practices for assessment of childhood diarrhea, besides continuing working on skill development for appropriate diagnosis and treatment.

1397

TRAVEL HEALTH PERCEPTIONS AND BEHAVIOR AMONGST PARTICIPANTS IN A TROPICAL MEDICINE DIPLOMA COURSE

Kyle Denison Martin[1], Sophie Dunin de Skrzynno[2], Yvonne Wekesa[3], Alex Fleming-Nouri[4], Stephanie Laura Wilson[5], Adam Boggon[2], Tembe Carveth-Johnson[2], Maria Henriksson[2], Joy Jones[2], Christopher Sanford[6]

[1]*Brown University, Providence, RI, United States,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Tenwek Mission Hospital, Bomet, Kenya,* [4]*Oxford University Hospitals, Oxford, United Kingdom,* [5]*University College of London Hospital, London, United Kingdom,* [6]*University of Washington, Seattle, WA, United States*

In an increasingly interconnected world, travelers face new risks to their health. Previous studies have explored travel health perceptions and behavior amongst the general population of international travelers. However, few studies have examined the perceptions and behaviors of health care professionals. This information could be used to identify knowledge gaps and improve safety for health care professionals who travel abroad. This study aimed to examine travel health perceptions and behaviors amongst participants in a tropical medicine diploma course. This study featured a survey presented to participants in the East African Diploma in Tropical Medicine and Hygiene course offered by the London School of Hygiene & Tropical Medicine in 2018. The response rate for the survey was 71% (n=52). The most common sources of travel health information were the internet (59%), Travel Health specialists (51%) and participants themselves (37%). Participants identified road traffic accidents as the primary threat to their health (78%). Nonetheless, 59% of participants admitted to riding on a motorcycle taxi during their travel and only one-third of respondents noted wearing a helmet with >90% frequency. In fact, 8% confessed to wearing a helmet <10% of the time when using a motorcycle taxi. 68% of survey participants received a prescription for malaria prophylaxis. Of this group, only 71% took the medication as directed. The most common reason for not receiving a prescription for malaria prophylaxis was that participants did not feel prophylaxis was necessary. The health care professionals in this study relied heavily on the internet and their own personal knowledge for travel health information. Participants identified road traffic accidents as the primary threat to their health. Nonetheless, the majority of respondents confessed to high-risk behaviors such as using motorcycle taxis, often without a helmet. Only half of participants were taking malaria prophylaxis as directed. The information from this study can be used to develop travel health education for health care professionals to improve knowledge and decrease high-risk behavior.

1398

MANAGEMENT OF COMMUNITY-DIRECT TREATMENT WITH IVERMECTIN (CDTI) CAMPAIGN DURING INSECURITY IN THE SOUTHWEST REGION OF CAMEROON

Georges Nko'Ayissi[1], Victor Mbome NJie[1], Nde Bea[1], Biholong Benjamin Didier[1], Julie Akame[2], Patrick Mbia[2], Yaobi Zhang[3], Steven D. Reid[4], Ismael Teta[2]

[1]*Ministry of Public Health, NTD Coordination Unit, Yaoundé, Cameroon,* [2]*Helen Keller International, Yaoundé, Cameroon,* [3]*Helen Keller International, Regional Office for Africa, Dakar, Senegal,* [4]*Helen Keller International, New York, NY, United States*

The 2018 community-direct treatment with ivermectin (CDTI) for onchocerciasis in the South West and North West regions of Cameroon was carried out amidst socio-political unrest. At the time of the CDTI some districts like Buea, Tiko and Ekondo-titi were affected by a mass population exodus from health districts (HDs) when rumors of a possible lockdown of the region were circulated. Since the census was completed the month prior to the CDTI, the target population was not the same during the CDTI. To ensure reaching those targeted for treatment, the ministry of health (MOH) developed several strategies that would allow the CDTI to continue during insecurity but obtain sufficient program coverage. To conduct health personnel training prior to the CDTI, pooled trainings in more secure health districts (HDs) in the region were developed as well as training sites established in neighboring HDs of other regions. Community drug distributor (CDD) training was organized according to the local context, for example, chiefs of health areas carried out training for CDDs in their safe locations. The 'Hit & Run' strategy was used to deliver the mass drug administration (MDA). The census and treatment were completed simultaneously in all HDs except one and the MDA was done in farms and camps. The HDs which could not begin the campaign the same time as the rest of the region were advised to begin whenever possible. Insecurity in some areas made it difficult to carry out MDA. In some areas there were rumors of poisoned medications being distributed so MOH staff used in-person discussions and opinion leaders to reassure population that IVM has been distributed safely for over 20 years. Despite a reduction in population of 37.9% from the 2018 MDA census data, these new approaches enabled a programmatic coverage of 74.2% of those who remained in the regions. To improve this performance during the next MDA campaign, the regional Delegation of Public Health agreed to inform the population beforehand of the distribution period, to carry out census and treatment simultaneously in all HDs in these regions and to intensify team work at all levels.

1399

NEMO: AN OPEN SOURCE SOFTWARE FOR SURVEY FORM DESIGN AND AGGREGATION FOR USE WITH OPEN DATA KIT COLLECT

Dottie Hunt, Andrew W. Nute, Gregory S. Noland, Emily Griswold, Lindsay J. Rakers, Brianna Poovey, Avery Davis-Roberts, Seseni Nu, Adam J. Weiss, E. Kelly Callahan, Scott D. Nash

The Carter Center, Atlanta, GA, United States

Collection of electronic data for global health and neglected tropical diseases (NTDs) in particular, is becoming the norm, and in some cases a requirement, by various stakeholders. However, most software available have high operating costs and create reliance on external parties for technical support. Beginning in 2011, The Carter Center began to create an open source data collection software for election monitoring called ELMO to be used in conjunction with the Android application, Open Data Kit Collect. The Center eventually developed the next generation of the software, now called NEMO, to facilitate the survey capabilities needed by its other programs. To date, NEMO has been used to design and deploy surveys for monitoring and evaluation efforts related to the NTDs guinea worm, trachoma, lymphatic filariasis (LF), onchocerciasis, schistosomiasis, soil-transmitted helminthiasis, and loiasis. Defined as a specific program/initiative in a given country, 75 missions have been established in 10 languages across 25 countries of which 12 (16%) missions in six countries are related to NTDs or global health. Data collection for election monitoring has involved as many as 25,000 enumerators and have produced as much as 1.3 gigabytes of survey data for a single mission. Common NTD assessments facilitated in NEMO include Trachoma Impact Surveys, Transmission Assessment Surveys for LF, and coverage surveys for mass drug administration of a variety of preventive chemotherapeutic drugs. Other programs at The Center have used NEMO for survey use cases investigating progress in human rights and access to information internationally. Through low skill requirements, NEMO empowers the user with holistic ownership of the data collection process resulting in better control of the data produced. By doing this, NEMO has proven the feasibility of high-quality data collection at scale without presenting the drawbacks that are typically associated with similar survey management software.

A MULTI-SECTOR ENGAGEMENT APPROACH TO DEVELOPING A PLATFORM FOR ETIOLOGICAL DIAGNOSIS OF FEBRILE ILLNESSES IN WEST AFRICA

Edward O. Nyarko[1], Andrew Letizia[2], William Asiedu[1], Patricia Adams[1], Mihret F. Amare[3], Jayda Jones[3], Suzanne Mate[4], Kara Lombardi[3], Leigh Ann Eller[3], Inger-Marie Vilcins[3], Zahra Parker[3], Abdulwasiu B. Tiamiyu[5], Edward Akinwale[5], Amy Castellano[3], Ayesha Rashid[3], Mark Milazzo[3], Heather Lieu[3], Jarrett Headley[3], Michael Iroezindu[5], Joseph Diclaro[6], Paul Scott[4], Merlin Robb[3], Nelson Michael[4], Julie Ake[4], Kayvon Modjarrad[4]

[137] *Military Hospital, Accra, Ghana,* [2]*Navy Medical Research Unit-3 Ghana Detachment, Accra, Ghana,* [3]*Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States,* [4]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [5]*Henry M. Jackson Foundation Medical Research International, Abuja, Nigeria,* [6]*Navy Entomological Center of Excellence, Jacksonville, FL, United States*

The 2014 West African Ebola virus disease (EVD) outbreak demonstrated the threat of infectious diseases and highlighted the need for improved surveillance of high-risk pathogens. The Joint West Africa Research Group (JWARG) is a military and academic collaboration between Ghana, Liberia, Nigeria and the United States. JWARG's goal is to improve partner nation capacity while looking to identify the etiology of febrile illness in West Africa. Since 2017, individuals presenting to select military treatment facilities in Ghana, Liberia, and Nigeria with signs and symptoms consistent with a fever of unknown origin were eligible. Those who consented provided clinical and laboratory data upon enrollment and subsequently at a convalescent encounter 28 days later. Although the testing methodology includes molecular, serologic and genomic analysis, preliminary results from rapid diagnostic tests (RDTs) provide an initial insight into the pathogens causing febrile illness. As of April 2019, 379 participants, 55% female, averaging 37-years old have been enrolled with 74% from Nigeria, 25% from Ghana and 1% from Liberia. At enrollment, 56 (14%) participants were positive for malaria by RDT and 49 (12%) thick/thin smear by microscopy with about 30% discordance. A total of 48 (12%) participants had two concordant positive HIV RDTs and 5 cases were positive for tuberculosis though identification of acid-fast bacilli or by GeneXpert testing. Schistosomisasis RDT was positive in 30 participants. Additionally, 112 participants samples have tested negative for viral hemorrhagic fever as well as flaviviruses and alphaviruses. JWARG improves biopreparedness by establishing a shared research platform for rapidly diagnosing various etiologies of febrile illnesses in West Africa. While still pending confirmatory testing, multiple pathogens of public health concern including HIV, malaria, TB and schistosomiasis have been identified. Further analysis with more specific testing is ongoing and will provide valuable insight into the epidemiology of febrile illness in Ghana, Liberia, and Nigeria.

1401

BUILDING AN EBOLA-READY WORKFORCE: LESSONS LEARNED ON STRENGTHENING THE GLOBAL WORKFORCE THROUGH UNIVERSITY NETWORKS

Katey Pelican[1], Saul Tzipori[2], **Jeff Bender**[3]

[1]*University of Minnesota, St. Paul, MN, United States,* [2]*Tufts University, North Grafton, MA, United States,* [3]*University of Minnesota, Minneapolis, MN, United States*

Recent and on-going threats around the world have underscored a critical need for health workers that are prepared to manage diseases that cross human, animal, and environmental health sectors. The 2013 emergence of the Ebola virus in West Africa posed a global threat to human and animal health, as well as national security and economic prosperity. The epidemic called for a workforce that had the technical skills and competencies to work well within disciplines and sectors, but also possessed the skills to work across sectors and disciplines to promote coordination and communication among all the stakeholders necessary for effective and efficient control of an infectious disease outbreak at this global scale. The USAID One Health Workforce (OHW) Project, launched in 2014, aimed to achieve a workforce that is better prepared to prevent, detect, and respond to emerging infectious disease threats. Focusing on two infectious disease hot spot regions in Africa and Asia, OHW strengthens training and educational programs in universities in 12 countries to create a skilled workforce in using a transdisciplinary approach known as One Health. The focus of the work is on multi-sectoral engagement, education and training, and strengthening of Universities. Accomplishments to date include 140 community outreach activities including 15 outbreak investigations. 12 countries have conducted 14 national health workforce assessments. The individuals trained include over 3,600 students, 1,200 in-service professionals, and 29 fellows placed in health-related organizations. To support University institutions, which includes over 162 Schools/faculties across 84 Universities, professional development to 3,500 faculty was provided and 24 new academic and professional programs (i.e. Wildlife Health and Epidemiology Programs in DRC and Senegal) were established. This One Health effort leveraged the resources from established University networks creating a sustainable transformation among the health workforce in Africa and Southeast Asia.

1402

CAPITALIZING ON A COLLABORATIVE MODEL TO STRENGTHEN INSTITUTIONAL HEALTH SERVICE DELIVERY: A SUCCESSFUL PARTNERSHIP BETWEEN THE AUSTERE ENVIRONMENTS CONSORTIUM FOR ENHANCED SEPSIS OUTCOMES (ACESO) AND A GHANAIAN TERTIARY HOSPITAL

George Oduro[1], Chris Oppong[1], Alex Owusu-Ofori[2], Daniel Ansong[3], Anne Fox[4], Andrew Letizia[4], Josh Chenoweth[5], Charmagne Beckett[6], Benjamin Espinosa[6], Danielle Clark[5]

[1]*Komfo Anokye Teaching Hospital, Kumasi, Ghana,* [2]*Department of Clinical Microbiology, School of Medical Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [3]*Department of Child Health, School of Medical Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [4]*Naval Medical Research Unit Number 3, Accra, Ghana,* [5]*Henry M Jackson Foundation, Austere Environments Consortium for Enhanced Sepsis Outcomes, Bethesda, MD, United States,* [6]*Naval Medical Research Center, Frederick, Austere Environments Consortium for Enhanced Sepsis Outcomes, Frederick, MD, United States*

We describe how a collaborative study with The Austere environments Consortium for Enhanced Sepsis Outcomes (ACESO) has positively strengthened health service delivery and research capacity in a Ghanaian tertiary hospital. ACESO is a consortium of military medical and academic research institutes aiming to improve early recognition, diagnosis, and treatment of sepsis in low-resource settings. KATH sees patients from the northern half of Ghana and three neighbouring West African countries. From July 2016, demographic and clinical data from 220 subjects with suspected sepsis were collected and analyzed. In addition to CBC, biochemistry, and blood cultures, RDT panels were run for malaria, Dengue, Chikungunya, Hepatitis A, B, and C, and HIV. Patients with sepsis had a mortality rate of 40%. Benefits to the host institution include ergonomic redesign of the microbiology laboratory, training of laboratory personnel in technologies such as DNA extraction and utilization of chromogenic bacterial agar, reliable access to ATTC quality control strains of bacteria, development of local expertise in bacterial species identification, improvement in antimicrobial susceptibility testing, and expansion of research infrastructure and skills. Patients benefited from quick turnaround of laboratory tests. The collaboration has enabled international educational exchanges. For example, KATH has hosted US military physicians with an interest in tropical diseases annually. Personnel from KATH have had training in Nigeria on malaria diagnosis and laboratory assays. These exchanges provide opportunities to gain knowledge in international best practices and improve biosurveillance capabilities for infectious disease threats in the subregion. In conclusion, the collaboration has facilitated training for clinical and laboratory personnel, and provided functional and infrastructural development to the host institution. We contend that this delivers a firm base for future

collaboration involving intervention studies, with prospects for developing tests to aid early recognition, diagnosis and treatment of sepsis in low-resource settings.

1403

CHOLERA IN INTERNALLY DISPLACED PERSONS CAMPS IN BORNO STATE—NIGERIA, 2017: A QUALITATIVE STUDY OF THE MULTI-SECTORIAL EMERGENCY RESPONSE TO STOP THE SPREAD OF THE OUTBREAK

Moise C. Ngwa[1], Alemu Wondimagegnehu[2], Ifeanyi Okudo[3], Collins Owili[4], Uzoma Ugochukwu[3], Clement Peter[3], Isabelle Devaux[5], Lorenzo Pezzoli[6], Chikwe Ihekweazu[7], David A. Sack[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*International Health Consultancy, LLC, Atlanta, GA, United States,* [3]*World Health Organization Country Office, Nigeria, Abuja, Nigeria,* [4]*World Health Organization Country Office, Nigeria, Abuja, Nigeria,* [5]*World Health Organization Country Office, Borno State, Nigeria, Maiduguri, Nigeria,* [6]*World Health Organization, Geneva, Switzerland,* [7]*Nigeria Centre for Disease Control, Nigeria, Abuja, Nigeria*

In August 2017, a cholera outbreak started in Muna Garage camp for internally displaced persons, Borno State-Nigeria, and circa 5000 cases occurred in six local government areas. This qualitative study evaluated perspectives about the emergency response to this outbreak. We conducted 39 key informant interviews, focused group discussions, and reviewed 21 documents linked with surveillance, water-sanitation-hygiene, case management, immunization, communications, logistics, and coordination. Data analysis used thematic techniques comprising key-words-in-context, and word-repetition. Authorities were alerted quickly of outbreak, but declaration took 12 days due to a 10 day delay in laboratory confirmation. Investigation revealed several transmission channels including a leaking latrine around the index cases' house. Families refused chlorine use due to rumors that it would sterilize women. This could have been avoided with improved community consultation. Initially, communication was in Hausa, although 'Kanuri' was the main language; later this was corrected. Preparedness plans lacked exercise drills to identify weaknesses. Response by the Rural Water Supply and Sanitation Agency was perceived to be slow and increased risk from Eid El Jabir festival with increased movement and food sharing was not recognized. Treatment centers provided case management, but some partners were concerned that their work was recognized asking, "who gets the glory and the data?" Oral cholera vaccine was provided to nearly one million people using a robust polio vaccine structure; however, peripheral staff payment needed resolution. Initial coordination of multi-sectoral response activities by Borno Ministry of Health was slow, but improved by activating an Emergency Operations Centre and Incident Management System. The synergy between partners and government improved when each recognized the government's leadership role. Despite a timely alert of the outbreak, the delayed declaration led to a slowed initial response, which improved during the course of the outbreak. Improvements in camp and laboratory capacities are urgently needed.

1404

OBSTETRICS-GYNECOLOGY GRAND ROUNDS AS A MEANS TO EVALUATE AND IMPROVE PROVIDER KNOWLEDGE OF CONGENITAL CHAGAS DISEASE

Erica L. Crosley, Federico Palacio-Bedoya

Emory University School of Medicine, Atlanta, GA, United States

Chagas disease, a vector-borne parasitic infection by *Trypanosoma cruzi*, affects over 340,000 people in the U.S. Vertical transmission perpetuates Chagas disease burden in non-endemic countries, and early detection decreases morbidity. A 2010 survey by the American College of Obstetricians and Gynecologists found limited knowledge of Chagas vertical transmission among obstetrician-gynecologists and suggested more provider education. Grady Memorial Hospital (GMH) in Atlanta, GA is a large component of Emory School of Medicine's academic medical training. 20% of GMH deliveries are to Hispanic females largely from endemic countries. This study seeks to replicate the ACOG survey among obstetrician-gynecologists from Emory satellite clinics and three main university hospitals. It also evaluates the effect of Grand Rounds on provider congenital Chagas knowledge. Faculty attendings, fellows and resident physicians from obstetrics-gynecology were present, along with medical students. 31 surveys were completed-38.7% by attending faculty, 19.4% by residents, 32.3% by medical students, and 9.7% by fellows/other. Before Grand Rounds, 93.5% rated their Chagas knowledge as 'limited' or lower, 83.8% reported 'never' or 'rarely' considering Chagas in patients from endemic areas, 80.6% incorrectly answered possible maternal infection timing in relation to vertical transmission, and 80.6% incorrectly answered vertical transmission risk in chronic Chagas. After Grand Rounds, there was a significant difference (α 0.05) in the percent reporting limited Chagas knowledge (64.5%), the percent incorrect regarding maternal infection timing and vertical transmission (19.35%), and the percent incorrect regarding vertical transmission risk of chronic Chagas (29.0%). Education is an important tool for Chagas awareness, and there is limited knowledge even at high-volume academic centers seeing at-risk patients. The study highlights the need for targeted provider education regarding Chagas screening. This educational activity resulted in the creation of a prenatal Chagas screening program at GMH by an interdisciplinary Emory team.

1405

PRECOSAN: CONCERTED RESEARCH PROGRAM IN HEALTH ECONOMICS AT KINSHASA SCHOOL OF PUBLIC HEALTH

Aimée Lulebo Mampasi[1], Serge Mayaka Manitu[1], Patrick Suykerbuyk[2], Diana De Graeve[2]

[1]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo,* [2]*University of Antwerp, Antwerp, Belgium*

The Democratic Republic of the Congo (DRC) lacks necessary resources to provide efficient and equitable health services. Reinforcing local capacity is essential to constructively evaluate all health-care financing alternatives, to demonstrate the economic burden of health-related conditions, and to meaningfully determine the value of proposed programs and interventions, appropriate within the Congolese context. To provide efficient and equitable health services for improving the health of the Congolese population, we developed a seed-grant funded project including the following two specific objectives (SO): SO1. Strongly reinforce a concerted research program in health economics (HE) at Kinshasa School of Public Health (KSPH). To achieve this goal, we organized and facilitated both interactive consultations and needs assessment with KSPH staff members and governmental, non-governmental, private, academic and international stakeholders. The main outcome of these bottom-up sessions is the development and implementation of a strategic sustainability plan for a HE research program at KSPH (PRECOSAN: Programme de Recherche Congolais en Economie de la Santé) that is both need and demand driven. Furthermore, we will increase the visibility of PRECOSAN through the development and implementation of a dissemination and outreach plan (e.g., website, networking, meetings and conferences). SO2. Strengthen the research and training capacities in HE at KSPH. To achieve this goal, we mentor and supervise two health economists (PhD-level) to improve their capacities to successfully navigate the academic ladder (both scientifically and management) as part of the capacity retention at KSPH. Furthermore, we offered three scholarships for a master training in HE at KSPH and will award four additional research grants (#2 per year) for master's thesis research in HE. The selected students will be offered research opportunities in the newly developed HE research program (PRECOSAN). Here we will present the main outcomes of the needs and demand assessment in HE conducted in 2018-2019 among the key health stakeholders in DRC.

GEOSPATIAL ANALYSIS REVEALS SUBNATIONAL VARIATION IN CHILD MORTALITY SURVEILLANCE COMPLETENESS ACROSS CENTRAL AND SOUTH AMERICA

Nathaniel Henry[1], Roy Burstein[2], Michael Collison[1]

[1]*Institute for Health Metrics and Evaluation, Seattle, WA, United States,* [2]*Institute for Disease Modeling, Bellevue, WA, United States*

Renewed emphasis on strengthening the capacity of district health programs and new technologies for storing and disseminating health records have fostered growth in both the quantity and quality of local health surveillance data in countries across the Global South. Given that national health agencies often use routine surveillance data to inform decisions about health funding priorities, the global health community must develop a suite of sophisticated and appropriate statistical tools for analyzing local health status and health program performance based on these data. However, despite analytical and policy advantages, spatially-resolved analyses of national health surveillance data have historically been limited due to the challenge of correcting for varying data incompleteness across space and time. This research develops a method for incorporating government surveillance data and household surveys into a unified model of child mortality at the sub-national level. The method integrates these two data types in a joint model that produces two space-time structured surfaces, one estimating child mortality rate, and the other estimating reporting completeness for surveillance data. The model is applied to produce estimates of both child mortality and vital registration incompleteness at the district level across 12 countries in Latin America, revealing local variation and inequality that are masked by national estimates.

1407

INCREASED ACCESS TO ESSENTIAL HEALTH COMMODITIES THROUGH SUPPLY CHAIN AND INFORMATION SYSTEM INTEGRATION IN LAO PDR

Bounxou Keohavong[1], Many Thammavong[2], Lauren Theis[3], Dalavone Sengamphay[3]

[1]*Ministry of Health Food and Drug Department, Vientiane, Lao People's Democratic Republic,* [2]*Ministry of Health Medical Product Supply Center, Vientiane, Lao People's Democratic Republic,* [3]*Clinton Health Access Initiative, Vientiane, Lao People's Democratic Republic*

Vertical supply chain systems lead to inefficient stock management, surveillance, and administration, causing patients in Lao People's Democratic Republic (Lao PDR) to face inconsistent access to essential health commodities due to stock-out and expiry. In 2014, 31% and 25% of high-burden health facilities reported a malaria rapid diagnostic test (RDT) or artemisinin-based combination therapy (ACT) stock-out, respectively. Between 2013 and 2015, more than $400,000 of anti-retroviral (ARV) drugs expired, equivalent to 70% of the country's annual ARV budget needs. In 2015, the Lao PDR Ministry of Health (MoH) began implementing significant reforms to address these issues, largely through the integration of multiple, vertical supply chains managed by programs into one supply chain system managed by the Food and Drug Department (FDD). These reforms include the adoption of an electronic logistics management information system, mSupply, at national, provincial, and district levels, which has led to efficiencies in stock forecasting, procurement, management, and distribution. In 2018, fewer than 15% of high-burden facilities in Lao PDR experienced an ACT or RDT stock out. In 2019, modifications enable interoperability between the national mSupply and DHIS2 surveillance systems so that health actors across all levels can view and analyze commodity and epidemiological data together in a single system. The Lao PDR MoH's supply chain and information system integration has created a robust surveillance system that transforms the country's ability to make data-informed decisions and increase access to essential health commodities and services.

1408

MANAGING OPERATIONAL AND FUNDAMENTAL RESEARCH TO CREATE SYNERGIES IN PUBLIC AND MILITARY HEALTH EFFORTS ADDRESSING MALARIA

Nicole Y. Zdrojewski, Thi Phuong Hoa Nguyen, John W. Fallon

Vysnova Partners, Inc., Landover, MD, United States

Operational malaria research is conducted to reduce the impact of malaria in civilian and military populations. A primary challenge associated with its design and execution is the presence of many actors carrying out research under malaria elimination agendas. Research and communications gaps are inherent in these multi-governmental and multi-agency programs. Such gaps are missed opportunities to harmonize research agendas and leverage resources. Developing shared research program management and knowledge management capabilities would enable funders, national malaria control programs (NMCPs), and militaries to enhance the impact of limited research funds on salient issues in the fight against malaria. Evaluative reports on complex foreign assistance programming (e.g., Global Fund or the US foreign assistance portfolio) have identified coordination challenges among funders with similar missions and goals. While supporting operational malaria research in Vietnam, we noted programmatic challenges in planning and executing (e.g., identifying duplicative efforts, cementing trusting partnerships, executing time-constrained funds, assuring quality) as well as systematized knowledge management (KM) within and among teams and institutions. We developed an adaptive program management model, including knowledge management, for operational research. Our cooperative approach engages partners and stakeholders, provides real-time analysis and manages interlocking projects with an evolving array of desired endpoints. Based on lessons learned from collaborations in Vietnam, we recommend program activities be developed considering the following critical elements: 1) situational awareness, 2) relationships (in place or in progress), 3) management infrastructure, 4) scientific infrastructure and 5) desired research endpoints. Instituting a research-focused program management office complemented with a KM platform for operational malaria research would facilitate more strategic protocol design and study execution that furthers funders' and NMCPs' goals among critical military and civilian populations.

1409

PORTABLE SCREENING DEVICES TO ASSESS MEDICINES QUALITY FOR NATIONAL MEDICINES REGULATORY AUTHORITIES

Céline Caillet, Paul N. Newton

Lao-Oxford Mahosot Hospital Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic

The World Health Organization estimated that ~10% of medical products circulating in low- and middle-income countries are either substandard or falsified (SF). SF risk increased morbidity and mortality, economic losses and diminished public confidence in health systems. SF antimicrobials, particularly those containing reduced quantities of Active Pharmaceutical Ingredients (APIs), may be key but neglected drivers of antimicrobial resistance. Medicines quality screening devices hold great promise to detect SF during post-market surveillance (PMS) by Medicines Regulatory Authorities. We will give insight into the advantages/limitations of diverse screening devices in the hands of end-users observed in a field setting evaluation in Laos. Most portable devices are accurate to detect zero and wrong API medicines. However, the screening of low % API remains a significant gap, as there are major concerns about their availability in diverse supply chains. Indeed, substandard medicines have been found in most of the recent large surveys. The abilities and feasibility of using screening devices to quantitate APIs in pharmaceutical products are explored. Our evaluation also suggested that policy makers wishing to implement devices in PMS should be aware that overconfidence in the

devices may cause harm by reducing inspectors' investment in visual inspection. The latest developments of portable and handheld devices will also be presented.

1410

UNDERWEIGHT AND STUNTING AMONG BANGLADESHI FEMALE ADOLESCENTS: FINDINGS OF A NATIONALLY REPRESENTATIVE SURVEY

Kazi Istiaque Sanin, Ahshanul Haque, Mansura Khanam, Gulshan Ara, Tahmeed Ahmed

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Optimum nutritional status of an adolescent girl is not only vital for herself but also for the future generation. Nutritional status of the adolescents are often under-reported in resource-poor countries like Bangladesh. Bangladesh Integrated Household Survey (BIHS) contains data on nutrition status of every household member, individual food consumption and other potential determinants of nutrition. We analyzed the BIHS 2015 round data to explore the nutritional status of the rural adolescent girls aged 10-19 years and to investigate associated factors. We collected data on households those are nationally representative (rural only). We extracted data for girls aged 10-19 years, their anthropometric measurements, 24-hour dietary recall data and additional information. We had information of 1,835 adolescent girls with an average age of 14.1±2.8 years. Majority of the girls (89.9%) were never married and attending school during the survey period (82.2%). Among the menstruating girls, only 10.4% used disposable sanitary pad. The average height was 146.4±9.4 cm and weight was 38.4± 9.7 kg. Among the girls, 14.8% had BMI-for-age Z score <-2SD (thinness) and 5.4% were overweight or obese. About 26.5% adolescent girls were stunted (height-for-age Z score<-2SD). The major sources of animal protein for these girls were fish (71.7%), dairy products (32.1%) and egg (22.5%). In multivariable regression, only age and education level of these adolescents were significantly associated with both underweight and stunting. Age was a protective factor in underweight (AOR=0.91, 95% CI 0.85-0.98) and girls having only primary or less education had 64% higher odds (AOR=1.64, 95% CI 1.16-2.34) of being underweight compared to those with secondary education. Age (AOR=1.23, 95% CI 1.17-1.30), primary or less education (AOR=1.94, 95% CI 1.48-2.55) and unhygienic toilet (AOR=1.29, 95% CI 1.03-1.63) were the factors associated with stunting in these girls. The prevalence of underweight and stunting was high among adolescent Bangladeshi girls. Policymakers must focus on this group, as they are the key to break the intergenerational cycle of undernutrition.

1411

MENTAL ILLNESS AND HOMELESSNESS FROM THE FEMALE PERSPECTIVE: INSIGHTS FROM LOS ANGELES COUNTY

Hannah L. Stewart

University of Southern California, Los Angeles, CA, United States

Abstract Research has consistently shown that individuals with mental illness are at increased risk of life events that may lead to homelessness, such as low income, poor coping skills, and incarceration. But little is known about how previous life events and mental illness may affect individuals once homeless. What is known about homelessness in urban environments is largely based on samples that are predominantly male. However, housing inadequacy in the United States is increasingly affecting women and female-headed families. This study analyses a large sample (n = 1351) of women experiencing homelessness in Los Angeles County. The cross-sectional data provides insights into the demographic makeup of unsheltered women in the county, including indicators of mental health. The mean age of the sample was 46 years of, with most the women identifying as either white (41%) or black (34%). Nearly half (48.7%) of the sample reported a history of depression, post-traumatic stress disorder, and/or another serious and persistent mental illness. More than half (55.9%) of these women reported a history of depression. The prevalence of post-traumatic stress disorder in this sample was 37.8% and rates of drug and alcohol abuse were 28% and 21% respectively. Chi-squared analyses showed that adults who were both mentally ill and homeless were more likely than homeless adults without mental illness to report prior domestic violence, human trafficking, and incarceration ($p < 0.01$). A t-test for independent samples revealed that mental illness was also statistically significantly associated with longer periods of homelessness ($p < 0.01$). This study provides support for the notion that traditional methods of alleviating homelessness, like job training programs, will do little to treat a one of the major drivers of chronic homelessness. The data presented here alludes to the fact that supportive housing with integrated mental health services and trauma informed services will be necessary to deal with the growing number of homeless women in Los Angeles.

1412

COMPARATIVE BEHAVIORAL RESPONSES OF *AEDES AEGYPTI*, *AEDES ALBOPICTUS* AND *CULEX QUEQUINFASCIATUS* (DIPTERA: CULICIDAE) TO PLANTS BASE REPELLENT OF VETIVER COMPOUNDS

Jirod Nararak[1], Sylvie Manguin[2], Theeraphap Chareonviriyaphap[1]

[1]*Department of Entomology, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand,* [2]*HydroSciences Montpellier (HSM), Institut de Recherche pour le Développement (IRD), CNRS, Université Montpellier, Montpellier, France*

There are many reports revealed that some plant-derived are considered non-toxic, alternative insect repellents for humans. Vetiver compounds were assessed as repellent mosquito vectors. *Aedes aegypti*, *Aedes albopictus* and *Culex quequinfasciatus* were testes behavior responses with vetiver compounds through the High Throughput Screening System (HITSS). As a result, the behavioral responses of mosquitoes to plant base of vetiver compounds indicated that some compounds had spatial repellent, contact irritant and/or toxic properties. The study provides informative data on the mosquito-repellent property of vetiver plant against *Ae. aegypti, Ae. albopictus* and *Cx. quinquefasciatus*. We conclude that the pure compounds from vetiver could potentially be developed as promising plant-based repellents fight against the bite of mosquitoes.

1413

ASSESSING THE IMPACT OF CLIMATE CHANGE ON SLEEPING SICKNESS IN ZIMBABWE USING A GEOSPATIAL MODEL OF TSETSE POPULATION DYNAMICS

Joshua Longbottom, Jennifer Lord, Stephen Torr

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Climate change influences the entomological and epidemiological components of vector-borne disease transmission. Rhodesian human African trypanosomiasis (rHAT), a zoonosis caused by trypanosomes transmitted by tsetse flies, occurs at localised *foci* across East and Southern Africa. At one focus in northern Zimbabwe, a long-term decline in the abundance of tsetse appeared to be correlated with recent increases in temperature. A mechanistic model of tsetse population dynamics suggests that this decline is due to the impact of temperature on tsetse mortality and development rates. We aimed to produce a geospatial model of tsetse population dynamics to explore the effect of climate change on the abundance of the rHAT vector *Glossina pallidipes* across all sites in Zimbabwe where rHAT has been reported. We compared remotely sensed MODIS temperature data to local weather station data previously used to fit a mechanistic model to longitudinal *G. pallidipes* abundance. We applied an adjustment to convert from land surface temperature to air temperature, and then used the adjusted data to estimate mortality and development rates in the existing ordinary differential equation (ODE) model, running simulations for each 1 km × 1 km cell in Northern Zimbabwe. The projection of this model throughout Northern Zimbabwe produced estimates of changes in tsetse abundance for locations currently lacking longitudinal data. Our model predicts decreasing abundance of tsetse within several low elevation areas in relation to increasing

temperature trends during 2000-2016. Conversely, we show that several high elevation areas, previously considered too cold to sustain tsetse, are now suitable climates, with viable population predictions. The model produced here details the first temperature-driven spatial projection of tsetse population dynamics within Zimbabwe, and suggests that tsetse abundance is decreasing across much of the Zambezi valley. Future work, including empirical studies to validate model predictions and forecasting in relation to future climate trends, is planned.

1414

RISK OF TRANSMISSION OF DENGUE, CHIKUNGUNYA AND ZIKA IN SOME YELLOW FEVER HOTSPOT AREAS IN NORTHERN GHANA

Joannitta Joannides[1], Mawuli Dzodzomenyo[2], Faustus Azerigyik[1], Esinam E. Agbosu[3], Deborah Pratt[3], Joseph H. Osei[1], Rebecca Pwalia[1], Godwin K. Amlalo[1], Maxwell A. Appawu[1], Hayashi Takashi[1], Andrea Buchwald[4], Rosemary Rochford[5], Daniel A. Boakye[1], Kwadwo A. Koram[6], Kofi Bonney[3], Samuel K. Dadzie[1]

[1]Department of Parasitology, Noguchi Memorial Institute for Medical Research, Accra, Ghana, [2]Department of Biological, Environmental and Occupational Health, School of Public Health, University of Ghana, Accra, Ghana, [3]Department of Virology, Noguchi Memorial Institute for Medical Research, Accra, Ghana, [4]Department of Environmental and Occupational Health, School of Public Health, University of Colorado, Denver, CO, United States, [5]Department of Immunology and Microbiology, University of Colorado, Anschutz Medical Campus, Denver, CO, United States, [6]Department of Epidemiology, School of Public Health, University of Ghana, Legon, Accra, Ghana

This study investigated the risk of transmission of Dengue (DENV), Chikungunya (CHKV) and Zika (ZIKV) viruses in Larabanga and Mole game reserve. Larabanga and Mole in the Northern part of Ghana have been hotspot areas for previous outbreaks of Yellow fever due to the presence of a high population of *Aedes (Ae.) aegypti*. We collected immature and adult stages of *Aedes* mosquitoes from Larabanga and Mole game reserve. A total of 1,930 *Aedes* mosquitoes were collected during the rainy season and morphologically identified. Of these, 1,915 (99.22%) were *Aedes aegypti* and 15 (0.22%) were *Aedes vittatus*. During the dry season, 27 *Aedes aegypti* mosquitoes were collected. The proportion of *Ae. aegypti* mosquitoes collected per area were 144 (7.46%) for Larabanga and 1,771(91.76%) for Mole in the rainy season. A total of 627 *Ae. aegypti* mosquitoes were molecularly identified to subspecies level and pools of 30 were examined by Reverse Transcriptase Polymerase Chain Reaction to detect Dengue (serotypes 1-4), Zika virus and Chikungunya. Both *Ae. aegypti aegypti and Ae aegypti formosus* exist in sympatry in the area. All the pools were negative for DENV, CHKV and ZIKV. Three Larval indices namely House Index, HI (percentage of houses positive for larvae or pupae), Container Index, CI (the percentage of containers positive for *Aedes* larvae or pupae) and Breteau Index, BI (the number of positive containers (with larvae and/or pupae per 100 inspected houses) were assessed. During the survey, a significantly ($P<0.05$) higher number of containers 70 (17.07%) were positive for *Aedes* larvae in the rainy season compared to the dry season 2 (0.92%). Larabanga had a HI, CI and BI of 36.4%, 15.5% and 67.6% respectively for the rainy season with the dry season recording an HI, CI and BI of 2.3%, 1.3% and 2.3% respectively. Mole had higher larval indices compared to Larabanga during the rainy season. The larval indices were low for both areas during the dry season but significantly ($P<0.005$) higher during the rainy season. The implications of these findings within the context of DEN, CHKV and ZIKV transmission in Ghana will be discussed.

KENYAN LONG-TERM EXCLUSION EXPERIMENT REPLICATION STUDY INVESTIGATING POTENTIAL INFLUENCE OF CATTLE ACARICIDES ON ENVIRONMENTAL TICK DENSITIES

Sheryne Zeitoun[1], Rachel Morrison[1], Lindsey Shields[2], Dawn Zimmerman[2], Dino Martins[3], Duncan Kimuyu[3], Wilfred Odadi[4], **Michael E. von Fricken**[1]

[1]George Mason University, Fairfax, VA, United States, [2]Smithsonian Institution, Washington, DC, United States, [3]Mpala Research Center and Wildlife Foundation, Laikipia, Kenya, [4]Egerton University, Department of Natural Resources, Nakuru, Kenya

African savannas support some of the most biodiverse large mammal populations in the world, which in turn, lead to diverse tick populations. To reduce the economic impact of tick-borne diseases in Kenya, cattle are often treated with acaricides. However, the impact of acaricides on the overall density and community composition of ticks in savanna ecosystems warrants additional investigations. Building upon previous work by Keesing et al., a team of George Mason University students sampled for ticks in different types of enclosures to assess the effects of wild life and acaricide treated cattle have on tick densities. This work was carried out in the Mpala Research Centres Kenya Long-term, Exclusion Experiment (KLEE), as part of a larger project conducting training on One Health and emerging infectious diseases. Over two weeks in August 2018, nymphal and adult ticks were sampled from KLEE enclosures that controlled for the presence of cattle and for the presence of two categories of large wild mammals: megaherbivores, and all other large wild herbivores. A lower tick density was observed on plots that cattle had access to compared to plots which other large mammals, which is likely due to acaricides on the cattle. Three species of adult ticks were found in the plots, 90% of which were *Rhipicephalus pulchellus*, 6% were *Amblyomma gemma*, and 4% were *Hyalomma dromedarii*. Our results suggest that the presence of acaricide-treated cattle greatly reduced the number of host-seeking adult ticks, but did not significantly reduce the number of host-seeking nymphs. Further efforts are underway to investigate if infection rates vary by enclosure plot, with additional training planned for August 2019. Continued monitoring of ticks and the pathogens they transmit is critical for understanding transmission dynamics that can eventually be used to guide education and control efforts.

1416

TISSUE-CULTURE PLATE-BASED FECUNDITY AND FERTILITY ASSAY SYSTEM FOR *AEDES* MOSQUITOES

Hitoshi Tsujimoto, Zachary N. Adelman

Texas A&M University, College Station, TX, United States

As major arboviral vectors, control of *Aedes* mosquitoes represents a substantial component of public health strategies to reduce transmission. Many studies aim to reduce survivorship, fecundity (number of eggs produced) and fertility (number of hatched larvae) of *Aedes* mosquitoes. Conventional methods to assess fecundity and fertility use 50-mL tubes or fly culture tubes, which involve significant labor to find and count eggs and hatched larvae. We introduce a tissue-culture plate-based fecundity and fertility assay for *Aedes* mosquitoes. We found that a 24-well tissue culture plate provide sufficient area for single females to lay eggs, while simplifying counting of eggs and larvae by imaging the wells. This method saves space and potentially reduces the workload for this type of assay, increasing the throughput that such experiments can be conducted.

1417

COMPARATIVE EFFICACY OF CATTLE-BAITED NET TRAPS (CBNT), CDC LIGHT TRAPS (LT) AND BG SENTINEL TRAPS (BG) FOR COLLECTION OF SANDFLIES IN SELECTED FIELD SITES IN SRI LANKA

Sanath C. Senanayake[1], Raushan Siraj[1], Nissanka De Silva[2], Nadira Karunaweera[1]

[1]University of Colombo, Colombo 10, Sri Lanka, [2]University of Sri Jayawardenepura, Nugegoda, Sri Lanka

Sri Lanka is a tropical country with rising number of cases of cutaneous leishmaniasis (CL). A few cases of visceral and mucosal leishmaniasis were also reported in recent years. The probable vector is *Phlebotomus aregentipes var glaucus* (*Ph. glaucus*). The characteristics of the sandfly fauna in Sri Lanka is poorly understood, hence the need for studies that can aid formulation of control methods to reduce transmission of leishmaniasis in the local setting. This study was carried out in two selected sites in North-Western (Ambanpola of Kurunegala district) and Southern provinces (Dickwella of Matara district) of Sri Lanka. The main objective of the study was to compare the three widely used trapping methods to collect sandflies to study their effectiveness. Two (2) CBNTs, twenty (20) CDC light traps and two (2) BG Sentinel traps were used to collect sandflies monthly for a period of 13 months from Jan 2017 to Dec 2018 in the selected field sites. A total of 5,111 sandflies were collected form CBNT (2661 Amabanpola, 2450 from Dickwella) with 4,394 males and 717 females (male: female 6:1) with an average of 98 flies per trap per night. CDC light traps gave a collection of 211 sandflies with 132 males and 79 females (male:female 3:2). There were no sandflies trapped in BG sentinel traps. *Ph. glaucus* was the only species found in CBNTs. Only fifteen (15) *Sergentomyia* species sandflies were found in CDC light traps. The CBNT is the best method for sampling *Ph. glaucus* in Sri Lanka though a higher male ratio was found. CDC light taps gave the best proportion of female flies though numbers were small. It is also effective in trapping the *Sergentomyia spp*. sandflies though the numbers may reflect the abundance and distribution of sandflies in selected sites. BG sentinel traps were totally ineffective in collecting sandflies in Sri Lanka.

1418

COMPARISONS OF TEMPERATURE-STABILIZING MATERIALS FOR LIVING ARTHROPOD SHIPMENTS

Catherine M. Hunt[1], Mark Q. Benedict[1], C. Matilda Collins[2], Ellen M. Dotson[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Centre for Environmental Policy, Imperial College London, London, United Kingdom

Shipments of living mosquitoes and other arthropods require temperatures that are stabilized within a range compatible with their health and survival. In addition to use of express shipping and insulated containers, materials are often included that either store heat (*i.e.* have thermal mass) or otherwise stabilize the temperature. We present the results of comparisons of thermal mass and phase change materials to stabilize the temperature under various conditions. We compared a rigid foam refrigerant and a number of phase change materials to bubble wrap for their capacity to moderate temperature change by measuring the temperatures in standard uninsulated shipping containers during exposure to high (37°C), cold (4°C) and freezing (-20°C) temperatures. We determined which of the tested materials maintain temperatures below 30 and 35°C at an ambient temperature of 37°C and above 5 and 10°C at cold and freezing temperatures. Under all conditions, one of the phase change materials (Phase 22™ Flex Packs by Cryopak) kept the temperature within these ranges for the longest period of time. The second best-performing material was the foam refrigerant, 'Re-Freez-R-Brix™.'

1419

MOLECULAR ANALYSIS OF ENGORGED SAND FLIES FOR IDENTIFICATION OF BLOOD MEAL SOURCES AND DETECTION OF *LEISHMANIA* AND *BARTONELLA* DNA

Marisa Lozano[1], Liz Espada[1], Victor Zorrilla[1], Michael Kosoy[2], Clifton McKee[2], Lynn Osikowicz[2], Heriberto Arevalo[3], Mario Troyes[4], Craig Stoops[1], **Gissella Vasquez**[1], Michael Fisher[1]

[1]US Naval Medical Research Unit-6, Callao, Peru, [2]Centers for Disease Control and Prevention, Fort Collins, CO, United States, [3]Peruvian Ministry of Health – San Martin Regional Health Directorate, San Martin, Peru, [4]Peruvian Ministry of Health – Jaen Health Directorate, Cajamarca, Peru

Blood meal analysis in wild caught sand flies can provide insights into sand fly host preference patterns and potential reservoirs of infectious pathogens. The objectives of this study were to identify blood meal sources, and detect *Leishmania* and *Bartonella* in wild-caught, engorged female sand flies from endemic regions in Perú. Engorged sand flies from the states of Ancash (86 specimens, 1 species), Cajamarca (18 specimens, 3 species), Madre de Dios (9 specimens, 3 species and 1 subgenus) and San Martin (91 specimens, 6 species and 4 subgenera) were identified morphologically and processed for blood meal identification by cytB and COI PCR, and for *Bartonella* and *Leishmania* DNA detection by combined ITS/gltA PCR and kDNA PCR, respectively. Preliminary testing of a subset of sand flies from San Martin (2 species) identified human blood in *Lutzomyia nevesi* by cytB PCR. Moreover, *Bartonella* DNA was detected in *Lu. nevesi* (8 out of 55 specimens) with two specimens found infected with a genotype close to *Candidatus* B. rondoniensis, originally described in *Erathyrus mucronatus* from French Guyana. *Bartonella* DNA was detected in a subset of *Lu. verrucarum* (8 out of 32 specimens) from Ancash; sand flies from Cajamarca and Madre de Dios were negative. A sub-set of sand flies from San Martin (3 species) were screened for *Leishmania* DNA, no positives were found. *Leishmania* screening and blood meal identification on remaining specimens is ongoing. Our combined blood meal source identification and pathogen detection analysis of engorged sand flies proves useful for vector-borne pathogen surveillance, and can provide valuable information for identification of potential reservoirs of *Bartonella* and *Leishmania* in highly diverse, remote endemic areas in Peru..

DISTRIBUTION OF TICK SPECIES COLLECTED FROM THREE WEST AFRICAN COUNTRIES

Shirley C. Nimo-Paintsil[1], Mba-Tihssommah Mosore[2], OgheneKaro Omodior[3], Seth O. Addo[2], Nermeen T. Fahmy[4], Reham Tageldin[4], Eric Behene[2], Arthur B. Kamuah[5], Andrew G. Letizia[1], Fatorma Bolay[6], Samuel Dadzie[2], Hanayo Arimoto[7], Joseph W. Diclaro II[8]

[1]Naval Medical Research Unit No. 3 Ghana Detachment, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]Indiana University Bloomington, School of Public Health, Bloomington, IN, United States, [4]Naval Medical Research Unit No. 3, Cairo, Egypt, [5]Central Agriculture Research Institute, Suakoko District, Bong County, Monrovia, Liberia, [6]Liberia Institute for Biomedical Research, Margibi County, Charlesville, Liberia, [7]Camp Pendleton, 1st Medical Battalion, Oceanside, CA, United States, [8]Navy Entomology Center for Excellence, Jacksonville, FL, United States

Ticks are blood sucking arthropods which serve as vectors and reservoirs for transmitting pathogens in both animals and humans. The blood meal activity of ticks depends on various ecological factors such as vegetation, host and temperature. There has been very little work done to understand the distribution of ticks in West Africa. Our study compares tick data from Ghana, Liberia and Nigeria. A total of 2,675 ticks were collected from domestic animals (cattle, dogs, goats, and sheep) between 2015 and 2016 and morphologically identified using taxonomical keys of African Ixodidae. Eleven tick species, including *Amblyomma variegatum* (64.1%), *Rhipicephalus sanguineus* (21.5%), *Hyalomma truncatum* (5.9%), *Boophilus annulatus* (3.8%), *Hyalomma rufipes* (1.9%), *Boophilus*

decoloratus (1.8%), and *Haemaphysalis leachi* (0.09%), were identified. *Amblyomma variegatum* was dominant in both Ghana (61%) and Nigeria (51%) whereas *Rhipicephalus* (92%) species was dominant in Liberia. Nearly 80% (N = 2,102) of the ticks were collected from cattle and the remaining 20% (N = 573) were collected from sheep, dogs and goats. There was a significant association between country and the type of tick species identified (P < 0.001). *Boophilus* and *Haemaphysalis* species were found only in Nigeria. The prevalence of *Amblyomma* and *Rhipicephalus* genera of ticks in these countries highlights the need for continuous tick surveillance to better understand the distribution and how ecology as well as the environment impact prevalence and transmission of tick-borne pathogens in West Africa to guide effective control measures.

1421

THE ROLE OF RELISH IN *RICKETTSIA RICKETTSII* INFECTION WITHIN THE AMERICAN DOG TICK

Chanida Fongsaran, Krit Jirakanwisal, Victoria I. Verhoeve, Kevin R. Macaluso

School of Vet Med, Louisiana State University, Baton Rouge, LA, United States

Rickettsia rickettsii is the causative agent of Rocky Mountain spotted fever (RMSF), which is considered the most severe of all tick-borne rickettsiosis. Several tick species are responsible for the spread of the disease, including *Dermacentor variabilis*, yet the contributing tick-derived factors associated with vector competence are not known. Relish-type nuclear factor-kappa B (NF-κB) molecules have been suggested to play a role in the immune response by functioning as an immune responsive transcription factor in *D. variabilis*. In this study, we characterized the regulation of Relish in *Dermacentor variabilis*. NF-κB transcription factors interacted with Rel homology domain (RHD), suggesting they play a role in tick immune response. Accordingly, to investigate *DvRelish* expression in ticks infected with *R. rickettsii* and to determine the effect of *DvRelish* gene knockdown on rickettsial infection we used RNA interference-mediated gene silencing in ticks to demonstrate that transcription of *DvRelish* was decreased after 24 hours post-injection of siRNA. Next, we will characterize the response of *D. variabilis* when exposed to spotted fever group *Rickettsia* in a species- or pathogen-specific manner. *D. variabilis* will be exposed to either *R. rickettsii* or *R. montanensis* and transcription of *DvRelish* will be determined by quantitative real-time PCR. Also, RNAi will be used to determine the effect of *DvRelish* gene knockdown on *R. rickettsii* acquisition and transmission. Therefore, *DvRelish* expression in *Dermacentor* tick could be functionally important for tick innate immunity to pathogens and the identification of the immune induction in ticks will lead to understanding the molecular determinants of vector competence.

1422

GALLERIA MELLONELLA (*LEPIDOPTERA*): A POTENTIAL *IN VIVO* MODEL FOR ASSESSING THE PATHOGENESIS OF GROUP B *STREPTOCOCCUS*

Maria del Pilar Crespo-Ortiz, Maria Elena Burbano-Torres, Mauricio Barreto-Parra

Universidad del Valle, Cali, Colombia

Group B *Streptococcus* (GBS) is a colonizing bacterium in the gastrointestinal tract and the urogenital tract particularly in women. GBS invasion leads to severe infections in neonates, pregnant women, immunocompromised patients and the elderly people worldwide. Nevertheless the mechanisms of pathogenesis and virulence factors involved in the GBS transition from commensal to pathogen and the immune host interactions remain to be fully elucidated. Moreover, studies on the pathogenesis of isolates from low and middle income countries are limited. As environmental determinants may regulate gene expression for GBS invasion, we have assessed the potential of the moth *Galleria mellonella* as an *in vivo* model to study invasive and noninvasive human GBS isolates from our population. The invertebrate model is rapid, low-cost, easy to adapt to laboratory conditions and it has an innate immune system similar to mammals. The survival of *G. mellonella* larvae inoculated with GBS strains (ATCC 12386 and ATCC 12403) was determined. Temperature, pH and bacterial competition effects were examined as well as the response of *Galleria* hemocytes to GBS infection. GBS strains were able to effectively grow and infect *G. mellonella* in a dose-dependent manner with a (half-lethal dose) LC_{50} $1x10^7$ CFU/larva after 24 h. Preliminary results showed depletion of the pool of hemocytes particularly for the most invasive strain (ATCC 12403, serotype III), however severe vacuolation in most hemocytes and melanization were observed in all infected larvae. The survival after 24 h improved in larvae inoculated with GBS strain ATCC 12403 and incubated at 27 °C whereas pre-incubation of GBS inocula at pH 5 and 6.4 seemed to have not effect on killing rates. These findings are similar to those obtained in other systems suggesting that *G. mellonella* may be used as an *in vivo* model to study the pathogenesis of GBS human isolates. While these are preliminary results, we will determine how representative may be this model by infecting *G. mellonella* larvae with invasive and noninvasive (colonizing) clinical isolates which have been fully characterized by DNA-based microarrays.

1423

LAND USE IN RELATION TO COMPOSITION AND ABUNDANCE OF PHLEBOTOMINES (DIPTERA: PSYCHODIDAE) IN FIVE FOCI OF DOMICILIARY TRANSMISSION OF CUTANEOUS LEISHMANIASIS IN THE ANDEAN REGION OF COLOMBIA

Mabel Moreno[1], Lina Guzmán-Rodríguez[1], Carlos Valderrama Ardila[2], Neal Alexander[1], **Clara B. Ocampo**[1]

[1]Centro Internacional de Entrenamiento e Investigaciones Médicas (CIDEIM), Cali, Colombia, [2]Universidad Icesi, Cali, Colombia

American cutaneous leishmaniasis is a public health concern in Colombia with incidence being sustained or focally increased principally due to the emergence of domestic transmission concomitantly with the adaptation of the phlebotomine vectors to habitat transformation around households. Critically, risk of leishmaniasis transmission varies even within individual townships and houses, hence the need to understand the factors favoring the presence and abundance of phlebotomines within and around houses. The study was carried out in five sites within the Andean region of Colombia having history of Leishmania transmission and differing land use. The peri-domestic habitat was evaluated using a rapid methodology along eight radial outdoor transects of 90m, and placement of 3 CDC light traps over two nights in both indoors and outdoors (10m from the house) settings. The study demonstrated site-specific dominance of one vector species associated principally with agricultural monoculture. Specifically, *Pintomyia* (*Pifanomyia*) *quasitownsendi* was associated with sugar cane in two sites; while *Pi.* (*Pif*) *longiflocosa* was associated with coffee plantations in other two sites. The fifth site had a more diverse array of land use and forest coverage, a lower number of specimens, but higher species diversity. In terms of distance from the house to a given land use, the abundance of *Pi.* (*Pif*) *quasitownsendi* was inversely related with distance to sugar cane (Spearman correlation coefficient, rho = -0.56, $p < 0.001$ for outdoors catches, and rho = -0.50, $p < 0.001$ indoors). A similar inverse relationship was observed for *Pi.* (*Pif*) *longiflocosa* with technified coffee (rho = -0.51, $p < 0.001$ outdoors and rho = -0.48, $p < 0.001$ indoors). This rapid characterization methodology could guide public heath decision makers in identifying houses at higher risk of domestic transmission, and also educate farmers to increase the distance between their crops and houses.

1424

INTERACTIONS AMONG CHAGAS DISEASE VECTORS AND NATURALLY INFECTED DOGS ALONG THE TEXAS-MEXICO BORDER

Alyssa C. Meyers, Lisa Auckland, Sujata Balasubramanian, Ashley Saunders, Sarah Hamer

Texas A&M University, College Station, TX, United States

In the southern US, triatomine vectors maintain *Trypanosoma cruzi* in sylvatic cycles with occasional spillover to humans and domestic animals. Infection with *T. cruzi* may be asymptomatic or lead to heart disease and death. With no vaccine, limited antiparasitic treatments for humans, and no approved animal treatments, reducing the burden of disease must focus on vector control. However, there is an incomplete understanding of vector-host interactions that impedes vector control efforts. In the epidemiological setting of south Texas, we previously identified widespread *T. cruzi* infection in working dogs along the US-Mexico border. Using these dogs as a model host system, our objective was to characterize the triatomine vector communities in environments where these dogs work and quantify the *T. cruzi* infection prevalence in the vector. To determine vector hosts we used Sanger sequencing and amplicon deep sequencing of a vertebrate gene from the vector's gut contents. Finally, we analyzed selected measures of cardiac health (from electrocardiograms, echocardiographs, and cardiac troponin I, a biomarker for cardiac injury) in infected vs. uninfected dogs with a goal of relating clinical status to the locally-circulating parasite DTUs. We found two triatomine species (*Triatoma gerstaeckeri* and *T. rubida*) (n=78) collected from canine environments, where 48.7% were infected with *T. cruzi* comprised of DTUs 'TcI' (52.9%), 'TcIV' (29.4%) and 17.6% mixed-DTU infections. Bloodmeal analysis based on Sanger sequencing (n=47) revealed vector feeding on dogs, wildlife, and humans. Ongoing analysis of amplicon deep sequencing data demonstrate the majority of these bugs feed on multiple host taxa. In our clinical investigation of 24 *T. cruzi*-infected and 24 uninfected dogs, we found only a single infected dog (4.2%) had *T. cruzi* PCR-positive blood ('TcI') and ECG abnormalities ($p<0.0001$) and cardiac troponin I levels ($p=0.044$) were higher in infected dogs. Ecological tracking of the host-vector-parasite interactions provides insight on the sylvatic maintenance and spillover risk of *T. cruzi* along the Texas-Mexico border.

1425

DEVELOPMENT OF A NOVEL APPLICATION FOR DIFFERENTIAL DIAGNOSIS OF TICK-BORNE DISEASES

Corey B. Meyer, Jaleal Sanjak, Audrey Cerles, Christian Garnier, Laurel MacMillan

Gryphon Scientific, Takoma Park, MD, United States

Timely diagnosis and treatment of tick-borne diseases (TBDs) is critical for mitigating their adverse health outcomes, but differential diagnosis of TBDs is challenging because many symptoms are non-specific and commonly used diagnostic assays have significant shortcomings. Further, although the local incidence of TBDs is recognized as an important factor in their clinical diagnosis, tools to help clinicians formally consider surveillance data in their diagnostic decision-making are not available. To address these gaps, Gryphon Scientific developed a differential diagnosis application (app) for TBDs that calculates a patient's likelihood of infection with specific TBDs based on their symptoms, risk factors, and state of suspected tick exposure. A differential diagnosis model for TBDs was developed using two types of data: (1) TBD symptom and risk factor prevalence in TBD patient populations, collected from clinical studies; and (2) human TBD incidence data from notifiable disease surveillance systems and tick infection prevalence data from reports and public databases, which were combined to develop an environmental risk measure. These data were used to build a Bayesian Belief Network (BBN) model that predicts TBD infection probabilities based on a patient's symptoms, risk factors, and state of suspected tick exposure, which was incorporated into an app developed using R-shiny, called TBD-DDx. A pilot application was developed that includes ten states (AR, CT, MA, ME, MN, MO, NH, RI, VT, and WI) and the eleven TBDs that are endemic to those states. Performance of the TBD-DDx model was validated using case studies from the biomedical literature. The model identified the correct disease within the top three predicted TBDs in 84% of cases, demonstrating that the TBD-DDx app is a promising tool for informing clinical diagnoses of TBDs to guide selection of diagnostic testing and treatment. Further, this study represents the first use of a BBN modeling approach that incorporates an environmental risk measure, and therefore could be adapted for differential diagnosis of other infectious diseases with environmental or other exposure risks.

1426

TICK-BORNE PATHOGENS IN TICKS OF HORSES, DOGS, AND MIGRATORY BIRDS IN THE REPUBLIC OF KOREA

Yun Sang Cho[1], Jinheong Noh[1], Mi-Sun Yoo[1], Hyun-Ji Seo[1], Keun Ho Kim[1], Yeojin Park[1], Hyunkyoung Lee[1], Jung-Won Park[1], Seunghee Lee[1], Soon-Seek Yoon[1], Heung-Chul Kim[2]

[1]Animal and Plant Quarantine Agency, Gimcheon, Republic of Korea, [2]65th Medical Brigade, Pyeongtaek, Republic of Korea

Recently, tick-borne diseases have been increasing due to changes in environments such as global warming, increase in outdoor leisure activity, increase in deforestation by expansion of development area, increase in international movement and trade. Therefore, there is an urgent need for national monitoring in the situation where the risk of global epidemics of ticks and tick-borne diseases is increasing. In this study, ticks were collected from Korean horses, dogs, and migratory birds, and their pathogens were examined using genetic diagnosis. In horses, 9,813 ticks were collected, among which 99.9% (n = 9,807) of *Haemaphysalis longicornis* were identified, followed by 0.1% (n = 6) of *Ixodes nipponensis*. In dogs, of the 1,836 ticks collected, 98.69% (n = 1,812) of them were identified as *H. longicornis* and were dominant species as well as horses. Next, 0.82% (n = 15) of *I. nipponensis* and 0.44% (n = 8) of *H. flava* were identified. In migratory birds, 992 ticks were collected. Among them, 63.7% (n = 587) of *I. turdus* and 17.1% (n = 158) of *H. flava* were found. There were many differences, compared with horses and dogs. Collected tick pathogens were examined by PCR. *Anaplasma phagocytophilum, A. platys, Ehrlichia chaffeensis, E. canis, Borrelia* spp., *Babesia* spp. in the horse tick-borne pathogen test, *A. phagocytophilum* (numbe of pools = 5) was positive in 0.5% and *Borrelia burgdoferi* (number of pools = 4) was positive in 0.4%. In dogs, *A. phagocytophilum* (number of pools = 15) was found in 1.98%, and *Babesia* spp. (number of pools = 7) were positive in 0.92%. In migratory birds, *A. phagocytophilum* (1 pool of *I. nipponensis*) and *Borrelia* spp. (14 pools of *I. turdus*) were positive. The major pathogens in ticks were *A. phagocytophilum*, *B. burgdoferi*, and *Babesia* spp., but the positive rate were less than 2%. Monitoring of pathogens in ticks will provide important information for improving public health and livestock hygiene. Moreover, it is thought that DB construction related to domestic and overseas will be a useful information resource for prevention of tick-borne diseases, which is one of the obstacles to the improvement of One Health.

1427

STUDY OF FRANSAIELLESIS DISEASE AMONG CATTLE IN AZERBAIJAN IN 2016 - 2018

Adalat Talibov

Azerbaijan Food Safety Institute, Baku, Azerbaijan

Fransaiellesis is a blood-parasitic disease of cattle and small ruminants, characterized by fever, jaundice, hematobyuria and animal death. *Fransaiella colchica* and *F. caucasica* types belong to *Babesiidae* family are considered the causative agent of the fransaiellesis disease of cattle. *Ixodes ricinus* and *Boophilosis calcaratus* are the vectors of the abovementioned causative agents. The disease is widespread in the plains and foothills areas of Azerbaijan, in the Kura-Araz Lowland and Lankaran zone per the previous studies' data. The goal of this study is to define the spread of

fransaiellesis disease among cattle in Azerbaijan in 2016 - 2018. During 2016 - 2018 the Central Veterinary Laboratory (CVL) received pathological materials from dead cattle to examine for piroplasmosis from Absheron, Gobustan, Khizi, Lankaran, Bilasuvar, Gakh, Barda and Shamakhi. Smears from the samples (livers and lungs) were stained with Romanovski-Gimza and analyzed by microscope. 50 pathological material samples were received by CVL in 2016-2018. 38 samples (38 - livers, and 37 - spleens, 10 - kidneys) were positive for fransaiellesis. There were 4 positive samples from Absheron, 1 from Gobustan, 1 from Khizi, 12 from Lankaran, 1 from Bilasuvar, 18 from Gakh, 1 from Barda. The received results showed that the most positive samples were found in Lankaran (32%) and Gakh (47%). According to the literary data the tick vectors of the disease mostly spread in these two rayons and this fact could impact the amount of the positive cases. Moreover, the analysis of the received results showed that the mortality rate from fransaiellesis is higher among imported cattle (25 out of 38) than local animals (13 out of 38). It's important to study the ticks that spread fransaiellesis in Azerbaijan. However, there is no veterinary entomology specialty in the animal healthcare system of Azerbaijan. It is crucial to train the veterinary specialists on veterinary entomology by the international specialists and to introduce this training into the veterinarian education program.

1428

CLIMATE CHANGE COULD EXPOSE 1.3 BILLION NEW PEOPLE TO ZIKA VIRUS TRANSMISSION RISK BY 2050

Sadie Jane Ryan[1], Colin J. Carlson[2], Blanka Tesla[3], Matthew H. Bonds[4], Calistus N. Ngonghala[1], Erin A. Mordecai[5], Leah R. Johnson[6], Courtney C. Murdock[3]

[1]*University of Florida, Gainesville, FL, United States,* [2]*Georgetown University, Washington, DC, United States,* [3]*University of Georgia, Athens, GA, United States,* [4]*Harvard Medical School, Boston, MA, United States,* [5]*Stanford University, Stanford, CA, United States,* [6]*Virginia Polytechnic Institute and State University, Blacksburg, VA, United States*

In the aftermath of the 2015 pandemic of Zika virus, concerns over links between climate change and emerging arboviruses have become more pressing. Given the potential for much of the world to remain at risk from the virus, we use a new model of thermal bounds on Zika transmission to project climate change impacts on transmission risk by mid-century (a generation into the future). Using a mechanistic, temperature driven model of Zika virus transmission in *Aedes aegypti* mosquitoes, we projected transmission suitability under multiple global circulation models (GCMs), for emissions pathways (RCPs) in the recent IPCC5 report on climate. We present globally gridded data as maps, demonstrating how many months of the year are suitable for transmission, in each pixel, for each scenario. As *Aedes aegypti* are tenacious, urban-adapted, container breeding mosquitoes, potential habitat is tied to human population density patterns. Thus, we projected transmission suitability onto future global population, accounting for socioeconomic conditions - the shared socioeconomic pathways projections (SSPs) - to measure current and future risk, in terms of people, as the geography of suitability shifts across the face of our planet. In the worst-case scenario emissions pathway, 1.3 billion previously unexposed people could face suitable environmental conditions for Zika virus by 2050, with over 1.1 billion living in areas outside those affected by the 2015 epidemic. Given these projections, we suggest an increased priority on research establishing the immune history of vulnerable populations, modeling when the next Zika virus outbreak might occur, evaluating the efficacy of conventional and novel intervention measures, and increasing surveillance efforts to prevent further expansion of Zika. The next generation will face substantially increased Zika virus transmission suitability in North America and Europe, where naïve populations might be particularly vulnerable. Mitigating climate change could significantly reduce global expansion of climates suitable for Zika virus transmission, potentially protecting up to about half a billion people.

1429

ABILITY TO RECOGNIZE THE LYME DISEASE VECTOR BY THE GENERAL PUBLIC IN THE NORTHEAST AND MIDWEST UNITED STATES.

Gebbiena M. Bron[1], Maria del Pilar Fernandez[2], Jean I. Tsao[3], Maria A. Diuk-Wasser[2], Lyric C. Bartholomay[1], Susan M. Paskewitz[1]

[1]*University of Wisconsin - Madison, Madison, WI, United States,* [2]*Columbia Univerisity, New York, NY, United States,* [3]*Michigan State University, East Lansing, MI, United States*

"An ounce of prevention is worth a pound of cure." A statement that holds true today, but incomplete information will undermine these efforts. Public health messages on tick-borne diseases have focused on the use of personal protective measures, with "check yourself for ticks" being the most commonly recommended measure. However, this strategy is likely ineffective if the primary vector of Lyme disease, the nymphal blacklegged tick, is not recognized due to its small size. In 2018, we launched a smartphone app, The Tick App, to study behavioral factors associated with tick exposure. Approximately 80% of Tick App users reported having checked for ticks (n=1,463). Interestingly, users identified 15.4% of submitted tick images as nymphs, but only half actually were (7.6%). In the summer of 2019, we compared the ability of residents from two Lyme disease endemic areas in the US to recognize ticks, in particular nymphs. We hypothesized that Lyme vector identification would be more accurate in the Northeast compared to the upper Midwest, because Lyme disease has long received ample media and research attention in the Northeast. We used The Tick App to solicit participant information and images of ticks encountered, and used an in-person survey to assess residents' ability to identify nymph-stage ticks from a specimen tray with three tick species, including nymphs and adults of the blacklegged tick, and two additional insects sometimes misidentified as ticks. We expected that Northeasterners, outdoor enthusiasts, and well-informed participants would be better at recognizing the nymphal blacklegged tick. This difference in ability to recognize the Lyme vector illustrates that the adoption of personal prevention is influenced by knowledge, risk perception and the perceived self-efficacy to carry out the intervention, but may vary by region. Ultimately, the comparison of vector recognition and, by extension the success of personal prevention measures, between two highly endemic regions will help inform regionally tailored prevention tools and public health messaging.

1430

DYNAMICS OF POWASSAN VIRUS AND *BORRELIA BURGDORFERI* INTERACTIONS IN CO-INFECTED *IXODES SCAPULARIS* TICKS AND THEIR POTENTIAL IMPACT ON HUMAN CLINICAL OUTCOMES

Charles E. Hart, Saravanan Thangamani

Upstate Medical University, Syracuse, NY, United States

Powassan virus (POWV) is a neurotropic flavivirus endemic to North America. It causes neuroinvasive disease resulting in up to 15% fatality with long-term neurological sequelae in 55% of survivors. It is transmitted by *the Deer tick Ixodes scapularis* which is also the primary vector of *Borrelia burgdorferi*, the causative agent of Lyme disease. Coincidentally, the white footed mice, *Peromyscus leucopus*, acts as a reservoir for both *B.burgdorferi* and POWV, and the immature state of *I. scapularis* ticks primarily feed on *P. leucopus*. Thus there is a greater chance of *I. scapularis* to be co-infected with both *B. burgdorferi* and POWV. Here we describe the dynamics of POWV and *B. burgdorferi* Interactions in co-infected *I. scapularis* ticks and their potential impact on human clinical outcomes. To facilitate this study, we generated co-infected ticks via oral infection route and dissection midgut and salivary glands at 3 weeks post infection. Pathogen load was quantified using quantitative RT PCR. Our preliminary data indicates that a significant decrease in *B. burgdorferi* was observed in female co-infected ticks when compared to that of ticks infected with just *B. burgdorferi*. However, we didn't observe any change in the POWV load. Currently, we are investigating the differential tick immune responses of

co-infected tick compared to a tick infected with one pathogen by RNAseq analysis. Similarly, the tick metabolic responses will also be compared. We are also investigating the pathogen transmission dynamics by a coinfected tick. Our preliminary data suggest that POWV /*Borrelia* coinfection in ticks is plausible, and that humans bitten by such ticks may be at risk for the development of combinational disease should both pathogens successfully transmit. Reductions in *B. burgdorferi* concentrations by POWV suggest the possibility of subtle interactions within their sylvatic cycle, potentially altering coinfection dynamics in nature.

1431

EVALUATING THE EFFECTS OF HUMAN MOBILITY PATTERNS ON TICK EXPOSURE USING A SMARTPHONE APPLICATION, THE TICK APP

Maria P. Fernandez[1], Gebbiena M. Bron[2], Pallavi A. Kache[1], Jean I. Tsao[3], Lyric C. Bartholomay[2], Susan M. Paskewitz[2], Maria A. Diuk-Wasser[1]

[1]*Columbia University, New York, NY, United States,* [2]*University of Wisconsin, Madison, WI, United States,* [3]*Michigan State University, East Lansing, MI, United States*

Vector-borne disease transmission to humans depends on infected vector densities and human-vector contact rates. In the case of Lyme disease, the most commonly reported vector-borne disease in temperate regions, the risk will depend not only on the density and distribution of vector ticks, but also on human behaviors that influence where and how often human-tick encounters occur. Thus, there is a need to simultaneously assess ecological and behavioral risk factors, although the latter remain poorly understood in part because of methodological limitations. In this study, we use a novel smartphone application, The Tick App, to collect data on self-reported human-tick encounters and personal protection measures, while simultaneously collecting GPS trajectories using location services in smartphones. We hypothesize that the combination of time spent in risky environments and frequency and type of outdoor activities will increase the risk of human-tick encounters. During May-September of 2018 and 2019, we recruited participants to download The Tick App in the Upper Midwest and Northeast regions of the United States. During 2018, 40% of the total number of recurring users (n=734) allowed for location services. Users had equal gender distribution, the median age was 50 years old, and were mostly located in the upper Midwest (54%). We collected GPS coordinates every 15 min, which led to a median of 858 points per user in approximately a 9-day follow-up period. The 2018 and 2019 data were combined to classify mobility patterns; identify dynamic and static (i.e., significant places) behaviors; and assess the effect of mobility patterns on self-reported tick encounters. This information will advance our understanding of how the interactions between human behavior and tick densities determine Lyme disease risk.

1432

A NETWORK ANALYSIS FRAMEWORK FOR THE EVALUATION OF MOSQUITO ABATEMENT SERVICE DELIVERY IN MACHALA, ECUADOR

Catherine A. Lippi[1], Anna M. Stewart-Ibarra[2], Liang Mao[3], Sadie J. Ryan[1]

[1]*Department of Geography and Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States,* [2]*Center for Global Health and Translational Science, Upstate Medical University, Syracuse, NY, United States,* [3]*Department of Geography, University of Florida, Gainesville, FL, United States*

Dengue fever places a high burden on the tropical coastal city of Machala, Ecuador (pop. 245,972), both in terms of human morbidity and economic strain on the community. Medical treatment for dengue mainly consists of palliative care, and consequently comprehensive vector control programs remain the primary method of controlling human disease outcomes through the reduction of mosquito populations. In Machala, vector control services are delivered through two deployment hubs managed by the Ecuadorian Ministry of Health. Currently, public health professionals in Machala face several logistical issues when delivering mosquito abatement services, namely applying limited resources in ways that will most effectively suppress dengue transmission. Mosquito control services, such as application of larvicides and truck-mounted ULV fogging, are not performed in a systematic manner. Using a transportation network analysis framework, we built models of service areas and optimized delivery routes based on distance-based costs associated with accessing census neighborhoods throughout the city. These models were compared to underlying risk factors and incidence for dengue fever in Machala, creating a visual tool to guide decision makers and maximize the efficiency of mosquito control programs. Using this framework, we identified different locations for targeting mosquito control efforts, dependent upon management goals and specified risk factors of interest, including human population and housing condition. Our models indicate that neighborhoods on the periphery of Machala, locations with the poorest housing conditions, are the most costly to access. Furthermore, we conclude that the current locations of mosquito control facilities in Machala are not ideal for reducing driving distances or maximizing populations served. This work represents a first step in creating a spatial tool for planning and critically evaluating the systematic delivery of mosquito control services in Machala.

1433

EXCITO-REPELLENCY ACTIVITY OF *CANANGA ODORATA* (MAGNOLIALES: ANNONACEAE) AGAINST DENGUE AND MALARIA VECTORS

Chutipong Sukkanon[1], Michael J. Bangs[2], Theeraphap Chareonviriyaphap[1]

[1]*Department of Entomology, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand,* [2]*Public Health and Malaria Control Department, PT Freeport Indonesia/International SOS, Papua, Indonesia*

The essential oils of *Cananga odorata* (CO) flowers was evaluated for its noncontact repellency, contact excitation, and knockdown/toxicity response against three colonized mosquito vector species; *Aedes aegypti*, *Anopheles dirus* and *Anopheles minimus* using an excito-repellency assay system under laboratory-controlled conditions. The escape responses from noncontact and contact oil-treated papers inside chambers were observed at four concentrations (0.5-5.0% v/v). CO oil showed strong spatial repellency against *An. minimus* (97-99% escape response) at the 2.5-5.0% concentrations. At 2.5%, higher repellency for *An. dirus* (64.4% escape) and *Ae. aegypti* (39.3% escape) was observed. Contact excitation was more pronounced compared to repellency alone with significantly quicker and higher percent escape seen in *An. minimus* (83-100% escape), and more moderate effects in *Ae. aegypti* (51-59% escape) and *An. dirus* (40-50% escape). After adjustment for repellency, escape due to contact alone was seen at low concentration (0.5%), with the greatest effect seen in *An. minimus* (67.2% escape). Relatively low percent knockdown or mortality at 24-h post-exposure was only observed in *Anopheles* mosquitoes at 5.0% concentration. These findings indicate the CO oil is more active against anopheline mosquitoes tested, particularly *An. minimus*; a primary malaria vector in mainland SE Asia. This study demonstrates compelling evidence that CO oil performs primarily as a spatial repellent at 2.5% and 5.0% concentrations, while contact irritancy is a contributor at low concentrations (0.5-1.0%). Further study is needed on this oil extract as a potential active ingredient in repellent products against mosquitoes and other biting arthropods.

1434

PROSPECTS OF THE GARDEN ANT, *LASIUS NIGER*, EXTRACT AS NON-FLORAL SOURCE OF ANTI-MALARIAL DRUG AND MOSQUITO INSECTICIDAL LEAD AGENTS

Israel K. Olayemi[1], Kamoru A. Adeniyi[1], Oluwatosin K. Shittu[1], Adeolu T. Ande[2], Chioma N. Amajoh[3], Azubuike Christian Ukubuiwe[1]

[1]*Federal University of Technology, Minna, Nigeria,* [2]*University of Ilorin, Ilorin, Nigeria,* [3]*Community Vision Initiative, Abuja, Nigeria*

The present need and, hence, aggressive search for alternative antimalarial and mosquito-larvicidal drugs and insecticides, respectively, from natural products other than floral sources informed this study. Entomo-bioactive extracts were prepared from black garden ant (*Lasius niger*) and analysed for entomo-chemical composition, after which graded concentrations (0.1 to 1.2 mg/L) of the extract were assayed against *Plasmodium berghei* in infected mice and 4th instar larvae of *Anopheles gambiae* s. l mosquitoes, following standard procedures.The antimalarial activity of the insect extract was performed against established infection in *Plasmodium berghei* infected mice. The entomo-chemical screening revealed the presence of medicinal metabolites such as flavonoid, saponnins and terpenoids. The results further indicated significant mosquito-larvicidal activities of the insect crude extract; with its toxicity been time and concentration dependent. Probit regression analysis revealed LC50 of 0.75 mg/L and LC90, 1.17 mg/L. Acute oral toxicity revealed an LD50 extrapolated to be above 5000 mg/kg body weight (b. wt). The antiplasmodial bioassay results showed that the extract significantly reduced the level of parasitaemia in the mice, with peak activity recorded on the last day of observation especially, in the highest dose tested (600 mg/kg b. wt). The extract, also, elongated the survival time of *P. berghei* infected mice relative to the infected non-treated group. This study, therefore, validates the prospect of mosquito larvicidal and antiplasmodial activities of crude extract of the black garden ant. However, further investigations are necessary, for isolating the specific bioactive entomo-chemicals and elucidating their mechanisms of actions.

1435

AN ASSESSMENT OF COMMUNITY ACCEPTANCE OF YEAST INTERFERING RNA BAITED OVITRAPS AS A BIORATIONAL MEANS OF CONTROL FOR *AEDES* MOSQUITOES IN TRINIDAD

Nikhella Winter[1], Akilah Stewart[1], Limb K. Hapairai[2], Jessica Igiede[3], Azad Mohammed[1], David W. Severson[3], Molly Duman-Scheel[2]

[1]*The University of the West Indies at St. Augustine, St. Augustine, Trinidad and Tobago,* [2]*Indiana University School of Medicine, South Bend, IN, United States,* [3]*The University of Notre Dame, Notre Dame, IN, United States*

Zika, dengue, chikungunya and yellow fever viruses are a major public health concern in Trinidad and throughout the Caribbean region. *Aedes* mosquitoes, the primary vectors for these viral pathogens, lay eggs in water-filled containers located in close proximity to humans and their dwellings. This preference for container breeding sites provides opportunities for surveillance and control of *Aedes* mosquitoes with larval lethal ovitraps, dark colored containers filled with water, attractants to lure gravid females, and larvicides to kill resultant larvae that hatch from eggs laid in the traps. Insecticide resistance and concerns for the impacts of pesticides on non-target organisms threaten the sustainability of this intervention. To address this, we are developing lure-and-kill interfering RNA ovitraps. A yeast-mediated interfering RNA delivery system employed in these traps is of particular interest due to combined attraction of gravid females and effective killing of mosquito larvae by the yeast. Prior to field evaluation of these ovitraps, paper surveys and community engagement forums were used to assess stakeholders living in prospective field site communities in the St. Augustine, Trinidad region. These assessment tools facilitated evaluation of study participants' general knowledge of mosquitoes, mosquito control practices, and feelings about the new technology. A majority of the paper survey respondents have good working knowledge of mosquitoes, practice some means of larval mosquito control, and were willing to use the new ovitrap intervention if it were shown to be safe and effective. After gaining more information about ovitraps and interfering RNA technology, forum participants voiced support for the new ovitraps and offered useful advice concerning product design, distribution, and pricing. The results of this investigation suggest that the study participants would be willing to both host field trials in their communities and to consider integrating yeast-based ovitraps into treatment regimes around their homes.

1436

A NON-LIVE INSECTICIDE DEVELOPED FROM THE BACTERIUM *CHROMOBACTERIUM SP.* PANAMA (*CSP_P*) EFFECTIVELY KILLS MOSQUITOES UNDER LABORATORY AND SEMI-FIELD CONDITIONS

Eric P. Caragata, Luisa Otero, George Dimopoulos

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Mosquitoes are the vectors of many clinically important human diseases including malaria, dengue, chikungunya and yellow fever. The human cost of these diseases remains high, and the development of novel insecticides is required to target mosquito populations that are becoming increasingly resistant to commonly used mosquitocidal chemicals. We have developed an insecticide based on crude, dried extracts of the bacterium *Chromobacterium sp.* Panama (*Csp_P*). Our *Csp_P* insecticide is non-live and highly effective at killing the larvae of prominent mosquito vectors including *Aedes aegypti*, *Anopheles gambiae* and *Culex quinquefasciatus*. It also effectively kills mosquito larvae that have developed genetic resistance to pyrethroids, suggesting that it could prove to be a useful tool to supplement current mosquito control programs. The non-live *Csp_P* insecticide has proven to be highly effective at killing mosquitoes under more natural environmental conditions at our field site in Gurabo, Puerto Rico, where we have translocated breeding sites from the field. Optimized *Csp_P* culturing regimes and larval and adult bait formulations give this product great potential as a tool for mosquito control.

1437

THE WEST AFRICAN *KNOCK DOWN RESISTANCE* MUTATION DETECTED IN THE PRIMARY MALARIA VECTOR *ANOPHELES ARABIENSIS* (DIPTERA: CULICIDAE) IN ETHIOPIA

Esayas Kinfe Woldesilasse[1], Habte T. Tekie[2], Irish R. Seth[3]

[1]*Ethiopian Public Health Institution, Adiss Ababa, Ethiopia,* [2]*Addis Ababa University, Addis Ababa, Ethiopia,* [3]*US President's Malaria Initiative and Entomology Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States*

Ethiopia has a long history of using indoor residual spraying, beginning with DDT. When DDT resistance was found to be widespread, malathion, deltamethrin was used as an IRS treatment. Quite quickly, deltamethrin resistance led to use of bendiocarb and propoxur in recent years. Insecticide resistance is an important concern for national malaria control programs in Ethiopia. Monthly larvae and adult *Anopheles* mosquitoes collections were undertaken from the two study sites Jolie and Gogete selected by using multistage sampling methods. A standard susceptibility tests were done following the WHO procedure and kit. To detect the presence of the L1014S (East African) and the L1014F (West African) *knock down resistance* (*kdr*) mutation a sub-sample of *An. gambiae* were tested using adapted versions of the allele-specific polymerase chain reaction. The L1014F *kdr* mutation in *An. arabiensis* was detected at a relatively high frequency 41.7% in Gogete and 35.9% in Jolie study site. The L1014S *kdr* alleles were not found in the study sites. The *kdr* mutation was related with high levels of both pyrethroid and DDT resistance; the phenotypic and genotypic resistance shows the needs to

urgently implement resistance management strategies such as bi-treated nets, combination of IRS and LLINs with different insecticides, or other strategies.

1438

DOES VEGETABLE FARMING CONTRIBUTE TO INSECTICIDE RESISTANCE SELECTION IN THE MALARIA VECTOR *ANOPHELES COLUZZII*?

Rousseau Djouaka

IITA- Cotonou, Benin, West Africa, Cotonou, Benin

This research analysed the contribution of vegetable production in insecticide resistance selection in malaria vectors in Benin. A KAP-study was undertaken with vegetable farmers to identify the most commonly used insecticides. The susceptibility profile of anopheles was assessed in surveyed farms and the presence of insecticide residues and heavy metals in their breeding sites was determined. λ-Cyhalothrin constituted the main insecticide used in surveyed vegetable farms. An.coluzzii was the main species found in surveyed vegetable farms. High resistance levels to λ-Cyhalothrin were recorded in sampled An. coluzzii. However, few of the examined breeding sites were found to be contaminated by λ-Cyhalothrin residues. Interestingly, a positive correlation was recorded between the presence of copper in breeding sites and the λ-cyhalothrin resistance profiles of sampled anopheles populations.In conclusion, These results suggest the presence in breeding sites of non-insecticidal compounds such as copper which likely contributes to insecticide resistance selection in An. coluzzii.

1439

SPATIO TEMPORAL DISTRIBUTION AND INSECTICIDE RESISTANCE STATUS OF *AEDES* MOSQUITOES IN GHANA

Christopher M. Owusu-Asenso[1], Julius A. Mingle[1], David Weetmann[2], Yaw Asare Afrane[1]

[1]*University of Ghana, Accra, Ghana,* [2]*Liverpool School of Tropical Medicine and Hygiene, Liverpool, United Kingdom*

The *Aedes* has been transmitting Yellow fever and dengue fever viruses and other unknown arboviruses in Ghana. This study investigated the spatio-temporal distribution and insecticide resistance status of *Aedes* mosquitoes in Ghana. This study was carried out in three ecological landscapes of Ghana. Indoor and outdoor sampling was done with BG traps, human landing catch (HLC) and prokopack aspirator (PPK) during the dry and rainy seasons of 2017/2018 to determine spatio-temporary distribution. Phenotypic insecticide resistance status of *Aedes* was determined using the WHO susceptibility bioassay. Host blood meal sources was determined by PCR. A total of 2193 adult *Aedes* mosquitos were collected comprising; *Aedes aegypti* (97.3%), *Aedes africanus* (2.2%) and *Aedes luteocephalus* (0.05%). The dry and rainy season had 73.5 (42.1%) and 103.95 (57.9%) Aedes respectively. HLC had the highest densities of 210.9 (77%) followed by PPK 74 (17.8%) and BG trap 15.5 (5.2%). The test results showed that *Aedes* mosquito populations from all study sites were resistant to DDT (0 - 84%). Vectors showed resistance to deltamethrin in Tema (68%) and patchy resistance in the other sites. Vectors showed resistance to permethrin in Accra (40.0%) and Larabanga (88.8%), suspected resistance in Konongo (90%), Navrongo (90%) and Paga (96%). *Aedes* mosquitoes showed resistance to bendiocarb in Larabanga. *Aedes* mosquitoes were susceptible to organophosphates at all sites. Blood meal analysis showed that the *Aedes* mosquitoes were mostly anthropophilic with HBI of 0.9. The development of resistance by Aedes mosquitoes to DDT, pyrethroids and carbamates may have an operational impact on the efficacy of insecticides on vector control interventions

1440

THE FORGOTTEN VECTORS IN INSECTICIDE RESISTANCE MONITORING OF MALARIA VECTORS

Duncan K. Athinya[1], Melinda P. Hadi[1], Seline A. Omondi[2], Eric O. Ochomo[2]

[1]*Vestergaard, Nairobi, Kenya,* [2]*Kenya Medical Research Institute, Kisumu, Kenya*

The reduction in global malaria cases since 2000 has been largely attributed to vector control with long lasting insecticidal nets and indoor residue spraying. This steady decline has stagnated, and the World Malaria Report 2018 highlighted an increase in malaria cases between 2016 and 2017. Insecticide resistance in malaria vector is one of the challenges identified. Monitoring of insecticide resistance in malaria vectors is essential for successful vector control campaigns. Visualizing such data in time and space provides an indication where insecticide resistance may play a role in persisting malaria burden. IR Mapper (www.irmapper.com) was launched in 2012 and continues to be updated monthly to geospatially display data from published literature on insecticide resistance in *Anopheles* species. As of March 2019, IR Mapper presented data from 20,953 tests from 430 published articles and reports of both phenotypic resistance and insecticide resistance mechanisms globally. 85.4% of this data is from Africa. *Anopheles gambiae s.l.* and *An. funestus s.l.* accounts for 90.1% and 9.5% of the tests, respectively. *An. coustani*, *An. pharoensis* and *An. labranchiae* together account for 0.4% of the tests. Among the phenotypic resistance tests between 2010 and 2018 using pyrethroids, 61.5% of the tests on *An. gambiae s.l.* reported confirmed resistance while 76.1% of tests on *An. funestus s.l* reported confirmed resistance. *Kdr* mutations were detected only in *An. gambiae s.l.* Most insecticide resistance monitoring efforts in Africa focus on *An. gambiae s.l.* Secondary vectors such as *An. coustani* and *An. pharoensis* are rarely tested. Such data gaps can present challenges for malaria control. It is essential for researchers to test relevant *Anopheles* species especially where they occur in sympatry in high malaria transmission zones and where possible, secondary malaria vectors. IR Mapper is useful for identifying such data gaps.

1441

EFFICACY OF A NEW INDOOR RESIDUAL INSECTICIDAL COMBINATION CONTAINING CLOTHIANIDIN AND DELTAMETHRIN ("FLUDORA® FUSION") IN SIMPLE HUT TRIALS AGAINST *ANOPHELES ARABIENSIS*

Abebe Animut[1], Meshesha Balkew[2]

[1]*Aklilu Lemma Institute of Pathobiology, Addis Ababa University, Addis Ababa, Ethiopia,* [2]*Abt Associates Inc., VectorLink Project Ethiopia Office, President's Malaria Initiative, Addis Ababa, Ethiopia*

The spread of insecticide resistant malaria vectors prompted a need for new insecticides. Residual efficacy of Fludora Fusion WP-SB56.25 ('Fludora'), Clothianidin WG70 and Ficam® was evaluated against *Anopheles arabiensis* in simple huts in Oromia Regional State, Ethiopia. Each insecticide was sprayed in three huts and the remaining hut was sprayed with water (control). The wall of each house was divided into four equal sprayable surface types (painted, dung, smooth mud and rough mud) and checked for insecticidal activity prior to the spray. Three cones were placed at different heights of each surface type. Ten unfed, 2-4 days old female *Anopheles arabiensis* of insectary colony DebreZeit (susceptible to all current public health insecticides), were transferred to each cone using mouth aspirator and exposed for 30 minutes. After 30 minutes, the mosquitoes were transferred to clean holding cages and supplied with sugar solution by moistening a pad of cotton. Knockdown effect was recorded at 60 minutes and mortality at 24 hours, 48 hours and 72 hours holding time post-exposure. The tests began one month after spraying and thereafter at monthly intervals for 12months. The Fludora combination caused the highest residual insecticidal activity at 24 hours, 48 hours and 72 hours holing time post-exposure until 12 months after treatment (MAT) compared to Ficam and Clothianidin WG70. Its activity

was 100% mortality on all wall surface types until 3 MAT. It caused ≥98% mortality on dung and smooth mud surfaces at 4 MAT, 5 MAT and 6 MAT, >90% on rough mud surfaces from 4 MAT to 12 MAT (except 11 MAT) > 80% from 4 MAT to 12 MAT on painted surfaces (except at 7 MAT and 11 MAT) at 24 hours post-exposure. The measured residual activity of Fludora increased when the holding time of exposed mosquitoes was extended from 24 hours to 48 hours and 72 hours. Ficam revealed the highest residual insecticidal activity on painted surfaces at 24 hours holding time post-exposure resulting in 100% efficacy until 4 MAT, 92% at 5 MAT and 74% at 6 MAT and 7% at 7 MAT and lost its efficacy thereafter. Fludora can be used as alternative insecticide in indoor residual spraying programs in Ethiopia.

1442

ACCREDITATION FOR ENHANCE VECTOR CONTROL IN MEXICO AND THE AMERICAS

Pablo Manrique-Saide, Anuar Medina-Barreiro, Abdiel Martin-Park, Yamili J. Contreras-Perera, Azael Che-Mendoza, Gabriela González-Olvera

Collaborative Unit for Entomological Bioassays, Mérida, Yucatán, Mexico

The roll out of good laboratory practice (GLP) in vector control led by the World Health Organization (WHO), aims at enabling consistent, reliable and repeatable data to be generated from vector control studies. The Collaborative Unit for Entomological Bioassays (UCBE by its initials in Spanish) from the University of Yucatan in Mexico, is an independent non-profit academic unit, currently in the last stage of WHO-GLP accreditation. Since its creation in 2014, UCBE has contributed to the generation of technical and scientific evidence to enhance and innovate the surveillance and control of vector-borne diseases, with an emphasis in *Aedes aegypti*, the main vector of dengue, chikungunya and Zika. Currently UCBE is recognized by the Federal Ministry of Health of Mexico as a reference unit for monitoring susceptibility of insecticides, evaluation of formulations and application equipment used for vector control. Transitioning UCBE to GLP status required restructuring personnel, with the establishment of roles and positions for trial performance and quality control; full-time members will be part of the unit, with additional temporary personnel hired for insecticide evaluations. Facilities were improved, thanks to funding from WHO, to add insectary space, bioassay laboratory space and administrative space. Standard Operation Procedures were developed in Spanish for unit administration, procedures and experiments as well as database management. Key UCBE personnel participated in WHO-sponsored training workshops aimed at transferring knowledge and skills. While UCBE-GLP is in the latest stage of accreditation, this poster will provide description of the challenges and opportunities of achieving GLP status. This accreditation represent a regional effort to promote health research and infrastructure development, to support local, regional and international evidence-based decision making for Control Programmes of ABD in developing countries.

1443

OPINIONS OF COMMUNITY MEMBERS TOWARDS TRADITIONAL AND NOVEL *AEDES AEGYPTI* CONTROL METHODS IN PONCE, PUERTO RICO

Carmen L. Pérez-Guerra[1], Sue A. Ramos-Díaz[1], Coral Rosado-Santiago[1], Karla M. Marrero-Santos[1], Angela F. Harris[1], Liliana Sánchez-González[1], Adriana Romero[2], Mary H. Hayden[3], Gabriela Paz-Bailey[1]

[1]*Centers for Disease Control and Prevention/CCID/NZVED/, San Juan, PR, United States,* [2]*Centers for Disease Control and Prevention/CSTLTS/PHAP, San Juan, PR, United States,* [3]*University of Colorado/Trauma, Health and Hazards Center, Colorado Springs, CO, United States*

Communities Organized for the Prevention of Arboviruses (COPA) is a project developed to evaluate *Aedes aegypti* control strategies to reduce morbidity and mortality associated with mosquito-borne diseases in Puerto Rico. Previous group discussions (GDs) in 2017 with community members from Ponce indicated that mosquitoes, debris, and containers with water were common problems, which increased their concerns for the transmission of arboviral diseases. The purpose of the present study was to elicit community opinions of traditional versus new methods to control *Aedes aegypti*, the mosquito vector of Zika, dengue and Chikungunya viruses. We conducted four GDs from April-May 2018 with leaders and residents selected through a snowball technique. Discussions were led using a guide and a slide set with mosquito-control method descriptions and illustrations. MAXQDA 12 software was used for content analysis. Thirty-two people from eight clusters participated. All participants supported Autocidal Gravid Ovitraps (AGOs) and source reduction, while almost all supported hand-applied larvicide and truck-mounted larvicide spraying. More than half would support the release of male mosquitoes with Wolbachia and genetically modified (GMO) mosquitoes because these methods would reduce the number of adult mosquitoes. Half would support the release of male and female mosquitoes with Wolbachia to block virus transmission although it would not reduce the number of mosquito bites. All requested information about the effectiveness, adverse effects on health, financial cost, and study results from other countries to support its implementation in their communities. Best practices to disseminate information included educational and promotional campaigns with experts and trained community leaders, using traditional and social media. AGOs, truck-mounted larvicide spraying, male mosquitoes with Wolbachia and GMO mosquitoes were the vector control methods supported by participants. Implementation of these methods is feasible if comprehensive education is provided to the community and government funding is allocated to ensure sustainability.

1444

EXPLORING RISK FOR MALARIA INFECTIONS ASSOCIATED WITH NOCTURNAL FISHING IN RUSINGA ISLAND, WESTERN KENYA

Evelyn Adhiambo Olanga[1], Wolfgang Richard Mukabana[2], Lucy Wachuhi Irungu[3]

[1]*Malaria Alert Centre of the College of Medicine, Malawi, Blantyre, Malawi,* [2]*University of Nairobi, Nairobi, Kenya,* [3]*Machakos University, Machakos, Kenya*

Malaria vectors traditionally bite humans indoors at night which led to the development of indoor-based interventions. Fishermen of Rusinga Island in Western Kenya work outdoors at night and are beyond the protective range of these interventions. In this study, spatial and temporal exposure to malaria mosquitoes and infection in relation to capture fishing activities was investigated. Hourly mosquito biting and human fishing activities were recorded on Kolunga fishing beach from 6pm till 7 am for 73 nights in 2012. Variation in mosquito numbers and prevalence of malaria among residents found within a transect measuring 1km by 2km from the shoreline was determined in Sienga village. A health facility-based malaria survey was carried out to determine association between occupation and malaria. A total of 1,577 female mosquitoes were captured in Kolunga of which 37 were *An. gambiae* s.l., 231 were *An. funestus* s.l. and 1,299 were non-malaria vectors. Two peak periods of biting activity were observed in *An. gambiae* s.l. between 10-11 pm and 4-5 am while *An. funestus* peaked between 10-11pm and 5-6 am. Similar peaks were noted for fishing activities between 9-11pm and 3-7am. A total of 4,338 female mosquitoes were captured in Sienga village of which 15 were *An. gambiae* s.l., and 10 were *An. funestus* s.l. Compared to malaria mosquitoes captured at close proximity to the shoreline, there was no significant difference in densities of *An. gambiae* s.l. (p=0.742) and *An. funestus* (p=0.424) caught at 1,800 metres from the shoreline. No association between malaria infection and distance of 1,800 metres from the shoreline (p=0.312) was observed in this study. Among patients, malaria was significantly associated with individuals involved in fishing (p=0.031) and farming (p=0.003) activities. The study demonstrated an association between malaria cases and individuals involved in fishing and related activities. The risk of malaria on Rusinga Island appears to be associated

with the time that individuals are found outdoors at night suggesting the need to develop complementary vector control tools to protect individuals engaged in nocturnal outdoor activities.

CHARACTERIZING THE MOSQUITO POPULATIONS ON THE ISLAND OF MAUI, HAWAII

Priscilla Seabourn[1], Helen Spafford[1], Lee Goff[2]

[1]*University of Hawaii at Manoa, Honolulu, HI, United States,* [2]*Chaminade University, Honolulu, HI, United States*

Mosquito-borne diseases present a global threat to public health and wildlife conservation. The introduction of mosquitoes to the Hawaiian Islands has supported several dengue virus outbreaks, with the most recent occurring in 2015 on Hawai'i island, and provides the capacity for arbovirus transmission for the future. Currently, there are six species of mosquitoes that have been reported in the state of Hawaii, *Culex quinquefasciatus*, *Aedes albopictus*, *Aedes aegypti*, *Wyeomyia mitchellii*, and *Aedes japonicus*, with all but *W. mitchellii* capable of transmitting human and zoonotic diseases. Hawaii is under constant threat of new species incursions due high levels of tourism and cargo shipments. To inform vector control strategies, the development of comprehensive distribution maps is critical but lacking for. some of the islands of Hawaii, like Maui, To address this gap, this project aimed to characterize the current distribution of mosquitoes (Diptera: Culicidae) on the island of Maui in Hawaii by deploying ovipositional and BG-sentinel traps around the island of Maui for one year at various elevations and in different habitats. *A. albopictus* is abundant and widely distributed around Maui but was not collected in some areas. *C. quinquefasciatus* was also found to be abundant,but had a more limited distribution as compared to *A. albopictus*. *A. vexans* and *W. mitchellii* were also infrequently collected. *A. japonicus* has been reported on Maui but was not sampled in our study. The unique landscape, high biodiversity, and year-round suitable climate in Hawaii make it an ideal environment for a diverse community of mosquitoes and reservoir for disease. Establishing the existing distribution or mosquitoes and continuous monitoring for new incursions is essential for mitigation of mosquito-borne disease.

BITES, BLOOD AND BEHAVIOR: BIOPHYSICAL APPROACHES TO UNDERSTANDING MOSQUITO BLOOD-FEEDING BEHAVIOR

Felix J. Hol[1], Louis Lambrechts[2], Manu Prakash[1]

[1]*Stanford University, Stanford, CA, United States,* [2]*Insect-Virus Interactions Unit, Institut Pasteur, Paris, France*

Mosquito-borne pathogens are transmitted during blood feeding, yet despite its crucial role in pathogen transmission, blood-feeding behavior remains ill understood. In particular, the sensory integration of physical and chemical cues on the skin and below its surface is poorly characterized and it is unclear how pathogen infections influence this behavior. These knowledge gaps are largely due to a lack of quantitative tools to study mosquito behavior. To overcome these limitations, we leverage machine vision and an engineered human skin mimic to create high-throughput assays to study *Aedes aegypti* blood feeding. Deep learning based analysis of mosquitoes feeding on a transparent skin mimic enables the characterization of the behavioral trajectory leading to blood feeding and the dynamics of arbovirus transmission. To unravel the effects of a mosquito›s physiological state on blood feeding, we quantitatively characterize how distinct physiological states (e.g. arbovirus infection, nutrition, age) shape blood-feeding behavior. This strategy will provide a deep understanding of the behavioral drivers of blood feeding in mosquitoes. Furthermore, we anticipate that the open availability of the developed tools will enable researchers to dissect the behaviors that make mosquitoes, and other insects, such efficient vectors of human pathogens.

MALARIA VECTOR POPULATION DENSITIES AND MALARIA TRANSMISSION IN A HOLOENDEMIC AREA OF WESTERN KENYA

Andrew A. Obala[1], Judy Mangeni[2], Emma Kimachas Kimachas[3], Kelsy M. Sumner[4], Steve M. Taylor[5], Lucy Abel[3], Wendy P. O'Meara[6]

[1]*School of Medicine, College of Health Sciences, Moi University, Eldoret, Kenya,* [2]*School of Nursing, College of Health Sciences, Moi university, Eldoret, Kenya,* [3]*Academic Model Providing Access to Healthcare, Eldoret, Kenya,* [4]*Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, United States,* [5]*Division of Infectious Diseases, Duke University School of Medicine, Durham, NC, United States,* [6]*Duke Global Health Institute, Duke University School of Medicine, Durham, NC, United States*

The population density and behaviour of malaria vectors determine the number of infective bites received by human hosts in high malaria transmission areas. In sub-Saharan Africa, daily exposure to infective bites is enormous due to high densities of the vector populations. We report malaria vector populations and transmission capacities in an area of high insecticide treated nets (ITNs) coverage. We used longitudinal cohort design to collect data. Malaria vectors were captured from three (3) sites, namely; Kinesamo, Maruti and Sitabicha villages in the Webuye Health and Demographic Surveillance System (HDSS) area. The malaria vectors were captured once a week on separate days for each site between 6am to 9am from June 2017 to July 2018. We used Prokopack technique to collect mosquitoes. *Anopheles gambaie* sl, *Anopheles funestus* and other anopheles species were identified morphologically and their abdominal status recorded after which each female mosquitoes were dissected, and head and abdomen stored, each of which were tested using real-time PCR to detect both human and *P. falciparum* DNA. Of the 1136 anopheles mosquitoes identified, 90% were *An. gambiae* sl while *An. funestus* comprised only 6.2%. Other anopheles species captured were *An. pretoriensis* (1.1%), *An. demeilloni* (1.1%), *An. coustani* (0.5%), *An. dancalicus* (0.4%), *An. salbii* (0.4%), *An. maculipalpis* (0.3%) and *An. rufipes* (0.2%). Indoor resting, which comprised half gravid and gravid components, was at 40%, with a human blood index of 54% suggests these mosquitoes predominantly bite and rest indoors in spite of high ITNs coverage. We report high entomological inoculation rate (EIR) of 13.97, however, malaria transmission intensity between the villages differed significantly (Fisher's exact test; p=0,029). For instance, sporozoite rate for Kinesamo was 10% compared to 9% and 7% for Maruti and Sitabicha respectively. Both high EIR and sporozoite rates reported here suggest the current control strategies are unlikely to lower malaria transmission in malaria endemic areas of western Kenya.

1448

METAGENOMIC SEQUENCING AND ANALYSIS OF THE VIROME OF *HAEMAGOGUS JANTHINOMYS*: A MAYARO VIRUS VECTOR IN TRINIDAD

Renee Ali[1], Azad Mohammed[1], Jayaraj Jayaraman[1], Chinnaraja Chinnadurai[1], Christine Carrington[1], Dave W. Severson[2], Adesh Ramsubhag[1]

[1]*University of the West Indies, St. Augustine, Trinidad and Tobago,* [2]*University of Notre Dame, Notre Dame, IN, United States*

In the last decade, several arboviral diseases including alphaviruses have significantly affected the Americas. The Mayaro virus, an emerging alphavirus that is endemic to the South American continent is raising concerns, with reports of sporadic outbreaks and imported cases to non-endemic regions. It is primarily transmitted by the mosquito vector *Haemagogus janthinomys* in its sylvatic cycle. The true burden of the Mayaro virus is not fully understood and the role of its mosquito vector in the transmission cycle has not been well investigated. The *Haemagogus* mosquito is also the sylvan vector for the yellow fever virus and may be a vector for other arboviral diseases; which needs to be further explored. In this study, a metagenomic approach using RNA sequencing was used to

characterize the viromes of field caught *Hag. janthinomys* from forested areas in Trinidad, West Indies. Here we report on the RNA metavirome of *Hag. janthinomys* collected from the Caroni Swamp during the rainy season (June to December). The characterized viruses that dominated were Phasi Charoen-like, Humaita-Tubiacanga and Semiliki Forest Complex virus. This study is the first report of metavirome work done on the *Haemagogus* mosquito vector and can contribute knowledge required to prevent and control emerging arboviruses for this region.

1449

ENVIRONMENTAL AND DEMOGRAPHIC RISK FACTORS FOR *AEDES AEGYPTI* VECTOR PERSISTENCE IN URBAN AND RURAL KENYA

Sindiso Nyathi[1], Harun N. Ngugi[2], Amy Krystosik[3], Bryson Ndenga[4], Donal Bisanzio[5], Uriel Kitron[6], Erin Mordecai[7], Desiree LaBeaud[3], Francis Mutuku[8]

[1]*Department of Health Research and Policy, School of Medicine, Stanford University, Stanford, CA, United States,* [2]*School of Biological Sciences, Department of Zoology, University of Nairobi, Nairobi, Kenya,* [3]*Department of Pediatrics, Division of Infectious Diseases, School of Medicine, Stanford University, Stanford, CA, United States,* [4]*Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya,* [5]*RTI International, Washington, DC, United States,* [6]*Department of Environmental Sciences, Emory University, Atlanta, GA, United States,* [7]*Department of Biology, Stanford University, Stanford, CA, United States,* [8]*Environment and Health Sciences Department, Technical University of Mombasa, Mombasa, Kenya*

Aedes aegypti is the vector for several disease pathogens, including the agents of emerging and re-emerging tropical diseases such as dengue, chikungunya and zika. Although vaccine development for these vector-transmitted diseases is still ongoing, vector control interventions at the household level remain the most effective option for disease control. In order to design and implement efficient vector control strategies, the ecology of *A. aegypti* must be well understood. We use household, demographic and environmental data to evaluate factors that contribute to pupal persistence in rural and urban sites in Kenya. Data were collected monthly from 89 households in 2 urban and 2 rural sites over a 4-year period. Pupae count data was collected via monthly survey sampling of potential breeding containers inside households and in the peri-domestic area. Demographic and household data were collected via written surveys and household/compound inspection. Locally collected hobo-logger data and remotely sensed environmental data were used to determine temperature, humidity and land use variables. We hypothesize that certain households have a high pupal persistence and consistently produce high pupae counts. We used a Kendall's W statistic to examine the consistency of pupal production of households across time. We then used Generalized Additive Models (GAMs) to examine the environmental and demographic risk factors for high pupal persistence, while accounting for temporal and spatial correlation, and non-linear effects. In our initial results, the total pupal count across 89 households in 4 sites is 6 221 (Kisumu – 1 197, Chulaimbo – 1 276, Ukunda – 1 680, Msambweni – 2 068). The average 4-year household pupae count is 69.90, with 33% of households falling above the mean (30% in Kisumu, 32% in Chulaimbo, 45% in Ukunda, and 26% in Msambweni). Our initial results suggest that control interventions targeting high persistence households could make vector control more efficient.

1450

BEHAVIORAL INTERACTION OF MOSQUITOES WITH TOPICAL REPELLENTS: A 3D FLIGHT TRAJECTORY ANALYSIS

Mathurin Fatou[1], Steven Nicholas Fry[2], Pie Müller[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*SciTrackS GmbH, Bertschikon, Switzerland*

Topical repellents are important tools for personal protection against mosquito bites and are available as lotions, sprays, gels, roll-ons, etc. that may contain a range of active ingredients. Though several active ingredients may provide protection over several hours we have little concept as to how these topical repellents impact mosquito behaviour. A better understanding of how mosquitoes interact with topical repellents may, however, lead the way to improved formulations or designs of more realistic assays for product evaluation. We measured the behaviour of host-seeking mosquitoes combining the standard arm-in-cage test with Trackit 3D, allowing for measuring the 3D flight trajectories of several mosquitoes with 90 position data points in real time. The real time functionality allowed us to monitor the measurement during the experiments and write the position data on disk without the need to store large amounts of video data, and process these off line. Filming under near-infra-red lighting allowed us to measure the natural behaviour of both day active *Aedes* and night active *Anopheles* mosquitoes under naturalistic lighting conditions. We are able to measure the 3D flight trajectories of several mosquitoes in parallel and in real time in the vicinity of topical repellents using a novel approach, and we will present our latest results.

WOLBACHIA AFFECTS *AEDES AEGYPTI* VECTOR COMPETENCE FOR MAYARO VIRUS

Sujit K. Pujhari, Marco Brustolin, Cory Henderson, Jason L. Rasgon

Pennsylvania State University, State College, PA, United States

Wolbachia is a gram-negative endosymbiont that can infect a broad range of hosts and can often alter the ability for mosquitoes to transmit pathogens. Recently, *Aedes aegypti* artificially infected with Wolbachia have been released at multiple geographic locations to control Dengue virus. Mayaro virus (MAYV) is an emerging alphavirus expanding its presence in the Americas. Here, we have investigated MAYV blocking by wMel and wAlbB strains of Wolbachia in *Aedes aegypti*. Our data indicate that both Wolbachia stains have suppressive effects on MAYV.

1452

ANTHROPOGENIC LANDSCAPES AND THE SPATIAL DYNAMICS OF VECTOR-BORNE DISEASE EMERGENCE IN COSTA RICA

Brett R. Bayles[1], Carlos Faerron Guzmán[2], Gabriellah Agar[1], Bobin Chen[1], Keira Dagy[1], Tyler Hummel[1], Emma Kelly[1], Kira Kuwada[1], Alec Murrer[1], Andria Rusk[3]

[1]*Dominican University of California, San Rafael, CA, United States,* [2]*Interamerican Center for Global Health (CISG), San Vito, Costa Rica,* [3]*Florida International University, Miami, FL, United States*

In the neotropics, agricultural intensification has resulted in large-scale changes to forest ecosystems. Such anthropogenic landscapes can significantly impact the transmission dynamics of vector-borne diseases (VBD), resulting in new or altered focal points of risk. We explored the spatial and temporal trends of three distinct categories of VBD in Costa Rica, including: 1) emerging flaviviruses (Zika virus disease and Dengue fever), 2) neglected tropical diseases (cutaneous leishmaniasis and Chagas disease), and 3) a recently declared eradicated disease (malaria). District-level incidence data was collected between 2006-2017 and spatial statistics were used to identify hotspots of statistically elevated risk. We then quantified the associations between types of human-altered land use (e.g. deforestation rates and agricultural land use) and both the presence (i.e. hotspot or not) and persistence (i.e. number of years as a hotspot) of elevated transmission risk over time. We detected clear patterns of non-random disease risk across each of the three categories of VBD, with Zika and Dengue exhibiting the most spatial overlap in the Caribbean and North Pacific regions. Districts with medium-high rates of deforestation were statistically significantly associated with the increased presence of Zika (OR=6.02, $p<0.001$), Dengue (OR=2.64, $p<0.05$), and leishmaniasis (OR=8.94, $p<0.001$) hotspots. Districts with the highest proportion of crop cover were also statistically significantly associated with the presence of hotspots for Zika (OR=15.19, $p<0.001$), Dengue (OR=13.00, $p<0.001$), leishmaniasis (OR=4.46, $p<0.01$), Chagas (OR=3.09, $p<0.05$), and Malaria

(OR=8.40, p<0.01). The association between land-use change and the persistence of hotspots over time was less clear. In summary, we identified hotspots of VBD of global public health significance and show that these focal points of disease risk may be attributable to human-altered landscapes. Additional research is needed to better understand the role that socioeconomic factors play in the geographic distribution of VBD risk.

1453

RAPID INDUCTION OF APOPTOSIS AS A DEFENSIVE MECHANISM IN THE MIDGUT OF *AEDES AEGYPTI* FOLLOWING FLAVIVIRUS INFECTION

Jasmine B. Ayers, Seokyoung Kang, Rhoel R. Dinglasan, Lei Zhou

University of Florida, Gainesville, FL, United States

Arbovirus transmission via a mosquito between mammalian hosts requires obligatory infection of the mosquito midgut. We hypothesize that following ingestion of virus, the mosquito attempts to clear infected cells via apoptosis to avoid productive infection of the midgut and subsequent dissemination. Apoptotic cell death has been considered as an immune pathway against viral replication in vertebrates, but the role of apoptosis had remained unclear in mosquitoes. We have shown that resistance of *Aedes aegypti* larvae to a mosquito baculovirus is mediated by rapid induction (less than 4 hours post-infection (hpi)) of apoptosis via Inhibitor of Apoptosis (IAP) antagonist *michelob-x* (*mx*). Caspase inhibitor treatment to delay induction of apoptosis negates the resistance phenotype and the mosquitos succumb to infection, suggesting that rapid cell death is vital to arresting viral spread before viral amplification occurs. *mx* is induced within 3 hours in adult *A. aegypti* mosquitos following feeding on blood containing dengue virus serotype 2 (DENV2), and the *mx* mRNA levels are 2.5-fold higher in the dengue-resistant MOYO-R strain than the susceptible MOYO-S strain of *A. aegypti*, supporting the hypothesis that rapid induction of apoptosis affects mosquito susceptibility to medically relevant flaviviruses. Current work involves characterization of the rapid induction of apoptosis following DENV2 and Zika virus (ZIKV) infection of the midgut both *in vivo* after blood feeding and in an *ex vivo* system where the midgut is maintained briefly in tissue culture. Induction of apoptosis has been observed by DNA fragmentation (Terminal deoxynucleotidyl transferase dUTP Nick-End Labeling assay) and active caspase assay at less than 2 hpi with DENV2 and ZIKV in both systems. Preliminary data shows inhibition of apoptosis in the midgut by treatment with aqueous Zn^{2+} (inhibitor of caspase), which is used to explore the function of the apoptotic response in suppressing viral replication. RNA *in situ* hybridization will examine earlier stages of apoptosis alongside virion labelling to clarify what role virus attachment/entry plays in midgut cell death.

1454

DISPERSAL DYNAMICS OF THE ASIAN TIGER MOSQUITO

Laura Vavassori[1], Ann-Christin Honnen[1], Adam Saddler[2], Pie Müller[1]

[1]*Swiss Tropical and Public Health Insitute; University of Basel, Basel, Switzerland,* [2]*Swiss Tropical and Public Health Insitute; University of Basel; Ifakara Health Institute, Bagamoyo, United Republic of Tanzania*

The Asian tiger mosquito (*Aedes albopictus*) is one of the most invasive insect species globally and is of considerable public and veterinary health relevance as a disease vector. While human-aided transport is clearly a key driver, it is still not clear to what extent the mosquito is passively dispersed and how far it colonises new areas through active flight. Understanding the dispersal dynamics at regional scale is, however, fundamental to improve vector surveillance and to target vector control efforts. In order to measure active dispersal we deployed devices by which field-caught mosquitoes are self-marked with a fluorescent dye, avoiding the negative impacts of traditional marking methods. To measure passive dispersal we sampled mosquitoes from Switzerland and neighboring countries and sequenced these using ddRAD next-generation sequencing, generating a vast number of Single Nucleotide Polymorphisms (SNPs). On the basis of these SNPs and the mark-release-recapture study we reconstruct the invasion of the Asian tiger mosquito in newly colonized areas in Switzerland, and we will present our latest results.

1455

AEDES AEGYPTI BLOOD AND SUGAR-FEEDING PATTERNS ARE ASSOCIATED WITH HOUSING QUALITY AND HUMAN BEHAVIOR IN LOS ANGELES, CALIFORNIA

Marisa A. Donnelly[1], Christopher M. Barker[1], Bradley Main[1], Susanne Kluh[2]

[1]*University of California Davis, Davis, CA, United States,* [2]*Greater Los Angeles County Vector Control District, Santa Fe Springs, CA, United States*

Since 2015, more than 1,000 travel-related human infections with Zika and dengue viruses (ZIKV and DENV) have been detected in California. Local transmission has not been reported, but many detections have occurred in areas infested with *Aedes aegypti*, which was first detected in California in 2013. Los Angeles County (LA) is California's most populous county, and accounts for more than 20% of the state's travel-related infections of ZIKV and DENV. In addition, *Ae. aegypti* has continued to spread in LA, with 82 cities reporting infestations. In the U.S., some studies suggest that improved housing quality reduces exposure to *Ae. aegypti* biting; however, no study has investigated how household characteristics and human behaviors (e.g. air-conditioner usage) may modify feeding patterns. To better understand the relationships between household risk factors and *Ae. aegypti* biting, we identified bloodmeal hosts, quantified sugar-feeding prevalence, and identified household predictors for blood and sugar feeding in LA. During summer 2017, we surveyed 163 households across six cities in LA. We administered a survey in English or Spanish to collect data on *Ae. aegypti*-relevant human behaviors and household characteristics, and collected adult mosquitoes indoors and outdoors. In total, we collected 185 adult female *Ae. aegypti*; 47 were blood-engorged and 138 were non-blood-engorged. We identified host species by sequencing 16S and cytochrome B mitochondrial *loci* using Illumina sequencing, and quantified the blood and sugar-feeding prevalence of non-blood-engorged mosquitoes using anthrone and vanillin assays. The anthrone assay quantifies fructose and glycogen and the vanillin assay quantifies lipids, together reflecting the balance of a mosquito's metabolic activities and nutritional inputs and storage from feeding on blood and sugar. Our study enhances our understanding of *Aedes*-borne virus epidemiology in relation to measurable socio-demographic factors, which is important for targeting vector control in the arid southwestern U.S. where travel-related infections are common and *Ae. aegypti* and other vectors continue to spread.

1456

IMPACTS OF CHEMOSENSORY ORGAN ABLATION ON HOST-SEEKING ACTIVITY IN THE MALARIA VECTOR *ANOPHELES COLUZZII*

Zachary R. Popkin-Hall, Michel A. Slotman

Texas A&M University, College Station, TX, United States

Host-seeking in mosquitoes is modulated by chemosensory organs, which include the antennae, maxillary palps, and labellum of the proboscis. The maxillary palps express CO_2 receptors, which are thought to activate the host-seeking process, and both the maxillary palps and labella express olfactory receptors. We conducted a series of ablation experiments in the highly anthropophilic malaria vector *Anopheles coluzzii* to determine the respective role of chemosensory organs in both host-seeking and host preference. We tested five treatment groups: unablated control, injury effect control (leg-ablated), antenna-ablated, maxillary palp-ablated, and labellum-ablated. Injury effect control mosquitoes had one metathoracic leg removed with fine forceps, while the chemosensory organs were ablated in pairs. Experiments were conducted in a two-port olfactometer at 28 °C and 80% humidity two hours after the start of the dark cycle. Mosquitoes were exposed to an air current containing 5% CO_2 and ports

containing either human or cow odor. Airflow was maintained at ~0.4 m/s. We measured response rates to both odors, as well as activation (i.e. leaving the release cage). Not surprisingly, preliminary results show the highest activation level in control mosquitoes, which entered the olfactometer 86% of the time. Antenna-ablated mosquitoes showed the lowest activation, at only a 35% rate, while 55% of labellum-ablated mosquitoes and 77% of palp-ablated mosquitoes entered the olfactometer. While injury effect may explain some reduction in activation, 67% of leg-ablated mosquitoes were activated, nearly double the rate of the antenna-ablated group. Total odor response rates show a similar trend: 27% of control mosquitoes entered an odor port, compared to 0% of antenna-ablated, 8% of labella-ablated, 11% of palp-ablated, and 8% of leg-ablated mosquitoes. This trend also holds true when considering only the response rates of activated mosquitoes. All experimental mosquitoes, and 99% of control mosquitoes that responded chose human odor over cow. However, these trends may change as sample sizes increase.

1457

TRACKING THE NATURAL DISPERSION OF ISOTOPICALLY MARKED *AEDES AEGYPTI* IN DONNA, SOUTH TEXAS

Selene M. Garcia-Luna[1], Jose G. Juarez[1], Edwin A. Valdez[1], Ester Carbajal[1], Courtney J. Avila[2], Wendy Tang[1], Luis F. Chaves[3], Estelle Martin[1], Ismael E. Badillo-Vargas[2], Gabriel Hamer[1]

[1]*Texas A&M University, College Station, TX, United States,* [2]*Texas A&M AgriLife Research, Weslaco, TX, United States,* [3]*Instituto Costarricense de Investigación y Enseñanza en Nutrición y Salud, Tres Ríos, Cartago, Costa Rica*

The movement of the mosquito *Aedes aegypti*, the primary vector of dengue, chikungunya and Zika viruses, has important implications for the transmission of the diseases the mosquito might carry and also to the development of effective vector population management. Studies of mosquito dispersal have used mark-release-recapture (MRR) designs with laboratory reared or field caught mosquitoes and mostly by marking the mosquitoes with fluorescent dusts. These approaches are subject to concerns regarding low marker retention or altered mosquito behavior. More recently, the marking of mosquitoes with stable isotopes has emerged with applications to other mosquito species. In this study, we utilized a stable isotope mark-capture design to identify movement and dispersal behavior of *Ae. aegypti* in South Texas. Isotopic enrichment with ^{13}C and ^{15}N was conducted in discarded containers and tires containing naturally occurring immature mosquitoes along a canal adjacent to a community of about 104 homes in Donna, Texas. We captured the mosquitoes using BG-Sentinel 2 traps located at different quadrants and at different distances from the larval source habitat. Mean distance traveled by unfed females, gravid females, and males was analyzed by equations calculating Mean Dispersal Distance (MDD) and a logistic mixed model. We documented that male *Ae. aegypti* traveled farther (MDD = 165m) than unfed and gravid females (MDD=105 and 123 m, respectively) for mosquitoes marked with ^{15}N. Similarly, for male mosquitoes marked with ^{13}C had a MDD= 243 m whilst unfed and gravid females (MDD= 179 and 131 m, respectively). Isotopically marked individuals collected in the community on the opposite side of the canal document successful flight across a canal, which is about 10 m in width. This study provides evidence that the stable isotope mark-capture approach is appropriate for studies of *Ae. aegypti* and will provide locally-relevant vector biology to inform vector management.

1458

ECOLOGICAL METACOMMUNITY DYNAMICS OF THE MOSQUITO MICROBIOME

Matthew C. Medeiros, Priscilla S. Seabourn, Helen Spafford

University of Hawaii at Manoa, Honolulu, HI, United States

The mosquito microbiome (an ecological community of microbial symbionts that live within a mosquito) is a major modulator of a host's capacity to sustain disease transmission. Paratransgenesis aims to suppress mosquito borne disease by exploiting these effects through the manipulation of the mosquito-symbiont metagenome, principally by adjusting the microbiome's composition. A common paratransgenic technique involves the manipulation of a natural symbiont's genome to express an effect molecule that depresses vectorial capacity, and the introduction of the modified microbial platform to natural vector populations that sustain disease transmission. Efficacy of this technique is dependent on the transmission efficiency of the transformed symbiont among individual mosquitoes. We hypothesize that the transmission and persistence of these new colonizing microorganisms is a function of ecological and stochastic forces associated with ecological metacommunity assembly, including niche effects (differential fitness across environments), dispersal, and ecological drift (stochastic changes in the demographic rates of community members). Here, we analyze a dataset of 116 *Aedes albopictus* microbiotas collected across the environmentally-heterogeneous island of Maui, Hawai'i. Specifically, we test how both niche effects associated with ecological (cosymbiont abundance, host sex) and environmental (temperature and rainfall) variables, and dispersal limitation influence the distribution of symbiont taxa that are under-development as paratransgenic platforms. The results of this research are expected to guide the development and implementation of paratransgenesis to reduce mosquito-borne diseases that threaten public health.

1459

WHAT IS THE ROLE OF AESTIVATING MOSQUITOES IN MAINTAINING *PLASMODIUM* BETWEEN WET SEASONS?

Samake Djibril[1], Zana Sanogo[1], Adama Dao[1], Alpha S. Yaro[1], Moussa Diallo[1], Ben Krajacich[2], Roy Faiman[2], Tovi Lehmann[2]

[1]*Malaria Research and Training Center (MRTC)/Faculty of Medicine, Pharmacy and Odonto-stomatology, Bamako, Mali,* [2]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States*

Mosquitoes are the engine of malaria transmission and for over a century, have been the most effective target for disease control. The dry season biology of the African malaria mosquito and its consequences for disease transmission are poorly understood. Recent findings showed that aestivating mosquitoes survive during the 7 month-long dry season. Whether these mosquitoes transmit malaria during the dry season, albeit in low levels, and whether they act as a reservoir of the parasite besides humans remains unknown. If so, aestivating mosquitoes will initiate disease transmission after the first rains, even if all humans were successfully cleared of their infection, complicating elimination efforts. We measured mosquito infection rate and malaria case load during the dry season in the Sahel. If mosquitoes act as a plasmodium reservoir, we predict that i) mosquito infection rate during the dry season will be moderate to high, and ii) 2-3 weeks after the late dry-season peak in mosquito density (mid-March—early April) malaria case load will rise and so will happen after the first rain (June). On the other hand, if aestivating mosquitoes are not infectious, the malaria case load will not change after the late dry season peak or shortly after the rain. Mosquito sporozoite infection, determined by CSP ELISA on ~10,000 *Anopheles coluzzii* females collected in the village Ballabougou between 2012 and 2016 showed that contrary to our prediction, infection rate during the dry season was very low (<1%), suggesting that these mosquitoes had minimal exposure to plasmodium, or have lost their infection. Likewise, malaria cases in the regional clinic 5 km from Ballabougou was low and stable throughout the dry season, with minimal case load after the high biting frenzy during the late dry-season peak. Our preliminary analysis provides evidence that aestivating mosquitoes do not act as a reservoir for *Plasmodium* during the dry season and that transmission rate by aestivating mosquitoes is minimal.

The creation of large-scale, high-resolution, ecological datasets on the abundance, distributions, and behavior of mosquito species is essential to lay the foundation for the successful application of promising new technologies for mosquito-borne disease management, such as genetic engineering and predictive modeling. However, the high-throughput collection, processing, standardization, and dissemination of reliable observations from the field remains the limiting factor in creating such datasets. In earlier work, we developed a method capable of crowdsourcing mosquito observations from the general public, by using simple mobile phones to record their species-specific wingbeat sounds for automated species identification together with metadata on the time and location of data collection, enabling low-cost, high-throughput spatio-temporal mapping of mosquito populations. Based on this concept, here we present ABUZZ - a citizen science initiative to collect acoustic data from mosquitoes using a custom mobile app, together with an associated web framework to organize, analyze, and visualize this data. Data recorded by mobile phones from users across the world is routed to a dedicated server, where our algorithms process the sound to identify the species and map the observation. We envision several use cases for this platform - (1) by researchers, as part of individual projects associated with answering scientific questions in mosquito-borne disease ecology, (2) by entomologists and public health workers, for creating and expanding the baseline for ecological mapping in a region, (3) by educators, as a teaching tool about mosquito-borne disease and mosquito biology for children and communities, and (4) by the lay public, to generate large quantities of mosquito surveillance data. We further outline our experience training local communities in various countries to use our tools, laying out a vision for multi-stage expansion of this platform, with applications in monitoring insect biodiversity, invasive species, and disease outbreaks.

CRYOPRESERVATION OF MOSQUITO (*ANOPHELES STEPHENSI*) EGGS

Eric Robert James, Yingda Wen, Kristen Pluchino, James Overby, Abraham G. Eappen, Stephen L. Hoffman, Peter F. Billingsley

Sanaria, Rockville, MD, United States

Research on mosquitoes, and in particular on *Anopheles* spp, is constrained by the lack of a method for the long-term preservation of stocks of the large number of wild type species, isolates, laboratory-bred strains, and genetically altered lines. Cryopreservation would provide a powerful tool for mosquito research. Several insect species have been successfully cryopreserved including some genera of dipterans, but to date, despite considerable effort, no method has been developed for mosquitoes - until now. We present a method for the cryopreservation of *Anopheles* spp. eggs that reproducibly yields a hatch rate of ~25%. The eggs are stable in liquid nitrogen vapor phase (LNVP) below -150 ^{o}C for >4 years, the longest storage time tested to date. Hatched larvae develop normally through to adults and the females blood feed normally, mate, and produce viable second generation eggs that also develop normally. Vector competency of adult mosquitoes obtained from cryopreserved eggs was demonstrated by infection with the malaria parasite, *Plasmodium falciparum,* and the development of salivary gland sporozoites in numbers identical to those produced in controls. Critical components of the cryopreservation technique are the time of egg harvest after oviposition, the cryoprotectant additive (CPA), the temperature and duration of exposure to the CPA, cooling and thawing rates, and dilution. The technique can easily cryopreserve small or large (>100,000) batches of eggs, adequate for banking species and strains, and to date has been used to bank *A. stephensi* SDA500, the mosquito used in manufacture of Sanaria® PfSPZ Vaccine, PfSPZ Challenge, and PfSPZ-GA1, several genetically altered lines of *A. stephensi*, and *A. gambiae*.

EVALUATION OF LONG LASTING NEUTRALIZING ANTIBODY AND ITS PROTECTIVE EFFICACY INDUCED BY A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE CANDIDATE, KD-382 IN DENGUE PRE-IMMUNIZED CYNOMOLGUS MONKEYS

Masaya Yoshimura[1], Kazuhisa Kameyama[1], Yasuhiko Shinmura[1], Kengo Sonoda[1], Sutee Yoksan[2], Kazuhiko Kimachi[1]

[1]*KM Biologics CO., Ltd., Development Department, Kumamoto, Japan,* [2]*Mahidol University, Center for Vaccine Development, Institute of Molecular Biosciences, Nakhon Pathom, Thailand*

One of challenges in dengue vaccine development, there being four serotypes of dengue virus, is that a vaccine has to induce long lasting neutralizing antibody (Nab) response against all four serotypes simultaneously. Our tetravalent dengue vaccine candidate KD-382, currently under development, is a live attenuated vaccine using a classical host range mutation strategy and thus, expected to induce strong and comprehensive immune response like dengue natural infection. To date, we have revealed that cynomolgus monkeys administered a single dose of KD-382 were seroconverted for all four serotypes (written as Tetra-Nab response from now on) regardless of the presence or absence of existing immunity for dengue. In this study, under pre-existing immunity induced by a monovalent dengue virus immunization, we evaluated the trend of Nab titer after single dose KD-382 administration and protective efficacy against secondary heterologous parental wild-type dengue virus challenged after immunization with KD-382. KD-382 (5 Log_{10} FFU/dose for each serotype) was injected to 12 cynomolgus monkeys pre-immunized with one of four serotypes of parental wild-type strains (DENV-3: 6 Log_{10} PFU/dose,DENV-1,2,4:5 Log_{10} PFU/dose). After KD-382 vaccination, Nab titer against each parental wild-type virus was evaluated by a focus reduction neutralization assay at intervals for over two years. As a result, regardless of the pre-immunized serotype, all the monkeys showed Tetra-Nab response and it maintained for over two years. The monkeys were then challenged with a heterologous serotype of parental wild-type virus 27 months after KD-382 administration, and it was revealed that the viral RNA in serum was under the lowest limitation of quantification, which indicates complete protection against the secondary heterologous challenge. Consequently, KD-382 successfully induced long-lasting and protective Tetra-Nab response in the dengue pre-immunized monkeys, suggesting that KD-382 is a promising vaccine candidate for both dengue seronegative and seropositive people.

Regional synchrony of dengue epidemics has been observed in Southeast Asia, yet few studies have examined the dynamics of dengue outbreaks across the Americas. We aimed to assess the synchrony of seasonal and major epidemics of dengue in Latin America & the Caribbean region. We applied wavelet decomposition to isolate seasonal (8-16 months) and multiannual (16-70 months) components of monthly dengue surveillance data from 220 provinces in 11 countries, spanning 22 years. We examined the coherence and phase differences between province pairs on both time scales to assess how coherence and phase differences relate to distance, country, and geographic location. Seasonal dengue patterns were strongly synchronized across most provinces, though timing of peaks varied with latitude. The multi-annual component showed that major epidemics occurred across many countries in the region in 2001, 2005, and 2009-2011. Overall mean coherence was similar across seasonal (0.48 [95% CI: 0.14 to 0.75]) and multiannual (0.46 [95% CI: 0.22 to 0.73]) components. Highest coherence and lowest phase differences occurred between nearby provinces, indicating higher synchrony. For the seasonal component, the average time lag increased linearly with increased distance. However, the multiannual component only increased up to approximately 1000 Km, after which the average phase difference remained approximately 7 months regardless of distance, indicating regional synchrony for major epidemics. These findings highlight important high-level regional dynamics. While individual provinces have seasonal patterns unique to their latitude and shared with nearby provinces, larger multiannual epidemics occur at a much larger scale with average time lags limited to only ~ 7 months even between faraway provinces. Ongoing work will further identify potential drivers of these patterns, such as climate variability, local transmission intensity, and serotype introductions. These findings can lead to a better understanding of the mechanisms leading to large epidemics and how to provide early warnings to mitigate their impact at a continental scale.

USE OF DENGUE RAPID DIAGNOSTIC TESTS TO DETECT HISTORICAL DENGUE VIRUS INFECTIONS IN POPULATIONS WHERE DENGUE AND ZIKA VIRUSES CO-CIRCULATE

Leah Katzelnick[1], Sully Marquez[2], Sandra Vivero[3], William Cevallos[3], Angel Balmaseda[4], Eva Harris[1], William Messer[5], Joseph Eisenberg[6], Gabriel Trueba[2], Josefina Coloma[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States, [2]Instituto de Microbiologia, Universidad San Francisco de Quito, Quito, Ecuador, [3]Universidad Central, Quito, Ecuador, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua, [5]Division of Infectious Diseases, School of Medicine, Oregon Health Sciences University, Portland, OR, United States, [6]School of Public Health, University of Michigan, Ann Arbor, MI, United States*

The licensed dengue vaccine, Dengvaxia, is protective in individuals who have experienced ≥1 previous dengue virus (DENV) infections but increases risk of severe dengue in those who have not been infected with DENV previously. The World Health Organization recommends use of a companion test such as the dengue rapid diagnostic test (RDT) to determine prior DENV infection history and thus vaccine suitability. We tested whether the SD BIOLINE Dengue IgM/IgG RDT detects historical flavivirus infections in healthy annual serum samples from 56 participants ages 2-60 years old in a dengue and Zika cohort study in Borbón, Ecuador (2018-2021). An earlier study in Borbón found 43% DENV seroprevalence for individuals age <5 years old, 74% for ages 5-13, 84% for ages 14-29, and 91% for ages ≥30. We developed a protocol to measure the IgG band in the dengue RDT using control serum samples. Images were taken of RDT strips at 15-20 minutes (as recommended by the manufacturer), 1, 2, and 3 hours. Pixel intensity was estimated in R by subtracting background intensity from each band (control, IgM, IgG). IgG positivity was also classified manually (negative, ambiguous, positive). Two dynamics in IgG pixel intensity were observed: flat with a small uptick at 3 hours and steadily increasing from 15 minutes to 3 hours. IgG pixel intensity was positively correlated with IgG positivity classified manually ($r=0.76$, $p<0.001$). At 15-20 minutes, none of those age <5 and 19-47% of those ages ≥5 were IgG-positive. by 1 and 2 hours, IgG positivity was observed for 22-33% of individuals age <5, 52-62% of those ages 5-13, 93-100% of those ages 14-29, and 100% of those ages ≥30. by 3 hours, IgG and IgM bands appeared in some otherwise negative samples, suggesting non-specific reactivity. Thus, IgG positivity measured with a dengue RDT increases with age in a DENV-endemic population. However, the RDT must be read later than current manufacturer recommendations. We will also estimate sensitivity and specificity using the Panbio IgG ELISA and test samples from individuals with known prior DENV and Zika virus infections in a pediatric cohort in Nicaragua and a traveler cohort in Oregon.

HOW MUCH OF PASSIVE DENGUE SURVEILLANCE CASES ARE NON-SECOND, AND DOES IT MATTER?

Angkana Huang, Derek Cummings

University of Florida, Gainesville, FL, United States

To most effectively identify dengue intervention targets, measures of transmission intensity are needed. Force of infection (FoI) is the often used measure. While seroprevalence data is the gold standard for FoI estimations, its availability is globally limited. Inferring FoI from age-stratified case counts provides a feasible alternative but requires the risk of clinical disease upon infection at different ages and upon first, second, third or fourth infection to be estimated or assumed. Current methods widely assumed that third and fourth infections were minimally observed. However, it is unknown if their contributions are small enough to be neglected. Here, we relax the structure of catalytic models in the literature to allow unrestricted contributions of all dengue infections (first thru fourth), assuming life-long homotypic protection against each infecting serotype. Model parameters were estimated from 37 years (1981-2017) of provincial age-stratified dengue case data in Thailand for all 72 provinces using Bayesian Monte Carlo Markov Chain estimation. During the time, mean age of dengue cases dramatically increased in all provinces from 9.7 (inner 95% quantile 7.7, 17.5) in 1990 to 22.9 (inner 95% quantile 17.9, 31.9) in 2017. Our models fit this transition with changes in the FoI suggesting the impact of human demographic changes on the transmission of dengue. We estimate the fraction of infections that are observable for first, second, third and fourth infections as well. Simulation studies show that our models 97.5% of times capture pre-assumed fractions, giving confidence in our results. FoI estimated under the unrestricted models differed from when capturable infections were restricted to only second infections. Bayesian information criterion supports the unrestricted estimates. Our results stress the need to include detailed disease process in models and show that information can be extracted from passive surveillance datasets, particularly when analyzed longitudinally. Our approach also highlights the continuing age shift of dengue cases in Thailand from a pediatric disease to a disease of late to middle adulthood.

Dengue virus (DENV) causes an estimated 390 million infections a year with an estimated 3.9 billion people at risk for infection globally. Approximately 75% of at-risk individuals reside in the Asia-Pacific region, including Thailand. A prospective cluster investigation study in Kamphaeng Phet (KPP), Thailand, was conducted between 2009 and 2012. In order to analyze trends in the spatio-temporal dispersal of DENV, we sequenced and analyzed 410 full viral genomes from this study, from 16 sub-districts of KPP. Consistent with previous whole genome studies of DENV dispersal on national, city and suburban scales, our discrete analyses on the sub-district level indicated a center-out DENV spread in KPP, with early season DENV introductions into the central sub-districts, followed by late-season virus dispersal to the rural areas. In order to determine viral spread on a finer spatial scale, we extended our discrete trait analyses to reconstructions of house-to-house transmission events utilizing select DENV sub-lineages only. For additional phylogenomic resolution, within-host DENV-1 minor variant frequencies were mapped on the taxa of these time-scaled phylogenies to confirm possible inter-household transmissions. This approach confirmed 8 inter-household transmissions, with 6 households sharing two or more transmission chain-specific DENV minor variants. The individual transmission chain households were located within 20-3000m, with median distance of 490m (IQR 70m - 1800m). A regression of transmission-pair distances over sampling time showed that DENV disperses an average of 70 meters per day (95% CI 54 - 86 m/day) between households in these communities. This relationship was strikingly linear (r^2=0.91), although the skew of the data prompts further sampling and analysis to avoid model misspecification and to mitigate any possible sampling bias. Remarkably, our approach also resolved three transmission chains involving individuals residing in the same households, providing the first genomic fine-scale confirmation for models suggesting that dengue transmission and infections are generally occurring close to home.

Dengue virus (DENV) is the most important arthropod-borne human virus associated with viral disease. Infection produces a variety of clinical presentations, but the factors contributing to differential disease severity are poorly understood. The lack of diagnostic tests to predict severe disease with haemorrhagic complications forces high levels of hospital admissions for safety purposes. Our objective, by adopting a liquid biopsy approach and integrating clinical and molecular data, is to correlate the spectrum of disease severity with DENV genetic diversity and host transcriptomic- changes observed in the periphery. This should enable identification of candidate virological and host biomarkers to develop diagnostics that predict progression to severe disease. We have developed pipelines to generate and analyse viral metagenomic and host transcriptomic data from prospectively-collected whole-blood and sera from DENV-infected patients. We assembled full-length DENV genomes without PCR-based enrichment and all four DENV serotypes were identified. Hotspots of intrahost codon diversity across the virus genome were found predominantly in a CD8 T cell epitope located in the NS5 RdRP domain. We defined whole-blood transcriptomic signatures of disease severity and identified genes that were deregulated in severe disease compared to dengue with/without warning signs. Network analysis revealed upregulated genes were involved in complement activation, coagulation and angiogenesis whereas downregulated genes were involved in the acute phase response and immune defence. Analysis of such patterns of gene abundance could lead to the identification of prospective biomarkers which can be tested further for their potential to discriminate DENV-mediated disease conditions

1468

NEUROLOGIC ILLNESS AMONG HOSPITALIZED PATIENTS WITH ARBOVIRUS INFECTION, PUERTO RICO, 2012-2018

Luisa I. Alvarado[1], Chelsea Major[2], Eva I. Gordian Rivera[1], Luzeida Vargas[1], Vanessa Rivera[3], Stephen Waterman[2], Gabriela Paz Bailey[2], Tyler Sharp[2]

[1]*Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, PR, United States,* [2]*Division of Vector-borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States,* [3]*Ponce Health Sciences University, Ponce, PR, United States*

Arboviruses transmitted by Aedes mosquitoes, including dengue (DENV), chikungunya (CHIKV), and Zika (ZIKV) have been associated with potentially fatal neurologic illness. Such manifestations may result from the direct effect of the virus, host immune responses to infection, or metabolic derangements presenting as encephalopathy. While the 2009 WHO case definition for severe dengue includes severe organ involvement of the central nervous system, better understanding of the burden and spectrum of neurologic illness caused by arboviruses is needed. Using data from the Sentinel Enhanced Dengue and Acute Febrile Illness (AFI) Surveillance System (SEDSS) in Ponce, Puerto Rico, we investigated the frequency of neurologic illness among hospitalized patients with arbovirus infection. The study population included patients hospitalized at the SEDSS clinical site during May 2012-December 2018 with evidence of DENV, CHIKV, and ZIKV infection by reverse transcription-polymerase chain reaction. Patients with neurologic illness were diagnosed with encephalitis/encephalopathy, seizures, aseptic meningitis, or acute paralysis. Chart abstractions are underway to further investigate clinical features. Of 599 hospitalized patients with arbovirus infection, six (2%) of 336 patients with DENV, 14 (6%) of 228 patients with CHIKV, and none of the 35 patients with ZIKV had neurologic illness. Median age of patients with neurologic illness was 3 years (range: 0-87), and 60% were male. Most (5, 83%) patients with DENV and 50% (7) of patients with CHIKV and neurologic illness had diagnoses of encephalitis/encephalopathy; 57% (8) of patients with CHIKV and neurologic illness had seizures. Among patients with DENV or CHIKV infection, those with neurologic illness were less likely to report joint and muscle pain (P<0.001), but were similar in reporting of other AFI symptoms, age and sex distribution, and length of hospitalization compared to those without. The frequency of neurologic illness among hospitalized DENV and CHIKV patients in Puerto Rico underscores the importance of arbovirus testing in patients with febrile neurologic syndromes.

1469

IDENTIFICATION OF GENES THAT ARE DIFFERENTIALLY EXPRESSED IN RESPONSE TO DENGUE, ZIKA OR CHIKUNGUNYA VIRUS INFECTION IN NICARAGUAN PATIENTS

Eunyoung Kim[1], Yan Che[1], Daniela Michlmayr[2], Steven Wolinksy[1], Eva Harris[2]

[1]*Division of Infectious Diseases, Northwestern University, Chicago, IL, United States,* [2]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States*

Dengue (DENV), Zika (ZIKV) and chikungunya (CHIKV) viruses cause mosquito-borne diseases endemic in many tropical and subtropical regions worldwide. These re-emerging arboviral diseases have similar epidemiology, transmission cycles and clinical symptoms, though complications differ significantly. Comparison of transcriptomes enables

identification of host genes that are differentially expressed in response to infection, providing important insights into the dynamics of the host-virus interaction. Here, we profiled the transcriptome in whole blood from children naturally infected with DENV, ZIKV or CHIKV. RNA-seq was used as an unbiased way to map host genes that are differentially expressed during acute and convalescent phases of infection. We cataloged transcript species (mRNAs, non-coding RNAs and small RNAs), resolved the transcriptional structure of genes (start sites, 5′ and 3′ ends, splicing patterns), and measured their abundance. Distinct transcriptomic signatures were associated with time of infection or symptom severity. Over 4,000 significant differentially expressed genes (DEGs) were shared among the 3 arboviruses (FDR<0.05), the most common being upregulated in the acute phase. Pathway and enrichment analyses showed the shared highly enriched (-log10(P) >20) DEGs that were upregulated involved defense responses to virus, interferon signalling, cytokine production, and regulation of innate immune response, whereas DEGs that were down-regulated involved eukaryotic translation elongation. There was an enrichment for blood transcriptome modules (BTMs) for monocytes, macrophages, NK cells, type-1 IFN, and cell cycle during the acute phase of infection, and B cells, T cells and Th2 cells during the convalescent phase of infection. Certain BTMs (e.g., T/NK cells, B cells) were enriched and others (e.g., neutrophils) were less enriched in CHIKV vs. DENV and ZIKV infections. Comparison of transcriptomes among DENV, ZIKV and CHIKV provide biological insights into the transcriptional and signaling networks in arboviral infections that can be used to resolve pathogenic mechanisms.

1470

A PHASE 1, RANDOMIZED, OPEN-LABEL, SINGLE-CENTER COMPARISON OF HETEROLOGOUS PRIME-BOOST VACCINATION SCHEDULES OF TETRAVALENT DENGUE VIRUS PURIFIED INACTIVATED VACCINE (PIV) AND TETRAVALENT DENGUE VIRUS LIVE ATTENUATED VACCINE (LAV) IN HEALTHY ADULTS IN A NONENDEMIC REGION THROUGH 28 DAYS POST VACCINATION

Michael Koren, Simon Pollett, Keisha Akerele, Christine Lee, Kristin Mills, James Moon, Paul Keiser, Jack Hutter, Melinda Hamer, Justin Curley, Nathaniel Copeland, Mark Sanborn, Wiriya Rutvisuttinunt, Rafael De La Barrera, Richard Jarman

Walter Reed Army Institute of Research, Silver Spring, MD, United States

A heterologous prime boost vaccination regimen may offer protection from dengue infection, and be particularly useful in dengue naïve individuals. It has been previously shown that a purified inactivated tetravalent dengue vaccine (PIV) followed by tetravalent dengue live attenuated vaccine (LAV) was highly immunogenic and safe, and that a PIV-LAV administration schedule of 0-6 months resulted in superior immunogenicity when compared to a 0-1 month schedule. In order to evaluate expedited prime-boost dosing schedules, we compared a 0-3 month PIV/LAV to a PIV/LAV 0-6 month regimen. 20 healthy dengue naïve adults 18-42 years of age were enrolled per group. Results through 28 days post final vaccination are presented. Both vaccination schedules were tolerated without any serious adverse events or potentially immune mediated events. Most adverse events reported were either mild or moderate in severity. There was a trend towards increased reactogenicity in the 0-3 month vaccination group following LAV. Rates of fever (32% versus 25%), headache (53% versus 38%), myalgia (42% versus 18%), arthralgia (31% versus 0%) and rash (32% versus 25%) were all higher in the 0-3 month compared to the 0-6 month group. Both regimens resulted in robust increases in measurable dengue neutralizing antibody at 28 days following LAV with a trend towards higher neutralizing antibody GMT per serotype in the 0-3 month group compared to the 0-6 month group. Geometric mean titers per serotype ranged from 2056(DENV-3) to 4254(DENV-2) for 0-3 month group and 1633(DENV-3) to 3188(DENV-2) in the 0-6 month group. Tetravalent seroconversion rates were 95% (95% CI 74%-99%) in the 0-3 month group and 100% (95% CI 79% - 100%) in the 0-6 month group. RNAemia was common in both groups, with dengue serotype 2, dengue serotype 4 and dengue serotype 1 detected. This interim analysis suggests that an expedited 0-3 month prime-boost DENV vaccination schedule is as immunogenic and safe when compared to a 0-6 schedule, but may be associated with relatively higher rates of reactogenicity. Further evaluation of heterologous prime boost strategies for protection from dengue is warranted.

1471

MICROSCALE SPATIOTEMPORAL TRANSMISSION DYNAMICS OF DENGUE IN PUERTO RICO, 2009-2013

Carlos A. Moreno[1], Kyra H. Grantz[1], Michael Johansson[2], Derek A. Cummings[1]

[1]*University of Florida, Gainesville, FL, United States,* [2]*Centers for Disease Control and Prevention (CDC) Dengue Branch, San Juan, PR, United States*

Puerto Rico has experienced constant dengue outbreaks since the 1960s, making it a prominent hub for dengue circulation in the Americas. Control efforts to reduce mosquito populations or exposure to mosquitoes are resource intensive, and difficult to deliver to all locations at once. An improved understanding of the spatiotemporal distribution of dengue could help public health authorities improve the targeting of intervention resources. While previous studies have demonstrated fine-scale transmission within cities and in rural areas, these studies have been primarily focused in Southeast Asia. In this study we analyzed the fine-scale spatiotemporal dependence of dengue in Puerto Rico. The data were collated from ongoing passive surveillance conducted by the US Centers for Disease Control and Prevention (CDC). A total of 6149 confirmed infections were serotyped and geolocated between 2009-2013. We characterized the spatial dependence of homotypic cases, $\tau(d_1, d_2)$, as the odds that cases occurring within twenty-one days and a specified spatial window (d_1 , d_2) are homotypic, relative to the odds that cases are homotypic within twenty-one days regardless of spatial location. This statistic is robust to variable reporting and other latent spatial heterogeneities (e.g., population density, environmental conditions). We constructed the 95% confidence intervals by using the 2.5% and 97.5% percentiles of 1,000 bootstrap samples. Our results suggest that cases within 100m have 4.63 (95% confidence interval [CI] 3.74, 5.81) times higher odds of being homotypic relative to all cases occurring within twenty-one days. This estimate falls to 1.32 (95% CI 1.22, 1.43) times higher odds for cases within 750m to 1-km, but continues to remain statistically significant up to 4.7 km. These findings are consistent with highly focal transmission of dengue at less than 1-km scales. This finding is also consistent with estimates from other urban areas endemic for dengue.

1472

ASSESSING RISK FOR DENGUE LIVE ATTENUATED VACCINE VIRUS ANTIBODY DEPENDENT ENHANCEMENT IN INDIVIDUALS PRIMED WITH A PURIFIED INACTIVATED DENGUE VACCINE

Natalie D. Collins[1], Mark Sanborn[1], Shannon Walls[2], Jun Hang[1], Greg Gromowski[1], Michael Koren[1], Richard Jarman[1]

[1]*Walter Reed Army Insitute of Research, Silver Spring, MD, United States,* [2]*Walter Reed Army Insitute of Research, USAMRU-G, Silver Spring, MD, United States*

There are four genetically distinct dengue viruses (DENV), termed DENV-1, -2, -3 and -4 that can cause a wide spectrum of disease manifestations from mild infections to severe. It is hypothesized that the more severe presentations of dengue disease, including hemorrhagic fever and shock syndrome, are the result of antibody dependent enhancement (ADE), where antibodies generated against one DENV serotype can enhance a subsequent infection with a heterologous serotype. Speculation that vaccination with Dengvaxia may have led to cases of severe dengue disease due to ADE, necessitates further research into ADE assay development and correlation with clinical outcomes. Typically, *in vitro* assays utilized to evaluate vaccine-related ADE involves use cells that are not permissive to DENV infection, such as the myeloid lineage K562 cells that support infection by Fc-receptor mediated uptake of the DENV-

antibody complex. However, this K562 based assay has several limitations, and the considerable dilution required to decrease serum toxicity of the cells restricts accurate depiction of the immune state of vaccine recipients. This was demonstrated previously when, subjects vaccinated with formalin inactivated DENV vaccine (DPIV) had undetectable DENV-2 ADE in the traditional K562 cell-based assay with diluted immune sera, despite 46% of subjects developing DENV-2 viremia following a live attenuated DENV vaccine (TDENV) boost at 6 months post DPIV vaccination. Therefore, an ADE assay was developed utilizing BHK cells expressing Fc γRIIA (BHK-Fc γRIIA) in order to evaluate *in vitro* ADE at very low serum dilutions. The DPIV primed, 6 month TDENV boosted subjects were re-evaluated utilizing the BHK-Fc γRIIA based ADE assay and greater than 50% of subjects had significant DENV-2 enhanced virus replication. Association of the BHK-Fc γRIIA based ADE assay resluts with viremia and symptoms in these vaccine recipients will be described. The BHK-Fc γRIIA *in vitro* ADE assay will help advance our understanding of the biological significance of ADE in humans.

DISCOVERY OF EPITOPE BIOMARKERS FOR THE DIAGNOSIS OF DENGUE AND ZIKA VIRUS INFECTION

Volker Stadler[1], Felix Loeffler[2], Renate Sekul[1], **Kirsten Heiss**[1], Magelda Montoya Cruz[3], Josefina Coloma[3], Eva Harris[3]

[1]*PEPperPRINT GmbH, Heidelberg, Germany,* [2]*Max Planck Institute of Colloids and Interfaces, Potsdam, Germany,* [3]*University of California, Berkeley, CA, United States*

Infections with dengue (DENV) and Zika viruses (ZIKV), co-circulating in tropical and subtropical regions of the world, have become a thread to public health. Severe disease outcomes are associated with infections with all DENV serotypes and ZIKV, respectively. A precise and early diagnosis of these viruses, however, is hampered not only by similar clinical symptoms, but also by the serological cross-reactivity among ZIKV, DENV and flaviruses in general. Therefore, novel diagnostic tests are urgently needed to identify and discriminate co-circulating ZIKV and DENV particularly in the acute phase, and to predict severe disease outcomes. Instead of using full length proteins, we intended to screen for epitope biomarkers for the differentiation of antibody responses against flaviviruses, i.e. immunodominant ZIKV and DENV peptides that are not shared with other flaviviruses. We generated proteome-wide DENV and ZIKV peptide microarrays and screened them for IgG and IgM antibody responses with ~1000 plasma samples of patients with acute and convalescent infections with DENV serotypes 1, 2 and 3 and ZIKV. For DENV, we observed distinctive and shared antibody responses and applied machine learning to predict discriminative epitopes for acute and convalescent stage of infection, primary and secondary infection and subtypes, respectively. The proteome-wide ZIKV screening revealed a very strong and common epitope in NS2b in both the acute and convalescent phase of infection. A substitution analysis of this immunodominant ZIKV epitope highlighted discriminative amino acid positions that enable a specific diagnosis of ZIKV infections in the acute phase. The differentiation of ZIKV and DENV antibody responses on epitope instead of on protein level yielded a more comprehensive picture of DENV and ZIKV infections and peptide biomarkers for early ZIKV diagnosis as well as for DENV serotypes 1, 2 and 3. This work was supported by the U.S. Department of Homeland Security Science & Technology Directorate (Contract HSHQDC-15-C-B0010).

ANALYSIS OF ANTIBODIES INDUCED BY A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE IN CHILDREN WHO SUBSEQUENTLY EXPERIENCED DENGUE SEROTYPE 1 BREAKTHROUGH INFECTIONS

Sandra Henein[1], Matthew Boneparte[2], Ralph Baric[1], Aravinda de Silva[1]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*Sanofi Pasteur, Allentown, PA, United States*

Dengue is the most significant arboviral infection of humans. The four dengue virus serotypes (DENV1-4) are estimated to infect several hundred million people each year. Sanofi Pasteur developed a live attenuated tetravalent dengue vaccine (Dengvaxia) that has been licensed in several countries. In clinical trials, Dengvaxia efficacy varied by DENV serotype and the baseline DENV immune status of subjects. In particular, overall vaccine efficacy was lower in children who were DENV-naïve at baseline compared to children who were DENV-immune. Here we present a comparative analysis of the level and quality of serum antibodies in 1) 16 baseline DENV seronegative subjects who were vaccinated and subsequently experienced DENV1 breakthrough infections; 2) 11 baseline DENV seronegative subjects who were vaccinated and did not experience DENV breakthrough infections; 3) 10 healthy individuals who had been previously exposed to primary DENV1 infections. DENV neutralizing antibodies after primary infection are strongly correlated with long-term protection against disease caused by the homologous serotype. We observed that Dengvaxia induced moderate levels of DENV1 neutralizing antibodies (NAbs) that were comparable in groups 1 and 2 and lower than the levels in group 3. The DENV1 NAbs in groups 1 and 2 were mainly driven by DENV-serotype cross-reactive Abs. The absence of DENV1 type-specific NAbs in the vaccine groups is indicative poor replication of the DENV1 vaccine component. On the other hand, individuals who had recovered from primary DENV1 natural infections mainly developed DENV1 serotype-specific NAbs. Our findings are applicable to understanding vaccine efficacy and for identifying immune correlates for guiding vaccine development.

EVALUATION OF DUAL PLATFORM IMMUNIZATION APPROACH USING TETRAVALENT DENGUE DNA VACCINE AND TETRAVALENT INACTIVATED WHOLE VIRUS DENGUE VACCINES

Appavu K. Sundaram[1], Daniel Ewing[1], Zhaodong Liang[1], Maria Blevins[2], Josef Lassan[2], Jorge Requena[2], Kanakatte Raviprakash[1], Maya Williams[3], John W. Sanders[2], Kevin R. Porter[3]

[1]*Viral and Rickettsial Diseases Department, Naval Medical Research Center, Silver Spring, MD, United States,* [2]*Section on Infectious Diseases, Wake Forest School of Medicine, Winston-Salem, NC, United States,* [3]*Infectious Diseases Directorate, Naval Medical Research Center, Silver Spring, MD, United States*

Viral pathogens produce B- and T-cell responses through immune interactions with both pathogen-specific proteins and nucleic acid. The nucleic acid also works through interactions with Toll-like receptors. Therefore, we hypothesized that simultaneous administration of a DNA vaccine and a protein vaccine will elicit the broadest possible immune responses by stimulating different arms of the adaptive immune system. Hence, we evaluated the Dual Platform immunization (DuPl) approach in nonhuman primates by simultaneous administration of a tetravalent dengue DNA vaccine (TVDVs) and the chemically inactivated DENV vaccines. Highly purified (by chromatographic methods) monovalent vaccine lots of formalin-inactivated DENV 1-4 (FIVs) and psoralen-inactivated DENV 1-4 (PsIVs) were prepared and tetravalent FIV and PsIV vaccines were prepared by combining the respective monovalent vaccines. Mice were immunized twice with either monovalent or tetravalent vaccine formulation. Immunogenicity of the tetravalent dengue PsIVs and FIVs was also evaluated in nonhuman primates along with the evaluation

of the DuPI immunization approach, which involved the simultaneous administration of TVDVs with either the tetravalent dengue FIVs or PsIVs. In mice, the DENV PsIVs elicited higher titers of DENV neutralizing Abs than the FIVs and the Ab profiling of sera samples with DENV3 and DENV4 proteome microarrays (PEPperMAP) confirms the better neutralizing antibody response from PsIVs over the FIVs. The tetravalent vaccines produced the same neutralizing antibody pattern (PsIV > FIV) in nonhuman primates as well. Although addition of TVDV to FIV enhanced the neutralizing Ab response, addition of TVDV to PsIV did not improve the immune response. Interestingly, PsIV by itself elicited the best neutralizing Ab response of all the groups tested. These results suggest that psoralen-inactivation (acting at nucleic acid level) of DENV preserves the native conformations of surface proteins important for protective immune responses and is better suited for eliciting DENV-neutralizing Abs.

Zika virus (ZIKV) infection became a worldwide public health concern due to its association with microcephaly and congenital malformations in infants born to infected mothers. After its introduction in 2015, Honduras had a dramatic increase of newborns with microcephaly. We describe a case where we detected/sequenced a viral isolated collected from the amniotic fluid of a fetus with microcephaly. The pregnant mother exhibit ZIKV-associated symptoms as myalgia, arthralgia, rash and joint inflammation at 7 weeks of gestation (January-2016). At the first-trimester of gestation, the ultrasonography was normal. At 22 weeks (May-2016), ultrasound revealed signs of cerebral malformation in the fetus with bilateral ventriculomegaly, microcephaly, rhomboencephalosynapsis and arthogryposis. At 23 weeks, amniotic fluid was collected. The fluid, which may contain viral particles and/or genetic material, was filtrated/concentrated. Viral-RNA was extracted at UNAH. The amniotic fluid was ZIKV positive by qRT-PCR (Lanciotti et al.-2008). Partial-genome-sequencing was done using targeted next-generation-sequencing with Ion-Torrent/Illumina technology at the J. Craig Venter Institute, La Jolla, CA, USA. The baby was born alive and diagnosed with congenital Zika syndrome. We detected ZIKV-RNA in the amniotic fluid. Subsequently, sequence-analysis revealed that this Honduran ZIKV isolate had the point-mutation S139N in the prM-region recently associated with fetal microcephaly by others. The signs of cerebral malformation in the fetus, could be expected to contribute to severe developmental difficulties in the baby. These findings strengthen the reports of the capability of ZIKV to cross the placental barrier and its association with neurological damage in fetus. Also highlights the value of molecular testing in the diagnosis of ZIKV during pregnancy. More studies are needed to determine the number of microcephaly cases that contain this point-mutation and its role in the severity in congenital Zika syndrome.

Dengue virus (DENV) severe infections are characterized by increased vascular permeability and hemorrhagic manifestations. Despite its substantial morbidity and mortality, no therapeutic agents exist for treatment of dengue, and the currently available vaccine does not confer full protection. Thus, development of therapeutic and/or preventive drugs is urgently needed. Nonstructural protein 1 (NS1) plays important roles in host immune evasion and viral pathogenesis by directly triggering endothelial barrier dysfunction and inducing inflammatory responses, contributing to vascular leak *in vivo*. Here we evaluated the *in vitro* and *in vivo* efficacy of the (1-6,1-3)-β-D-glucan isolated from *Agaricus brasiliensis* fruiting bodies (FR) and its sulfated derivative (FR-S) against DENV infection and DENV NS1-mediated pathogenesis. FR-S, but not FR, significantly inhibited DENV2 (strain N172-06) replication in human monocytic U937-DC-SIGN cells (EC_{50}=30.5 μg/mL) when added simultaneously with viral infection. No inhibitory effect was observed when FR or FR-S were added 1 hour post-infection, indicating viral entry inhibition as the main mechanism of action of FR-S. In an *in vitro* model of endothelial permeability, FR (0.25 ug/mL) significantly inhibited Trans-Endothelial Electrical Resistance (TEER) reduction (>50%) induced by DENV2 NS1 treatment of human pulmonary microvascular endothelial cells (HPMECs), while FR-S displayed 100% efficacy in blocking TEER reduction at 0.12 ug/mL. Confocal microscopy indicated 64 and 73% inhibition of DENV NS1 binding to HPMECs by treatment with 0.25ug/mL of FR and FR-S, respectively. Further, FR-S significantly reduced (42%, p=0.048) hyperpermeability in mouse skin induced by DENV2 NS1 injected intradermally into wild-type mice (C57BL/6). In summary, we demonstrate FR-S efficacy against DENV infection *in vitro*, as well as against NS1-induced endothelial disruption *in vitro* and permeability *in vivo*. The findings stimulate further exploration of FR-S and other glycan candidates for dengue treatment alone or as combination therapies with compounds with different mechanisms of action.

For many currently licensed vaccines and natural infections, antigen-specific antibody (Ab) neutralization titers are used as a correlate of protection. In our long-standing cohort study of dengue in Nicaragua, we have shown that pre-infection dengue virus (DENV) neutralizing Abs play an important role in protection against symptomatic infection, while low pre-existing Ab titers can enhance dengue disease severity. Beyond antigen-specific Ab titers and neutralization, Abs can confer protection or mediate risk through multiple other mechanisms. The role of Fc effector

function in dengue has not been systematically investigated and is a critical gap in knowledge. We investigated antibody-dependent cellular phagocytosis (ADCP) and antibody-dependent neutrophil activation/phagocytosis (ADNP) in pre-infection sera from 35 inapparent and 36 symptomatic DENV infections in our Nicaraguan pediatric cohort study. Fluorescent beads were labeled with DENV2 and DENV3 virions and recombinant envelope (recE), incubated with test sera and then THP-1 monocytic cells or primary neutrophils, and analyzed by flow cytometry. Significant differences between pre-inapparent and pre-symptomatic infections were observed in ADCP (p=0.0007) and ADNP (p=0.01) for DENV3 but not DENV2 recE-coated beads. When analysis was restricted to DENV3 inapparent (n=10) and symptomatic (n=30) infections, significant differences in ADCP were maintained (p<0.001). Thus, Fc-effector profiles indicate that differential monocyte phagocytosis tracks with inapparent DENV infection. Currently, pre-infection sera from symptomatic vs. inapparent DENV1 and DENV2 infections, as well as from DF vs. DHF/DSS cases, are being analyzed via multiplexed Fc biophysical profiling (e.g., subclass, glycosylation variants, interaction with innate immune Fc receptors, lectin-like molecules, and complement) and a larger panel of cell-based assays to measure Fc effector function. Antigens include Nicaraguan DENV viruses, recE, stabilized E homodimers, E domain III, and NS1 from DENV1-4 and Zika virus. This work addresses the critical role of Ab Fc functionality in dengue.

Clinical trials of vaccines and controlled Human Infection Models (CHIMs) play an important role in determining the safety and efficacy of future dengue vaccines. Viremia is used to evaluate safety, infectivity, and efficacy of a vaccine or challenge strain. It is measured by viral amplification in cell culture (VAC) or by a more sensitive assay, qRT-PCR. Our aim was to determine if vaccine viremia can be detected in volunteers with previous exposure to dengue. Since vaccination with the NIH live attenuated tetravalent (serotypes DENV1-4) vaccine causes low-level viremia in naïve volunteers by culture, we hypothesized that dengue-exposed volunteers would only have vaccine -induced viremia for the serotypes for which they had not been previously exposed. To address this, we evaluated the NIH TV005 dengue vaccine in a Phase II trial in Dhaka Bangladesh for post-vaccine viremia by VAC and real-time qRT-PCR at days 7 and 14. Dengue seropositivity was defined as a Plaque Reduction Neutralization Titer ($PRNT_{50}$) of ≥ 10 against any serotype from pre-vaccination serum. A serotype was determined dominant as follows: serotype was the only one with $PRNT_{50}$ ≥ 10 or $PRNT_{50}$ ≥ 4 fold higher than the next highest serotype titer. VAC-positive post-vaccination viremia for any serotype was low; detected in 4/72 (5.6%) subjects: 4/30 (13%) naïve and 0/30 dengue-exposed. by PCR, viremia was detected in 46/72 (65%) subjects, 23/30 (77%) naïve and 23/42 (55%) exposed. Only serotypes to which the volunteers did not have prior exposure were detected by PCR. Among subjects for whom DEN1 was the dominant previous exposure serotype, post-vaccination viremia was found for DEN3 1 of 2 (50%), and DEN4 2/2 (100%). Similarly, for DEN2 previous exposure, PCR was positive for DEN3 5/8(63%) and DEN4 4/8 (50%). For DEN3 as the dominant previous exposure, viremia was found for DEN2 1/6 (17%) and DEN4 3/6 (50%). In previously exposed volunteers, there was no evidence of enhanced viremia. Since PCR is more sensitive than VAC, these data support the addition of genomic methods to detect vaccine viremia in vaccine trials and as an appropriate efficacy trial endpoint in experimental challenge models.

TYPE-SPECIFIC AND CROSS-REACTIVE B CELL RESPONSES ELICITED BY A LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE

Daniela Michlmayr[1], Paulina Andrade[1], Parnal Narvekar[1], Mayuri Sharmna[2], Hansi Dean[3], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Vaccines Business Unit, Takeda Pharmaceuticals Inc., Cambridge, MA, United States,* [3]*Vaccines Business Unit, Takeda Pharmaceuticals Inc., Cambridge, MA, United States*

Dengue is caused by four antigenically distinct serotypes of dengue virus (DENV-1-4). Takeda's live attenuated tetravalent dengue vaccine candidate (TAK-003) is composed of an attenuated DENV-2 (TDV-2) and chimeric viruses containing prM and E genes of DENV-1, -3 and -4 on the DENV-2 genomic backbone. An effective dengue vaccine should elicit immune responses to all four DENV serotypes. Binding and neutralizing antibodies to DENV-1-4 after natural infection or vaccination can be quantitated; however, these assays cannot distinguish between type-specific (TS) and cross-reactive (CR) antibodies. A Multi-Color FluoroSpot assay has been developed to enable quantitation of serotype specificity and cross-reactivity of individual memory B cells (MBCs) secreting DENV-specific antibodies. We determined the frequency of TS and CR MBCs in 15 randomly selected individuals who received a single TAK-003 vaccination in a Phase 2 trial in Singapore (DEN-205). Peripheral blood mononuclear cells collected on days 0, 30 and 180 post-single-dose TAK-003 vaccination were tested. Eight individuals were seronegative for dengue prior to vaccination, and 7 had evidence of prior immunity to at least one DENV serotype. Pre-existing MBC responses were only detected in pre-immune vaccinees at day 0. Following vaccination, both TS and CR MBCs to all four DENV serotypes were observed in all individuals, in whom the proportion of TS MBCs was higher than CR MBCs and remained stable between days 30 and 180 post-vaccination. The pattern of TS MBCs following TAK-003 vaccination was distinct from natural DENV infection; tetravalent vaccination elicited tetravalent TS MBCs, while primary natural DENV infection elicits monovalent MBCs, and the ratio of TS to CR MBCs was higher following vaccination. These results demonstrate that all four antigen components of TAK-003 contribute to the DENV-specific MBC response following vaccination.

Dengue virus (DENV) belongs to the flavivirus family of arboviruses, which have a long-standing history of causing human disease. There are several live-attenuated vaccines against DENV in phase 3 clinical trials and a recently licensed one. Unfortunately, the licensed DENV vaccine showed low efficacy in DENV-naïve individuals (and even enhancement of disease). Interestingly, the vaccine efficacy was markedly improved in the presence of cross-reactive flavivirus antibodies in pre-immune individuals. Hence, a better understanding of how pre-existing immunity modulates protective mechanisms is important to improve and assess the immunogenicity of vaccines currently under development. Pre-existing cross-reactive

antibodies have the potential to shape both antigen-recognition and effector functions of vaccination-induced humoral response through Fcγ-receptor (FcγR) mediated signaling. Therefore, to characterize the role of pre-existing DENV antibodies in modulating immune responses to a subsequent heterotypic DENV infection, our group recently enrolled both primary and secondary DENV infected patients (with serotype 2) from an adult Singaporean population. Patients were followed up for one year, with blood sampling at 4, 6 and 12 months. We then conducted a series of serological assays to profile both the antigen-recognition properties (such as IgG antibody titers, neutralization, avidity) and effector properties (IgG subclassed, antibody-dependent cellular phagocytosis and antibody-dependent cellular cytosis) of the polyclonal response to the most recent DENV infection, which in this study was DENV2. We observed that the presence of cross-reactive antibodies significantly affected both antigen-recognition properties (such as antigen binding, neutralization and affinity) as well as effector properties. Our current work provides additional insight into protective mechanisms following flaviviral vaccination, particularly in the presence of pre-existing immunity, and may improve current flaviviral vaccine regimens.

EVOLUTION AND EPIDEMIOLOGIC DYNAMICS OF DENGUE VIRUS SEROTYPES IN NICARAGUA DURING THE EMERGENCE OF CHIKUNGUNYA AND ZIKA VIRUSES

Sean V. Edgerton[1], Chunling Wang[2], Panpim Thongsripong[1], Saira I. Saborio[3], Magelda Montoya[2], Josefina Coloma[2], Angel Balmaseda[3], Eva Harris[2], Shannon N. Bennett[1]

[1]*California Academy of Sciences, San Francisco, CA, United States,* [2]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [3]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministry of Health, Managua, Nicaragua*

Arthropod-borne viruses (arboviruses) comprise a significant and ongoing threat to human health, infecting hundreds of millions annually. Three such arboviruses include the circumtropical dengue, Zika, and chikungunya viruses. All three viruses continue to emerge geographically along with their same urban domestic *Aedes* mosquito vector. Nicaragua has experienced endemic dengue virus (DENV) transmission involving multiple serotypes since the mid 1990s; chikungunya virus (CHIKV) was first reported in 2014, followed by Zika virus (ZIKV) first reported in 2016. In order to identify patterns of genetic variation and selection pressures shaping the evolution of co-circulating DENV serotypes preceding and in light of the arrival of CHIKV and ZIKV, the latter of which is a close relative and known to interact with DENV at a population level via the host immune response, we employed whole-genome sequencing on an Illumina MiSeq platform of random-amplified total RNA libraries to characterize 45 DENV isolates collected from viremic patients in Nicaragua between 2013 and 2016. Our approach also revealed clinically undetected co-infections with both CHIKV (8) and ZIKV (1). Of the three DENV serotypes (1, 2, and 3) co-circulating during our study, we uncovered distinct patterns of evolution using comparative phylogenetic inference. DENV-1 genetic variation was structured into two distinct co-circulating lineages with no evidence of positive selection in the origins of either lineage, suggesting that they are equally fit. In contrast, evolutionary history of DENV-2 was marked by positive selection, and a unique, divergent lineage correlated with high epidemic potential that emerged in 2015 and drove an outbreak in 2016. DENV-3 genetic variation remained unstructured into lineages throughout the period of study. This study reveals insights into evolutionary and epidemiologic trends exhibited prior to and during the circulation of multiple arboviruses in Nicaragua.

SUSTAINABLE, HEALTHY CITIES: PROTOCOL OF A MIXED METHODS CLUSTER RANDOMIZED CONTROLLED TRIAL FOR *AEDES* CONTROL IN BRAZIL

Kate Zinszer[1], Andrea Caprara[2], Antonio Lima[3], Monica Zahreddine[1], Kellyanne Abreu[2], Mabel Carabali[4], Beatriz Parra[5], Beatriz Parra[5], Neil Andersson[4], Valery Ridde[6]

[1]*University of Montreal, Montreal, QC, Canada,* [2]*Universidade Estadual do Ceará, Fortaleza, Brazil,* [3]*Fortaleza Public Health Department, Fortaleza, Brazil,* [4]*McGill University, Montreal, QC, Canada,* [5]*Universidad del Valle, Cali, Colombia,* [6]*Research Institute for Sustainable Development, Paris, France*

Dengue is increasing in its global presence with an estimated 4 billion people at-risk of infection in at least 128 countries. The only preventive measure of dengue infection is through mosquito vector control and there is increasing resistance to insecticides and larvicides and growing evidence of their negative environmental and health impact. In a context of sustainable healthy cities promoted the sustainable development goals, environmentally friendly approaches to *Aedes* control are needed to attain permanent reductions in mosquito populations. Despite the promising results of EcoHealth and community mobilization approaches for *Aedes* reduction, more evidence of their efficacy on reducing dengue risk is needed. The principal research question is to determine if interventions based upon community mobilization reduce the risk of dengue virus infection among children 3 to 9 years old compared to usual dengue control practice in Fortaleza, Brazil. The present study is a pragmatic cluster RCT design with randomization at the census tract level with equal allocation to the two arms. There will be 34 clusters in each arm of 80 children between 3 to 9 year olds for an expected total of 5,440 children enrolled in the study. Household visits will occur every six months for a total of six visits over a 3 year period to cover both dry and rainy seasons. Following allocation, community mobilization activities will begin. There will be qualitative studies included within the cRCT to evaluate the process, acceptability, fidelity, and sustainability of the intervention. Baseline results will be available by November 2019. The results of our study will provide evidence on community mobilization as an intervention for dengue control. Our study contains several innovative aspects including embedded qualitative research and a biomarker of individual exposure to *Aedes* saliva. We anticipate that if community mobilization is effective in Fortaleza, through broad and active dissemination, the results of this study will help develop evidence-based vector control programs in Brazil, and also in other countries struggling with *Aedes*-transmitted diseases.

ANALYSIS OF THE POST-VACCINATION ANTIBODY RESPONSE OF DENGUE SEROTYPE 2 BREAKTHROUGH INFECTIONS

Usha Nivarthi, Emily Gallichotte, Matt Delacruz, Mathew Boneparte, Ralph Baric, Aravinda de Silva

University of North Carolina, Chapel Hill, NC, United States

The four serotypes of dengue virus (DENV1-4) are estimated to cause 390 million infections annually, mostly in the tropical and subtropical regions of the world. Sanofi Pasteur developed a live attenuated tetravalent dengue vaccine, (Dengvaxia) that was tested in two large phase III trials (CYD14/15) in Asia and Latin America before it's licensure in 2015. Overall vaccine efficacy was 22% and 78% in children who were dengue seronegative and seropositive at baseline, respectively. Moreover, vaccine efficacy varied by DENV serotype and the lowest efficacy was observed against DENV2. Using methods to deplete specific populations of DENV binding antibodies as well as recombinant chimeric DENVs displaying epitopes of interest, we characterized the level and quality of vaccine-elicited serum antibodies in naïve and pre-immune individuals who subsequently experienced DENV2 breakthrough infections. Dengvaxia failed to induce DENV2 serotype-specific (TS) neutralizing antibodies in the majority of subjects who experienced breakthrough infections. The absence of DENV2 TS neutralizing antibodies is indicative of limited if

any replication of the DENV2 vaccine component in these individuals. As antibodies that develop after primary WT DENV2 infection are strongly correlated with long-term protection against DENV2, we compared vaccine induced antibodies in DENV2 breakthrough cases to antibodies in people who had recovered from primary DENV2 infections. Unlike in the case of vaccine breakthrough cases, all individuals exposed to primary WT DENV2 infections had high levels of DENV2 TS binding and neutralizing antibodies. We discuss the implications of our results for understanding vaccine efficacy and for identifying immune correlates to guide vaccine development.

1485

A COMBINATION OF INCIDENCE DATA AND MOBILITY PROXIES FROM SOCIAL MEDIA PREDICTS THE INTRA-URBAN SPREAD OF DENGUE IN YOGYAKARTA, INDONESIA

Aditya L. Ramadona[1], Yesim Tozan[2], Lutfan Lazuardi[3], Joacim Rocklöv[1]

[1]*Department of Public Health and Clinical Medicine, Section of Sustainable Health, Umeå University, Umeå, Sweden,* [2]*College of Global Public Health, New York University, New York, NY, United States,* [3]*Department of Health Policy and Management, Faculty of Medicine, Universitas Gadjah Mada, Yogyakarta, Indonesia*

Few studies have investigated the potential of using geotagged social media data for predicting the patterns of spatio-temporal spread of vector-borne diseases. We herein demonstrated the role of human mobility in the intra-urban spread of dengue by weighting local incidence data with geo-tagged Twitter data as a proxy for human mobility across 45 neighborhoods in Yogyakarta city, Indonesia. To estimate the dengue virus importation pressure in each study neighborhood monthly, we developed an algorithm to estimate a dynamic mobility-weighted incidence index (MI), which quantifies the level of exposure to virus importation in any given neighborhood. Using a Bayesian spatio-temporal regression model, we estimated the coefficients and predictiveness of the MI index for lags up to 6 months. We used a Poisson regression model with an unstructured spatial covariance matrix and compared the predictability of the MI index to that of the dengue incidence rate over the preceding months in the same neighborhood (autocorrelation) and that of the mobility information alone. We based our estimates on a volume of 1·302·405 geotagged tweets (from 118·114 unique users) and monthly dengue incidence data for all study neighborhoods in Yogyakarta city from August 2016 to June 2018. The MI index, as a standalone variable, had the highest explanatory power for predicting dengue risk in the study neighborhoods, with the greatest predictive ability at a 3-months lead time. The MI index was a better predictor of dengue risk in a neighborhood than the recent transmission patterns in the same neighborhood or the mobility patterns between neighborhoods. Our results suggest that human mobility is an important driver of dengue spread within cities when combined with information on local circulation of the dengue virus. The geotagged Twitter data can provide important information on human mobility patterns to improve our understanding of the direction and risk of spread of diseases, such as dengue. The proposed MI index together with traditional data sources can provide useful information for the development of more accurate and efficient early warning and response systems.

IDENTIFYING DENGUE ILLNESS PHENOTYPES USING LATENT TRAJECTORY ANALYSIS

Robert C. Reiner[1], William Elson[2], Gonzalo Vazquez-Prokopec[3], John Elder[4], Valerie Paz-Soldan[5], Alan Rothman[6], Amy Morrison[7], Thomas Scott[7]

[1]*University of Washington, Seattle, WA, United States,* [2]*University of California Davis, Lima, Peru,* [3]*Emory, Atlanta, GA, United States,* [4]*San Diego State University, San Diego, CA, United States,* [5]*Tulane, New Orleans, LA, United States,* [6]*University of Rhode Island, Kingston, RI, United States,* [7]*University of California Davis, Davis, CA, United States*

Dengue is an acute febrile illness lasting 4-7 days typically accompanied by headache and musculoskeletal pain, which is caused by any of the four serotypes of dengue virus (DENV). It has been increasingly recognized that individuals infected by DENV display a much greater variation in clinical manifestations and evolution of symptoms over time than is captured by classical descriptions. However, efforts to classify this spectrum of illness have been limited by a lack of individual-level data over the course of illness. We leveraged a detailed dataset from Iquitos, Peru of 423 surveys of the intensity of 12 dengue-related symptoms on 79 subjects with PCR-confirmed DENV infections to identify distinct clinical phenotypes of dengue-related illness. Using a multidimensional, spline-based finite mixture model that accounted for a varying number of repeated observations within each individual, we identified 4 latent classes of dengue illness, each corresponding to a unique temporal trajectory across symptoms. In particular, one phenotype clustered all individuals who experienced a resurgence across numerous symptoms in the second week of illness. Beyond also identifying which symptoms are most predictive of overall illness phenotype, our modeling approach also identified how much data is needed before an individual's illness can be classified as one phenotype or another. A well described phenomenon associated with some moderate to severe dengue is a clinical deterioration at around 7 days despite an earlier ebb in symptoms; improving our ability to predict which individuals are most likely to develop severe dengue would afford health care personnel additional time to more adequately treat these patients. Moreover, though the detailed data we used in this analysis is relatively rare due to the resource-intense nature of its collection, our modeling approach should be applicable more broadly to instances where individual-level data on a number of symptoms is collected repeatedly across the duration of an illness.

DENGUE AS A CAUSE OF NON-MALARIAL FEBRILE ILLNESS IN SOUTHWEST UGANDA

Ross Mathew Boyce[1], Matthew C. Collins[2], Rabbison Muhindo[3], Regina Nakakande[3], Emily Ciccone[1], Samantha Grounds[1], Matte Michael[3], Moses Ntaro[3], Dan Nyehange[4], Edgar Mulogo[3], Jonathan J. Juliano[1]

Despite being endemic in over 100 countries, there is little consensus regarding the incidence and geographic distribution of dengue in sub-Saharan Africa. However, the indirect evidence for the presence of endemic dengue transmission in many countries, including Uganda, is strong. Given the lack of reliable diagnostic tools and non-specific nature of symptoms, dengue fever may be misdiagnosed as malaria, contributing to unnecessary antimalarial administration and overestimation of the malaria burden. Therefore, we conducted a prospective cohort study to determine if dengue was unrecognized cause of febrile illness among pediatric outpatients (age <18 years) presenting to three health facilities located in areas of differing urbanicity and malaria transmission intensity in southwestern Uganda. After consent was obtained, eligible children were screened for malaria with a HRP-2 based rapid diagnostic test (RDT). Individuals with a positive result were excluded from further consideration, while those with a negative malaria test underwent additional testing with a dengue RDT (Dengue Duo, SD Bioline). Blood spots were collected for serological testing and participants at the referral hospital in Mbarara had serum collected for RT-PCR (Real Star, Altona Diagnostics). In total, we screened 1,705 children (median age 5 years, IQR 2-10). Overall, 371 (21.8%) had a positive malaria RDT result, which varied from 33.9% of children at the rural site in Bugoye to 3.7% of children at the urban site in Mbarara. Only 7 (0.04%) children had a positive dengue RDT, including 3 with a positive IgM band, 3 with a positive IgG band, and 1 with both

IgM and IgG bands. Serological testing identified 21 (3.3%) children with a reactive IgG antibodies. Notably, 15 of the 21 positives occurred at the urban site in Mbarara, where the prevalence was 7.7% (95% CI 4.7 - 12.2) of participants. All samples (n=196) tested negative for dengue virus by RT-PCR. These results suggest that dengue is not a common cause of febrile illness in southwestern Uganda. However, the relatively high seroprevalence at the urban site suggests that sustained, low-level transmission is occurring.

DENGUE VIRUS DEFECTIVE INTERFERING PARTICLES IN MOSQUITOES

Leon E. Hugo[1], Melissa C. Graham[1], Malik Hussain[2], Kym Lowry[2], Gregor J. Devine[1], John G. Aaskov[2]

[1]*QIMR Berghofer Medical Research Institute, Herston, Australia,* [2]*Institute of Health and Biomedical Innovation, Queensland University of Technology, Herston, Australia*

Defective Interfering Particles (DIPs) are naturally occurring particles of RNA and DNA viruses that are missing large (90-99%) and essential portions of the parent virus genome. DIPs are non-pathogenic and can only be replicated in the presence of full-genome virus but can inhibit parent virus replication at high abundances. DIPs are therefore being developed as novel antivirals against RNA viruses, including Influenza. DIP genomes also naturally co-evolve with the parent virus, therefore DIP-based therapies would not be prone to the development of resistance. Dengue virus DIPs have been isolated from patient sera but not previously from mosquitoes and the role that mosquitoes would play in DIP therapies against dengue or other vector-borne diseases is unknown. Here, we present entomological investigations into the involvement of mosquitoes in a potential DIP therapy against dengue as part of the DARPA INTERfering and Co-Evolving Prevention and Therapy (INTERCEPT) program. We developed a DIP detection system in which mosquitoes are orally challenged with dengue virus via glass membrane feeders, incubated for 14 days and DIPs detected in bodies, legs and wings and saliva by RT-PCR, cloning and sequencing. We show that DIPs do infect mosquitoes and accumulate within mosquito tissues to form large populations with a high diversity of RNA sequence forms (30-58 variants identified per serotype for DENV-2 and DENV-3). We identified variants in mosquitoes that have been previously isolated from patient sera. Importantly, we also isolated DIPs from mosquito saliva, demonstrating that DIPs can be transmitted to new hosts. We present the results from systematic experiments testing the antiviral efficacy of specific DIPs by administering the DIP or DIP RNA to virus-challenged mosquitoes. Mosquitoes are likely to be active participants in DIP based therapeutic strategies against DENV and may even play a role in community dissemination of DIP-based antivirals.

SEROLOGICAL SCREENING FOR INAPPARENT FLAVIVIRUS INFECTION IN U.S. TRAVELERS

Mariam Goreish, Lillian Chen, Daniel Espinoza, Yerun Zhu, Matthew H. Collins

Emory University, Decatur, GA, United States

Flaviviruses are a group of mosquito-borne viruses that can cause symptoms ranging from mild to severe. Dengue (DENV) and Zika (ZIKV) viruses are two medically important flaviviruses, and recent epidemics have demonstrated how viruses can be introduced into new populations. These introductory events are facilitated by marked rises in international travel in recent times. Additionally, travelers from the US and Europe are increasingly traveling to destinations in the tropics where many flaviviruses are endemic. Travelers constitute an important subpopulation for surveillance of emerging and global infections. Data on travel-related infections enable clinicians to properly advise travelers. Additionally, this population can serve as a sentinel for potential spread of infectious diseases into new areas. Finally, robust surveillance of travel-related infection can supplement public health activities in travel destination sites, where surveillance systems may not be well developed. For flaviviruses such as DENV, the majority of infections are inapparent. Thus, surveillance that focuses on symptomatic presentations will at best capture a minority of travel-related infections. We conducted a pilot study in a busy travel medicine clinic to recruit international travels and serologically assess for interval flavivirus infection by testing paired pre and post travel specimens. Fifty patients were enrolled. No subjects reported an acute febrile illness consistent with flavivirus infection during or within 1 month of travel. Eleven (22%) had detectable DENV IgG by antigen capture ELISA prior to travel. Most (87.5%) of DENV positive specimens were also ZIKV IgG positive. Of the flavivirus IgG positive subjects, 44% reported some history of vaccination. Two subjects exhibited seroconversion to DENV, one of which did not receive yellow fever vaccine and tested negative for ZIKV IgG. Our pilot suggests that the incidence DENV infection could be captured by serologic surveillance. A larger sample size and more specific assays could clarify the true epidemiology of inapparent flavivirus infection in travelers.

Arthropod-borne viruses (arboviruses) are among the most rapidly emerging infectious diseases globally. However, quantifying their burden remains challenging due to the large proportion of asymptomatic infections. Here, we present preliminary findings from our population based studies conducted in Piedecuesta, Colombia between 2014 and 2017 around the time of chikungunya (CHIKV) and Zika (ZIKV) emergence. These studies included a baseline household-based cross-sectional serosurvey conducted among 1200 individuals in 2014, as well as a longitudinal cohort that enrolled 2400 participants between 2015-2017. The cohort study involved active fever surveillance (via a call center followed by medical care and blood sampling for febrile illnesses) as well as yearly visits in which a blood sample was collected. Serological testing was performed using a multiplex bead based immunoassay that simultaneously quantifies IgG against multiple arboviruses. This assay was validated using ~500 well characterized samples from the cohort study and shown to have good sensitivity and specificity for CHIKV, DENV and ZIKV. At baseline, 66.5% (95% CI= 64.6%-68.3%) of participants tested positive for IgG against dengue (1632/2453) and the age-specific seroprevalence was consistent with endemic circulation of this flavivirus. Throughout 4.983person-years of follow-up, there were 860 incident cases of febrile illness, including 16 cases of DENV, 18 cases of CHIKV, 87 cases of ZIKV and 19 cases of unspecified-flavivirus confirmed by PCR and/or serology. Preliminary results suggest that the attack rates of the CHIKV (2014/2015) and ZIKV (2016) outbreaks were 22% (95% CI= 18.7%-26.1%) and 34% (95%CI=30%-38%) respectively. The dengue seroconversion rate between 2016 to 2017 was 6% (95% CI=2.4%-11.9%). We estimate that 43% of chikungunya infections and 30% of Zika infections were symptomatic. Additional analyses will evaluate risk factors associated with infection and disease. In particular, we will explore whether prior exposure to DENV modified the risk and/or outcome of ZIKV infection during the 2016 outbreak, as has been suggested in other settings.

Epidemiological findings on longer duration per epidemic wave and higher transmission intensity were strongly associated with increasing cases of dengue hemorrhagic fever (DHF) in Tainan in 1998 and in Kaohsiung in 2001-2002. Additionally, genetic and phenotypic variants of dengue virus (DENV) with higher replication, transmissibility, and selection advantages were identified in dengue clusters during later periods of the epidemics. Therefore, geographic information system (GIS) has applied from surveillance though epidemiologically spatial-temporal data analyses and policy evaluation to minimize dengue clusters. As southern Taiwan with tropical climate facilitating dengue vectors of *Aedes aegypti* and *Aedes albopictus* had the largest and most severe epidemics of dengue in Tainan and Kaohsiung in 2015. Since then, a community-based integrated surveillance informatics system was designed involving clinical syndromic surveillance, virological surveillance, serological surveillance, mosquito surveillance, environment surveillance, and all important risk factors identified from epidemiological investigations (such as lower land levels associate with flood, past outbreak areas with mosquito-breeding sites, rainfall etc.). Once the surveillance indices or risk factors were above the thresholds or with warning signs, health education and community-based mosquito source reduction campaign were immediately implemented. As Taiwan had the oldest severe and fatal dengue cases caused by serotype 2 (DENV-2), syndromic groups of dengue using age-stratified data from a local regional hospital and a medical center in Tainan showed that elderly over 65 years of age did have lower body temperature of fever. In addition, the syndromic groups of elderly with different comorbidities also varied. In conclusion, our successful experiences in starting from integrated public health informatics plus timely prevention and control of dengue can extend to many dengue-epidemic or endemic countries/areas worldwide.

FLAVIVIRUS ANTIBODY SCREENING ASSAY UTILIZATION FOR DIFFERENTIATION OF FLAVIVIRUS-NAÏVE AND EXPOSED SUBJECTS

Tim Powell[1], Melissa Zahralban-Steele[1], Ginger Young[1], Lydia Young[1], Kelly Bohning[1], Hetal Patel[1], Eric Shaw[1], Tim Betit[2], Laurie Stephen[3], Hansi Dean[1]

[1]*Takeda Vaccines, Cambridge, MA, United States,* [2]*Luminex Corp, Austin, TX, United States,* [3]*Ampersand Biosciences, Saranac Lake, NY, United States*

Flavivirus (FV) vaccine development is complicated by the continued spread of multiple flaviviruses (e.g. dengue, Zika, West Nile), and the complexity of determining flavivirus exposure history in clinical trials and preclinical studies. Here we describe the development and use of a simple, high throughput, rapid, and broadly reactive antibody screening assay to differentiate between flavivirus-naïve and previously exposed individuals. The FV antibody screening assay utilizes a multiplex Luminex® platform and includes envelope and/or NS1 antigens from dengue (all 4 serotypes), Zika, Japanese Encephalitis, West Nile, Yellow fever, St. Louis Encephalitis and Usutu viruses. The antigens were coupled to beads with unique fluorescent signals and the antigen sets optimized. The bead/antigen set are multiplexed and incubated with serum. IgG binding level to each antigen is assessed by the beads' fluorescent signal. Results from over 45 samples can be obtained in less than 5 hours. The FV screening assay was assessed using both non-human primate (NHP) and human samples with regard to background noise, naïve cutoff, and reactivity to known human positive serum. Naïve cutoff was determined using randomly selected human sera from Kansas. Assay positivity demonstrated the presence of flavivirus-reactive antibodies in a Midwestern population. Analysis of over 800 human and NHP samples revealed a wide spectrum of responses, and demonstrated that the FV assay is able to differentiate between pre-exposed and naïve subjects, and NHP responses to vaccination. Human samples were used to identify antigen cross-reactivity among the different flaviviruses. The FV screening assay demonstrated the capability of differentiating flavivirus-naïve from flavivirus-exposed subjects. Many antigens were shown to be cross-reactive, potentially allowing for a rapid, single test, and identification of a broad range of flavivirus exposures during pre-screening for both preclinical NHP studies and human vaccine and natural history studies.

1493

DECLINE IN MAGNITUDE OF ZIKA VIRUS-SPECIFIC LONG TERM MEMORY T-CELLS

Hannah Greig

University of Western Australia, Nedlands, Australia

The immune response to flavivirus infection may play roles in both protection and pathogenesis. Longer duration of pre-existing DENV immunity is associated with more severe disease outcomes. Recent studies indicate that long term DENV -specific T-cell immunity is associated with decline in proliferative and cytokine responses years to decades after infection. Prior flavivirus exposure is increasingly reported to also influence flavivirus-specific immunity, however most studies have focused on immune responses 1 month post-infection (MPI), and little is known about the effect months to years after infection. Using INFγ ELISpot and ZIKVPRVABC59-based peptides we measured ZIKV-specific T-cell responses in 8 individuals with monotypic ZIKV infection or ZIKV infection in the context of other flavivirus exposure (DENV infection; YFV vaccination), sampled between 9 and 42 MPI. Sequential samples were analysed in 4 individuals. A decline in magnitude of the ZIKV-specific IFNγ response was seen between 9 and 20 MPI (3 individuals) and 30 and 37 MPI (1 individual). A reduction in breadth of responses to ZIKV peptides was noted in 2 of the 4 individuals. For all 8 ZIKV-infected individuals the magnitude of the ZIKV-specific response was not associated with any high or low magnitude HLA alleles previously reported for DENV. ZIKV-infected subjects with prior flavivirus exposure had higher magnitude responses

to ZIKV peptides compared with ZIKV monotypic subjects, however the difference was not statistically significant. In summary, the frequency of ZIKV-specific IFNy-producing cells declines over time in the absence of re-exposure. Memory phenotype and cytokine profiles are currently being determined and will inform our understanding of long-term ZIKV-specific memory T-cell responses.

ESTIMATING JAPANESE ENCEPHALITIS BURDEN AND IMPACT OF VACCINATION

Tran Minh Quan[1], Nguyen Manh Duy[2], Tran Minh Nhat[2], Tran Thi Nhu Thao[3], **Hannah Clapham**[4]

[1]*Notre Dame University, South Bend, IN, United States,* [2]*Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam,* [3]*University of Bern, Bern, Switzerland,* [4]*University of Oxford, Ho Chi Minh City, Vietnam*

Japanese Encephalitis (JE) has wide spread transmission across Asia. Though most infections are asymptomatic, of patients who have clinical symptoms, a large proportion die or experience long-term disabilities. Humans are dead-end hosts for JE, with transmission from animal reservoirs such as pigs, via mosquitoes. There are a number of effective vaccines for JE, with countries such as Japan with long running vaccination programs seeing a dramatic reduction in cases; however the price has meant vaccination is of reach for many countries. The recently developed cheap and Gavi funded vaccine means vaccination is now a possibility for many more. Therefore now is the optimal time to assess the impact vaccination has had, and to quantify the disease burden across Asia to provide recommendations for future vaccination. In order to make these estimates, we undertook systematic reviews to find papers and surveillance data with case data with age information and with numbers who died or experienced disabilities. We fit a catalytic model to the age-stratified case data to estimate the transmission intensity for JE in these study locations. We then extrapolated transmission intensity to other locations using WHO area grouping, regression and machine-learning models using relevant co-variates such as climate and pig density. by applying this extrapolated transmission intensity to populations across Asia, and including information on vaccination in the model we made estimates of the number of JE infections with and without vaccination. We then used the detailed case data to update estimates of the morbidity and mortality rates, estimating that mortality rates are in fact decreasing over time. These estimates provide an update to the previously cited estimates, and an evidence base for these numbers. Combining our morbidity and mortality rates with our infection number estimates we estimated the number of deaths and DALYs due to JE across Asia with and without vaccination, and therefore impact of vaccination. With our new estimates of burden we highlight areas of high transmission that should be future targets for vaccination.

The recent outbreak of Zika virus (ZIKV) has highlighted the urgency of a vaccine but the close relationship with Dengue virus (DENV) can lead to immune cross-reactivity, with detrimental effects if it involves poorly neutralizing antibodies. In this work we developed and validated two vaccines based on a mutant E sequence that creates a disulphide bridge between DII of two interacting E proteins, stabilizing their dimeric conformation and abrogating trimerization. The generation of these covalent dimers (cvD) entails a double advantage: i) it reduces the exposure of immunodominant epitopes located on DI/DII, recognized by cross-reactive poorly neutralizing antibodies, and ii) it favors instead the display of Envelope Dimer Epitopes (EDE), hopefully overcoming the risk of Antibody-Dependent Enhancement (ADE) of other Flavivirus infection. We tested the immunogenicity of cvD both in form of soluble protein (sE-cvD) and incorporated in virus-like particles (VLP-cvD), in comparison with the wild-type counterparts. In both cases, the cvD mutation promoted the production of antibodies binding to E dimer with a good neutralizing capacity against ZIKV. Both vaccines fully protected the vaccinated mice from lethal challenge with no detectable viremia in blood and peripheral organs as brain, testis and ovaries. In vitro ADE assay showed that the cvD vaccines are less likely to enhance DENV infection compared to the WT. All together, these results suggest that ZIKV E covalent dimers are a promising element for an effective ZIKV vaccine.

PREGNANCY AND INFANT OUTCOMES POST-ZIKA VIRUS INFECTION IN NICARAGUA

Anna Gajewski[1], Oscar Ortega[1], Liliam Llufrio[1], Douglas Elizondo[1], Magelda Montoya[2], Damaris Collado[1], Anna Urbina[1], William Rivas[1], Guillermina Kuan[3], Angel Balmaseda[4], Eva Harris[2]

[1]*Sustainable Sciences Institute, Managua, Nicaragua,* [2]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [3]*Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua,* [4]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua*

The rapid spread of Zika virus (ZIKV) throughout the Americas has spurred interest in screening, diagnosis, and treatment for microcephaly, congenital hearing loss, and congenital ophthalmological issues, as well as other birth defects associated with Congenital Zika Syndrome (CZS). ZIKV was first detected in Managua, Nicaragua, in January 2016 and was followed by an explosive epidemic that peaked between July and September 2016. A cross-sectional seroprevalence study of ZIKV-related birth outcomes was conducted in 3 districts of Managua. Women who were pregnant before June 15, 2016, and who had a due date after September 15, 2016 (including miscarriage or stillbirth) and their infants were eligible for participation in the study. Mothers and infants provided a blood sample upon enrollment. These samples were tested for evidence of previous ZIKV infection using the ZIKV NS1 blockade-of-binding (BOB) assay. Infants were followed at 12 and 24 (ongoing) months of age and were screened for microcephaly, vision problems, hearing loss, and neurodevelopmental delays. A total of 615 women were enrolled, including 3 miscarriages, 2 stillbirths and 7 women whose children died between birth and the study visit. ZIKV seroprevalence is different across the 3 districts of Managua and an overall seroprevalence of ~50%, with 80% of the samples processed. Of the 478 children with a completed neurodevelopmental screening at 12 months, 50 (10.5%) were outside of the normal range in one or more areas. Follow-up assessment using the Bayley-III test confirmed delays in 15 (34%) of the 44 children who completed follow-up. Thirteen children had cerebral circumferences that were below the 3rd percentile; of those, 9 (69%) had abnormal results on the neurodevelopmental screening and abnormal follow-up results with the Bayley III. Ten children had abnormal ophthalmological findings that are associated with CZS. Our study found evidence of CZS-related disorders in a Central American population 12 months after the Zika epidemic. Analysis of the associations between these disorders and ZIKV seroprevalence in the mother is ongoing and will be reported.

1497

DENGUE VIRUS IMMUNE STATUS AND ANTIBODY TITERS AMONG ASYMPTOMATIC PREGNANT WOMEN DURING THE ZIKA OUTBREAK IN SALVADOR, BRAZIL

Kaitlin Driesse[1], Wen-Yang Tsai[1], Carlos Brites[2], Celia Pedroso[2], Wei-Kung Wang[1]

[1]*John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States,* [2]*LAPI-Laboratório de Pesquisa em Infectologia-School of Medicine, Federal University of Bahia, Salvador, Brazil*

The outbreak of Zika virus (ZIKV) and associated congenital Zika syndrome in dengue virus (DENV)-endemic regions raised questions about DENV immunity and ZIKV infection. Although DENV antibodies were found to enhance ZIKV infection *in vitro and in vivo*, two non-human primate studies reported conflicting results. Recent studies showed that preexisting high DENV antibody titers are associated with reduced risk of symptomatic ZIKV infection. Herein we investigated DENV antibody titers in non-ZIKV-infected individuals during the ZIKV outbreak in Salvador, Brazil. 120 serum samples collected from asymptomatic parturient women between Nov. 2015 and Dec. 2016 that tested negative by Euroimmun ZIKV non-structural protein 1 (NS1) IgG kit were analyzed. We employed combined DENV and ZIKV NS1 ELISAs to examine DENV and ZIKV serostatus (Tsai et al. Clin Infect Dis 2017;65:1829) and virion IgG ELISA to determine ELISA titers. Of the 120 samples, 20 were from primary DENV, 8 secondary DENV, 73 DENV (unclassified primary/secondary) infections, 1 primary ZIKV infection, 5 ZIKV with previous DENV infection and 13 naive. The DENV seroprevalence was 88.3% (106/120). A linear relationship was found between DENV and ZIKV ELISA endpoint titers. Higher endpoint titers to DENV and ZIKV were found in secondary DENV than primary DENV panels. The DENV ELISA endpoint titers of samples collected during the second period (22 Mar. 2016 - Dec. 2016) were higher than those during the first period (Nov. 2015 - 21 Mar. 2016) (P<0.0001). Our findings suggest that higher DENV antibody titers among ZIKV uninfected individuals may contribute to the decline of the ZIKV outbreak, though the underlying causes and mechanisms remain to be investigated.

1498

SURVEY FOR CELL FUSING AGENT VIRUS (*FLAVIVIRUS*) IN *AEDES AEGYPTI* MOSQUITOES FROM TEXAS, USA AND THE INFLUENCE ON ZIKA VIRUS VECTOR COMPETENCE

Estelle Martin, Selene Garcia-Luna, Jose Juarez, Megan Wise de Valdez, Ismael Badillo-Vargas, Gabriel Hamer

Texas A&M, College Station, TX, United States

The emergence and re-emergence of mosquito-borne diseases such as Zika, chikungunya and dengue fever remain a global public health challenge that threatens many communities in tropical and subtropical regions of the world. These viruses are driven principally by *Aedes aegypti* mosquitoes and naturally-occurring microbes are intrinsic factors that can influence the ability of mosquitoes to transmit viruses. Viral symbionts (i.e. insect-specific viruses) are examples of microbes that are not only capable of influencing vector competence for other viruses but also offer opportunities for innovative vector control strategies such as the way in which *Wolbachia* plays a role in creating populations refractory to the transmission of certain arboviruses. We had previously identified the presence of cell fusing agent virus (CFAV) in *Ae. aegypti* population in Texas. Our objective was to better understand the prevalence of CFAV in natural *Ae. aegypti* population and to investigate its impact on Zika virus transmission in the Lower Rio Grande Valley, a region in South Texas where local transmission of Zika virus occurred in 2016-2017. Our preliminary results showed the year around presence of cell fusing agent virus (CFAV). Although variation was observed in the minimum infection rate (MIR) between month of the study (2017-2018), no clear pattern of seasonality was identified. Detection of the virus was done in male and females mosquitoes confirming the vertical transmission of this virus. Additionally, CFAV MIR was similar between specimens sampled using Autocidal Gravid Ovitraps (AGO) and BG Sentinel 2 traps which documents the utility of AGOs to function as not only surveillance of vector populations but also for arboviruses. Additionally, in an effort to understand the interaction of CFAV with Zika virus, we conducted sequential infection in cell culture. No impact was observed in the *in vitro* experiment using C6/36 cells. We are currently conducting *in vivo* experiment using naturally CFAV infected *Ae. aegypti* mosquitoes to confirm these results.

Accurate estimates of Zika virus (ZIKV) cryptic transmission during the recent ZIKV pandemic and assessments of serological cross-reactivity with dengue virus (DENV) are needed to inform risk mitigation efforts during future outbreaks. The first Puerto Rico ZIKV case was detected in November 2015, but it is unclear how long ZIKV may have been circulating before then. We therefore performed a ZIKV seroepidemiology study of 500 active duty military members who were assigned to Puerto Rico through 2014 - 2016, and who had paired sequential sera collected within-deployment or pre-deployment and then in January - June 2015. The mean age of this sample was 28.0 years and 84.2% were male. At least 69.0% were born in a DENV endemic area and the mean time in Puerto Rico prior to the second sample was 5.1 years. We employed a high-throughput, flow cytometry-based neutralization (FlowNT) assay to screen serum samples for ZIKV and DENV neutralizing antibody (NAb). Samples that demonstrated >80% neutralization of ZIKV infectivity at a 1:40 FlowNT screening dilution were subsequently screened at a 1:10 dilution using a standard plaque reduction neutralization (PRNT) assay. The PRNT assay appeared to have better specificity than FlowNT for detecting ZIKV-specific NAb in sera from individuals that also had DENV NAb. Only 1.4% (7/500) individuals had detectable ZIKV NAb by both FlowNT and PRNT screening assays by June 2015. The 50% neutralization titers were determined for these 7 paired sera in order to identify ZIKV seroconversions. Only one individual seroconverted to ZIKV during this time period, providing serological evidence that ZIKV may have been circulating in this country for at least 4 months before the first cases were recognized and reported. Our findings emphasize the value of serosurveillance in evaluating the threat of ZIKV to at-risk populations, and prompts further studies that leverage archived sera available from military members that were stationed in or deployed to ZIKV endemic locations.

PRETREATMENT WITH PUTATIVE NOVEL ADJUVANTS MODULATE T FOLLICULAR HELPER AND B CELL RESPONSES TO ZIKV-E ANTIGEN

Brien K. Haun, Albert To, Teri Wong, Lishomwa Ndhlovu, Axel Lehrer

University of Hawaii, Honolulu, HI, United States

Emerging infectious viruses such as Zika virus (ZIKV) pose serious threats to human health. Currently there are no clinically available treatments or vaccines for ZIKV. Our lab has developed a vaccine candidate using recombinant envelope protein (E) of the ZIKV. Macaques immunized with this ZIKV-E antigen produced robust humoral response and neutralizing antibodies, which were determined to be protective factors. While eliciting humoral responses may benefit a large population of people, persons with select immune deficiencies may benefit from broader immune responses. It is known that prime-boost strategies can broaden immune response. Therefore, we investigated the immunological effects of administering novel adjuvants one day prior to recombinant antigen immunization in BALB/c mice. We observed an increase in CD4 T cells among the adjuvanted pretreatment groups, changes in overall T follicular helper

cell (Tfh) populations, and overall phenotypic changes in Tfh and B cell subsets. Based on our preliminary observations, we believe that pre-treatment with our novel adjuvant formulations prior to immunization may modulate the magnitude of humoral responses to recombinant antigen vaccination. The work to investigate these phenomena in more detail is ongoing.

INTERFERON LAMBDA (IFNΛ1, IFNΛ2, AND IFNΛ3) ENHANCES ZIKA VIRUS REPLICATION IN GLIAL CELLS

William G. Valiant, **Joseph John Mattapallil**

Uniformed Services University, Bethesda, MD, United States

Zika virus (ZIKV) is an arbovirus that has emerged as a major public health threat worldwide. Infection with ZIKV has been associated with congenital birth defects such as microcephaly, eye abnormalities, and neurological sequelae. Using a glial cell line derived from the human eye, we show that ZIKV replicates efficiently in these cells leading to productive infection that was accompanied by complete suppression of IFNα responses. Interestingly, increased replication was associated with a significant increase in the mRNA and protein levels of all the 3 subtypes of Type III IFN namely, IFNλ1, IFNλ2, and IFNλ3. Production of Type III IFN was accompanied by a dramatic increase in the expression levels of Interferon Stimulated Genes (ISG). Blocking of IFNλ1, IFNλ2, and IFNλ3 with neutralizing antibodies significantly suppressed ZIKV replication and ISG expression as compared to untreated cells. Pretreatment of glial cells with recombinant IFNλ1, IFNλ2, and IFNλ3 was found to protect the cells from infection suggesting that once the cells are infected, secreted IFNλ1, IFNλ2, and IFNλ3 contribute to an amplification of ZIKV replication in these glial cells. Gene expression analysis of cells harvested 6 hours after infection with ZIKV using focused nanoString arrays in combination with pathway analysis identified a number of candidate genes that likely contribute to increased ZIKV replication in the presence of IFNλ1, IFNλ2, and IFNλ3. Studies are currently underway to characterize the role of these genes. Our results, for the first time demonstrates a pathogenic role for Type III IFN in ZIKV infection and identifies a potential innate immune mechanism that is subverted by ZIKV to efficiently replicate inside glial cells. These findings have significant implications for understanding the pathogenesis of ZIKV infection.

ZIKA VIRUS MEMORY B CELL RESPONSES DIFFER IN DENGUE IMMUNE AND DENGUE NAIVE INDIVIDUALS WITHIN A US-BASED TRAVELER STUDY COHORT

Alena Janda Markmann[1], Huy Tu[2], Stephen Graham[1], Matthew Collins[3], Sean Diehl[2], Aravinda de Silva[1]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*University of Vermont, Burlington, VT, United States,* [3]*Emory University, Atlanta, GA, United States*

Zika virus memory B cell responses differ in Dengue immune and Dengue naïve individuals within a US-based Traveler Study cohort Alena J Markmann[1], Huy Tu[2], Stephen D. Graham[3], Matthew H. Collins[4], Sean Diehl[2], Aravinda de Silva[3] [1]Department of Medicine, Division of Infectious Diseases, University of North Carolina School of Medicine, Chapel Hill, North Carolina, USA [2]Cellular, Molecular, and Biomedical Sciences Program, University of Vermont, Burlington, Vermont, USA [3]Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, North Carolina, USA [4]Department of Medicine, Emory University, Atlanta, Georgia, USA, and Hope Clinic of the Emory Vaccine Center, Division of Infectious Diseases, Department of Medicine, School of Medicine, Emory University, Decatur, Georgia, USA Zika virus is an enveloped, positive-sense RNA arbovirus in the family *Flaviviridae.* The recent Zika virus epidemic in Latin America in 2015-2016 has been associated with significant neurologic sequelae as well as severe congenital abnormalities that were not seen in past Zika virus outbreaks. A fundamental question in the field is whether or not prior flaviviral exposure predisposed these populations to more severe disease manifestations. Prior work from multiple groups on B cell responses acutely after Zika virus infection or in early convalescence have identified differences in memory B cell (MBC) populations between flaviviral naïve and immune individuals. In order to better understand long-term adaptive immunity after Zika virus infection, we are examining the antibody and MBC responses in both primary and secondary Zika virus cases at late-convalescence. Our studies use late-convalescent samples from travelers and we have successfully developed a flow-based assay to screen MBCs using *in vitro* infected cells. Here we will show the results of MBC profiling and monoclonal antibody isolation from these travelers. This work is fundamental to understanding Zika-specific flaviviral memory B cell responses in late convalescence and whether or not prior flaviviral infections can influence this.

1503

DETERMINING THE BINDING SITES OF NEUTRALIZING ANTIBODIES ISOLATED FROM A ZIKA VIRUS INFECTED INDIVIDUAL

Stephen Graham[1], Alena Janda[2], Huy Tu[3], Sean Diehl[3], Aravinda de Silva[4]

[1]*Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, NC, United States,* [2]*Department of Medicine, Division of Infectious Disease, University of North Carolina School of Medicine, Chapel Hill, NC, United States,* [3]*Cellular, Molecular, and Biomedical Sciences Program, University of Vermont, Burlington, VT, United States,* [4]*Department of Microbiology and Immunology University of North Carolina School of Medicine, Chapel Hill, NC, United States*

Zika virus (ZIKV) is an emerging flavivirus that has rare but serious disease manifestations, including neurological complications and birth defects. The similarities between ZIKV and dengue virus (DENV), a closely-related flavivirus, can result in the formation of cross-reactive antibodies in infected individuals. Recent studies have shown that ZIKV disease manifestations can vary from individual to individual, depending on their DENV infection history. Through the Arbovirus Traveler Study at the University of North Carolina at Chapel Hill, two late-convalescent neutralizing monoclonal antibodies (nAbs) from individual DT 172 have been isolated through memory B-cell isolation and sorting in collaboration with Sean Diehl's lab at the University of Vermont. Both a type-specific and a cross-reactive monoclonal antibody from donor DT 172 have been isolated, and their binding sites on the ZIKV envelope protein, which is the major ZIKV antigenic determinant, have been identified. Mapping antigenic epitopes on the envelope protein of ZIKV using highly neutralizing monoclonal antibodies from late convalescence is critical to informing ZIKV vaccine and diagnostic testing development.

ZIKV ANTIBODY DEPENDENT ENHANCEMENT OF INFECTION MEDIATED BY WNV AND DENV SEROPOSITIVE CORD-BLOOD SAMPLES FROM MOTHERS IN EL PASO-TEXAS

Jeanette Orbegozo[1], Pedro M. Palermo[1], Anjali Joshi[2], Himanshu Garg[2], Douglas M. Watts[1]

[1]*University of Texas at El Paso, El Paso, TX, United States,* [2]*Texas Tech University Health Sciences Center, El Paso, TX, United States*

The recent Zika virus (ZIKV) outbreak and association with increased microcephaly cases are important public health concerns. ZIKV infection during the first trimester increased the likelihood of microcephaly and fetal demise because of infection of the fetal neuronal progenitor cells. A phenomenon known as antibody dependent enhancement (ADE) of dengue virus (DENV) infection has been demonstrated in epidemiological studies in DENV endemic areas. The mechanism involves preexisting flavivirus antibodies that serve to enhance the severity of a second infection with a different flavivirus. ADE has been observed in children born to DENV seropositive mothers instead of protecting by mutual cross reactivity to new infection with other DENV serotype resulting in a severe infection. Since ZIKV is closely related to flaviviruses like West

Nile virus (WNV) and DENV, prior exposure to these viruses could induce cross reactive antibodies that may enhance a subsequent ZIKV infection. Therefore, the aim of this study was to determine if WNV and DENV antibodies in cord blood enhanced ZIKV infection *in vitro*. A sero-surveillance study for WNV and DENV antibodies was conducted among mothers at the time of delivery in El Paso, Texas. From this study, a subset of 45 cord blood seropositive samples for DENV (n= 8) and WNV (n=37) were selected based on their reactivity in specific ELISAs and neutralization assays. The samples were used to determine neutralizing and enhancing titers against ZIKV, WNV and DENV using respective reporter virus particles (RVPs). ADE assay in K562 cells demonstrated that ZIKV infection was enhanced by WNV and DENV antibody positive samples. ZIKV infection was enhanced by 1:40-1:160 dilutions of the WNV and 1:40- 1:320 dilutions of DENV antibody positive samples respectively. This suggests that low titers of preexisting WNV and DENV antibodies could enhance ZIKV infection *in vitro*. Further studies are warranted to determine if low titers of pre-existing WNV and DENV antibodies in cord blood samples could enhance ZIKV infection *in-vivo* using an appropriate ZIKV disease murine model and to determine the clinical outcome, if any, in this model

1505

EXPERIMENTAL WEST NILE VIRUS TRANSMISSION CYCLES USING WILD BIRDS AND MOSQUITOES

Alex D. Byas[1], Angela M. Bosco-Lauth[1], Claudia Rückert[1], Alexis Robison[1], Michael C. Young[1], Dalit Talmi-Frank[1], Todd A. Felix[2], Aaron Brault[3], Richard Bowen[1], Gregory D. Ebel[1]

[1]*Colorado State University, Fort Collins, CO, United States,* [2]*Wildlife Services, Animal and Plant Health Inspection Service, United States Department of Agriculture, Lakewood, CO, United States,* [3]*Division of Vector-borne Diseases, National Center for Emerging Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Fort Collins, CO, United States*

West Nile virus (WNV) emerged in North America in 1999 and continues to be the leading cause of mosquito-borne disease in the United States. The rapid adaptation of WNV to local transmission ecologies and its continued diversification highlight the ability of RNA viruses to evolve in response to changing conditions. Different WNV hosts impose unique evolutionary pressures on virus populations, with virus undergoing genetic diversification in mosquitoes and restriction in vertebrates. In addition, species-specific impacts of birds (American robins, house sparrows and American crows) and mosquitoes (*Culex (Cx.) pipiens*, *Cx. quinquefasciatus* and *Cx. tarsalis*) have been documented. However, the impact of distinct vector-vertebrate pairs on virus transmission and evolution remain poorly understood. Accordingly, we developed laboratory transmission systems involving pairings of ecologically-relevant mosquitoes and birds to evaluate whether the effects of evolutionary pressures including avian purifying selection and mosquito bottlenecks are maintained when WNV is forced into a combined vector-vertebrate system. Specifically, we predict that mutations that arise during infection of highly competent *Cx. tarsalis* will be removed by purifying selection following transmission to robins, ultimately resulting in fitness gains. Conversely, we expect that strong population bottlenecks imposed by the moderately competent vector *Cx. pipiens*, coupled with relatively weak purifying selection in crows will result in diminished virus fitness and possible extinction. A field isolate of WNV was used to infect wild birds and three consecutive cycles of bird-to-mosquito transmission were performed. Bird serum and mosquito saliva were sequenced to assess viral populations. Future work includes cell culture competition assays to assess the effects of specific bird-mosquito pairings on viral fitness and evolution. Ultimately this work will provide knowledge on how new viral genotypes emerge and help understand the evolutionary forces that shape their populations in nature.

1506

ARTHROPOD-BORNE VIRAL ENCEPHALITIDES IN THE DOMINICAN REPUBLIC: THE VIRAL-HUMAN INTERFACE AND UNDERESTIMATION IN A REGION WITH VIRAL CIRCULATION

Leandro Tapia[1], Miguel Delgadillo[2], Wenceslao Hernandez[2], Zayda Menier[2], Ricardo Domingo[1], Robert Paulino-Ramirez[1]

[1]*Institute for Tropical Medicine & Global Health - Universidad Iberoamericana, Santo Domingo, Dominican Republic,* [2]*School of Medicine, Universidad Iberoamericana, Santo Domingo, Dominican Republic*

West Nile Virus (WNV) and Eastern Equine Encephalitis Virus (EEEV) are well-established viral pathogens found in many tropical and sub-tropical countries. Viral dynamics have evolved over time due to climatologic factors, vector-host interactions, and of particular importance the influx of birds through new migration patterns.The aim of this study was to review data exploring the distribution of reported human and zoonotic infections for arthropod-borne related viruses capable of inducing encephalitis in the Dominican Republic within the indexed scientific literature. Following the Cochrane review methodology, we searched keywords: "West Nile Virus" AND "Eastern Equine Encephalitis" AND "St. Louis Encephalitis" AND "Venezuelan Equine Encephalitis" each linked with "Dominican Republic" in the English and Spanish languages in PubMed and Google Scholar databases. A total of 17 articles were identified, among them eight (8) met the inclusion criteria, five (5) for WNV, three (3) for EEEV, zero (0) for VEEV and zero (0) for SLEV. After eliminating duplicates, only six (6) articles were included in the analysis. Articles reporting positive cases were published between 1950-1978 identifying EEEV and between 2003-2006 identifying WNV, in avian, mosquito, and equine populations. The first report describing EEEV in La Hispaniola occurred as a result of an outbreak in 1948. The first report for WNV in the Dominican Republic was published in 2002, where the presence of virus and antibodies were identified in migratory and residential birds in two locations within the national territory. Some discrepancies were observed between articles regarding horse positive cases. Subsequent studies were performed investigating vectors and avian populations yielding no evidence of human infections. Supplemental studies should examine the current circulation of encephalitides and their impact on humans in the Dominican Republic to enhance surveillance and disease control regarding future outbreaks in a country with one of the largest touristic industries in the Caribbean.

1507

EXPANDING FORECASTS OF HUMAN ARBOVIRAL DISEASE: PREDICTING WEST NILE VIRUS IN LOUISIANA

Justin K. Davis[1], Raoult Ratard[2], Mike Wimberly[1]

[1]*University of Oklahoma, Norman, OK, United States,* [2]*Louisiana Department of Health, New Orleans, LA, United States*

West Nile virus threatens public health in many parts of the U.S., but annual incidence varies widely and there is need for forecasting risk to help target public health responses. We developed and implemented the Arbovirus Monitoring and Prediction (ArboMAP) system in South Dakota, which typically has the highest annual incidence out of all US states, and successfully predicted human risk in SD in 2016-2018 using weather and mosquito infection data. In 2019 we began predicting human risk in Louisiana, another area of high transmission, with distinct meteorological and other characteristics requiring modifications to ArboMAP. In particular, we discuss the extraordinary, disruptive impacts of hurricanes, which are more than just heavy rain and wind events, and perform model selection with new covariates summarizing hydrological conditions, which are necessary to characterize risk in a state where water balance is a constant concern. We investigate the possibility of using SD and LA as sentinels for risk in the whole country, and identify states in which risk cannot yet be accurately predicted with these data. This sets out a path for expansion towards a more comprehensive national arboviral prediction system.

1508

SEROLOGICAL EVIDENCE OF WEST NILE VIRUS INFECTION IN WHITE-TAILED DEER FROM 2014 TO 2018 IN TEXAS

Pedro M. Palermo[1], John C. Morrill[2], Douglas M. Watts[1]

[1]*University of Texas at El Paso, El Paso, TX, United States,* [2]*Orion Research & Management Services Inc., Gatesville, TX, United States*

White-tailed deers (WTD) are abundant mammals widely distributed across the United States. Due to this feature, WTD are considered to be excellent sentinels for detecting arboviral activity in certain geographic areas. Evidence of West Nile virus (WNV) antibody in WTD has been reported previously in several states. However, there is a lack of reports of West Nile infection in WTD from Texas even though is among the states with the highest clinically reported cases of West Nile neuroinvasive disease. Therefore, the aim of this study was to determine the prevalence of West Nile antibody in deers from Texas. Deer sera samples (n=526) were collected during the hunting season (fall and winter) in Travis County, Texas from 2014 to 2018 and tested for IgG antibody to Flavivirus by an indirect Enzyme-linked immunosorbent assay (ELISA). ELISA antibody-positive samples were further tested for West Nile and St. Louis encephalitis virus (SLEV) antibody by an 80% plaque-reduction neutralization tests (PRNT80). Overall, 9.51% (n=50) and 0.19% (n=1) of the deer samples had serological evidence of West Nile and St. Louis encephalitis infections respectively. WNV seroprevalence increased by age ($p<0.05$), and there was no significant difference between gender. Interestingly, 3% (n=16) of the samples were positive for Flavivirus antibody but negative for SLEV and WNV antibodies, suggesting that other Flaviviruses may be circulating in WTD from Texas. Finally, these results support the circulation of WNV among WTD and highlight the potential role of WTD as sentinels for WNV in Texas.

1509

SYSTEMATIC REVIEW OF MARBURG VIRUS VACCINE CLINICAL TRIALS

Melinda J. Hamer

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Background: Recent deadly outbreaks of Marburg virus underscore the need for an effective vaccine. Marburg virus outbreaks can be equally or more disastrous than Ebola. This systematic review aimed to determine progress towards a vaccine for Marburg virus. Methods: Article search criteria were developed to query PubMed for peer-reviewed articles from 2010 through 2018 on Marburg virus vaccine clinical trials in humans and non-human primates (NHP). Abstracts were reviewed by two authors. Relevant or possibly relevant articles were reviewed in full. Discrepancies were resolved by a third author. Data abstracted included year, author, title, mechanism of action, number of subjects, effectiveness or efficacy, and demographics. Assessment for risk of bias was done using the Syrcle tool for animal studies, and the Cochrane Collaboration risk of bias tool for human studies. Results: 83 articles were identified; 29 were related to Marburg vaccines. After full text review, 13 articles were selected. 215 human subjects were in three phase 1 trials, and 109 NHP in 10 trials. Vaccine mechanisms were DNA plasmids, recombinant vesicular stomatitis virus, adenovirus vectors, virus-like particles (VLP) and siRNA. A Phase 1 human study of MARV glycoprotein (GP) with adenovirus vector vaccine had 0 vaccine-related severe adverse events and 100% with detectable IgG response. Two human phase 1 studies of DNA plasmid vaccines had 4 adverse effects requiring vaccine discontinuation out of 128 participants and 31-80% immunogenicity. In NHP, an adenovirus vector vaccine with MARV GP was 100% effective in two challenge studies with 18 subjects. A NHP VLP vaccine challenge trial was 100% effective in 13 subjects. 4 articles were rated low risk of bias; 5 were moderate, 3 were high, and one with insufficient evidence to rate. Conclusion: The MARV glycoprotein vaccine with adenovirus vector had the most favorable safety profile, 100% protection in NHP challenge, and the best immunogenicity among vaccines tested in humans in this review. Further research is needed to develop this and other vaccines to limit the spread of this highly lethal virus.

1510

SOCIAL RESISTANCE DRIVES PERSISTENT TRANSMISSION OF EBOLA IN THE EASTERN DEMOCRATIC REPUBLIC OF CONGO, 2018: A MIXED-METHODS STUDY

Jack Underschultz[1], Claude Kasereka Masumbuko[2], Michael Hawkes[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Université Catholique de Graben, Butembo, Democratic Republic of the Congo*

The second largest Ebola epidemic in history is currently raging in Eastern Democratic Republic of Congo (DRC). Stubbornly persistent Ebola transmission has been associated with social resistance, ranging from passive non-compliance to overt acts of aggression toward Ebola reponse teams. We explored community resistance using focus group discussions and assessed the prevalence of resistant views using standardized questionnaires. Despite being generally cooperative and appreciative of the foreign-led Ebola response, focus group participants provided eyewitness accounts of aggressive resistance to control efforts, consistent with recent media reports. Mistrust of Ebola response teams was fueled by perceived inadequacies of the response effort ("herd medicine"), suspicion of mercenary motives, and violation of cultural burial mores ("makeshift plastic morgue"). Survey questionnaires found that the majority of respondents had compliant attitudes with respect to Ebola control. Nonetheless, 78/630 (12%) respondents believed that Ebola was fabricated and did not exist in the area, 482/630 (72%) were dissatisfied with or mistrustful of the Ebola response, 60/630 (9%) sympathized with perpetrators of overt hostility, and 102/630 (15%) expressed non-compliant intentions in the case of Ebola illness or death in a family member, including hiding from the health authorities, touching the body, or refusing an official burial team. Denial of the biomedical discourse and dissatisfaction/mistrust of the Ebola response were statistically significantly associated with indicators of social resistance. We concluded that social resistance to Ebola control efforts was prevalent among focus group and survey participants. Mistrust, with deep political and historical roots in this area besieged by chronic violence and neglected by the outside world, may fuel social resistance. Resistant attitudes may be refractory to short-lived community engagement efforts targeting the epidemic but not the broader humanitarian crisis in Eastern DRC.

1511

TRACKING EBOLA VIRUS GENOMIC DRIFT WITH A RESEQUENCING MICROARRAY

Carolyn Fisher[1], Bryan Lanning[1], Irina Tiper[1], Moussa Kourout[1], Krishnamurthy Konduru[1], Anjan Purkayastha[2], Gerardo Kaplan[1], Robert Duncan[1]

[1]*FDA Center for Biologics Evaluation and Research, Silver Spring, MD, United States,* [2]*OpenBox Bio, LLC, Vienna, VA, United States*

Currently, Ebola Virus Disease in the African Congo is the world's second-worst outbreak of the deadly disease. Diagnosis depends on Ebola-specific PCR assays for detection, but genomic sequencing information is needed for outbreak management. The ability to monitor genomic drift, to identify the Ebola strain and discover any mutations occurring are important for efficacy of diagnostics and therapeutics and disease surveillance. We have designed and tested an Ebola Virus Resequencing Microarray Assay (EBOV-RMA) to determine the sequence of the critical genes of the Ebola virus genome in a 12-hr protocol adaptable for use in remote areas. The EBOV-RMA is a high-density GeneChip manufactured by Affymetrix. We optimized multiplex PCR conditions to amplify and hybridization to provide the sequence of four Ebola species with <400,000 copies of viral genome, well below the amount typically isolated from patients. The Ebola sequences were obtained with a >98% base call rate. An in-house developed bioinformatic pipeline uses the raw base calls to search the

GenBank database and identify the closest sequence match. Sequence obtained for a repository sample of Zaire Ebola RNA was 99.97% identical to the Illumina Next Generation Sequencing (NGS) result for the same sample. To evaluate use of the chip to study genetic drift, we developed a recombinant vesicular stomatitis virus expressing green fluorescent protein (GFP) and EBOV glycoprotein (GP) genes of the Zaire strain (rVSV-ZEBOVgp-GFP). The recombinant virus was cultured in Vero E6 cells with the presence of the monoclonal antibody, KZ52, that binds the Ebola GP and neutralizes infection. Over two or three rounds of virus selection, EBOV-RMA sequence data showed GP coding changes, including the mutation N(506)D, that permitted escape from KZ52 binding in other studies; thus demonstrating the effectiveness of the RMA to detect genomic drift. The EBOV-RMA gives targeted sequence as accurately as NGS, identifies, and types samples on a phylogenetic tree. Genetic drift studies with the Ebola pseudovirus showed effectiveness at detecting changes in the genome of a replicating virus.

1512

ESTIMATING SUBNATIONAL FIRST-DOSE MEASLES-CONTAINING VACCINE (MCV1) COVERAGE USING MODEL-BASED GEOSTATISTICS IN LOW AND MIDDLE INCOME COUNTRIES FROM 2000 TO 2018

Alyssa N. Sbarra, Jason Q. Nguyen, Sam Rolfe, Lucas Earl, Ashley Marks, Natalie C. Galles, Di Zheng, Simon I. Hay, Jonathan F. Mosser, Stephen S. Lim

Institute of Health Metrics and Evaluation, Seattle, WA, United States

Estimates that capture local patterns of vaccine coverage are critical for understanding progress in childhood survival, strategic planning to improve health delivery systems, and preparing for associated-disease risk and burden. Recognizing the importance of subnational coverage, the Global Vaccine Action Plan (GVAP) and the Sustainable Development Goals (SDGs) on immunization coverage recognize the have set coverage targets to obtain 80% district-level coverage for all routine childhood immunizations, including the first doses of the measles-containing vaccine (MCV1). Data was collected from over 325 surveys conducted between 2000 and 2018, which included over 1,700,000 children aged 12-23 months old in 107 low and middle income countries. Using a Bayesian geostatistical model, annual high geographic resolution (5x5 km) estimates of routine MCV1 coverage, calibrated to the Global Burden of Diseases, Injuries, and Risk Factors Study 2019, were used to produce district-level coverage estimates for 113 low and middle income countries. Subnational MCV1 coverage reveals within-country inequities that would be overlooked if only focusing on national-level estimates, such as in Nigeria, where districts range from 3 to 96% MCV1 coverage. MCV1 coverage is generally increasing over time, however there are areas of consistently low coverage that suggest that there many persistent drivers of coverage inequities. Current trends in coverage are inadequate for reaching 80% target goal; less than 60% of districts have a 95% probability of reaching 80% target goals in 2018. Additional doses from supplementary immunization activity programs were considered to determine how coverage might have been impacted, by assuming a series of different geographic distributions of campaign doses, and additional locations for targeted SIA activity were identified.

1513

IDENTIFICATION OF A ROTAVIRUS OUTBREAK THROUGH PHYSICIAN CALL CENTER IN A RURAL COMMUNITY OF BANGLADESH

Afruna Rahman[1], Kyu Han Lee[2], Sanwarul Bari[1], Farzana Islam[1], Mustafizur Rahman[1], Muntasir Alam[1], Sabbir Ahmed[1], Shams El Arifeen[1], Emily Gurley[2]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Johns Hopkins University, Baltimore, MD, United States*

Delayed recognition of danger signs and seeking care for illness contribute to maternal and child mortality in Bangladesh. Mobile phones are widely available in Bangladesh; over 93% of households own cell phones in the study area. The objective of this study was to monitor trends in illness notification and investigate any unusual findings. Since September 2017, a private company has been providing toll-free access to physicians for all residents of Baliakandi, a rural sub-district with a population of 220,461. Physicians refer patients with danger signs to six designated facilities following referral guideline. From September 2017 to March 2019, total 6642 calls have been made; 2461 (37%) for illnesses among children under-5; diarrhoea, fever and cough being the most common causes. During November 2018 - January 2019, we noticed a peak in number of calls related to diarrhoea among under-5 children in the bi-weekly reporting graph. We received 128 calls in these 3 months, a number clearly greater compared to previous 5 months data when 77 calls were made between June-October 2018. In response, we visited the Baliakandi sub-district hospital to test stool samples for rotavirus among under-5 children coming to the facility with diarrhoea. From 16 January - 9 February 2019, we collected samples from 22 children (7 - 30 months) to be tested using commercial ELISA kit. Out of 22, 18 samples had detectable group A rotavirus antigen. We notified Baliakandi sub-district hospital and Institute of Epidemiology, Disease Control and Research (IEDCR) about the outbreak on 24 January 2019. IEDCR promptly contacted the hospital authority but as the situation improved, intervention was not required. We have developed a guideline to minimize the response time in the future. For a known disease, the hospital outbreak management team will start initial management; IEDCR team will provide support if required. For any unknown disease, IEDCR will send a team immediately upon notification. Our finding suggests that routine monitoring of illness notification through the call centre has potential to identify health crisis in a rural context.

1514

COMMUNITY BASED RESPIRATORY SYNCYTIAL VIRUS (RSV) MORTALITY STUDY IN KARACHI PAKISTAN: FORMATIVE PHASE

Fauzia A. Malik[1], Lauren B. Guterman[1], Saima Jamal[2], Asad Ali[2], Saad B. Omer[1], Abdul Momin Kazi[2]

[1]*Emory University, Atlanta, GA, United States,* [2]*Aga Khan University, Karachi, Pakistan*

Respiratory syncytial virus (RSV) is a respiratory pathogen with potentially high disease burden in developing countries. Global estimates suggest that RSV may contribute to morbidity and mortality in infants. In developing countries post-mortems on young infants are not often performed to identify the cause of infant death due to religious and cultural barriers, while taking a nasopharyngeal (NP) swab from a deceased infant would present challenges in any setting. We have less direct data on the incidence and severity of RSV and the associated early deaths in specific populations. The objectives of this study were to understand views of the community for taking nasopharyngeal swab (NP) sample of a deceased infant and understand how timely notification of infant deaths can be achieved. This is a qualitative exploratory study conducted from November 2017 to March 2018. Purposive sampling was used to conduct sixty in-depth interviews with the caregivers, elders, religious & local leaders, and funeral workers. Five focus group discussions were conducted with healthcare providers providing services within study catchment area. From the formative phase, we explored the acceptance of study procedures within the communities and assessed the benefits to families of deceased infants for participating in the study. Data from the in-depth interviews and focus group discussions with our key informants show that taking a nasopharyngeal swab at the point in the ritual bath when the nose is cleaned would be religiously and contextually acceptable. We obtained a Fatwa document from different mosques, stating that the procedures of our study are in accordance with Islam and other religious affiliations. Based on formative phase findings RSV mortality-based surveillance will give us the estimates of the burden of severe RSV infection and associated deaths in young infants. Surveillance phase activities will include collecting nasopharyngeal swabs from recently deceased infants and we will conduct ongoing community engagement.

COMPARATIVE PATHOGENESIS OF BANGLADESH AND MALAYSIAN ISOLATES OF NIPAH VIRUS IN THE AFRICAN GREEN MONKEY

Mike Holbrook[1], Yu Cong[1], Dima Hammoud[2], Ji Hyun Lee[1], Elena Postnikova[1], Jonathan Kurtz[1], Louis Huzella[1], Vincent Munster[3]

[1]*NIAID Integrated Research Facility, Frederick, MD, United States,* [2]*Center for Infectious Disease Imaging, Radiology and Imaging Sciences, Clinical Center, National Institutes of Health, Bethesda, MD, United States,* [3]*Virus Ecology Unit, Laboratory of Virology, Rocky Mountain Laboratories, Hamilton, MT, United States*

The development of animal models that accurately recapitulate human disease is an ongoing challenge in infectious disease research. In this project we focused on developing a nonhuman primate model for Nipah virus (NiV) infection by modifying the exposure dose and route to more accurately mimic potential human exposure. In the studies discussed here we used a relatively low dose (~500 pfu) and large particle (~12 um) aerosol exposure to replicate fomite or droplet exposure. Using this approach, we found that animals infected with the Malaysian isolate of NiV (NiV-M) developed distinct neurological lesions, with both restricted and facilitated diffusion, suggestive of microinfarctions and encephalitis, respectively. Animals that succumbed following infection with NiV-M survived until 16-22 days post-exposure. Animals exposed to the Bangladeshi isolate of NiV (NiV-B) that succumbed survived until 8-12 days post-infection when they developed a rapidly progressing hemorrhagic pulmonary disease with no evidence of neurological disease. Analysis of clinical data found few clear differences between animals exposed to either NiV-M or NiV-B. In general, animals that succumbed had increased glucose, slightly increased creatinine and decreased platelet levels. Animals that succumbed to NiV-B infection had decreased albumin levels possibly associated with the hemorrhage seen in the lungs of these animals. Of the two animals that survived NiV-M exposure, one seroconverted and had a NiV-specific IgM and IgG response and neutralizing antibody titer. The second survivor did not seroconvert. Two animals that succumbed to NiV-M exposure had IgM and IgG responses with one also demonstrating neutralizing antibody titers. Serological testing of animals exposed to NiV-B is pending. Through the use of a low exposure dose and large particle aerosol, an animal model that closely recapitulates human disease has been developed. Further work with this model and on-going analysis of immune response data could be useful for the development of immune modulators and antivirals for the treatment of NiV infection.

GLOBAL EL NIÑO-SOUTHERN OSCILLATION TELECONNECTIONS AND PATTERNS OF DISEASE OUTBREAKS

Assaf Anyamba[1], Radina P. Soebiyanto[1], Jennifer L. Small[1], Sarah Hutchinson[1], Richard Damoah[1], Brett M. Forshey[2], Christine Toolin[2], Seth C. Britch[3], Compton J. Tucker[1], William Karesh[4], Wassila Thiaw[5], Jean-Paul Chretien[6], Jose L. Sanchez[2], Kenneth J. Linthicum[3]

[1]*NASA Goddard Space Flight Center, Greenbelt, MD, United States,* [2]*Department of Defense, Armed Forces Health Surveillance Branch, Silver Spring, MD, United States,* [3]*US Department of Agriculture, Agricultural Research Service, Center for Medical, Agricultural and Veterinary Entomology, Gainesville, FL, United States,* [4]*EcoHealth Alliance, New York, NY, United States,* [5]*National Oceanic and Atmospheric Administration, National Centers for Environmental Predictions, Climate Prediction Center, International Desks, College Park, MD, United States,* [6]*National Center for Medical Intelligence, Fort Detrick, MD, United States*

Climate variability associated with the El Niño-Southern Oscillation (ENSO) has marked effects on environmental conditions, favoring several infectious diseases outbreaks including Rift Valley fever, dengue, and cholera. Although studies have linked ENSO events with a particular disease transmission, the impacts of ENSO on climate conditions and disease outbreaks at global scale remains elusive. We analyzed patterns of some disease outbreaks during the strong 2015/2016 El Niño event in relation to climate anomalies derived from satellite measurements. Our results, published in February 2019, indicated disease outbreaks in El Niño-connected regions (southeast Asia, Tanzania, western US and Brazil) followed shifts in rainfall, temperature and vegetation, where both drought and flooding occurred in excess (14-81% rainfall departures from normal). Our results showed 2.5-28% increase in disease intensity during years with El Niño events than those without. Plague in Colorado and New Mexico, and cholera in Tanzania were significantly associated with above normal rainfall ($p<0.05$); while dengue in Brazil and southeast Asia were significantly associated with above normal land surface temperature ($p<0.05$). During this strong 2015/2016 El Niño event and under the umbrella of US interagency collaborative efforts, we issued alerts when elevated conditions for certain climate extremes were projected in regions with possible outbreaks of climate-sensitive diseases. The alerts led to Rift Valley fever vaccination in livestock in Kenya, averting a potentially damaging outbreaks and economic impacts. We continue to monitor reports of several climate-sensitive diseases worldwide from ProMED. After the 2015/2016 El Niño event, we observed a decreasing trend in intensity of several disease outbreaks. This work not only highlights the global impacts of ENSO in triggering or amplifying disease outbreaks but also demonstrates the prolonged impact of such climate perturbations. Given the changing and variable climate, climate observations and forecasts are going to be a critical tool in disease outbreak preparedness, prevention and control.

[1]*U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*Clinical Trials Center, Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [3]*ICON Government and Public Health Solutions, Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [4]*Medical Countermeasure Systems (MCS), Joint Vaccine Acquisition Program (JVAP), Fort Detrick, MD, United States,* [5]*Janssen Vaccines and Prevention, Leiden, Netherlands,* [6]*Janssen Research and Development, Beerse, Belgium*

Earlier studies of different regimens with Ad26.ZEBOV (Ad26) and MVA-BN-Filo (MVA) vaccines showed the strongest immune responses are induced with Ad26 as dose 1 followed by MVA 2 months later. Shorter schedules for heterologous vectored vaccines are desirable for accelerated induction of protection against Ebola virus disease (EVD). This pilot study (RV456/EBL2003) evaluated safety and immunogenicity of a 2-dose regimen of $1x10^8$ Inf U MVA-BN-Filo dose 1 followed by $5x10^{10}$ vp Ad26.ZEBOV administered intramuscularly 14 days apart in HIV infected & non-HIV infected adults in the US. Safety and binding antibody (ab) concentrations to the Zaire glycoprotein were co-primary objectives. Fifty non-HIVinfected and 25 antiretroviral therapy (ART) treated HIV infected adults received vaccine or placebo (4:1 ratio). Solicited adverse events (AEs) were collected for 7 days post vaccination. Unsolicited AEs were analyzed for 14 days post-dose 1 and 28 days post-dose 2 and serious AEs until the study's end. CD4 T cell counts and HIV viral loads were monitored for HIV infected adults. Binding ab responses were assessed via EBOV GP FANG ELISA at baseline, pre-dose 2, 21 days, 42 days, 6 months and 1 year post dose 2. Study participants were 63% male, with median age 47 years (range: 19-70). The regimen was well-tolerated in both the non-HIV infected and ART treated HIV infected groups. Local and systemic solicited AEs were generally mild or moderate with no vaccine related serious AEs. In HIV infected adults, vaccination had no effect on CD4 T cell counts and

no durable impact on HIV viral load suppression. 21 days post dose 2, 100% uninfected and 95% HIV infected adults responded to vaccination. In non-HIV infected adults, geometric mean ab concentration (GMC) of EBOV specific binding abs was 6286 EU/mL (n=36) and 2005 EU/mL (n=19) for HIV infected adults at day 21 post dose 2. The vaccine-induced immune response in non-HIV infected adults was similar to other studies in HIV infected adults. While ab response tended to be lower in HIV infected than in non-HIV infected adults, this accelerated vaccination regimen is well-tolerated and immunogenic in both populations.

1518

ENSURING COMPLETE INACTIVATION OF ARBOVIRUSES BY HEAT WITH STRINGENT SAFETY TESTING

Michael Parker, Jessica Shifflett, Sujatha Rashid

ATCC, Manassas, VA, United States

Inactivated viruses are useful for assay development at reduced biosafety levels and can serve as process controls in research and detection assays. Heat inactivation may be preferential to other inactivation methods due to cost-effectiveness and avoidance of chemical manipulation. However, standardized parameters for heat inactivation of arboviruses are not established for treatment temperature and duration, nor are they verified for safety by detection of residual viable virus, posing material biosafety concerns. For example, treatment of dengue virus at 56°C, under commonly used, published conditions, resulted in virus infectivity upon extended incubation period and serial passaging. In this study, yellow fever, zika, dengue type 2, chikungunya and mayaro viruses were incubated at 65°C completely submerged in a water bath, and inactivation was assessed at three time points. Complete inactivation was demonstrated by inoculating permissive host cells and incubating for 14 days under optimal growth conditions for two passages. Samples collected throughout incubation were tested for infectivity by monitoring cytopathic effect (CPE), immunofluorescence-staining (IFA) using virus-specific antibodies and qRT-PCR. Our results indicate that treated samples were not infectious by CPE/IFA. Significant reductions in Cq values over the 28-day incubation period suggest the presence of non-replicating virus in the samples. The heat-inactivated viruses were sufficiently stable for immunological (IFA) and molecular (qRT-PCR) assays, demonstrating their utility as controls for detection assay development. Our results demonstrate that specific, reproducible conditions for heat inactivation can be established that are applicable to multiple arboviruses and ensure material safety compliance. Heat-inactivated viruses with quantified viral genome copy number are available through BEI Resources.

URBAN ARBOVIRAL EPIDEMICS AND HEALTH SYSTEM RESPONSE IN EL SALVADOR

Mirna P. Amaya Amaya

University of Florida, Gainesville, FL, United States

Major historical, demographic and societal changes, including the growth of population centers in tropical countries, have impacted the emergence of arboviral diseases in Central America. The increase in vector borne diseases, has resulted in an overwhelmed vector control system and public health sector. At the same time, there has been a growing global concern on the shortage of health care workers. A recent joint World Health Organization and World Bank estimate calculates the shortage of Human Resources for Health (HRH) at 18 million by 2030, more than doubling the 2013 estimate of 7 million. Therefore, a greater focus has been placed on the importance of an adequate density of HRH within low and low-middle income countries, in order to sustain the country public health efforts. Through an extensive review of scientific literature, country reports, and in depth semi-structured interviews with key stakeholders; this paper explores the health system response to recent arboviral epidemics in El Salvador from a HRH perspective. The study aims to identify barriers healthcare workers face during health emergencies, using the recent Zika epidemic as a point of comparison. Low and Low-Middle income countries are disproportionately affected by arboviral diseases, due to an unequal distribution of wealth and resources. Strengthening health system infrastructures and processes for early identification of outbreaks, then becomes imperative. This would help overcome health disparities and adequately prepare for the necessary public health emergency response to epidemics. The study findings suggest that some of the main barriers that the health workforce encounter during health emergencies are the product of poverty, social inequality, security issues, a fragmented health system, as well as internal politics, among others. However, there is a lot of hope for change and an unrelenting optimism on the part of El Salvador's healthcare workers; evident through their recommendations to the ministry of health, and also through personal accounts of ingenuity in overcoming the barriers they face before, during, and after health emergencies.

1520

THE COMPOSITION AND CLINICAL RELEVANCE OF THE BLOOD VIROME IN FEBRILE PEDIATRIC OUTPATIENTS IN TANZANIA BY UNBIASED NEXT GENERATION SEQUENCING

Mary-Anne Hartley[1], Samuel Cordey[2], Florian Laubscher[2], Kristina Keitel[3], Thomas Junier[4], Francisco J. Pérez-Rodriguez[5], Gael Vieille[2], Josephine Samaka[6], Tarsis Mlaganile[6], Frank Kagoro[6], Zainab Mbarack[7], Mylène Docquier[8], Laurent Kaiser[2], Valérie D'Acremont[3]

[1]*University of Lausanne, Lausanne, Switzerland,* [2]*Division of Infectious Diseases and Laboratory of Virology, University of Geneva Hospitals, Geneva, Switzerland,* [3]*Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland,* [4]*Swiss Institute of Bioinformatics, Geneva, Switzerland,* [5]*University of Geneva Medical School, Geneva, Switzerland,* [6]*Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania,* [7]*Mwananyamala Hospital, Dar es Salaam, United Republic of Tanzania,* [8]*UiGE*[3] *Genomics Platform, University of Geneva, Geneva, Switzerland*

Viruses are present in every human tissue with associations spanning from integral parts of the heritable human genome, to tolerated guests or unwelcome infections. Together, this diverse and changeable group of viruses comprise the human virome. The composition and role of the virome in human blood is largely unknown. We previously benchmarked a technique of unbiased next generation sequencing able to detect genetic traces of all vertebrate viruses. This retrospective cohort study investigates the potential clinical relevance of its extreme sensitivity by describing the composition and clinical associations of the blood virome in 803 febrile paediatric (2-59 months) Tanzanian outpatients. We found 62 viruses (25 RNA, 37 DNA) across 20 families, including several viruses novel to human blood from the Astroviridae, Circoviridae, Genomoviridae, Parvoviridae and Papilloviridae families. At least 1 virus/sample was detected (median=3; IQR=1-8; range=1-9). Most DNA viruses comprised ubiquitous commensal viruses (UCVs) of the Anelloviridae family; and 37% of samples (n=298/803) had only UCVs detectable. Patients with >1 non-UCVs were 3.6 months younger than those with none (CI95=1.7-2.4; p<0.001). Amongst numerous clinical associations, many aligned with known presentations. For example, children carrying classic gastroenteritis viruses were more likely to present with vomiting (Rotavirus: RR=2.0, p=0.001. Norovirus: RR=5.4, p=0.001); rhinoviruses were associated with pneumonia (RR=2.8, p=0.050); roseola viruses tended to present in younger children with fever only (RR=1.4, p=0.050); and HIV-1 was associated with higher severity (RR=6.2, p=0.019). Thus, we present a highly diverse virome with a wealth of clinical associations, many of which aligned with expected presentations. However, the complexity of these findings blurs human comprehension, and we conclude that the use of such high-resolution data would require objective pattern detection algorithms for unbiased validation. Further the results still need to be complemented by conventional techniques before they could be used at a clinical level.

1521

A METAPOPULATION MODEL FOR THE 2018 EBOLA VIRUS DISEASE OUTBREAK IN EQUATEUR PROVINCE IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Sophie Meakin, Mike Tildesley, Emma Davis, Matt Keeling

University of Warwick, Coventry, United Kingdom

Ebola virus disease is a viral haemorrhagic fever with high mortality that has caused a number of severe outbreaks in Central and West Africa, placing huge strains on already limited healthcare resources. Mathematical models matched to early case reporting data can be used to identify outbreaks that are at high risk of spreading and thus allocate resources more effectively. Here we consider the Ebola virus disease outbreak in Equateur Province in the Democratic Republic of the Congo, which was declared on 8 May 2018. We use a simple stochastic metapopulation model to capture the dynamics in the three affected health zones: Bikoro, Iboko and Wangata. We use approximate Bayesian computation methods to determine parameters by matching between reported and simulated cases. We use this framework to calculate the force of infection in each health zone and so indicate which areas are most at risk. by allowing the transmission parameter to change over time, we can also determine how the basic reproductive ratio changes over time as various intervention measures are implemented.

CLINICAL DEVELOPMENT OF LHF-535 AS AN ORAL THERAPEUTIC FOR LASSA FEVER

Sean M. Amberg[1], Portia A. Vliett-Gregg[1], Alison E. Heald[2], Eric J. Tarcha[1], Jeff Posakony[1], Kristin M. Bedard[1], Clinical Network Services (CNS) Pty Ltd[3], Nucleus Network[4]

[1]*Kineta, Seattle, WA, United States,* [2]*Alison Heald Consulting, LLC, Seattle, WA, United States,* [3]*Hamilton QLD, Australia,* [4]*Melbourne VIC, Australia*

Lassa fever is a viral hemorrhagic disease endemic in West Africa. LHF-535 is a small molecule antiviral currently under development as a therapeutic option to treat Lassa fever and other viral hemorrhagic fevers of arenavirus origin. The human safety and pharmacokinetics of LHF-535 was evaluated in a single ascending dose double-blind phase 1a trial in healthy volunteers. Six cohorts of eight subjects each were randomized to LHF-535 (six per cohort) or placebo (two per cohort) and administered oral LHF-535 with weight-based dosing. Doses ranged from 0.3 mg/kg in the first cohort to 40 mg/kg in the last cohort. Plasma concentrations generally increased dose proportionally with respect to total exposure (mean AUC 1430 to 118,000 h·ng/mL). The frequency of treatment-emergent adverse events (TEAE) were similar between placebo (50%) and LHF-535 recipients (42%). TEAE frequency did not correlate with LHF-535 dose. Human exposure from oral LHF-535 reached exposures comparable to exposure provided by daily intraperitoneal dosing in guinea pigs at a dose that was fully protective against a lethal challenge with Lassa virus. These results support the continued clinical development of LHF-535.

1523

ZAIRE EBOLA VIRUS GLYCOPROTEIN - INSIGHTS FROM EPITOPE MAPPING AND INFECTIVITY ANALYSES

Edgar Davidson[1], Tabb Sullivan[1], Aubrey L. Bryan[1], Andrew Flyak[2], James E. Crowe[2], Benjamin J. Doranz[1]

[1]*Integral Molecular, Inc., Philadelphia, PA, United States,* [2]*Departments of Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN, United States*

Recent disease outbreaks due to Ebola virus (EBOV) highlight the need to characterize the immune response to ebolaviruses to develop vaccines and therapies. We have used extensive GP mutation libraries to map the epitopes for >200 monoclonal antibodies (MAbs) targeting the EBOV surface glycoprotein, GP. A broad variety of MAbs has been mapped, as described in publications, including the ZMapp therapeutic MAb cocktail; MAbs from survivors of EBOV and Bundibugyo ebolavirus infection; cross-neutralizing MAbs targeting the GP membrane-proximal external region (MPER); a broadly cross-reactive MAb that blocks GP interaction with its endosomal receptor Niemann-Pick C1; GP binding activity in sera of mice injected with DNA encoding MAbs (DMAbs), and MAbs whose synergistic combination transforms a non-neutralizing MAb into a potent neutralizer. With the Viral Hemorrhagic Consortium, we characterized how MAb *in vitro* neutralization correlates with *in vivo* protection. The epitope maps expand our understanding of how the immune system recognizes EBOV GP, and allow correlation of epitopes with MAb neutralizing capabilities, to develop anti-EBOV therapeutics and vaccines. Mapping also identified mutations that increase the exposure of neutralizing epitopes and that affect EBOV function, impacting future anti-ebolavirus vaccine strategies. Such insights are being used design new immunogens to serve as improved vaccines. To identify GP residues important for EBOV infectivity, we performed infectivity assays with the full GP mutation library, using a lentivirus pseudotype system. We identified critical residues whose mutation abrogated infectivity without affecting GP conformational integrity. The locations of the residues suggest that they are crucial for GP conformational changes that cause virus-host membrane fusion. Additionally, to identify uncharacterized EBOV cellular receptors, we assayed wild-type GP infectivity in non-permissive cells individually expressing 5,300 unique human membrane proteins of our membrane proteome array (MPA). This has identified candidate membrane proteins that enable EBOV infectivity.

1524

SEROPREVALENCE OF THE *ARARAQUARA VIRUS* ANTIBODIES IN A POPULATION FROM A PROSPECTIVE COHORT IN SÃO JOSÉ DO RIO PRETO, SP, BRAZIL

Gislaine Celestino da Silva[1], Marcílio Jorge Fumagalli[2], Victor Miranda Hernandes[1], Bruno Henrique Milhim[1], Caroline Rodrigues da Silva[1], Lucas Celestino Araujo[1], Nathalia Zini[1], Eliane Aparecida Favaro[1], Luiz Tadeu Figueiredo[2], Ana Carolina Terzian[1], Mauricio Lacerda Nogueira[1]

[1]*São José do Rio Preto School of Medicine, São José do Rio Preto, Brazil,* [2]*Ribeirão Preto School of Medicine - University of São Paulo (FMRP-USP), Ribeirão Preto, Brazil*

Hantaviruses (family *Peribunyaviridae*, genus *Orthohantavirus*) are spherical and enveloped presenting glycoproteins in the surface with approximately 120 nm in size. The genome consists of a negative and tri-segmented ssRNA. The three RNA segments are defined as small (S), medium (M) and large (L) which encode N proteins, enveloped G1 and G2 glycoprotein, and viral RNA polymerase, respectively. Hantaviruses have as natural reservoirs wild rodents that can eliminate the virus through urine, saliva, and feces. Rodents can carry the virus for life without becoming ill. In Brazil, epidemiological surveys detected the genotype Araraquara virus (ARAV) in *Necromys lasiurus* rodents are predominantly found in the cerrado, a predominant biome in the São Paulo State. The aim of this study is to perform a serological survey to detect the presence of anti-ARAV IgM and/or IgG antibodies in patients from a prospective cohort study in a neighborhood of the municipality of São José do Rio Preto, SP, Brazil. A total of 831 patients were randomly selected, and submitted to an interview for investigation of patient›s health history, living conditions and workplace. So far 253 sera samples were collected and tested by an IgG/IgM indirect-ELISA using the N recombinant protein of ARAV as the antigen, as described previously. The cut-off was established as the mean value + 2 standard deviations control samples and showed a cut-off Optical Density (OD) equal to or greater than 0.300. Our results showed 0.8% (2/253) of positivity to ARAV-IgG, 0.4% (1/253) of undetermined and 98.8 % (250/253) of negative samples. None of the samples were positive to ARAV-IgM while 0.4% (1/253) of the samples were undetermined and (252/253) 99.6% were negative. São José do Rio Preto is endemic to Dengue and other arboviruses; however, several cases of the acute febrile disease are negative for these viruses. In this way, we will be

able to estimate the prevalence of the hantavirus antibodies, contributing to surveillance in the municipality and with a better diagnosis and patient care.

1525

THE SECRET 'LIVES' OF MOSQUITO-ASSOCIATED VIRUSES: METAGENOMIC RNA SHOTGUN SEQUENCING HELPS DECIPHER VIRAL ECOLOGY BUT SHOWS THAT HOST SPECIES IS THE MOST IMPORTANT DRIVER OF VIROME COMPOSITION

Panpim Thongsripong[1], James Angus Chandler[2], Amy B. Green[3], Pattamaporn Kittayapong[4], Bruce A. Wilcox[5], Durrell D. Kapan[6], Shannon N. Bennett[1]

[1]*Department of Microbiology, California Academy of Sciences, San Francisco, CA, United States,* [2]*Department of Molecular and Cell Biology, Berkeley, CA, United States,* [3]*Department of Microbiology, University of Hawai'i at Manoa, Honolulu, HI, United States,* [4]*Center of Excellence for Vectors and Vector-Borne Diseases, Faculty of Science, Mahidol University, Bangkok, Thailand,* [5]*Integrative Research and Education Program, Faculty of Public Health, Mahidol University, Bangkok, Thailand,* [6]*Department of Entomology and Center of Comparative Genomic, California Academy of Sciences, San Francisco, CA, United States*

The discovery of novel viruses in the environment has accelerated greatly in recent years with the accessibility of high-throughput *de novo* sequencing, yet challenges remain to interpret their biology and the major drivers of their diversity and evolution. Mosquitoes, because of their public health importance, are among organisms whose viromes are being intensely characterized. Even as the number of new mosquito-associated viruses exponentially increases, our understanding of the viral ecology and association with other mosquitoes' symbionts remains limited. Using RNA-seq, and a laboratory method to enrich microbial RNA, we characterized viruses with RNA-based genomes and other symbionts in three mosquito species: *Armigeres subalbatus*, *Culex fuscocephala*, and *Mansonia uniformis*, collected from three previously-characterized habitats along an urbanization gradient in Thailand. We found multiple novel and known viruses belong to at least 12 viral families. In addition, we investigated how the mosquito's virome changed across the host species and habitat, and found that the pattern of virus presence was defined primarily by the host species rather than by the geographical locations or habitats. This result suggests that the insect-associated viruses displayed relatively narrow host ranges but were capable of spreading through a mosquito population efficiently, at least within the geographical scale of this study. Other single-celled and multicellular microorganisms such as bacteria, alveolates, fungi, nematodes, and lophotrochozoan were also found. The biological role of the mosquito-associated viruses should be further validated. These results emphasize the importance of including ecological information in viromic studies, and characterizing other microorganisms associated with hosts, in order to gain further insights into viral ecology in systems where host specificity is driving both viral ecology and evolution.

1526

HEPATITIS E IN BANGLADESH: INSIGHTS FROM A NATIONAL SEROSURVEY

Andrew Azman[1], Kishor K. Paul[2], Taufiq Rahman Bhuiyan[2], Firdausi Qadri[2], Henrik Salje[3], Emily Gurley[1]

[1]*Johns Hopkins School of Public Health, Baltimore, MD, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Institut Pasteur, Paris, France*

Hepatitis E is thought to be responsible for more than 70,000 deaths and another 3,000 stillbirths. Large outbreaks of HEV have been documented in South Asia and studies from Bangladesh suggest that up to 10% of maternal mortality may be caused by this vaccine-preventable disease. However, little is know about the geographic distribution and transmission intensity of hepatitis E in countries like Bangladesh. With an efficacious vaccine licensed for use in China and improved prospects for future WHO prequalification, endemic countries like Bangladesh need more detailed data on where HEV transmission occurs, thus providing important geographic targets for interventions. We conducted a nationally representative serosurvey across Bangladesh of 2,778 individuals from 70 randomly selected communities and tested serum samples for anti-IgG antibodies with the Wantai ELISA kit. We found that 20.9% of the population had evidence of historical HEV infection (IgG+) with large variation between communities (range 0-78%). Using Bayesian model-based geostatistical models, we explored the relationship between key individual- household- and community-level covariates and developed 5km by 5km maps HEV IgG positivity throughout the country. We found that males had a 2.3 fold (95% CrI 1.8-3.0) increased odds of being seropositive with increasing risk by age. A number of factors related to travel history, household wealth, community poverty and remoteness were associated with HEV seropositivity in univariate analyses, however, they were not significant in multivariable models. Our maps reveal Dhaka as a significant *foci* of HEV transmission with seroprevalence over 60% in some areas. In total, we estimate that 40.4 (35.6-45.6) million people in Bangladesh have been infected with HEV. These data provide insights into HEV epidemiology and can be used to guide future interventions and research in Bangladesh.

1527

EVALUATION OF A TWO TARGET RT-PCR ASSAY FOR DETECTION OF LASSA VIRUS

Ketan Patel[1], Bobbie Rae Erickson[1], Timothy Flietstra[1], Leonie-Sophie Hecht[2], Hussein El Halas[2], Stuart Nichol[1], John Klena[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Altona Diagnostics, Hamburg, Germany*

Lassa virus (LASV), a member of the family Arenaviridae, is an enveloped single stranded RNA virus, causing endemic disease in West Africa. Natural host of LASV is *Mastomys natalensis*, a small rodent. Human-to-human transmission is possible within the community as well as in the health care setting, via aerosols, contact with contaminated body fluids or re-use of contaminated medical equipment. LASV can cause Lassa Hemorrhagic Fever (LHF) with high fatality rates, reaching 15-20% among hospitalized patients. The considerable sequence diversity between LASV strains is challenging for the development of molecular diagnostic assays. The likelihood of false-negative results can be decreased significantly by using multiple genomic sequences as target regions, e.g. the L gene and the GPC gene. Here we present the performance evaluation of a real-time RT-PCR based molecular diagnostic test, comprised of two independent assays targeting specific sequences within the L and GPC genes, respectively. The reactivity of the RealStar® Lassa Virus RT-PCR Kit 2.0 toward the wide spectrum of virus variability was evaluated using infected Vero cell culture isolates of 39 different Lassa virus strains from different endemic areas: Nigeria, Guinea, Sierra Leone, Liberia, and Togo. All 39 tested samples were detected positive for Lassa virus RNA using the RealStar® Lassa virus RT-PCR Kit 2.0. The sensitivity and accuracy of the kit is 100% using the panel of Lassa Virus available at CDC. The RealStar® Lassa Virus RT-PCR Kit 2.0 detected all 39 strains representing 5 out of 6 linages from the Lassa fever endemic areas. Lineage V was not available for testing. The L and GPC assays showed strain and lineage dependent differences in reaction efficacy. The combined testing of GPC and L assay in one kit reduces the risk of non-reactivity towards certain strains or lineages.

1528

DRUG REPURPOSING FOR SEVERE FEVER WITH THROMBOCYTOPENIA SYNDROME VIRUS

Jasper Chan, Shuofeng Yuan, Lei Wen, Zi-Wei Ye, Dong-Yan Jin, Kwok-Yung Yuen

The University of Hong Kong, Hong Kong, Hong Kong

Severe fever with thrombocytopenia syndrome virus (SFTSV) is an emerging tick-borne bunyavirus that causes severe disease in human with a case-fatality rate of up to 30%. It causes an acute febrile illness,

known as SFTS, which is characterized by high fever, thrombocytopenia, and hemorrhagic complications in infected humans. Patients with SFTS may also develop other clinical manifestations such as systemic upset, coma, slurred speech, gastrointestinal upset, hepatosplenomegaly, and lymphadenopathy, and abnormal laboratory findings including leukopenia, prolonged activated partial thromboplastin time, deranged liver function tests, proteinuria, hematuria, and elevated creatinine kinase and lactate dehydrogenate levels. It is prevalently found in ticks and mammals in the Northeastern part of China, and parts of Japan and South Korea. There are currently very limited treatment options for SFTSV infection. In this study, we conducted a drug repurposing programme using an *in silico* structure-based screening approach to screen a large chemical library to identify potential inhibitors of the nucleocapsid protein (NP) of SFTSV. The *in vitro* antiviral activity of the drugs which potentially bind to SFTSV NP were assessed in Huh-7 cells using cytopathic effect inhibition, viral load reduction, and plaque reduction assays. Among the drugs predicted to bind with SFTSV NP, clofazimine, an antimicrobial for treating leprosy, was found to have the most potent antiviral activity *in vitro*. The IC_{50} and CC_{50} of clofazimine were 0.8 μM and 10.1 μM, respectively. Molecular docking predicted that clofazimine bound to the NP with high stability. The inhibition of SFTSV NP by clofazimine was validated by a mini-replicon assay which reflected the NP polymerase activity. Clofazimine-treated type I interferon receptor-deficient A129 mice had significantly improved clinical and virological parameters. Clinical trials should be considered to assess the treatment effects of clofazimine in patients infected with SFTSV.

FIRST REPORT OF THE OROPOUCHE VIRUS IN COLOMBIA

Doris Esther Gomez[1], Jorge A. Egurrola[1], Cristopher Cruz[2], Margarita Ochoa[1], Carolina Guevara[2], Maria Silva[2], Julia S. Ampuero[2]

[1]*Universidad de Cartagena, Cartagena, Colombia,* [2]*Naval Medical Research Unit-6, Lima, Peru*

Oropouche fever is an emerging zoonotic disease caused by the Oropouche virus (OROV) belonging to the family Bunyaviridae, genus *Orthobunyavirus*. OROV was initially reported in Trinidad and Tobago in 1955 and since then human cases have been reported in Brazil, Peru, Panama and Ecuador. Here, we report a case of a 28-year-old female patient from Turbaco (Bolivar, Colombia) with 1-day history of fever, malaise, chills, myalgias, headache, retroocular pain, photophobia, dizziness, sore throat, anorexia, dysgeusia and nausea. A blood sample was taken after informed consent was obtained as part of a passive febrile surveillance study in the area with the approval of the NAMRU-6 and Cartagena University IRBs. A real time RT-PCR was negative for dengue, Zika and chikungunya virus. Subsequently, the sample was inoculated in Vero 76 cells, and cytopathic effect was observed four days after inoculation. Indirect immunofluorescence (IFI) was performed with pools of polyclonal antisera for flavivirus (yellow fever and dengue-3), alphavirus (Venezuelan equine encephalitis, Eastern equine encephalitis, and Mayaro), HAC (encephalomyocardiovirus, Allpahuayo and Tacaribe) and bunyavirus (Guaroa, caraparu and OROV). A positive signal was observed with the mix of bunyavirus antisera. Guaroa, caraparu and OROV-specific antisera was then individually used to perform IFI and a positive signal was observed with OROV antisera. The sample was also analyzed for OROV, Guaroa, Mayaro and Tacaribe by ELISA IgM using antigens produced in-house and no positive signal was detected. Cell culture supernatant from grown virus was used to sequence the complete genome by unbiased amplifications and sequencing on the Illumina MiSeq platform. The isolated OROV is similar to Ecuadorian and Peruvian strains in its three genome segments (GenBank: MK643115, MK643116, MK643117). This would be the first human case confirmed with infection by OROV in Colombia.

1530

THE ROLE OF RON4 IN *PLASMODIUM* SPOROZOITE INFECTION OF THE LIVER

Minami Baba, Mamoru Nozaki, Mayumi Tachibana, Motomi Torii, Takafumi Tsuboi, Tomoko Ishino

Ehime University, Toon, Japan

Rhoptry neck protein 4 (RON4) is known as one of the *Plasmodium* merozoite rhoptry proteins and discharged to the moving junction during invasion. Since RON4 is refractory to gene disruption, it is thought to be essential for merozoite invasion of erythrocytes. RON4 is also expressed and localized to rhoptries in sporozoites, other invasion form of *Plasmodium*. It was reported that RON4-repressed sporozoites show lower infectivity to cultured hepatoma cells *in vitro*. This finding indicates that RON4 in sporozoites has an important role for infection of hepatocytes similar to that in merozoites. However, it remains unclear when RON4 works in the liver infection. To elucidate the molecular mechanism of RON4 during sporozoite infection of the liver *in vivo*, we applied a stage-specific knockdown system by promoter swapping in a rodent malaria parasite strain, *Plasmodium berghei*. The *ron4* promoter region was replaced by an erythrocytic-stage specific promoter, *msp9* promoter, by homologous recombination. The parasite amount in the mouse liver at 1h after intravenously inoculation of 30,000 RON4-knockdown sporozoite was approximately 3-fold less than that of control, indicating that RON4 has a role in sporozoite migration from hepatic sinusoid towards liver parenchyma. The parasite amount in the mouse liver at 42h after RON4-knockdown sporozoite inoculation was also reduced to 10-fold less than the control sporozoite infection. Taken together, these results suggest that RON4 has a role(s) also in hepatocyte invasion and/or development in hepatocytes. In vitro gliding assay demonstrates that RON4-knockdown sporozoites has lower adhesion ability and circular movement than that of control sporozoites. This study indicates that RON4 is required for sporozoite targeting to the liver via involving in its migration ability.

VISIBLE AND BIOCHEMICAL EVIDENCE OF ENDOTHELIAL GLYCOCALYX DEGRADATION IN TANZANIAN CHILDREN WITH FALCIPARUM MALARIA

Salvatore M. Florence[1], Ayam Kalingonji[1], Margaret A. Bush[2], Youwei Chen[2], Tsin W. Yeo[3], Nicholas M. Anstey[4], Matthew P. Rubach[5], Donald L. Granger[6], Esther D. MwaiKambo[1], J. Brice Weinberg[2]

[1]*Hubert Kairuki Medical Center, Dar es Salaam, United Republic of Tanzania,* [2]*Duke University and Veterans Affairs Medical Centers, Durham, NC, United States,* [3]*Lee Kong Chian School of Medicine, Singapore, Singapore,* [4]*Menzies School for Health Research, Darwin, Australia,* [5]*Duke University Medical Center, Durham, NC, United States,* [6]*University of Utah and Veterans Affairs Medical Centers, Salt Lake City, UT, United States*

Endothelial dysfunction in patients with *Plasmodium falciparum* malaria plays a major role in pathogenesis. The endothelial glycocalyx (eGC) composed of membrane-bound proteoglycans and glycoproteins is a gel-like layer covering the vessel luminal surface. The eGC functions to maintain vascular homeostasis by regulating permeability, modulating blood flow-induced shear stress signals including formation of nitric oxide, and inhibiting endothelial adherence of blood cells. We hypothesized that breakdown of the eGC occurs in malaria leading to endothelial activation and microvascular dysfunction. At the Hubert Kairuki Medical Center in Dar es Salaam, Tanzania, we measured eGC breakdown products glycosaminoglycans (GAG) and syndecan-1. We used dark-field SDF microscopy to visually quantify eGC damage at the axilla and pinna, including analysis of the perfused boundary region (PBR) that reflects eGC integrity. *P. falciparum* diagnosis was established by microscopy and RDT. Total urinary GAG levels were measured by dimethylmethylene blue assay, and plasma angiopoietin-2 & syndecan-1 by ELISA. We studied 59 healthy (HC), 49 moderately severe malaria (MSM), and 36 severe malaria (SM), age 1 to 10 years. Imaging revealed significantly higher

PBR in malaria vs HC (1.63±0.04 microns vs 1.51±0.04; p = 0.047). Total urinary GAG was higher in SM [13.4±1.0 mol/g creatinine (mean±SEM)] and MSM (12.4±1.0) than in HC subjects (4.3±0.4); p<0.0001. Plasma syndecan-1 was higher in malaria patients than HC (334±33 vs 79±7 ng/mL; p<0.0001). Both urine GAG and plasma syndecan-1 correlated significantly with plasma angiopoietin-2 (R=0.8 & R=0.7, respectively; p<0.0001), indicating an important relationship of GCX degradation and disease severity. Thus, Tanzanian children with falciparum malaria have evidence of glycocalyx degradation based on increased levels of urinary GAG and plasma syndecan-1, as well as increased eGC damage detected by visual imaging. It is likely that this glycocalyx damage contributes to the pathogenesis of vascular dysfunction. Agents that protect against glycocalyx damage may be useful as adjunctive treatments for malaria.

1532

PLACENTAL PATHOLOGY AND THE RISK OF PREECLAMPSIA IN WOMEN EXPOSED TO *PLASMODIUM FALCIPARUM* INFECTIONS IN THE PLACENTA

Dorotheah Obiri[1], Isaac Erskine[2], Kwame Adu-Bonsaffoh[3], Daniel Oduro[4], Kwadwo A. Kusi[5], Michael F. Ofori[5], Ben Gyan[5]

[1]*West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana,* [2]*Department of Pathology, Korle-Bu Teaching Hospital, Accra, Ghana,* [3]*Department of Obstetrics and Gynecology, Korle-Bu Teaching Hospital, Accra, Ghana,* [4]*Department of Animal Biology and Conservation Science, University of Ghana, Accra, Ghana,* [5]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana*

Preeclampsia (PE) is a placental disorder with multifactorial etiologies that present with different phenotypes. In malaria-endemic regions, high incidence of PE is reported, with debilitating maternal and fetal effects particularly among first time pregnant women. However, the relationship between placental pathology, *Plasmodium falciparum* infection in the placenta and PE is underexplored. A total of 134 placentas were sampled at delivery from 69 women without PE (non-PE group) and 65 women diagnosed with PE (PE group) at a tertiary hospital in Ghana. Demographic details were documented and placentas examined histologically for pathological lesions and placental malaria (PM). Placental pathology was increased in the PE group compared to the non-PE group, with syncytial knots being the specific pathology associated with PE ($P = 0.003$). Pathology was also found to be dependent on first-time pregnancy and blood pressure to induce PE using a regression model (AOR 2.8, 95% CI = 1.2 – 6.4). Of 133 placentas scored for placental parasite exposure, 64 (48.1%) and 21 (15.8%) represented active and past infections respectively. Placental parasite exposure was significantly higher in the PE group [39 (29.3%) and 15 (11.3%) active and past infections respectively] compared to the non-PE group [25 (18.8%) active infections and 6 (4.5%) past infections, $P < 0.0001$]. The absence of placental exposure was 10 (7.5%) in the PE and 38 (28.6%) in the non-PE group. Multivariate analysis showed placental pathology (AOR 3.0, 95% CI = 1.2 – 7.5), exposure to PM [(active infection: AOR 6.7, 95% CI = 2.3 – 19.1); (past infection: AOR 12.4, 95% CI = 3.0 – 51.0)], first pregnancy (AOR 6.6, 95% CI = 2.4 – 18.2) but not blood pressure to be significantly associated with PE. Placental histological changes and PM are risk factors for PE particularly in primigravids. Mechanisms associated with this finding should further be investigated.

1533

CHARACTERIZATION OF A *PLASMODIUM FALCIPARUM* HECT E3 UBIQUITIN LIGASE

Brajesh Kumar Singh, Xin-zhuan Su

National Institutes of Health, Rockville, MD, United States

The gene encoding *Plasmodium yoelii* HECT ubiquitin ligase (*Pyheul*) is a large essential gene (22.5 Kb) that regulates parasite growth and virulence. We have shown that *Pyheul* influences parasitemia and host mortality in mice. This finding inspires us to study this gene in the human malaria parasite *P. falciparum*. Protein ubiquitylation is an important post-translational regulation that has been shown to be necessary for life cycle progression and survival of *P. falciparum*. The *P. falciparum* E3 ubiquitin ligase is substantially variable and divergent compared to the homologs from other eukaryotes, which make the E3 ligase a potential parasite-specific target. To better understand the function of the ligase, we created a transgenic parasite line using pSli-HA-glmS plasmid that enables us to knock down the expression of E3 ubiquitin ligase. The pSli-HA-glmS plasmid is designed for C-terminal tagging of proteins with 3X-HA tag and addition of glmS sequence. The glmS ribozyme allows a candidate gene to be down regulated with the addition of glucosamine. Our study will help toward a better understanding of ubiquitylation and new ubiquitination targets. The ubiquitin targets may therefore represent excellent molecules for future development of anti-malarial drugs.

1534

A POTENTIAL ROLE FOR ANTIBODY-MEDIATED *THROMBOCYTOPENIA* IN PEDIATRIC CEREBRAL MALARIA

Iset Medina Vera[1], Anne Kessler[2], Visopo Harawa[3], Wilson Mandala[4], Stephen J. Rogerson[5], Terrie Taylor[6], Karl Seydel[6], Morayma Reyes[7], Kami Kim[1]

[1]*University of South Florida, Tampa, FL, United States,* [2]*New York University, New York, NY, United States,* [3]*Blantyre Malaria Project, Blantyre, Malawi,* [4]*Academy of Medical Sciences, Malawi University of Science and Technology, Malawi University of Science and Technology, Thyolo, Malawi,* [5]*The University of Melbourne, Melbourne, Australia,* [6]*Michigan State University, East Lansing, MI, United States,* [7]*Albert Einstein College of Medicine, Bronx, NY, United States*

Cerebral malaria (CM) is characterized by coma with peripheral *P. falciparum* parasitemia, parasite sequestration, and associated endothelial dysfunction, pathologic immune activation, and thrombocytopenia with intravascular coagulation. CM pathology is reminiscent of heparin-induced thrombocytopenia (HIT), a pro-thrombotic adverse response to exogenous heparin treatment where pathologic antibodies (Ab) recognize a neo-antigen within platelet factor 4 (PF4) complexed to heparin. PF4/heparin/Ab complexes cross-link platelets and other immune cells via Fcγ receptor leading to a positive feedback loop. Autoimmune HIT can occur in patients without prior heparin exposure. In CM, autoimmune, non-malaria antibodies have been described, but the contribution of antibody-mediated thrombocytopenia has not been addressed. We hypothesized that HIT-like antibodies may contribute to malaria pathogenesis. Children with uncomplicated malaria (UM, n=84) or CM (n=123) were recruited at Queen Elizabeth Central Hospital (Blantyre Malaria Project, Malawi; 2015-2017 seasons) and plasma was analyzed. In CM, median levels of HIT-like IgG in plasma were elevated relative to UM (OD: 0.27 *vs* 0.18, p=<0.0001). Notably, the proportion of CM (33 of 123) with IgG levels above the established clinical threshold (OD=0.4) defining HIT positivity was 22-fold higher than in UM (1 of 84). Furthermore, heparin-dependent and independent binding of IgG (confirmed by inhibition with high dose heparin) were observed. Levels of HIT-like IgG in acute infection decreased with convalescence (30 days; p=<0.0001). Analysis of non-malaria, auto-immune antibodies/complexes (anti-dsDNA antibodies and circulating immune complexes; CIC) showed no differences between UM and CM. Levels of soluble PF4 were elevated in UM relative to CM, indicating an early platelet activation that may result in consumptive coagulopathy as malaria progresses. Further studies will focus on analysis of platelet activation markers and functional studies on HIT. Overall, this preliminary work points to a role for auto-antibody mediated thrombocytopenia in severe malaria pathology.

Malaria erythrocyte binding-like (EBL) proteins play a critical role in parasite invasion. Previously we identified a C741Y substitution at the trafficking domain VI of PyEBL and performed allelic exchanges between two isogenic parasites, leading to altered disease phenotypes and host immune response. In addition to expression in merozoites, PyEBL is also expressed in iRBCs, resulting in changed surface protein expression, PS exposure, and osmotic fragility. The parasites with C741 allele triggered stronger inflammatory cytokines and chemokines. The parasites with Y741 allele stimulated CD36 mediated phagocytosis, type I interferon signaling, T cell differentiation, isotype switching and improved host survival. This study reveals a previously unknown mechanism of PyEBL in regulating innate immune response and host pathogen interaction.

1536

THE IMPACT OF ALPHA-GLOBIN GENE VARIANTS ON ENDOTHELIAL FUNCTION IN ADULTS WITH SEVERE MALARIA

Jessica Nino de Rivera[1], Matthew Grigg[2], Dongying Ma[1], Yu Yang[1], Bridget Barber[2], Timothy William[2], Kim Piera[2], J. Brice Weinberg[3], Tsin W. Teo[2], Nicholas M. Anstey[2], Hans C. Ackerman[1]

[1]*National Institute of Allergy and Infectious Diseases, Rockville, MD, United States,* [2]*Menzies School of Health Research, Darwin, Australia,* [3]*Duke University, Durham, NC, United States*

The human alpha globin genes HBA1 and HBA2 are highly polymorphic, with deletions and sequence variants that decrease the transcription or synthesis of functional alpha globin protein causing a spectrum of alpha thalassemia syndromes. While some variants have been associated with decreased susceptibility to malaria, precise mechanisms of protection remain to be elucidated. Recently, alpha globin was discovered to be expressed in vascular endothelial cells where it regulates nitric oxide signaling. Genetic or pharmacologic inhibition of alpha globin expression increases nitric oxide signaling in intact vessels; therefore, we hypothesized that human polymorphisms that inactivate alpha globin will increase endothelial nitric oxide signaling. This is relevant to the pathogenesis of malaria where the loss endothelial nitric oxide signaling may contribute to adhesion of infected blood cells, occlusion of small vessels, and impairment of vasoregulation. Using droplet digital PCR, we precisely quantified the known structural *HBA* variants -3.7, -4.2, --SEA, and --FIL as well as the Constant Spring and Adana sequence variants in two case-control studies of severe malaria conducted in Timika, Indonesia (n=324) and Sabah, Malaysia (n=194). We are now analyzing the association between alpha globin genotype and physiologic measures of endothelium-dependent vasodilation as well as biomarkers of endothelial activation such as angiopoietin-2 and osteoprotegerin. These studies will extend our understanding of the role of endothelial alpha globin in nitric oxide signaling and determine whether alpha globin gene variants alter endothelial function in severe malaria.

1537

ASSOCIATION OF EPCR POLYMORPHISMS RS867186-GG WITH PROTECTION AGAINST HUMAN CEREBRAL MALARIA (HCM)

Mingli Liu[1], Juan Cespedes[1], Bharti Praveen[2], Sri Krishna[2], Jonathan Stiles[1]

[1]*Morehouse School of Medicine, Atlanta, GA, United States,* [2]*National Institute for Research in Tribal Health (NIRTH), Jabalpur, India*

Cerebral malaria (CM) is characterized by the sequestration of *Plasmodium*-infected erythrocytes (pRBC) to host brain microvasculature beds via *P. falciparum* erythrocyte membrane protein 1 (PfEMP1). Under normal situation, activated protein C (APC) bound to endothelial protein C receptor (EPCR) has cytoprotective properties by activating protease-activated receptor 1 (PAR1) while pRBC transports PfEMP1 to their membranes, which can bind EPCR in the same region as APC. As a result, APC is less capable of inducing cytoprotective effects via PAR1. Two studies involving adult malaria patients revealed that EPCR rs867186-G allele could mediate protection against severe malaria, while three other studies involving child malaria patients showed that EPCR gene variants are not associated with severe malaria or increased mortality among children with CM. We examined the association of the EPCR rs867186-G allele with protection against severe malaria. *1)* 47 malaria patient and 4 healthy control individual samples were collected from 2004 to 2007 at NSCB Medical College Hospital, India. CM and malaria associated complications were defined using WHO criteria. *2)* Genomic DNA was isolated from the peripheral blood mononuclear cells of subjects. Primer sequences were designed to contain rs867186 of the *PROCR* gene (NM 006404) and were used to amplify a 660 bp product. PCR products were purified, and DNA sequences were determined by Sanger Sequencing (www.Genewiz.com. Genewiz, NJ). *3)* Statistical analysis: Nonparametric tests compared groups, and the chi-square or Fisher's exact test for 2x2 table was used for categorical variable, if the expected value was less than 5, to analyze differences in allele frequencies. P-value <0.05 was considered statistically significant. Fisher's exact test showed that there is significantly higher rates of A/G plus G/G in CM patients compared to mild malaria ($p = 0.0034$); similarly, there is significantly higher rates of A/G in CM patients compared to mild malaria patients ($p = 0.0017$). Our results indicate that rs867186-GG or rs867186-GA genotypes do not mediate protection against HCM.

1538

USING SEASONAL MALARIA CHEMOPREVENTION (SMC) TO SCREEN FOR ACUTE MALNUTRITION

Moumouni Bonkoungou[1], Youssouf Sawadogo[1], Stanislas Nebie[1], Thierry Ouedraogo[1], Yacouba Savadogo[2], William Brieger[3], Gladys Tetteh[4], Blami Dao[4]

[1]*PMI Improving Malaria Care Project, Ouagadougou, Burkina Faso,* [2]*Ministry of Health, National Malaria Control Program, Ouagadougou, Burkina Faso,* [3]*Johns Hopkins University, Baltimore, MD, United States,* [4]*Jhpiego Baltimore, Baltimore, MD, United States*

Malaria and malnutrition remain a major public health burden in Burkina Faso for children under five years of age. In 2017 case fatality rate of malaria was 1.5 percent among children under five years of age and malaria was responsible for 35.9 percent of deaths in primary health facilities. In the same year, malnutrition was responsible for 4.6 percent of deaths in primary health facilities and 3.3 percent of deaths in hospitals. Malaria is aggravated by the presence of malnutrition. In 2018, the Burkina Faso Seasonal Malaria Chemoprevention (SMC) campaign integrated malnutrition screening in 65 out of 70 health districts. During the SMC campaign, community health workers administer sulfadoxine-pyrimethamine + amodiaquine (SP+AQ); they also screened for malnutrition using the Shakir sling to measure mid-upper arm circumference to detect for acute malnutrition. Children who are not severely malnourished receive the standard malaria preventative treatment by SP+AQ. Children diagnosed with severe malnutrition do not receive SP+AQ and are referred to health facilities for appropriate

case management. In October 2018, during the last monthly round of SMC, 419,705 children aged 6 to 59 months were screened by community distributors in 12 President's Malaria Initiative (PMI) supported health districts. Among these children, 2,009 cases of moderate acute malnutrition, and 525 cases of severe acute malnutrition (0.6 percent of children) were detected. In November, after the last round (October), 427 children with severe acute malnutrition have been reported by health facilities. This represents 81.3 percent of severe acute malnutrition detected during SMC. In 2017 malnutrition screening was not combined with SMC and children screened for the whole year were 988,529 compared to 1,177,316 in 2018 (with SMC), an increase of 19 percent of children benefited from screening. In the context of a limited resource country, SMC is a good strategy for the reduction of malaria cases as well as a great opportunity for the detection and management of malnutrition in children under five years of age.

1539

PROBING THE REGULATION OF TARGETABLE METABOLIC PATHWAYS IN MALARIA PARASITES

Philip M. Frasse, Audrey R. Odom John

Washington University School of Medicine, St. Louis, MO, United States

Malaria continues to be an enormous economic and global health threat. We study unique and targetable metabolic pathways in the malaria parasite, *Plasmodium falciparum*, to guide future antimalarial drug development. Using a drug resistance screen, we have identified mutations in multiple haloacid dehalogenase (HAD) enzymes that confer resistance to fosmidomycin, an inhibitor of the first committed step of the methylerythritol phosphate (MEP) pathway of isoprenoid biosynthesis in the parasites. We now use genetic, biochemical, and metabolomic approaches to determine the enzymatic functions of these enzymes and illuminate the mechanism(s) of resistance in our mutant parasites. We have found that parasites with mutations in HAD1 or HAD2 have increased availability of the isoprenoid precursor, deoxyxylulose-5-phosphate (DOXP), which outcompetes the inhibitor. We find that HAD enzymes are phosphatases that dephosphorylate intermediates of central carbon metabolism, in turn modulating DOXP levels. In addition, we have identified genetic changes in a related HAD protein, phosphomannomutase (PMM), in parasites evolved for resistance to the Malaria Box compound MMV665917. We hypothesize that MMV665917 targets mannose biology or central carbon metabolism, and ongoing studies address this hypothesis. Altogether, these HAD proteins and their homologs are involved in many branches of metabolism, and may be key to understanding the finely-tuned metabolic regulation in malaria parasites. We therefore are assessing the sensitivity of these resistant strains to other antimalarials to determine whether drug resistance by these mechanisms may sensitize parasites to other drugs. By expanding our understanding of parasite metabolism, we are informing future endeavors to target these unique pathways for therapeutics.

1540

ELEVATED LEVELS OF HEMOZOIN AND ERYTHROPHAGOCYTOSIS PREDICT LONGITUDINAL EPISODES OF SEVERE MALARIAL ANEMIA IN KENYAN CHILDREN

Samuel B. Anyona[1], Evans Raballah[1], Elly Munde[1], Caroline Ndege[1], Qiuying Cheng[2], Paul Fenimore[3], Benjamin H. McMahon[3], Nick Hengartner[3], Collins Ouma[4], Christophe G. Lambert[2], Douglas J. Perkins[2]

[1]*University of New Mexico-Kenya Global Health Programs, Kisumu, Kenya,* [2]*University of New Mexico Center for Global Health, Albuquerque, NM, United States,* [3]*Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States,* [4]*Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Kisumu, Kenya*

In western Kenya, severe malaria manifests as severe malarial anemia [SMA; hemoglobin (Hb)<5.0 g/dL] in children <48 months. Our previous studies showed that enhanced uptake of *Plasmodium falciparum* hemozoin (*Pf*Hz, malarial pigment) in cultured peripheral blood causes dysregulation in inflammatory mediators known to impact on the development of SMA. We have also shown that elevated levels of pigment-containing monocytes (PCM) in Kenyan children increases the risk of developing SMA in cross-sectional analyses. However, the impact of naturally-acquired *Pf*Hz and erythrophagocytosis on the development of longitudinal episodes of SMA are unexplored. As such, we determined levels of intraleukocytic *Pf*Hz and erythrophagocytosis in circulating mononuclear cells in children (n=1,610) over a 36 month follow-up period during the phase of naturally-acquired malarial immunity (>19,000 visits). Logistic regression modeling (controlling for anemia promoting covariates) over 36 months of follow-up revealed that presence of PCM increased the odds of SMA up to 3.54-fold (P=8.63x10^{-17}), while erythrophagocytosis enhanced the odds of SMA up to 67.36-fold (P=3.90x10^{-3}). Taken together, these results suggest that phagocytosis of *Pf*Hz and erythrophagocytosis by mononuclear cells increase the longitudinal risk of SMA.

1541

TEMPERATURE DRIVES MALARIA TRANSMISSION: IMPLICATIONS FOR DISEASE CONTROL

Courtney Murdock[1], Kerri Miazgowicz[1], Erin Mordecai[2], Sadie Ryan[3], Richard Hall[1]

[1]*University of Georgia, Athens, GA, United States,* [2]*Stanford University, Stanford, CA, United States,* [3]*University of Florida, Gainesville, FL, United States*

Dramatic reductions in disease burdens of human malaria in the last 20 years has led to ambitious calls for eradicating the disease by 2030. However, eradication hinges on our ability to eliminate transmission 1) from both symptomatic and asymptomatic hosts, 2) across highly heterogeneous landscapes created by biotic and abiotic factors, and 3) with the emergence of multi-drug resistance to the last remaining anti-malarials, artemisinin-combination therapies. Despite growing research efforts to develop new therapeutics and vaccines, mitigating malaria transmission still largely depends on conventional mosquito control methods (e.g. bed nets, indoor residual spraying). Developing tools that will allow us to successfully predict outbreaks and efficiently target current and future interventions to specific times and locations will aid effective mosquito and disease control. Current work revolves around experimentally testing common assumptions made by mathematical models that predict transmission, identifying additional sources of ecological variation these models should incorporate, and building new models to improve prediction. This includes assessing how transmission models perform when key mosquito life history traits (e.g. daily per capita mortality rate, egg production, and biting rate) change across the lifespan of the mosquito vector, in thermally variable environments, across different species of *Anopheles* mosquitoes, and with parasite infection. Results from these studies combine both empirical and mathematical models to resolve uncertainty in current malaria models.

SINGLE STEP MEROZOITE RELEASE STRATEGY FOR RED BLOOD CELL INVASION ASSAYS

Jurgen Bosch, Quentin D. Watson, Rajeev K. Mehlotra, Howard J. Meyerson, Peter A. Zimmerman

Case Western Reserve University, Cleveland, OH, United States

Investigating fundamental features of malaria blood stage infection has relied on synchronization of parasites propagating in culture.

Traditionally, parasite growth has been synchronized by exposing cultures to refrigeration, treating 5% D-sorbitol or mannitol, sedimentation in Plasmagel or gelatin. More recently, parasite synchronization has been achieved by isolating a brood of merozoites and adding them to target red blood cells (RBC). In this method, late-developmental stages are purified from cultures using magnetic columns followed by a mechanical rupture through a syringe filter. This method requires at least 6-8h and four steps (E64 inhibition of parasite growth/propagation, magnetic column enrichment, schizont maturation, mechanical rupture). Here we demonstrate a novel, single-step chemical treatment to rapidly and efficiently release merozoites from infected RBC. 40 μL of resuspended parasite culture was mixed with 1 mL of the treatment solution. The cells are then incubated on ice. We varied treatment exposure (2, 5 and 10 minutes) and resting in complete media (0, 10, 30 minutes) times to optimize parasite invasion. Extent of RBC lysis/merozoite liberation and parasite invasion was monitored by imaging flow cytometry (IFC), counting 200000 cells. Invasion assays occurred over 72 hr. Results showed that 2-5 minute treatment times were optimal, while 10 minutes diminish parasite invasiveness completely. At these optimal treatment times, highest levels of parasite RBC invasion was observed at 10 minutes of resting, although all of the resting times were compatible with onward parasite growth. Optimal starting parasitemia and invasion culture seed volume was 0.2 μL of the RBC lysate is added to 7.2 μL of packed RBC (final hematocrit of 4%).

1543

MODELING RESISTANCE-CONFERRING MUTATIONS AND ANTIMALARIAL DRUG INTERACTIONS IN THE PFCRT 3.2 Å CRYO-EM STRUCTURE

Kathryn J. Wicht, Jonathan Kim, Yong Zi Tan, Filippo Mancia, David A. Fidock

Columbia University Medical Centre, New York, NY, United States

Resistance to weak-base 4-aminoquinoline antimalarials has primarily been attributed to mutations in the 49 kDa drug *P. falciparum* chloroquine resistance transporter (PfCRT), resident on the parasite's digestive vacuole (DV) membrane. These mutations first arose in the field from chloroquine (CQ) drug pressure. More recently, PfCRT mutations associated with resistance to piperaquine (PPQ), a partner drug of artemisinin-based combination therapies, have been reported. In this study, we performed computational protein modeling based on our structure of the CQ-resistant (CQ-R) 7G8 PfCRT isoform from South America. This structure was solved by single-particle cryo-electron microscopy to 3.2 Å resolution in the open-to-DV conformation. Here, we mutated CQ and PPQ resistance-conferring mutations *in silico* and docked antimalarials into the structures. Residue changes on the transmembrane (TM) helices contributing to CQ resistance (CQ-R) or PPQ resistance (PPQ-R) map to a central cavity, implicating this as the major site of drug interaction. Leveraging the 2-fold pseudo-symmetry of PfCRT's ten TM helices, a homology model was built by performing sequence alignment of the symmetrically related TM pairs in order to generate the closed conformation of the transporter. Subsequent mapping of mutations, drug docking and molecular dynamic simulations suggest differences in the way that PfCRT interacts with PPQ vs CQ to regulate their transport away from the acidic DV (pH ~5). Simulation analyses revealed favorable H-bonding between positively charged drugs and negatively charged or polar residues in the binding cavity, except in the case of CQ with the CQ-sensitive isoform, where CQ cannot access the binding site. These findings support the hypothesis that transport of protonated CQ^{2+} out of the DV is controlled by drug access to PfCRT's binding cavity, whereas protonated PPQ^{4+} transport may be influenced by deprotonation and release from PfCRT in the closed-to-DV conformation. These structural insights provide new opportunities to define approaches for blocking PfCRT's ability to function as a pleiotropic drug resistance transporter.

Sulfadoxine-pyrimethamine (SP) in combination with amodiaquine is now recommended by the World Health Organization for seasonal malaria chemoprevention (SMC) in children from 3 to 59 months of age in the Sahel region of Africa. Since 2012, SP has also been used to prevent plasmodial infection and malarial disease in pregnant women (Intermittent Preventive Treatment of Malaria during pregnancy, IPTp-SP). For this reason, there is concern about the spread of parasites resistant to sulfadoxine-pyrimethamine from selective pressure to the intensive use of SP in SMC campaigns and for IPTp. The objective of this study was to examine the frequency of quintuple mutants in the *Pfdhfr* and *Pfdhps* genes and to identify potential new mutations using Sanger sequencing during and after the 2018 SMC campaign in children and in pregnant women at the time of their first visit to the Ante-Natal Clinic. Of the 428 children with confirmed malaria who were enrolled in this study, 254 received SP/AQ during the 2018 SMC campaign. The preliminary results show the presence of the mutation at position 540 in the *Pfdhps* gene with an amino acid change from K to E (Lysine to Glutamate). This mutation may be essential for the resistance of *Pfdhps* to sulfadoxine. In addition, new mutations have been found with other codon changes in the same gene. Processing of the remaining isolates should clarify the impact of SMC on the polymorphisms in the *Pfdhps* and *Pfdhfr* genes in Mali.

Artemisinin combination therapies (ACTs) are used to treat uncomplicated malaria in most endemic regions and have been extremely important in decreasing morbidity and mortality. However, resistance to artemisinins, defined as delayed clearance after therapy, has emerged in Southeast Asia, and the potential spread of resistance to high transmission areas, such as much of sub-Saharan Africa, could have devastating consequences. Artemisinin resistance has been associated with multiple non-synonymous SNPs (NS-SNPS) in the propeller domain of the *K13* gene (*K13PD*) in Southeast Asia, yet the relevance of such mutations in sub-Saharan Africa is unclear. Over 200 NS-SNPs, including some that have been associated with resistance in Southeast Asia, have been reported at low prevalence in clinical isolates from Africa, but the delayed clearance phenotype is uncommon and ACTs continue to be highly efficacious. Hypothesizing that changes in the diversity of *K13PD* following ACT exposure would serve as

an early indication of the evolution of artemisinin resistance in Uganda, we compared the genetic diversity of the *K13PD* locus in clinical isolates collected before and after the implementation of ACT use from seven sites across the country. We detected NS-SNPs in the *K13PD* locus in 17 of 682 (2.5%) clinical isolates collected between 1999 and 2004 and in 21 of 574 (3.7%) isolates collected between 2012 and 2016 (p = 0.25), representing a total of 26 different polymorphisms at 24 codons. Individual NS-SNPs generally were detected only once and were never found in more than 0.7% of the total isolates. Two SNPs (P574L and A675V) associated with delayed clearance in Southeast Asia were seen in samples collected between 2012 and 2016, but each in a single isolate. No differences in diversity following implementation of ACT use were found at any of seven sites across Uganda. In conclusion, we found no evidence that selection by ACTs is impacting on *K13PD* diversity in Uganda.

TREATMENT PILOT IN BURKINA FASO, 2017-2018

Ousmane Badolo, Mathurin Dodo, Thierry Ouedraogo, Moumouni Bonkoungou, Youssouf Sawadogo, Stanislas Nebie, Blami Dao, Gladys Tetteh, William Brieger

Jhpiego, Ouagadougou, Burkina Faso

Malaria is the main cause of morbidity, hospitalization and death in health facilities in Burkina Faso. The Improving Malaria Care (IMC) project funded by the US President's Malaria Initiative (PMI) and implemented by Jhpiego provides technical and logistical support to the National Malaria Control Program (NMCP) to implement pre-referral treatment of severe malaria with rectal artesunate in children under 5 by 1244 Community-based Health Workers (CHWs) covering 117 health centers in four health districts in the Sahel region. This study aims to describe the process and compare malaria-attributable deaths before and after the pilot. In August 2018, a stakeholder orientation workshop discussed the implementation of the pre-referral treatment policy. This was followed by an advocacy workshop at regional level, a training-of-trainers session and training of CHWs on the pre-referral treatment. A total of 564 children under 5 with RDT-confirmed severe malaria received pre-referral treatment using rectal artesunate during the period October to December 2018. In 2017, from October to December, before the IMC-supported intervention, 4,159 cases of severe malaria and 154 deaths from malaria were recorded in the Sahel region, with a case fatality proportion of 3.7%. From October to December 2018, 5383 cases of severe malaria and 128 deaths from malaria among children under 5 were recorded with a case fatality proportion of 2.4%. Despite the increase in cases of severe malaria (29.4%) between 2017 and 2018, the number of malaria-attributable deaths decreased by 16.8%, and the case fatality proportion decreased by 35.8%. While a reduction in deaths from malaria in the Sahel region is seen, we saw an increase in other regions. For example, the number of malaria related deaths increased from 28 to 103 in North region, from 48 to 125 in Center East region and from 85 to 143 in East region. The pre-referral treatment of severe malaria cases may have contributed to reducing the number of malaria related deaths in the Sahel region. Based on this result, PMI is planning support for extension of this intervention to cover the 6 health districts of the Center-North region.

ANTI-PARASITIC PROPERTIES FOR NEEM DERIVATIVES: POTENTIAL NOVEL THERAPEUTIC OPTIONS FOR CONTROLLING RESISTANT *PLASMODIUM FALCIPARUM* MALARIA

Angela O. Achieng[1], Caroline Ndege[1], Bernard Guyah[2], Collins Ouma[2], Cristian Bologa[3], Tudor Oprea[3], Douglas J. Perkins[4]

[1]*University of New Mexico-Kenya Global Health Programs, Kisumu, Kenya,* [2]*Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Kisumu, Kenya,* [3]*Division of Translational Informatics, Department of Internal Medicine, University of New Mexico, Albuquerque, NM, United States,* [4]*University of New Mexico Center for Global Health, Albuquerque, NM, United States*

Malaria control largely depends on the use of chemotherapy. However, the emergence and spread of multi-drug resistant *Plasmodium Spp*. provides significant challenges to malaria control. Conventional antimalarials were primarily discovered and adopted for malaria treatment based on their *in vitro* anti-plasmodial activity; with little knowledge of their molecular mechanism of action. *Azadirachta indica* (neem) is traditionally used as herbal therapy to treat malaria in Asia and Africa. Neem antimalarial activity is primarily attributed to its terpenoid derivatives. The potential use of neem derivatives in combinatorial therapeutics, and the molecular mechanism(s) underlying their anti-plasmodial activity remain largely unexplored. This study investigated *in vitro* anti-plasmodial efficacy of neem leaf extract and 17 neem derivatives individually, and in combination with dihydroartemisinin (DHA) against *Plasmodium falciparum* D6 and W2 strains using the SYBR® GREEN I assay. *In silico* molecular docking studies were also conducted for identification of plausible putative parasite targets for characterization of anti-plasmodial mechanisms of action for neem. *In vitro* screening experiments identified 10 compounds with potent anti-parasitic activity (IC_{50} <2μM) against *Pf*D6 and *Pf*W2, and with low or no cytoxicity on human cells. In addition, significant synergistic interactions were observed between five neem derivatives in combination with DHA. Molecular docking identified *P. falciparum* histone deacetylase 1 protein *(Pf*HDAC1) as a target for a methyl 2, 5-dihydroxycinnamate neem derivative. Additional *in vitro* target bioassay confirmed that methyl 2, 5-dihydroxycinnamate possess antimalarial potential through binding to *Pf*HDAC1. Taken together, these results suggest that neem derivatives are promising novel candidates for use as antimalarial drugs.

ASSESSMENT OF PARASITE CLEARANCE AFTER TREATMENT WITH PYRONARIDINE-ARTESUNATE, ARTESUNATE-AMODIAQUINE, ARTEMETHER-LUMEFANTRINE AND DIHYDROARTEMISININ-PIPERAQUINE IN *PLASMODIUM FALCIPARUM* MALARIA: RESULTS FROM THE WEST AFRICAN NETWORK (WANECAM) TRIAL

Issiaka Soulama[1], Issaka Sagara[2], Habib Beavogui[3], Jean Bosco Ouedraogo[4], Sodiomon B. Sirima[5], Abdoulaye Djimde[2]

[1]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso,* [2]*Malaria Research and Training Center, Bamako, Mali,* [3]*Centre National de Formation et de Recherche en Sante Rurale (CNFRSR), Conakry, Guinea,* [4]*Institut de Recherche en Sciences de la Santé, Institut des Sciences et techniques (INSTech), Bobo, Burkina Faso,* [5]*Centre National de Recherche et de Formation sur le Paludisme, Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso*

Reports from the Greater Mekong Subregion (GMS) showed the emergence of delayed parasite clearance with known artemisinin based combination therapies. We conducted the WANECAM to comparatively assess the antimalarial safety/efficacy and monitor the parasite clearance time in patients treated for uncomplicated *P. falciparum* with three-day regimens of pyronaridine-artesunate (PA), artesunate-amodiaquine (ASAQ), artemether-lumefantrine (AL) and dihydroartemisinin-piperaquine (DP). A randomized phase IIIb/IV comparative, multicentre, open-label parallel 3 arms trial was conducted in Burkina Faso, Guinea and Mali in patients aged more than six months with 42 days of follow-up. We monitored patients over a 2-year period to capture the incidence of repeated episodes of malaria and to assess PA and DP safety and efficacy, compared with AL or ASAQ (no direct comparison between PA and DP). Treatment was directly observed, and blood smear samples were collected twice daily (12 h ±2 h) until parasite clearance. The endpoint of interest for this present sub-study was parasite clearance slope half-life for the first episode of malaria. The estimates of parasite clearance time (PCE) was derived using the WorldWide Antimalarial Resistance Network (WWARN) PCE tool. PCE estimates were summarized from well-fitting profiles (with R-squared >0.8). A total of 4,710 patients were recruited in the study

with the PCR-adjusted efficacy on day 28 in the per protocol population estimated at 99.8%, 99.7%, 99.3%, and 99.9% in PA, ASAQ, AL, and DP arms respectively. Parasite clearance slope half-life was available from 4,205 (89.3%) participants for the first episode with the profile adjudged as good fitting for 2,136 (50.1%) participants. The day 2 parasite positive proportion was 1.3% (58/ 4632) and day 3 positive proportion was 0.06% (3/ 4627). The overall median parasite clearance slope-half-life was 2.8 h (inter-quartile range (IQR): 2.4 to 3.2h) and this was similar between the study drugs. The four ACTs included in this trial demonstrated excellent efficacy and had comparable parasite clearance slope half-life.

1549

COMBINATION THERAPIES FACILITATING THE SPREAD OF ARTEMISININ-RESISTANCE IN THE GREATER MEKONG SUBREGION

Kristan A. Schneider[1], Ananias A. Escalante[2]

[1]*University of Applied Sciences Mittweida, Mittweida, Germany,* [2]*Temple University, Philadelphia, PA, United States*

The spread of artemisinin resistance due to several mutations in the Kelch13 gene in the the Greater Mekong Subregion is a source of concern, and its containment a public health priority. Susceptibility of *Plasmodium falciparum* to antimalarial drugs is typically evaluated by therapeutic efficacy studies. While many confounding factors contribute to the clinical outcome it is difficult to identify mutations associated with drug resistance if these are at low frequency in the initial phase of their spread. From a clinical perspective the focus lies on therapeutic efficacy of chemotherapy. However, the spread of drug resistance is an evolutionary process, determined by the relative fitnesses of resistance-conferring haplotypes. Although therapeutic efficacy is related to evolutionary fitness, the former is just one of many so-called fitness components contributing to determine the latter. When considering the complex compounds of fitness components, it becomes clear that certain drug combinations can facilitate the spread of artemisinin resistance despite improved therapeutic efficacy. This fact, that sounds like a paradox at the first sight, is the consequence of the parasite's life history. By using a formal qualitative model, this argument can be put forward in a simple way without digging into mathematical details. Formalizing this argument give rise to new study designs to be conducted in the future to get better estimates on the spread of drug resistance and new strategies for containment.

1550

CHARACTERIZATION OF DORMANT *PLASMODIUM FALCIPARUM* PARASITES IN HUMAN PARTICIPANTS FOLLOWING ARTESUNATE THERAPY

Chris Peatey[1], Nanhua Chen[1], Karryn Gresty[1], Karen Anderson[1], Paul Pickering[1], Rebecca Watts[2], James McCarthy[2], **Qin Cheng**[1]

[1]*Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia,* [2]*QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Artemisinin (ART) monotherapy has been associated with frequent recrudescence. ART-induced dormancy, shown *in vitro* and in animal models, provides a plausible explanation. However, there has been no documentation and characterisation of ART-induced dormancy in human infection. In an *Plasmodium falciparum* induced blood stage malaria (IBSM) infection study, participants were infected with either 3D7 (ART-sensitive) or K13M (ART-resistant) and blood samples were collected from participants prior to, and 48-72 hrs post artesunate treatment. We characterised ART-induced dormant parasites using microscopy, FACs, *in vitro* culture and molecular methods. Dormant parasites were observed in peripheral blood samples from all participants 48-72 hrs post artesunate treatment. Both pre- and post-treatment blood samples seeded parasite growth *in vitro*. Compared to pre-treatment samples, post-treatment samples showed a 10-12 day delay to reach 2% parasitemia *in vitro*. Recovered parasites had the same K13 genotype as pre-treatment parasites. Upregulation > 80 fold, of an apicoplast enzyme encoding gene, the molecular signature of ART-induced dormancy, was detected 48 hrs post-artesunate treatment. Combined with the observed dynamics of parasitemia *in vivo*, this study provides strong evidence for the presence of ART-induced dormant parasites in patients infected with ART-sensitive *P. falciparum* which go on to cause recrudescence. Combination treatment regimens with partner drugs targeting dormant parasites likely improve efficacy of ART antimalarials.

1551

IN-VITRO AND *EX-VIVO* SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* TO ANTIMALARIAL DRUGS IN BINH PHUOC PROVINCE OF VIETNAM FROM 2018 TO 2019

Thu Huong Pham, Tong Thanh Nguyen, Thanh Viet Ngo, Thuy Thu Do, Guy Thwaites, Hien Tinh Tran

Oxford University Clinical Research Unit - Vietnam, Ho Chi Minh, Vietnam

The reduced susceptibility of anti-malarial drugs to *Plasmodium falciparum* highlights the urgent need to monitor the efficacy of the current regimens and identify the alternative potent compounds for the treatment. To assess the susceptibility of *Plasmodium falciparum* to antimalarial drugs at the study sites, *in-vitro* and *ex-vivo* drug sensitivity assays in *Plasmodium falciparum* malaria patients were undertaken. A total of 69 *Plasmodium falciparum* isolates from patients with uncomplicated malaria in Binh Phuoc Province of Vietnam, where multidrug-resistant strains of *P. falciparum* have been documented, were collected from 2018 to 2019. Three *in-vitro* tests were used: The World Health Organization schizont inhibition assay (WHO microtest) in which parasites are exposed to different concentrations of antimalarial drugs; the ring-stage survival assay (RSA) parasites are exposed to 700 nM dihydroartemisinin for 6 hours whereas in the piperaquine survival assay (PSA) parasites are expressed to 200 nM piperaquine for 48 hours. The development of parasites from trophozoits to schizonts (microtest); from ring stages to trophozoits (RSA, PSA) were assessed. The microtest assay showed 33% (18/55) of parasites resistant to mefloquine (MQ), 82% (45/55) resistant to chloroquine (CQ), and 31% (17/55) resistant to piperaquine (PIP). Only 2% (1/55) of the isolates were resistant to quinine (QN). The RSA and PSA assay showed the resistance rates to DHA and PIP were 91% (63/69) and 83% (57/69), respectively. Lumefantrine (LM) and amodiaquine (AQ) with the low inhibitory concentrations - IC_{50} (mean IC_{50}: LM=33 nM and AQ=20.21 nM), were highly active against *P.falciparum*. This study reconfirmed that RSA and PSA; are useful surveillance tools to monitor the artemisinin and piperaquine resistance in Vietnam and SEA countries where the artemisinin and artemisinin-based combination (ACTs) therapy resistance are worsening, and help to adjust the management of malaria patients.

1552

GAMETOCYTE CLEARANCE IN KENYAN CHILDREN WITH UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA AFTER ARTEMETHER LUMEFANTRINE OR DIHYDROARTEMISININ PIPERAQUINE TREATMENT

Francis T. Kimani, Protus O. Omondi, Kelvin K. Thiong'o, Eva A. Nambati, Edwin K. Too, William K. Chege, Maureen A. Otinga

Kenya Medical Research Institute, Nairobi, Kenya

The efficacy and safety of Artemether-lumefantrine(AL) and Dihydroartemisinin-piperaquine phosphate (DP) against asexual parasite population has been well documented. However, the effect of these antimalarials on sexual parasites is still unclear. Children from western Kenya with uncomplicated *P. falciparum* malaria were assigned randomly to AL or DP treatment. A total of 334 dried blood spot samples were collected for up to 5 weeks after treatment. *P. falciparum* gametocytes were detected by *Pfs25* qRT-PCR. Gametocytes prevalence, density and duration of gametocyte carriage were determined. At baseline all the 334 children had positive asexual parasite by microscopy, 12% (40/334) had detectable gametocyte by microscopy and 83.7% (253/302) had gametocytes by RT-qPCR. Overall, 12% of the study population at baseline was gametocyte positive by microscopy vs 83.7% by RT-qPCR a 10-fold

higher than microscopy. The prevalence of gametocytes decreased from 84.6% (125/148) to 7.04% (5/71) at day 42 in AL group and from 82.4 % (127/154) to 14.5% (11/74) in DP group. The duration of gametocyte carriage as estimated by qRT-PCR was slightly shorter in AL group(4.5days) than in DP group (5.1days) but not significant (p=0.301). Submicroscopic gametocytes persisted in some patients up to day 28 despite a significant number of patients being negative for asexual parasites by microscopy on day 7. The study indicates that AL may clear *Plasmodium falciparum* gemetocytes slightly faster than DP. However, presence of submicroscopic gametocyte densities after highlights the limitation of interventions that aim to reduce malaria transmission by use of antimalarial drugs therefore a gametocidal drug in combination to ACTs will be useful in blocking malaria transmission more efficiently.

1553

EXAMINING THE EPISTATIC INTERACTION BETWEEN PLASMEPSIN II AND PFCRT IN *PLASMODIUM. FALCIPARUM* PIPERAQUINE RESISTANCE

Sachel Mok[1], Leila Ross[1], Satish Dhingra[1], Tomas Yeo[1], Melanie Shears[2], Abhai K. Tripathi[2], Lise Musset[3], Photini Sinnis[2], David A. Fidock[1]

[1]*Columbia University Medical Center, New York, NY, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Institut Pasteur de la Guyane, Cayenne, French Guiana*

Clinical failure to the artemisinin combination partner drug, piperaquine (PPQ), has recently emerged in the Greater Mekong Subregion countries of Cambodia, Vietnam and Thailand. A genome-wide association study identified *Plasmodium falciparum* plasmepsin II (*pfpm2*) gene amplification as a molecular marker of resistance. However, genetic modifications by conditional knockdowns or overexpression did not phenocopy resistance, defined *in vitro* as >10% survival of parasites exposed to 200nM PPQ for 48h. Recent evidence indicates that resistance is also associated with novel variants of PfCRT on the Dd2 haplotype background, including mutations F145I and G353V that have recently emerged in Cambodia. To elucidate molecular determinants of PPQ resistance, we implemented a genetic cross between the PPQ-resistant Cambodian isolate PH1008-C and the sensitive NF54 line, using four huHep FRG-NOD mice transfused with human erythrocytes. Asexual blood stage progeny were cloned and whole-genome sequenced to generate a high resolution genetic map. To date, we have 13 unique genetic recombinants each represented by 1 to 22 clones. Interestingly, progeny with distinct recombinant patterns segregated by mouse, suggesting that host factors can exert selective pressures to favor certain parasite genotypes independent of virulent antigens. Genetic association analyses reveal that PPQ IC_{50s} were positively associated with *pfpm2* copy number in progeny expressing wild-type PfCRT. The combination of *pfpm2* with Dd2+M343L PfCRT gave the highest resistance, with a 5-fold increase in IC_{50} relative to NF54. In parallel, we derived clones from the PPQ-resistant S. American isolate S170 that harbors the 7G8+C350R variant, and observed significant association of multi-copy *pfpm2* with percent survival at lethal PPQ concentrations, yet only a 1.3-fold shift in IC_{50}. This suggests that PPQ response is modulated by an epistatic interaction between *pfpm2* and *pfcrt*. Using transfection, we are investigating the contribution of *pfpm2* to PPQ-R on a panel of contemporary *pfcrt* alleles, which will help us to predict the PPQ response of clinical isolates.

1554

MOLECULAR MECHANISMS AND SELECTIVE REVERSAL OF PIPERAQUINE, LUMEFANTRINE AND AMODIAQUINE RESISTANCE IN *PLASMODIUM BERGHEI* ANKA.

Fagdéba David Bara[1], Loise Ndung'u[1], Noah Machuki Onchieku[1], Beatrice Irungu[2], Peter Mwitari[2], Francis Kimani[3], Damaris Matoke-Muhia[3], Gabriel Magoma[1], Alexis Nzila[4], Daniel Kiboi[5]

Antimalarial drugs, lumefantrine (LM), amodiaquine (AQ) and piperaquine (PQ) are essential components in artemisinin-based combination therapies. Using a model malaria parasite *Plasmodium berghei* we studied the mechanisms of resistance and reversal to LM, AQ, and PQ. Here, we used *P. berghei* parasites resistant to LM, PQ or AQ selected by *in vivo* drug pressure. We tested the ability of known resistance reversing agents (RA): probenecid, verapamil, or cyproheptadine to restore susceptibility of the resistant parasite to LM, AQ or PQ in the standard 4-day suppressive test. We first tested RA alone to identify the highest dose that does not inhibit parasite growth. Oral treatment with LM, AQ, and PQ alone or in combination with RA was administered for a total of four daily doses. Parasite density was estimated microscopically (×100) 96 hours post parasite inoculation. Parent strain was sensitive to LM, AQ and PQ with an ED_{90} of 3.52, 4.29 and 3.93mg/kg respectively. LM resistant (LM^R), AQ resistant (AQ^R) and PQ resistant (PQ^R) parasites obtained after 1-2 years of drug pressure had ED_{90} of 52.06, 20.32 and 63.39mg/kg respectively. At 5mg/kg, cyproheptadine restored LM activity by 65% against LM^R but failed to restore PQ activity against PQ^R. Probenecid (400mg/kg) and verapamil (50mg/kg) did not chemo-sensitize either LM^R to LM or PQ^R to PQ. We have previously shown that PQ^R is also resistant to LM (ED_{90} 97.25mg/kg). Surprisingly, these three chemosensitizers restored LM potency against PQ^R. Our data revealed that cyproheptadine restores LM activity in LM^R and also indicate that the selection of PQ^R is associated with LM decreased efficacy; however, this efficacy can be restored by chemosensitizers. We have currently employed a reverse genetics approach (using PlasmoGEM vectors) to delete or overexpress selected genes associated with mediating transport and metabolism of drugs. We aim to measure the impact of the deletion or elevated expression on parasite susceptibility to antimalarial drug alone and in combination with RA. We hope to provide clues on the possible molecular mechanisms of LM, AQ and PQ resistance and the interaction with the selected RA.

1555

IDENTIFICATION OF THE *PLASMODIUM FALCIPARUM* ACETYL-COA SYNTHETASE AS AN EMERGING ANTIPLASMODIAL DRUG TARGET

Robert L. Summers[1], Manu Vanaerschot[2], James M. Murithi[2], Charisse F. Pasaje[3], Madeline R. Luth[4], Pamela Magistrado-Coxen[1], Emma F. Carpenter[5], Jade Bath[2], João P. [1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Columbia University, New York, NY, United States,* [3]*Massachusetts Institute of Technology, Cambridge, MA, United States,* [4]*University of California San Diego, La Jolla, CA, United States,* [5]*Wellcome Sanger Institute, Hinxton, United Kingdom,* [6]*University of Dundee, Dundee, United Kingdom,* [7]*Pennsylvania State University, University Park, PA, United States,* [8]*Broad Institute, Cambridge, MA, United States*

The evolution of drug resistance by the malaria parasite *Plasmodium falciparum* highlights the need for new generations of antimalarial compounds with novel modes of action. In recent years high-throughput phenotypic screening has identified thousands of new drug-like antiplasmodial compounds, however the mode of action of many remains unknown. The Malaria Drug Accelerator (MalDA) has applied a range of chemogenomic approaches to identify the targets of promising new antimalarial compounds and thereby aid the development of novel drug targets for malaria. By conducting resistance selection experiments and using whole genome sequencing, we identified mutations in the parasite's

Acetyl-CoA Synthetase (PF3D7_0627800; PfAcAS) which confer resistance to two structurally distinct antimalarial compounds, MMV084978 and MMV019721. Allelic exchange using the CRISPR/Cas9 system confirmed that the A597V mutation was sufficient to confer resistance to both compounds. Orthologues of PfAcAS in eukaryotes catalyze the formation of the central metabolite acetyl-CoA from acetate, coenzyme A and ATP, and participate in a range of essential processes including fatty acid biosynthesis, nutrient sensing and acquisition, and epigenetic regulation. Homology modelling of PfAcAS revealed that the A597V and T648M mutations cluster around the predicted active site of the protein, suggesting that MMV019721 and MMV084978 may act by competing with the substrates of PfAcAS. Such active-site mutations may be expected to impair the function of the protein and reduce parasite fitness, however *in vitro* competitive growth experiments between wildtype and drug-resistant parasite lines demonstrated that parasites bearing the T648M or A597V mutations do not incur a fitness cost relative to wildtype parasites, whereas preliminary data indicate a small fitness-cost associated with the A597V mutation. These findings identify the malaria parasite's Acetyl-CoA Synthetase as the target of structurally distinct antiplasmodial compounds and support the development of inhibitors of PfAcAS as antimalarial compounds with a novel mode of action.

INVESTIGATION OF MOLECULAR MARKERS OF ANTIMALARIAL RESISTANCE DURING A THERAPEUTIC EFFICACY STUDY CONDUCTED IN THE DEMOCRATIC REPUBLIC OF THE CONGO, 2017

P. Mandoko[1], J. Matangila[2], E. Mukomena[3], P. Mitashi[2], J. Likwela[4], D. Mbongi[2], Samaly Souza[5], Gireesh Subramaniam[5], Naomi Lucchi[5], **Eric Halsey**[6], Leah Moriarty[6], Venkatachalam Udhayakumar[5], D. Mumba[1], G. Mesia[7]

Due to the threat of emerging antimalarial resistance, the World Health Organization recommends incorporating surveillance for molecular markers of antimalarial resistance into routine therapeutic efficacy studies (TESs). In 2017, a TES of artemether-lumefantrine, artesunate-amodiaquine (ASAQ), and dihydroartemisinin-piperaquine was conducted in six sites in the Democratic Republic of Congo (DRC). Mutations in *K13, Pfcrt,* and *Pfmdr1* were identified by Sanger sequencing samples from 260 children experiencing treatment failure. For the *K13* gene, no artemisinin resistance associated mutations were found in the 245 and 229 successfully sequenced pre-treatment and post-treatment samples, respectively. The *Pfcrt* gene was investigated only for the 47 subjects in the ASAQ arm. All 47 pre-treatment samples were successfully sequenced and 38 showed a K76T mutation, associated with chloroquine resistance. Of the 258 pre-treatment samples successfully sequenced for the *Pfmdr1* gene, 133 (70 single and 63 mixed infections) carried the NYD haplotype (corresponding to codons 86, 184, and 1246), 82 (31 single and 51 mixed infection) carried the NFD haplotype, and 40 (20 single and 20 mixed infection) carried the YYY haplotype. The implications of these haplotypes remain unclear, with some reports linking NFD and YYY haplotypes to lumefantrine and amodiaquine resistance, respectively. While the *K13* findings are reassuring for DRC, we are conducting further *Pfmdr1* analyses, including comparing frequencies of haplotypes between subjects who did or did not experience a recrudescent infection.

Resistance to artemisinins and key partner drugs such as piperaquine (PPQ) have become well-established in regions of Cambodia and neighboring countries. In 2016, Cambodia replaced dihydroartemisinin-piperaquine with artesunate-mefloquine as the first-line therapy. We and others have previously shown that mutations within the *Plasmodium falciparum* chloroquine resistance transporter (PfCRT) are associated with reduced susceptibility to PPQ. Subsequent gene-editing studies have shown that these mutations can independently confer PPQ resistance in parasites with single copy plasmepsin II. To better understand the emergence and distribution of PfCRT mutations associated with PPQ resistance, we are examining parasites from 478 clinical infections collected from eight provinces in Cambodia from 2009-2017. We are using PacBio amplicon sequencing or whole genome sequencing data to identify PfCRT mutations and quantitative PCR (or read coverage for samples with whole genome sequences available) to estimate plasmepsin II (pfpm2) copy number. In this dataset, amplified pfpm2 is observed in <1% of samples in 2009, does not reach high frequency until 2013 (62%) and 2014 (79%), then decreases in frequency in 2016 (48%) and 2017 (55%). Our preliminary data from a site in northern Cambodia identify multiple PfCRT mutations, including mutations H97Y, F145I, A195V, I218F, and G353Y. F145I is first observed in 2013 (24%), peaks in 2014 (34%), then decreases in prevalence in 2016 (24%) and 2017 (13%). However, H97Y, I218F, and G353V each increase in prevalence to 24% in 2017 from 10%, 13%, and 20% in 2016, respectively. Whole-genome sequencing will be performed on parasites with PfCRT mutations of interest to determine parasite origins. This work provides insight into the emergence, dynamics, and origins of PfCRT mutations contributing to PPQ resistance.

1558

SELECTION OF DRUG-RESISTANCE MARKERS FOLLOWING TREATMENT WITH ARTEMETHER-LUMEFANTRINE IN HIV-INFECTED AND HIV-UNINFECTED CHILDREN AND ASSOCIATION WITH LUMEFANTRINE PK EXPOSURE

Richard Kajubi[1], Ou Joyce[2], Hanna Ehrlich[3], Justin Goodwin[4], Tracey L. Freeman[3], Liusheng Huang[5], Norah Mwebaza[1], Francesca Aweeka[5], **Sunil Parikh**[3]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*Yale University, New Haven, CT, United States,* [3]*Yale School of Public Health, New Haven, CT, United States,* [4]*Yale School of Medicine, New Haven, CT, United States,* [5]*University of California San Francisco, San Francsisco, CA, United States*

The use of artemisinin-based combination therapies has been associated with the directional selection of mutations in key transporters, with *pfmdr1* N86 and *pfcrt* K76 appearing to confer lower susceptibility to lumefantrine. The relationship between drug levels and resistance selection has not been extensively evaluated. We used samples from a previously conducted PK/PD study of artemether-lumefantrine (AL) for the treatment of malaria in HIV-uninfected and HIV-infected children followed for 42 days in Tororo, Uganda. Paired samples for those individuals who had recurrent malaria by 42 days (n=185 cases) are being genotyped 1) to assess complexity of infection (six microsatellites) and 3) to analyze SNPs

using luminex-based assays (*pfmdr* N86Y, Y184F, and *pfcrt* K76T). 96% if cases were new infections at 28 days (n=11 recrudescent infections) in our high transmission setting. Transporter genotypes were compared between day 0 and day of failure, and grouped as wild-type (WT), mixed, or mutant. Thus far, n= 133 paired samples have been analyzed for *pfmdr* N86Y. On day 0, 81% were wild-type, 2.% mutant, and 17% mixed. At the time of recurrent parasitemia, N86Y genotype had not changed in 77% (n=103), WT was selected for in 18% (n=24), and mutant in 5% (n=6). For Y184F, n= 154 paired samples have been analyzed with 15% wild-type, 18% mutant, and 66% mixed on day 0. At the time of recurrent parasitemia, Y184F genotype did not demonstrate directional selection. The K76T mutation on *pfcrt* was genotype on day 0 (n=140 paired samples), with WT in 26%, mutant in 52%, and mixed in 22%. At the time of recurrent parasitemia, K76T genotype had not changed in 36% (n=45), WT was selected for in 42% (n=53) and mutant in 22% (n=27). Remaining samples will be completed for transporter genotyping. Following completion, the relationship between resistance selection (N86Y and K76T) and drug exposure will be assessed using previously quantified intensive and population PK parameters for lumefantrine. Final analysis will be presented.

1559

DUAL PRONGED ATTACK ON MALARIA: DRUGS WITH ANTIPARASITIC AND IMMUNOMODULATORY PROPERTIES

Jessica Simpson[1], Yash Gupta[2], Steven Goicoechea[1], Whelton A. Miller III[2], Brijesh Rathi[3], Ravi Durvasula[2], Prakasha Kempaiah[2]

[1]*Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States,* [2]*Loyola University Chicago Stritch School of Medicine and Department of Medicine, Loyola University Medical Center, Maywood, IL, United States,* [3]*Department of Chemistry, Hansraj College University Enclave, University of Delhi, Delhi, India and Loyola University Chicago Stritch School of Medicine, Maywood, IL, United States*

Despite recent advancements in reducing the disease burden of malaria caused by *Plasmodium falciparum*, malaria still remains a significant global health problem. Although artemisinin combination therapies are first-line therapy for malaria, there is an urgent need for new drugs due to the development of drug resistant parasites. Additionally, it is well established that the severity of the disease depends upon the host immune response. In malaria, the erythrocytic stages are the only symptomatic stages, but the parasite evades the host immune system at multiple stages. Thus, a molecule with anti-parasitic activity and beneficial immunomodulatory effect on the host response to infection, could be more beneficial as a therapeutic drug. In this study, as part of our larger drug repurposing effort, we investigated three of the identified FDA-approved drug compounds identified to have anti-malarial activity in PfD6 and Dd2 strains with a mean 50% growth inhibitory concentration (IC50) in the erythrocyte stage of the parasite (IC50<2μg/ml). Using the in-vitro malaria (Hemozoin (PfHz) treated PBMCs) model, we found that these drugs rescued the dysregulated inflammatory mediators known to be modulated during malaria by PfHz. Fexofenadine Hydrochloride (antihistamine), Simvastatin (statin: lipid-lowering agent), and Posaconazole (antifungal) are immunomodulatory and active against *P. falciparum* strains (drug sensitive and resistant). We employed a reverse docking and datamining in-silico strategy to identify the targets of these compounds. The predicted interactions were validated by target modelling followed by molecular docking and molecular dynamics simulations. Currently, we are performing target specific assays to validate in-silico data to discover novel molecules with dual properties.

1560

SPATIAL PATTERNS OF ANTI-MALARIAL DRUG QUALITY AND AVAILABILITY PROVIDED BY PRIVATE AND PUBLIC OUTLETS IN EQUATORIAL GUINEA

Jordan M. Smith[1], Jeremias Nzamio[1], Restituto Mba Nguema[1], Norberto Bosepa Cuba Cuba[1], Gninoussa Akadiri[1], Wonder P. Phiri[1], Carlos Cortes[1], Matilde Riloha Rivas[2], Harpakash Kaur[3], Guillermo A. Garcia[4]

Falsified and substandard artemisinin-based combination therapies (ACTs) represent a serious concern for malaria endemic countries, as they can endanger patients, contribute to drug resistance, and undermine public trust in national health systems. In order for Ministries of Health to take action against this threat, evidence on the prevalence of poor-quality ACTs must be provided through systematic assessments of drug quality availability. The Bioko Island Malaria Control Project (BIMCP) has carried out two such assessments in Equatorial Guinea, with the latest occurring in 2018 (drug content analysis currently underway). The latest assessment was undertaken throughout Bioko Island and in each of the five provincial seats within the continental region of Equatorial Guinea, during which 660 antimalarials were purchased from all 548 drug outlets using a mystery client sampling approach. This study aims to describe the spatial patterns of drug outlets selling ACTs in a socio-demographic and geo-political context. Prevalence of falsified and/or substandard ACTs will be associated with the outlet type and neighborhood characteristics within which they are sold, with special attention being given to outlet proximity to ports of entry. Prevalence of high-quality ACTs distributed through the public sector at no cost but were ultimately purchased from private outlets will also be quantified to describe patterns of commercial redistribution of freely available ACTs. The findings of this study will highlight the importance of national authorities to track the sale of ineffective ACTs and the commercial redistribution of high-quality freely available ACTs, which together may drive therapeutic failure and strain public health systems.

1561

DUAL SITE AND MECHANISM OF ACTION OF ARTEMISININ ANTIMALARIALS

Wenchuan Ma[1], **Victoria A. Balta**[2], Katy N. Olafson[1], Ognjen S. Miljanić[1], David J. Sullivan[2], Peter G. Vekilov[1], Jeffrey D. Rimer[1]

[1]*University of Houston, Houston, TX, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

The delayed clearance of *Plasmodium falciparum* parasites following artemisinin combination therapy is characterized by a ring stage-resistance to artemisinins measured by elevated drug pulse concentrations to inhibit ring stages. The trophozoite stages remain sensitive to low nanomolar drug. The phenotype is closely associated with the Kelch13 genotypic changes at numerous amino acids. Here we investigated for parasiticidal activity and mechanism of action on heme crystallization the heme-artemisinin adduct metabolite, previously thought to be inactive after heme or iron cleavage of the endoperoxide bridge. Heme-artemisinin adduct was synthesized in reducing conditions, column purified and validated by mass spectrometry with sharp peaks at *m/z* 838 and 898, with the absence of *m/z* 282 of free artemisinin. Observations of beta-hematin crystal growth inhibition in the presence of ART and H-ART by time-resolved *in situ* atomic force microscopy (AFM) revealed that the addition of non-activated ART had no effect on the surface features and the kinetics of layer nucleation and growth. In contrast heme artemisinin adduct demonstrated near irreversible heme crystal growth inhibition by absorbing at growth sites to prevent subsequent addition. Biologic validation of exogenous heme-artemisinin adduct effect on parasites showed 50% inhibition in the 10 to 70 nmolar range varying by

artemisinin or artesunate as the heme adduct in both resistant Kelch13 mutant and sensitive parasites. After a 6 hour exogenous 700 nM H-ART pulse of trophozoites, followed by extensively SDS/ bicarbonate/water washes to purify hemozoin, H-ART is detected with hemozoin heme by a mass spectrometry at *m/z*s 838. The previously thought inactive heme-artemisinin adduct kills parasites when exogenous in culture medium. Artemisinins work in the parasite cytosol at ring stages and in the cytosol and digestive vacuole at the trophozoite stage via suicide activation by iron or heme to generate radicals which damage bystander proteins. In the digestive vacuole there is an additional quinoline-like mechanism of heme crystal inhibition by the heme-artemisinin adduct.

1562

MOLECULAR SURVEILLANCE OF *PLASMODIUM FALCIPARUM* DRUG RESISTANCE IN NIGERIA

Ifeyinwa C. Aniebo[1], Wellington A. Oyibo[2], Oladipo Oladosu[2], Ndukwe Kalu Ukoha[3], Lilian Anomnachi[3], Gordon A. Awandare[4], Kelechi Ohiri[3]

[1]*Harvard T.H Chan School of Public Health, Boston, MA, United States,* [2]*ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria,* [3]*Health Strategy and Delivery Foundation, Abuja, Nigeria,* [4]*West Africa Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana*

Monitoring drug resistance is essential for early detection and subsequent prevention of the spread of drug resistance. We investigate the presence of mutations associated with malaria drug resistance in Lagos, Nigeria.A cross-sectional study was carried out in health facilities and households across 12 local government areas. Finger-prick blood samples from 200 consenting individuals of all ages provided blood films for microscopic examination and blood spots on filter paper. All samples were screened for malaria parasites using nested PCR. Direct sequencing was used to determine the frequency distribution of genetic variants in the anti-malarial drug-resistant *P. falciparum* genes in malaria-positive isolates. Complexity of infection of all samples were investigated using both the COIL and McCOIL.One hundred and nine (109) samples were positive for *P.falciparum*. The frequency of chloroquine resistant haplotype (CVIET) was 32% and NFD haplotype in *Pfmdr1* was 39%. There were 8 nonsynonymous mutations identified in *Pfkelch13* gene, two have been described while the others have not been described or validated in any known study. Mutations in *Pfdhfr* were present with the triple mutants having the highest frequency at 95% (IRNI). The quadruple mutation at position 164L was identified at very low frequency (0.9%). Mutations in *Pfdhps* were identified with haplotype frequency 35% (SGKAA), 17% (AGKGS) and 8.3% (AGKAA) being the majority. All samples were WT at positions V127M and D128Y/H in the *Pfarps10* protein, D193Y in ferredoxin, N326S in *Pfcrt* and T484I in *Pfmdr2*, however, 18% of the samples had the I356T mutation (VDDNTT). All samples were wildtype for *P.falciparum* exonuclease and *Plasmepsin*. Our results show that chloroquine appears to be in use even though Nigeria had a first-line treatment policy change to ACT's in 2005. The results show the presence of drug resistance to commonly used antimalarials and suggests piperaquine is likely to remain highly efficacious. Consequently, it is imperative to implement a national surveillance system for monitoring malaria drug resistance to inform resilient response to malaria control in Nigeria.

1563

MALARIA PARASITEMIA INCIDENCE AMONG DIFFERENT AGE GROUPS IN A STABLE TRANSMISSION AREA OF MALI RECEIVING SEASONAL MALARIA CHEMOPREVENTION

Abdoulaye Katile[1], Bourama Kamate[1], Cheick O. Guindo[1], Mamady Kone[1], Bakary Traore[1], Jacob Dara[1], Ousmane A. Poudiougo[1], Bayaya Haidara[1], Amatigue Zeguime[1], Allaye Tolo[1], M'Bouye Doucoure[1], Boucary Ouologuem[1], Souleymane Traore[1], Sidiki Perou[1], Baba Djiguiba[1], Mahamadou S. Sissoko[1], Issaka Sagara[1], Jen C.C. Hume[2], Jennifer Kwan[3], Patrick E. Duffy[2]

[1]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Laboratory of Clinical Immunology and Microbiology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

The intensity and seasonality of malaria transmission influence the age distribution of parasitemia and disease, and age-specific incidence information is used by policymakers to plan the allocation of diagnostic and therapeutic tools. Doneguebougou is in a holoendemic area where malaria transmission is highly seasonal, typically from June to December. Under-five year old children have been receiving seasonal malaria chemoprevention (monthly sulfadoxine-pyrimethamine + amodiaquine) from August through November since 2014. We aimed to determine the current malaria parasitemia incidence rate among different age groups. These data were collected during a community study of the dynamics of malaria transmission. We screened and enrolled 597 volunteers aged 6 months to 65 years and followed for 5 months (August to December 2018). Blood samples were collected at routine monthly visits and the time of any clinical illness. Malaria infection diagnosis and the density of parasitemia were determined by RDT and blood smear respectively. The population was relatively young with a mean age of 19 years with 54% of the study group female. Among our study population, under-fives represented 18%, 5-12 year olds 28%, 13-18 year olds 20%, and >18 year olds 34%. *Plasmodium falciparum* was the most frequently encountered species at 94.4% of positive blood smears, while 3.9% were recorded as *Plasmodium malariae.* A total of 22% of the subjects carried *Plasmodium falciparum* gametocytes: 7% in under-fives years, 23% in 5-12 year olds, 31% in 13-18 year olds and 22% in >18 years olds. This higher incidence of malaria parasitemia in older versus younger children may reflect a shift in an area receiving seasonal malaria chemoprevention and should continue to be monitored. This data and additional clinical malaria cases will be presented with additional follow up of the cohort.

1564

DECREASING *IN VITRO* ARTEMISININ SENSITIVITY OF *PLASMODIUM FALCIPARUM* ACROSS INDIA

Rimi Chakrabarti[1], John White[1], Prasad H. Babar[1], Shiva Kumar[1], Devaraja Mudeppa Gouda[1], Anjali Mascarenhas[1], Ligia Pereira[1], Rashmi Dash[1], Jennifer N. Maki[1], Ambika Sharma[1], Kabita Gogoi[2], Devojit K. Sarma[2], Ipsita P. Bhowmick[2], Suresh Kumar[1], Edwin Gomes[3], Jagadish Mahanta[2], Pradyumna K. Mohapatra[2], Laura Chery[1], Pradipsinh Rathod[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Regional Medical Research Center - Northeast Region, Dibrugarh, India,* [3]*Goa Medical College and Hospital, Bambolim, India*

The geographic proximity and ecological similarities of northeastern India to the Greater Mekong subregion may affect the long-term management and sustainability of Artemisinin Combination Therapy (ACT) in India. ACT has been used to treat uncomplicated *Plasmodium falciparum* infections in India since 2004. However, since 2008, decreasing artemisinin effectiveness is seen throughout the Greater Mekong region. The resistant SE Asian parasites could propagate further to the 1.2 billion people of India who live in malaria transmission areas, and possibly even to Africa. To layout baseline data to track changing ACT resistance in

Indian parasites, 11 *P. falciparum* isolates from northeast India and 10 isolated from southwest India were studied *in vitro.* Ring Stage Survival Assay (RSA) showed significant parasite resistance to dihydroartemisinin from a remarkable 50% of the 2014-2015 northeast Indian samples. Even more surprising, 2/10 samples from the southwest region of India, from as far back as 2012, also showed decreased sensitivity to artemisinin. This establishes that RSAs will be useful for tracking changes in artemisinin effectiveness against *P. falciparum* in India with respect to geography and time, and for estimating the magnitude of parasite resistance. Such cell-based assays will also guide placement of clinical studies to assess patient responses to ACT in different parts of India. In the present work, Kelch gene sequences in Indian isolates were found to be unique but could not predict ACT resistance as measured by RSA. Unique Indian Kelch genotypes may still help track movements and evolution of artemisinin resistant parasites in India.

1565

CHARACTERIZATION AND ANALYSIS OF FALSE-NEGATIVE RAPID DIAGNOSTIC TESTS DUE TO *PFHRP2* AND *PFHRP3* DELETIONS IN WESTERN KENYA *PLASMODIUM FALCIPARUM* POPULATION

Nathaniel Idquival Dizon[1], Samuel Elberts[1], Karina Rivas[1], Janet Oyieko[2], Carolyne Kifude[2], Shirley Luckhart[3], V. Ann Stewart[1]

[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*US Army Medical Research Directorate-Kenya, Kisumu, Kenya,* [3]*University of Idaho, Moscow, ID, United States*

To combat rising drug costs and increasing drug resistance for *P. falciparum* infections, the WHO has recommended that only patients whose infections are confirmed via rapid diagnostic test (RDT) or microscopy be treated with anti-malarial drugs. Many of the common malarial RDTs rely on the detection of histidine-rich protein 2 and 3 (*PfHRP2/PfHRP3*) antigens. Recent published reports indicate that genetic polymorphisms in these genes include deletions, and that such polymorphisms may lead to false-negative RDT results. An increased prevalence of false negative RDT results due to *PfHRP2/3* gene mutations have become a concern, as the use of RDTs as a diagnostic tool has increased over microscopy. Using PCR we did a pilot study to determine the presence of *PfHRP2/3* deletions in blood samples from a population of asymptomatic adults who presented for voluntary HIV testing in Kisumu, Kenya. All human samples used were collected as part of a larger cross-sectional molecular epidemiology study of HIV and malaria status in pre-treatment asymptomatic adult individuals. Two single copy *P. falciparum* housekeeping genes were then compared and used to confirm parasitemia of *PfHRP2/3* negative blood samples, and determine a lower limit of DNA-based gene detection. We failed to amplify a significant number of *PfHRP2*, *PfHRP3,* and dual *PfHRP2/3* gene targets in our asymptomatic, *Plasmodium* 18S-positive sample population. We will obtain deep sequence information to confirm and further characterize any mutations in this sample set and compare with RDT results above a reasonable threshold of sensitivity. Our study will inform implications for the utility of current diagnostic assays for malaria control and eradication efforts.

1566

DETECTION OF DRUG RESISTANCE SNPS IN *PLASMODIUM FALCIPARUM* WITH THE CRISPR-BASED DIAGNOSTIC SHERLOCK

Clark H. Cunningham, Jonathan J. Juliano, Jonathan B. Parr

The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

CRISPR-based diagnostics are an exciting and rapidly-growing technology with a wide range of applications for detecting tropical diseases. These technologies combine the base-pairing abilities of CRISPR RNAs (crRNAs) and nuclease activity of Cas proteins to detect specific nucleic acid sequences with extreme sensitivity, achieving single-copy limits of detection. One promising CRISPR-based diagnostic assay is SHERLOCK, or Specific High-Sensitivity Enzymatic Reporter UnLOCKing. As previously published, SHERLOCK pairs isothermal recombinase-polymerase amplification (RPA), *in vitro* transcription, crRNA base-pairing, and collateral cleavage of fluorescent RNA reporters by Cas13a to detect nucleic acid targets. We previously developed SHERLOCK assays capable of detecting malaria, with pan-*Plasmodium*, *P. falciparum* and *P. vivax* species-specific SHERLOCK assays capable of detecting parasite DNA at levels at or below the sensitivity of current PCR assays. We are now harnessing SHERLOCK's ability to discriminate single nucleotide polymorphisms (SNPs) to develop assays capable of detecting drug resistance mutations in *P. falciparum*. We will present results from our ongoing efforts to adapt these assays for use at the point-of-care, involving both lateral flow and handheld fluorometry. We will also present optimized methods for streamlined sample collection and preparation. Taken together, these findings will demonstrate SHERLOCK's potential to improve patient care and molecular surveillance in diverse settings.

1567

QUALITY OF MALARIA CASE MANAGEMENT IN OUTPATIENT AT HEALTH FACILITIES IN RWANDA

Jean Louis Ndikumana Mangala[1], Aline Uwimana[1], Noella Umulisa[2], Michee S. Kabera[1], Aimable Mbituyumuremyi[1], Jean Damascene Niyonzima[1], Didier Uyizeye[2], Jeanine U. Condo[1]

[1]*Rwanda Biomedical Center, Kigali, Rwanda,* [2]*Maternal and Child Survival Program/JHPIEGO, Kigali, Rwanda*

Malaria remains the world's most important tropical parasitic disease, and one of the major public health challenges in the poorest countries of the world, particularly in sub-Saharan Africa. Although significant progress has been made, malaria remains one of the most important diseases in Rwanda, causing significant morbidity, mortality, and economic loss for the country. The objective of the Rwanda Malaria Health Facility Survey (RMHFS) was to assess health facility readiness for malaria diagnosis and treatment and to evaluate the supply chain and the quality of malaria case management. This survey was conducted in 100 health centers between July and September 2018. Facility Inventory Sheet, Health Worker Interview, Observation of Outpatient Consultations Tool and Exit Interviews were used for data collection after obtaining a signed consent form from respondents with respect to their confidentiality and anonymity. Eight teams of five interviewer-observers conducted the RMHFS. For 961 patients present at time of the survey, 152 patients were diagnosed of malaria using microscopy, with a positivity rate of 15.8%. Artemether and Lumefantrine for the treatment of simple malaria cases were available at 100% compared to pre-transfer treatment (Quinine and Artesunate) that were available at 88% in health facilities. Health providers in public health facilities trained in malaria case management and Integrated Management of Childhood Illnesses in the past 3 years represent 44.3% and 62.6% respectively compared to 37% and 61.1% in faith-based health facilities. Overall, 98.7% confirmed simple malaria cases were diagnosed using blood smear or rapid diagnostic test and received first line antimalarial treatment according to National policy at health centers. Findings of RMHFS show that although Rwanda is striving to improve access to early diagnosis and appropriate case management to reduce malaria burden through 24/7 continuity of care in all surveyed health facilities; but there is still need for training of staff in malaria case management and increasing availability of pre-transfer drugs.

1568

EVALUATION OF A NEW POINT OF CARE MALARIA DIAGNOSTIC DEVICE GAZELLE™: A PILOT STUDY

Praveen K. Bharti[1], Rajat Kumar[1], Priyaleela Thota[2], Anil K. Verma[1], Sweta Srivas[1], Tyler Witte[2], Anne Rocheleau[2], Mrigendra Singh[3], S. Rajasubramaniam[1], Aparup Das[1]

[1]*National Institute of Research in Tribal Health, Jabalpur, India,* [2]*Hemex Health, Portland, OR, United States,* [3]*National Institute of Malaria Research-Field station (NIMR-FS), Jabalpur, India*

Despite a considerable progress in control and management of malaria in India, malaria remains a major public health problem especially in rural and tribal parts of the country. Prompt and accurate diagnosis is very critical for management of malaria and also to achieve malaria elimination goals. However, diagnosis is a challenge in resource poor settings because of lack of infrastructure and unavailability of skilled healthcare workers. Currently, microscopy and RDT are the standard tools for malaria diagnosis in Primary/Community health centres as well as in the private sector. Although inexpensive, microscopy is labor intensive, time consuming, requires skilled manpower and has poor sensitivity and specificity, especially for low parasitemia. On the other hand, RDTs provide faster turnarounds, easy handling and storage but cannot reliably detect low density parasitemia and sensitivity is affected by malaria species and variants. In this pilot study, we evaluated the performance of Gazelle™, a point of care malaria diagnostic device which employs the principle of Magneto-Optical Detection (MOD) to detect hemozoin (a paramagnetic by-product of all malaria parasite species) in blood sample for diagnosis of malaria. In the pilot study conducted with a total of 300 samples, the accuracy of Gazelle™ was found to be 94.7%, 94.3% and 95.4% in comparison to microscopy, RDTs and PCR respectively. When compared with PCR, Gazelle™ had higher accuracy than microscopy and RDTs. Gazelle is faster than microscopy, RDT, and PCR and it is a field-oriented device. Notably, the performance of Gazelle™ was comparable with microscopy; specificity of Gazelle™ was higher than RDTs. A validation study with a larger sample size (~1000 samples) is currently ongoing and the final results will be presented at the conference. Gazelle™ may be an alternative potential diagnostic solution for settings where there is a need for speed, accuracy and ease of use.

ASSESSMENT OF MALARIA USING NEW HIGHLY SENSITIVE RAPID DIAGNOSTIC TEST IN TWO TOWNSHIPS SELECTED FOR SUBNATIONAL MALARIA ELIMINATION IN MYANMAR

Myaing Myaing Nyunt[1], Nay Yi Yi Lin[2], Zaw Lin[2], Aung Thi[3], Tint Wai[2], Poe Poe Aung[2], Zaw Win Thein[2], Thura Htay[2], Zin Min Tun[2], Aye Kyawt Paing[2], Drzayar Han[2], Kaythwe Han[2], Christopher Plowe[1], Norbert Odero[1], Alyssa `. Platt[1], Elizabeth Turner[1], Manfred Meng[1]

[1]*Duke University, Durham, NC, United States,* [2]*Myanmar Ministry of Health and Sports, Yangon, Myanmar,* [3]*Ministry of Health and Sports, Yangon, Myanmar*

Malaria-associated morbidity and mortality have been progressively declining in Myanmar in the last five years. Myanmar is committed to eliminate malaria by 2030, and five regions with the lowest malaria burden have been slated for subnational elimination. An extensive cross-sectional survey of malaria was conducted in January-December, 2018 in two townships in Mandalay, one of the five regions, in preparation for the assessment of different approaches such as targeted mass drug administration or focal screen and treatment using appropriately-sensitive diagnostics for accelerated elimination. The major objectives were to evaluate the baseline prevalence of asymptomatic malaria reservoir and to assess the performance characteristics of a new highly sensitive rapid diagnostic test (hsRDT), at a population level. Villages with potential malaria transmission were selected using a multistage cluster sampling with lot quality assurance method. Extensive data on demographic information, malaria history, occupational, travel, migration, mobility information were collected from 11,128 consented participants. Finger prick blood was collected for testing of malaria, using routine conventional rapid diagnostic test (cRDT), and new highly sensitive RDT (hsRDT). Blood was also collected as dried blood spots for ultrasensitive PCR testing, as gold standard, conducted at the malaria laboratory at the Department of Medical Research in Yangon, Myanmar. External quality control was provided by an independent analytical team at the malaria laboratory at Duke Global Health Institute, Duke University. Preliminary analyses showed that hsRDT identified 2–3-folds more *P. falciparum* infections than cRDT. Individual and village-based performance characteristics of hsRDT, using usPCR as gold standard, heterogeneity of malaria in the study sites, and risk factors associated with asymptomatic malaria will be presented. The potential role of the new diagnostics hsRDT in identifying populations with low-density malaria in pre-elimination setting will be discussed.

A REPORT ON THE INTEGRATION OF A MALARIA RAPID DIAGNOSTIC TEST IN A POINT OF CARE CLINICAL DECISION SUPPORT PLATFORM, MEDSCINC, FOR USE IN PRIMARY HEALTHCARE SETTINGS IN KANO STATE, NIGERIA

Karell G. Pellé[1], Meg McLaughlin[2], Aisha Giwa[3], Ezra Mount-Finette[2], Sam Scarpino[4], Nada Haidar[3], Fatima Adamu[3], Temitope Adeyoju[3], Nirmal Ravi[3], Adam Thompson[3], Barry Finette[5], Sabine Dittrich[1]

[1]*Foundation for Innovative New Diagnostics, Geneva, Switzerland,* [2]*THINKMD, Burlington, VT, United States,* [3]*eHealth Africa, Kano, Nigeria,* [4]*Northeastern University, Boston, MA, United States,* [5]*THINKMD and University of Vermont College of Medicine, Burlington, VT, United States*

In primary health care (PHC) settings in developing countries, clinical algorithms such as WHO's Integrated Management of Childhood Illness (IMCI) are widely used by healthcare workers (HCWs) to provide treatment and care. However, adherence to these paper guidelines is often poor. One solution to this issue is to provide computed clinical care algorithms or clinical decision support systems (CDSS). In these algorithms, tools such as thermometers or malaria RDTs (mRDTs) are recommended to perform accurate assessments and provide disease diagnoses. MEDSCINC is a point of care (POC) CDS platform that determines disease risks for several childhood illnesses based on Bayesian cluster pattern logic independent of diagnostic tests such as malaria RDTs. As malaria is a common childhood febrile illness in sub-Saharan Africa, we hypothesized that integrating mRDT results within the algorithm is feasible and would improve malaria assessment compared to standard care, IMCI. In a pilot in Kano State Nigeria, 7 HCWs in 5 PHCs were trained to use a modified MEDSCINC algorithm that integrates an mRDT. In total, 555 children ages 2-59 months were assessed with the platform during a 4-week period. With the platform, mRDTs were performed on all 480 children who presented with fever or a history of fever, per IMCI protocol. Of those, 66.7% were mRDT positive and 33.3% mRDT negative. In terms of performance accuracy, MEDSCINC had a sensitivity of 42.8% (95% CI: 37.3-48.4) and a specificity of 63.8% (95% CI: 55.7-71.1). In addition, the MEDSCINC malaria assessments positive predictive value (71%) was better than historical (50%) and current (67%) Nigeria IMCI screening. This study shows the feasibility of integrating mRDTs into CDSS and provides insight into the accuracy of MEDSCINC to predict malaria risk, enabling algorithm improvements tailored to high burden settings during and after use. It also shows the importance of validating new or predictive algorithms alone and with POC diagnostics whenever available and highlights the need for publicly available datasets generated from relevant patient cohorts to develop and improve clinical algorithms.

FIELD PERFORMANCE OF CONVENTIONAL AND HIGH-SENSITIVITY MALARIA RAPID DIAGNOSTIC TESTS IN TWO TRANSMISSION SETTINGS IN HAITI

Eric Rogier[1], Karen E. Hamre[1], Vena Joseph[2], Mateusz Plucinski[1], Jacquelin Presume[3], Ithamare Romilus[3], Gina Mondelus[3], Tamara Elisme[3], Lotus L. van den Hoogen[4], Jean F. Lemoine[5], Chris Drakeley[4], Ruth Ashton[2], Michelle A. Chang[1], Alexandre Existe[3], Jacques Boncy[3], Gillian Stresman[4], Thomas Druetz[6], Thomas Eisele[2]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States,* [3]*Laboratorie National de Santé Publique, Port au Prince, Haiti,* [4]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [5]*Ministère de la Santé Publique et de la Population, Port au Prince, Haiti,* [6]*University of Montreal School of Public Health, Montreal, QC, Canada*

Accurate diagnosis of malaria serves as the foundation for multiple elimination and control strategies. Finding active infections becomes increasingly difficult as *Plasmodium falciparum* transmission is reduced in an area, and new diagnostic tools could serve to more accurately detect asymptomatic infection and estimate prevalence rates in these low-transmission and elimination settings. Malaria elimination in Haiti relies on histidine-rich protein 2 (HRP2) field-deployable rapid diagnostic tests (RDTs) for routine identification of *P. falciparum* infections in both clinical and community settings. In 2017, two easy-access group (EAG) and one household-based survey took place in Haiti for which enrollees (N=32,506 total) were tested by a conventional RDT (cRDT) and high-sensitivity RDT (hsRDT). Subsets of participants were selected from each survey and filter paper blood samples assayed for HRP2 and malaria DNA in a laboratory (n=1,154 total) for direct comparison with RDT results. Both cRDT and hsRDTs were able to detect low concentrations of HRP2 antigen in participant's blood with sensitivity estimates between 2.6 and 14.6 ng/mL. In comparison with the laboratory HRP2 assay, the sensitivity estimates in the two EAGs were 86.3% and 95.0% for the cRDT and 88.2% and 96.0% for the hsRDT. Specificity in the two EAGs was 99.6% and 92.9% for the cRDT and 98.0% and 90.0% for the hsRDT. In the EAG surveys, we observed no significant differences between the estimated detection levels for HRP2 and parasite DNA in host blood. In the household-based survey, the hsRDT returned a significantly higher number of positive tests than DNA detection in all age categories, but this represented a very small proportion (less than 0.2%) of all participants in the survey. In this low-transmission setting, both types of RDTs performed well. The hsRDT identified more antigen positive persons than the cRDT in all three surveys, but this was only significant in the household survey, and was a small proportion of additional positives from all three surveys.

1572

COMPARISON AND EVALUATION OF TWO PCR ASSAYS FOR THE QUALITATIVE DETECTION OF *PLASMODIUM* SPECIES IN CLINICAL SPECIMENS

Lynne Sloan, Emily Fernholz, Heather Arguello, Susan Schneider, Bobbi Pritt

Mayo Clinic, Rochester, MN, United States

Malaria is a major tropical disease caused primarily by four members of the genus *Plasmodium*: *P. falciparum*, *P. vivax*, *P. malariae*, and *P. ovale.* A fifth species, *P. knowlesi,* is responsible for a significant number of malaria cases in parts of Southeast Asia. While microscopic examination of Giemsa-stained thick and thin blood films remains the gold standard method for laboratory diagnosis, PCR-based tests are increasingly available and offer increased sensitivity and specificity over conventional microscopy. We compared the performance of a commercially-available real-time TaqMan PCR assay to a previously-published, laboratory developed real-time FRET probe-based PCR test (LCMAL) for the detection and differentiation of *Plasmodium* species in clinical specimens. Forty-six archived microscopy positive whole blood specimens were concurrently tested by the LCMAL and the RealStar® Malaria PCR by Altona Diagnostics (RSMAL) using Roche LightCyclers following DNA extraction using the Roche MagNA Pure LC 2.0. Both PCR assays detect and differentiate the five *Plasmodium* spp., but the LCMAL cannot reliably differentiate *P. vivax* from *P. ovale,* which is a known limitation of this assay. The LCMAL detected *Plasmodium* DNA from all 46 specimens as follows: 19 *P. falciparum*, 2 *P. vivax*, 3 *P. malariae*, 6 *P. ovale* and 16 *P. vivax/P. ovale.* In comparison, the RSMAL PCR assay detected 45 of 46 specimens: 18 *P. falciparum*, 11 *P. vivax*, 3 *P. malariae*, and 13 *P. ovale*; the single discordant result (LCMAL+/RSMAL-) contained a very low level of *P. falciparum* (cycle threshold >35 cycles). Original microscopy results showed: 19 *P. falciparum*, 9 *P. vivax*, 3 *P. malariae*, 4 *P. ovale,* 10 *P. vivax/P. ovale* and 1 *Plasmodium* sp., NOS. The RSMAL PCR showed an excellent (97.8%) agreement with the LCMAL. While both PCR assays compared well to the original pre-archival microscopy results, the RSMAL had the added advantage over the LCMAL and microscopy of reliably identifying *P. vivax/P. ovale* results to the species level. As a commercially-available kit, the RSMAL may be easier to implement in a clinical laboratory than the LCMAL which requires separately-sourced custom reagents.

1573

EVALUATION OF A PAN *PLASMODIUM* LACTATE DEHYDROGENASE DETECTION ASSAY USING MICROCAPILLARY CYTOMETRY

Xuemei Wan, Julie Clor, **Kamala Tyagarajan**

Luminex Corporation, Hayward, CA, United States

The rise of HRP2 deletions worldwide has increased the importance of *Plasmodium* Lactate Dehydrogenase (LDH) markers for malarial *Plasmodium* species detection. While several RDTs have been developed for detection of Pan LDH, sensitivity of RDT-based detection for this antigen remains poor. We have recently demonstrated that the microcapillary-based, low-cost Muse® Cell Analyzer and bead-based immunoassays have the capability to provide high sensitivity, yes/no confirmation on the presence of multiple *Plasmodium* antigens. Using this approach, the performance of the research use only Muse® Malaria *P.f.-P.v.* Detection Assay for the detection of *P. falciparum* HRP2, *P. falciparum* LDH, and *P. vivax* LDH was shown. Here we describe a new assay on the Muse System that allows for detection of the Pan LDH antigen region in different *Plasmodium* species. The assay was developed to allow for high sensitivity detection of LDH from *P. falciparum*, *P. vivax,* and *P. malariae,* allowing for better characterization of samples. Our data demonstrate the Pan LDH assay is capable of LDH antigen detection at low ng/mL and is superior to RDTs. Further, linear response is observed over a wide dynamic range of LDH antigen concentrations. Analysis of frozen blood samples with the Pan LDH Assay demonstrates that the assay can universally detect *P. falciparum* LDH, *P. vivax.* LDH, and *P. malariae* LDH, and LDH from mixed infections. Clear responses can be observed in a wide range of parasitemia. Testing of *P. malariae* samples with the Muse Malaria *P.f.-P.v.* Detection Assay demonstrates no cross-reactivity of the assay. Dilution studies demonstrate the capability to detect Pan LDH from *P. malariae* samples down to 50-100 parasites/µL, and more sensitive detection capability with *P. vivax* and *P. falciparum* samples down to <20 parasites/µL. The availability of a simplified, yes/no, sensitive Pan LDH-based assay on the Muse Cell Analyzer provides a powerful tool for malarial researchers to optimally characterize *Plasmodium* antigens.

PERFORMANCE EVALUATION OF A NOVEL MULTIPLEXED LATERAL FLOW ASSAY TO IDENTIFY COMMON CAUSES OF FEVER IN ASIA AND INFORM TREATMENT DECISIONS

Sonia Arafah[1], Stuart Blacksell[2], Mark Mayo[3], Bart Currie[3], Aurelien Macé[1], Stefano Ongarello[1], Angelo Gunasekera[4], Javan Esfandiari[4], Sabine Dittrich[1]

[1]*FIND, Geneva, Switzerland,* [2]*Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University and Oxford*

University, Bangkok, Thailand, [3]Menzies School of Health Research, Darwin, Australia, [4]Chembio Diagnostic Systems, Inc., Medford, NY, United States

Fever is the most frequent symptom in patients seeking care globally and particularly in low and middle income countries (LMICs); several infectious causes of fever have been identified and are due to parasitic, viral or bacterial agents. In South East Asia, malaria, dengue, *Rickettsial pathogens* (like *Orientia tsutsugamushi* and *R. typhi*), *Leptospira* and *Burkholderia pseudomallei* have been described as causes of febrile illness with a high prevalence, depending on the population and setting. Patient management is however often driven by detection of malaria with RDTs: malaria negative cases are usually treated with broad spectrum antibiotics, contributing to the raise of global antimicrobial resistance. To circumvent those common practices, more guidance is required to inform treatment decision and allow more targeted treatment of Acute Febrile Illness (AFI). Conventional laboratory methods require a lot of resources and are not always performed in LMICs. Several single-plex RDTs are currently on the market and could help clinicians but due to cost, procurement challenges, and limited data on their performance, they are rarely used. Chembio has developed a multiplex lateral flow immunoassay (DPP® Fever Panel II Assay) that is able to detect serum IgM and specific antigens of common treatable causes of AFI in Asia (malaria, dengue, chikungunya, scrub and murine typhus, *Leptospirosis* and *Melioidosis*). This multiplex RDT aims to support treatment decisions at level 2 or 1 facilities with all bacterial pathogens requiring a change to specific antibiotics (eg. Doxycycline). A retrospective clinical study is being conducted in Thailand and Australia to assess the performance (sensitivity, specificity, positive and negative predictive values) of the test. A total of 510 samples are being tested from 3 countries (Bangladesh, Sri Lanka, Australia). All test lines are assessed in comparison to the appropriate gold standard diagnostic (e.g. IFA, MAT, blood culture). The presented results represent the first data from this novel tool and are instrumental to inform its utility and impact on prescribing practices and health outcomes in the region.

DISTINGUISHING BETWEEN *PLASMODIUM FALCIPARUM* AND *P. VIVAX* BY CONSIDERING BROWNIAN RELAXATION TIMES USING MAGENTO-OPTICAL DETECTION (MOD)

Robert J. Deissler[1], D'Arbra Blankenship[2], Emma McCann[2], Brian T. Grimberg[2]

[1]*Department of Physics, Case Western Reserve University, Cleveland, OH, United States,* [2]*Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States*

As pointed out by the CDC, once a determination of malaria infection has been made, one of the factors that should guide treatment is the infecting *Plasmodium* species. Here we propose a method to distinguish between *P. falciparum* and *P. vivax* using our magneto-optical detection (MOD) device, which relies on the magnetic and optical properties of the hemozoin produced by the infecting parasites. A beam of polarized light is projected through a blood sample. As a magnetic field is applied to the blood sample, the hemozoin crystals align, causing a change in the transmitted light intensity. When the field is removed, the hemozoin relax back to their random orientations due to the thermal motion of the blood molecules, causing the light intensity to return to its previous value. The time for this relaxation to take place, referred to as the Brownian relaxation time, depends on the size of the hemozoin crystals, being proportional to the cube of the length of the crystals. Since the length of *P. vixax* crystals are roughly an order of magnitude less than the full length of *P. falciparum* crystals, the Brownian relaxation time of the *P. vixax* crystals will be roughly three orders of magnitude less than the relaxation time of the *P. falciparum* crystals. In order to distinguish between these two crystal sizes based on the relaxation times, we found that it was necessary to increase the viscosity of the blood samples. In this way we found that it was possible to distinguish between *P. falciparum* and *P. vivax* infections.

1576

VALIDATION OF BREATH BIOMARKERS FOR NONINVASIVE DIAGNOSIS OF MALARIA

Amalia Berna[1], Lucy Bollinger[2], Josephine Banda[3], Patricia Mawindo[3], Tasha Evanoff[1], Diana Culbertson[4], Karl Seydel[5], **Audrey R. Odom John**[1]

[1]*Washington University School of Medicine, St. Louis, MO, United States,* [2]*University of Washington, Seattle, WA, United States,* [3]*University of Malawi College of Medicine, Blantyre, Malawi,* [4]*Lao Friends Hospital for Children, Luang Prabang, Lao People's Democratic Republic,* [5]*Michigan State College of Osteopathic Medicine, East Lansing, MI, United States*

Despite substantial worldwide investment in malaria control, *Plasmodium falciparum* infection still remains a serious global health problem. The most widely available and sensitive RDTs rely on detection of a *P. falciparum*-specific protein, HRP2. Unfortunately, HRP2-based RDTs possess critical weaknesses, including rising incidence of *hrp2*- parasite strains. In clinical settings, there is a pressing need for new highly sensitive and specific tests that are simple, affordable. We previously used state-of-the-art mass spectrometry techniques to identify volatile organic compounds (VOCs) produced by cultured *P. falciparum*. Recently, we have found that uncomplicated falciparum malaria leads to characteristic changes in breath VOC composition. Using just six breath biomarkers, we diagnosed falciparum malaria noninvasively with over 82% accuracy in children from Lilongwe, Malawi. Here we present work from our ongoing studies to determine the reproducible changes in breath composition in response to malaria infection, in an independent cohort of children in a malaria endemic area. In addition, we evaluate breath composition before and after antimalarial use, to establish biomarkers that change in response to treatment. We are currently enrolling children aged 4-12 with and without uncomplicated *P. falciparum* malaria in Blantyre, Malawi for breath analysis. Blood smear test or RDT is used to diagnose malaria. Furthermore, blood samples will also be used for PCR quantification of asexual parasites and gametocytes. We expect that our data will provide robust evidence that infections such as malaria cause specific, reproducible changes in breath VOCs. Critically, our studies will determine the limit of parasite detection by breath VOCs. In addition, our work will inform the fundamental biological principles that drive breath volatile production during clinical pediatric malaria.

1577

EVALUATION OF A NOVEL HEMATOLOGY ANALYZER FOR MALARIA DIAGNOSIS USING FINGER-PRICK BLOOD IN AN ENDEMIC AREA OF COLOMBIA

Tatiana Maria Lopera-Mesa[1], Lina Zuluaga-Idarraga[1], Alexandra Rios[1], Veronica Sierra[1], Edwar Garzón[1], Ikki Takehara[2], Yuji Toya[2], Chiaki Takeuchi[2], Kinya Uchihashi[2], Alberto Tobón-Castaño[2]

[1]*Universidad de Antioquia, Medellin, Colombia,* [2]*Sysmex Corporation, Kobe, Japan*

As defined by WHO guidelines, finger-prick blood collection is a standard method of malaria diagnosis, and is preferable for new diagnosis methods in endemic areas. The XN-30 is an analyzer that requires only small amounts of fresh blood (20uL min.), and is able to perform simultaneously complete blood-cell count (CBC) with 8 parameters as well as quantitative analysis of malaria-infected cells, for research purposes. This study describes the XN-30 performance for malaria parameters compared to microscopy and real-time PCR (RT-PCR), when measured from finger-prick blood, and the performance of CBC parameters between venous and finger-prick blood in an endemic area of Colombia where *P. falciparum* and *P. vivax* are present. A cohort of 60 subjects with acute febrile syndrome were enrolled (30 malaria negative and 30 malaria positive). Malaria diagnosis was done by microscopy and RDT in the field, and it was later confirmed by RT-PCR. Venous and finger-prick blood in EDTA collected from single patients were processed on the XN-30. The sensitivity, specificity, positive/negative predictive values (PPV, NPV), and likelihood ratio of positive and negative tests (LRP and LRN) were

calculated. The intra-class correlation coefficient (ICC) and Bland-Altman plot were used to evaluate concordance of parasitemia. Compared with microscopy, *Plasmodium* detection in the XN-30 showed a sensitivity of 93.6% (95% CI 83.3 - 100), specificity of 100% (95% CI 98.2 - 100), PPV of 100% (95% CI 98.3 - 100) and NPV of 93.3% (95% CI 82.7 - 100). Concordance analysis of parasitemia between microscopy thick smear and the XN-30 showed ICC 0.89 (95% CI 0.78 - 0.95) and compared with thin smear ICC 0.99 (95% CI 0.97 - 0.99). In concordance analysis of the XN-30 CBC parameters between venous and finger-prick blood, ICC of WBC/RBC/HGB/HCT/MCV/PLT were 0.82 (95% CI 0.71 - 0.89) / 0.86 (95% CI 0.78 - 0.92)/ 0.93 (95% CI 0.88 - 0.96)/ 0.90 (95% CI 0.84 - 0.94)/ 0.88 (95% CI 0.80 - 0.92) / 0.94 (95% CI 0.90 - 0.96) respectively. These results suggest that the XN-30 is effective for malaria detection and CBC parameters, even when analyzing finger-prick collected blood.

1578

INFORMATION ON MALARIA DIAGNOSIS AND TREATMENT INCLUDED IN HEALTH MANAGEMENT INFORMATION SYSTEMS IN 23 COUNTRIES

Emily Stammer, Kate Gilroy, Michel Pacqué

John Snow Inc/MCSP, Washington, DC, United States

Most low and middle-income countries use data from health management information systems (HMIS) to monitor malaria programs on a routine basis. WHO provides guidance for malaria control program indicators, however the data elements needed for reporting these indicators are often not included in national HMIS. The USAID Maternal and Child Survival Program conducted a review of child health data elements, including malaria, in 23 low and middle-income countries' HMIS to identify commonalities and gaps. We collected national HMIS registers, summary forms and patient forms used at the facility and community level and extracted the data elements on each form or register into a standardized template. A number of malaria data elements are more commonly collected at the community level than the facility level. At the community level, 10 out of 23 countries consistently capture (in both registers and summary forms) information about malaria diagnosis using rapid diagnostic tests (RDT) among children under five years of age (< 5) compared with 7 out of 23 countries capturing the same information at the facility level. We found that 9 out of 23 countries consistently capture the treatment of RDT+ children < 5 at the community level compared with 3 out of the 23 at the facility level. At the facility level, the majority of data related to malaria diagnosis and treatment is collected only in summary forms, indicating the summary forms rely on data aggregated from open "diagnosis" fields in registers, which has implications for quality of the data. Finally, about half of the countries do not report on malaria treatment at all in their community (10 of 23 countries) or facility forms (13 of 23 countries). Not all countries are routinely collecting and reporting WHO-recommended malaria diagnosis and treatment data elements, which are necessary to monitor malaria management and epidemiology across geographic areas, time or service locations. The findings can help country and global stakeholders understand what data elements are available in each country's routine HMIS to calculate key indicators and advocate for inclusion of priority indicators during HMIS reviews.

MALARIA MICROSCOPY PARAMETERS AFFECTING ATTAINMENT OF COMPETENCY LEVELS IN NATIONAL COMPETENCY ASSESSMENTS IN GHANA, 2019

Alexander Asamoah, Mildred Komey, Akosua Gyasi Darkwa, Keziah Lawrencia Malm

National Malaria Control Program, Accra, Ghana

Malaria tests are now the bedrock of malaria diagnosis. As microscopy remain the gold standard for testing, the competency of malaria microscopists to retain prescribers' confidence and improve case management cannot be overemphasized. As such the National Malaria Control Programme set out to determine the competency levels of regional malaria microscopists, certify them and determine parameters that affect attainment of competency levels in a national competency assessment in malaria microscopy for onward training of laboratory scientists. A 5-day national competency assessment in malaria microscopy was conducted in 3 sessions across the country from November 2018 to April 2019. Malaria microscopists were purposively selected to participate in the assessment. Each microscopist examined 74 blood slides obtained from Slide Bank. The microscropists' assessments were scored and graded using a standardized computer-based template. The assessment scores for malaria microscopy parameters (parasite detection, species identification and density determination) was used to determine competency levels. Analysis of Odds Ratio was done using Epi-Info version 7 stat cal to determine associations between parameters. Of 80 microscopists assessed, 61% (49) attained either Level A or B competence. All regions obtained at least one certified microscopist with Level A (expert) competence. The proportion of microscopists who could not attain competency levels in all three areas assessed was 26% (8/31), two was 16% (5/31) and in one area was 55% (17/31). Species identification scores accounted for 39% (12/31) of microscopists not attaining competency levels. The odds of attaining competency levels with species identification was about 3 times OR=2.85(CI:1.29-6.30) whilst parasite density was about 2 times OR=1.69(CI:0.74-3.89) than compared with parasite detection. Microscopists that attained Levels A and B were certified as National malaria microscopists. Species identification was significantly associated with attainment of competency levels. We recommend regular training in species identification for effective case management.

1580

OPENMM - A LOW-COST, MODULAR, AND AUTONOMOUS MICROSCOPE FOR MALARIA DIAGNOSIS AND BEYOND

Hongquan Li, Hazel Soto-Montoya, Lucas F. Valenzuela, Maxime Voisin, Manu Prakash

Stanford University, Stanford, CA, United States

Microscopy has been the gold standard for the diagnosis of malaria since its first adoption more than a century ago. Today the practice of manually examining stained blood smear with an oil immersion objective remains largely the same. While more than 200 million patients were tested by microscopic examination in the year of 2016, implementation of microscopy-based diagnosis is limited by the requirement of trained technicians, very low throughput and presence of errors due to human factors. With the advent of artificial intelligence and ever-increasing compute power at the edge, automated robotic microscopes are poised to enable a new era in the diagnosis of malaria and many other diseases but current platforms remain cost prohibitive. Here we present openMM, a low-cost, open-source, modular and autonomous microscopy platform capable of brightfield/darkfield and fluorescent imaging. Modularity of the platform allows rapid reconfiguration of the microscope and makes it easy to tailor the platform to specific applications. Motorized slide scanning, autofocus as well as software processing pipelines make the platform autonomous and give rise to high throughput. The cost of 300 USD makes wide deployment of the tool in resource-limited settings possible. At low magnification, initial tests in the lab suggest achievable detection limit of better than 150 parasites/ul of blood for *Plasmodium* Falciparum, with imaging speed of more than 1 million blood cells per minute. We have also developed a high magnification module, using which morphology of ring stage parasites are clearly resolved. With about two orders of magnitude in cost reduction, openMM will open up access to networks of robotic microscopes and bring together communities with diverse expertise and accesses to complementary resources for collectively advancing microscopy-based disease diagnostics.

1581

MALARIA DIAGNOSIS IN THE MOBILE GOLD MINERS' POPULATION OF SURINAME IN 2018: AN EVALUATION OF THE MALARIA SERVICE DELIVERS' SYSTEM USING RAPID DIAGNOSTIC TEST

Hedley Cairo

Ministry of Health Malaria Program, Paramaribo, Suriname

Currently malaria infections in Suriname occur mainly among persons engaged in small-scale gold mining and related activities. Since 2006, lay persons living in mining areas have been trained to perform malaria diagnosis with Rapid Diagnostic Test (RDT) and to treat malaria. Blood films are also prepared for each subject tested. Blood smear prepared by the Malaria Service Deliverers (MSDs) in the miners' communities are sent to TropClinic malaria laboratory in the Capital Paramaribo. The TropClinic is staffed with trained malaria microscopy technicians. In Suriname and many other countries, microscopy is considered the gold standard for malaria diagnosis. A study was conducted to evaluate the accuracy of MSD system using RDTs in the field compared to microscopy done at the central clinic for malaria diagnosis in Suriname. The EpiTools and MedCalc websites were used for the calculation of the RDT test performance characteristics. In 2018, 2265 subjects were tested by the MSDs with RDT. For 2022 (89.3%) RDT result a microscopy result was available for comparison. The majority of malaria cases, 88 (37.3%) of the 236 cases diagnosed in Suriname in 2018, were diagnosed by the MSD network. Considering microscopy as the reference test, the sensitivity and specificity of the MSD system were respectively 88.1% [95%CI: 77.8 - 94.7] and 98.4% [95%CI: 97.8 - 98.9] . The PPV was 65.5% [95%CI: 57.0 - 73.2]. The NPV system was 99.6% [95%CI: 99.2 - 99.8]. The overall accuracy of the MSD system was 98.1% [95% CI: 97.37 - 98.6]. Early and accurate malaria diagnosis is essential to initiate prompt and adequate treatment. The sensitivity of the MSD system calculated was below the 95% recommended by the World Health Organization. Continuous training of the workers and ensuring optimal conditions for the storage of RDTs in the field could improve the performance of the MSDs. These result should be interpreted with some degree of reserve, because there are studies in which RDT and microscopy are compared to PCR as reference test revealing a higher sensitivity for RDT. This study emphasizes the need of a QA & QC system for diagnostics to achieve the malaria elimination goal.

ADVANTAGES, DISADVANTAGES AND PITFALLS IN THE DETECTION OF MIXED-SPECIES MALARIA CASES IN A NON-ENDEMIC SETTING

Alexander Oberli, Trang Ha Thu Nguyen, Konrad Mühlethaler

Institute for Infectious Diseases, Bern, Switzerland

A precise laboratory diagnosis of the *Plasmodium* spp. causing malaria is of critical importance with regard of a species targeted treatment. So far, microscopic detection and identification of *Plasmodium* spp. in Giemsa-stained blood smears is the gold standard for the laboratory diagnosis of malaria. Nevertheless, in clinical practice mixed-species malaria infections are often not detected by light microscopy (LM) or rapid diagnostic test (RDT), as a notable decrease in the number of parasites of one species may occur. Mixed species infections in humans with *P. vivax* and *P. ovale* have only been described in a triple or quadriple species infection together with *P. falciparum* and/or *P. malariae*. The case of an 8-year-old girl migrating with her family from Afghanistan to Central Europe is to our knowledge the first report of a mixed *P. vivax* / *P.ovale* infection confirmed by LM and molecular diagnostic tools. Subsequent molecular testing of other family members revealed a submicroscopic *P.vivax* / *P. falciparum* mixed infection of one family member, indicating that microscopic examination of blood smears does not reliably distinguish *Plasmodium* spp., especially when one species dominates the other numerically. To our knowledge this is the first documentation of an uncommon two-species mixed infection comprising both *P. vivax* and *P. ovale*, confirmed by light microscopy and different molecular diagnostic tools. Here, we discuss and compare advantages, disadvantages and pitfalls of LM, RDTs, commercially available multiplex rtPCR and species-specific singleplex rtPCR for the detection of mixed-species infections in the case of a migrating refugee family but also in a general non-endemic setting.

1583

HIGHLY SENSITIVE MALARIA DIAGNOSITCS USING A NOVEL SET OF ANTI-PFHRP2 ANTIBODIES

Rolf Fendel[1], Andrea Kreidenweiss[1], Johanna Griesbaum[1], Sofia Dembski[2], Torsten Klockenbring[3]

[1]*Institute of Tropical Medicine, Tübingen, Germany,* [2]*Fraunhofer Institute for Silicate Research ISC, Würzburg, Germany,* [3]*Fraunhofer Institute for Molecular Biology and Applied Ecology IME, Aachen, Germany*

Despite global efforts to stop malaria , *Plasmodium falciparum* transmission is ongoing, and mortality remains high. WHO recommends diagnostic confirmation before starting antimalarial treatment. Most rapid diagnostic tests currently in use are detecting *Plasmodium falciparum* histidine rich protein (PfHRP2). Overall, current PfHRP2-RDTs have an acceptable performance but fail to detect malaria parasites a lower parasitemia. In the present work, we generated a novel set of anti-PfHRP2 antibodies with high affinity against PfHRP2 antigen. Several protein assays (ELISA, TR-FRET, etc.) were conducted to compare the performance and detection limit of our antibodies to commercially available anti-HRP2 antibody sets The novel anti-HRP2 antibodies specifically detected various HRP2 antigen products at considerably lower quantities. The limit of detection using the novel antibodies was below 10 pg/ml which was significantly lower than the commercially available antibodies under the same experimental setup. In conclusion, the present work describes a novel set of anti-HRP2 antibodies with high potential for use in malaria diagnostic tests. In combination with new technological approaches (TR-FRET), sensitive and simple assays for malaria diagnosis are within reach.

SYSTEMATIC REVIEW OF STATISTICAL METHODS FOR ANALYSIS OF SAFETY DATA IN MALARIA CHEMOPREVENTION AND TREATMENT IN PREGNANCY CLINICAL TRIALS

Noel P. Patson[1], Miriam K. Laufer[2], Mavuto Mukaka[3], Alinune Kabaghe[4], Don Mathanga[4], Victor Mwapasa[4], Lawrence Kazembe[5], Kennedy N. Otwombe[1], Marinus J. Eijkemans[6], Tobias Chirwa[1]

[1]*University of the Witwatersrand, Johannesburg, Johannesburg, South Africa,* [2]*University of Maryland, School of Medicine, USA, Baltimore, MA, United States,* [3]*Centre for Tropical Medicine, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [4]*University of Malawi, College of Medicine, Blantyre, Malawi,* [5]*University of Namibia, Department of Biostatistics, Windhoek, Namibia,* [6]*University Medical Center Utrecht, Utrecht, Netherlands*

Improved statistical analysis of safety data in premarketing randomized controlled trials (RCTs) aids in generation of high quality drug safety evidence through efficient use of data. Currently, lack of high quality antimalarial drug safety evidence during pregnancy may have limited introduction of antimalarial drug treatment and prevention options. Pregnant women are systematically excluded from RCTs due to fear of potential drug harms. Although some RCTs are done in pregnant women, the collected safety data can be complex; the data may have multiple outcomes, repeatedly measured over time, and non-adherence to the treatment induced by adverse events (AEs) may be present. This complex data need powerful statistical analysis methods beyond the traditional descriptive approaches to account for the event-dependence, missing data and time-dependencies. We conducted a systematic review to establish the current practice in statistical analysis methods in antimalarial drug safety data in pregnancy trials. We systematically searched five databases (PubMed, Embase, Scopus, Malaria in Pregnancy Library (MiPL) and Cochrane Central Register of Controlled Trials (CENTRAL)) for original

English articles reporting Phase III RCTs on antimalarial drugs in pregnancy published from 2010 to 2018. A total of 26 RCTs, included in this review, collected multiple safety outcomes including AEs. Statistical analysis of the RCTs used descriptive statistics, mainly proportions (94.4%, 24/26). The commonly used inferential statistical method was Fisher`s exact test (61.5%, 16/26). Negative binomial, Poisson and logistic regression were used in three trials only. Five trials addressed the subject of missing data but did not explore a potential link with safety outcomes. Only two trials used graphs next to tables to aid in summarizing patterns of safety outcomes. Current statistical analysis of antimalarial drug safety data in pregnancy trials is predominantly descriptive and univariate. Further attention is required to consider methods that include time-varying dependence of AEs, informative censoring, recurrence of AEs and correlation.

1585

EFFICACY AND TOLERANCE OF "SAYE", AN HERBAL REMEDY IN THE TREATMENT OF MALARIA

Maminata Coulibaly Traore[1], Ibrahima Fayama[2], Toussaint Rouamba[1], Sibidou Yougbare[1], Daniel Valia[1], Innocent Valea[1], Ollo Da[3], Jean Claude W Ouedraogo[2], Serge R. Yerbanga[4], Halidou Tinto[1]

[1]*URCN/IRSS, Nanoro, Burkina Faso,* [2]*Université Ouaga 1, Ouagadougou, Burkina Faso,* [3]*IRSS/DRO, Bobo-Dioulasso, Burkina Faso,* [4]*IRSS-DRO, Bobo-Dioulasso, Burkina Faso*

Saye is an antimalarial phytomedicine composed of a mixture of three plants: *Cassia alata* Linn, *Cochlospermum planchonii* Hook, *Phyllanthus amarus* Schum and Thonn) widely used for the treatment of malaria in Burkina Faso. Saye has shown interesting *in vitro* and *vivo* antiplasmodial activity without toxicity. A clinical trial was then conducted to demonstrate its efficacy and tolerance. This was an open-label Phase II/III clinical trial in patients with uncomplicated *P. falciparum* malaria in Nanoro, Burkina Faso. A total of 57 patients meeting the inclusion criteria were included and actively followed up for 42 days with a daily appointments the first 7 days during which, they received 3 capsules of Saye dosed at 130.5mg, 3 times per day and weekly follow up visits. The PCR -unadjusted cure rates were 54%, 45%, 33% and 25% at days 7, 14, 28 and 42, respectively. Day-42 PCR-corrected adequate clinical and parasitological response (ACPR) with Saye was 45.1 [95% CI (31.4 - 59.5)]. A total of 168 mild adverse events (AE) were reported during the 42 days follow up and mainly represented by vomiting (7%), diarrhoea (13%), abdominal pain (13.9%), headache (11.3%), cough (6.1%), asthenia (5.2%), hyperthermia (7.8%), anemia (41.2%), thrombopenia (5.9%), hyper-transaminases (17.6), hyperglycemia (13.7%) and leucopenia (5.9%). Only, few of them (10%) were found related to the study medication. Saye was able to cure a little more than half of the patients with malaria, with no toxic effect. Saye was well tolerated by patients. However, further studies should be conducted comparing Saye to an ACT with probably new treatment regimens or new Saye compositions.

1586

ASSESSMENT OF POTENTIAL PHARMACOKINETIC DRUG INTERACTION BETWEEN ARTEMETHER-LUMEFANTRINE (AL) AND PRIMAQUINE

Jay Prakash Jain[1], Helen Gu[2], Katalin Csermak Renner[3], Pramod J Math[4]

[1]*Novartis Institutes for BioMedical Research, Inc., Emeryville, CA, United States,* [2]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States,* [3]*Novartis Pharma AG, Basel, Switzerland,* [4]*Novartis Healthcare Pvt. Ltd., Hyderabad, India*

Until the approval of tafenoquine, primaquine (PQ) has been the only available radical treatment for *Plasmodium vivax* and *P. ovale* malaria due to its hypnozoitocide activity, PQ has high *P. falciparum* gametocytocidal activity as well. WHO recommends PQ with other antimalarials including artemisinin based combination therapy (ACT) as cure for *P. vivax, P. ovale* and mixed infections and as low single dose with ACT for reducing transmission. It has been reported that PQ's activity is primarily dependent on its metabolism mediated by cytochrome P450 (CYP)2D6 to form active metabolites. Artemether-Lumefantrine (AL) is one of the most used ACT and because lumefantrine (LUM) is a potent CYP2D6 inhibitor it can potentially impact the PQ metabolism thereby alter its efficacy and safety. The objective was to assess the PK-related drug interactions for PQ as a CYP2D6 victim drug with LUM. To achieve this, integrated *in vitro* and in silico studies were conducted. The inhibitory effect of LUM on PQ metabolism was investigated in human liver microsomes and hepatocytes. The results showed that *in vitro* hepatic clearance of PQ was affected by changed in intrinsic clearance (CLint) in the presence of LUM. Additionally, physiologically-based pharmacokinetic (PBPK) models for PQ and LUM were developed. The predicted PQ exposure would be increased by ~1.4 fold when co-administration with 3-QD of LUM. Although the impact on the metabolites could not be studied inhibition of CYP2D6 in exposure dependent manner was seen in silico. Other effects (e.g., polymorphism of CYP2D6) can influence the PQ activity, which were not studied. Overall, there seems to be a theoretical potential reduction of PQ efficacy due to the CYP2D6 inhibition by LUM, especially in patients who are not extensive CYP2D6 metabolizers. However, Novartis safety database did not reveal a significant risk of loss of efficacy due to the interaction. Recent evidence suggests that the risk of recurrence after *P. vivax* malaria with AL-PQ is low. Due to the lack of clear clinical data, complex PQ metabolism and pharmacodynamic relationship, guidance on the need for dose adjustment, if any, cannot be provided.

1587

A POTENTIALLY SAFER RADICAL CURE REGIMEN OF PRIMAQUINE - EARLY RESULTS FROM A PRIMAQUINE CHALLENGE STUDY IN HEALTHY GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENT MALES

Podjanee Jittamala[1], James Watson[2], Sasithon Pukrittayakamee[1], Borimas Hanboonkunupakarn[1], Cindy Chu[3], Germana Bancone[3], Joel Tarning[2], François Nosten[3], Nicholas Day[2], Nicholas White[2], **Walter Taylor**[2]

[1]*Mahidol University, Bangkok, Thailand,* [2]*MORU, Bangkok, Thailand,* [3]*SMRU, Mae Sot, Thailand*

Primaquine is the only widely used drug for the radical cure of *Plasmodium vivax* malaria. In areas with high relapse rates, the WHO recommended primaquine dose is 0.5 mg base/kg/day x 14 days. This is highly efficacious but contraindicated in patients with G6PD deficiency (less than 30% of normal enzyme activity). A once weekly regimen of 0.75 mg/kg for 8 weeks is recommended currently in all G6PD deficient variants but may cause clinically significant haemolysis in some patients. These concerns and the difficulty of testing for G6PDd in low resource settings mean primaquine is little used. We aim to develop a safe and efficacious primaquine regimen for G6PD deficient patients that obviates the need for G6PD testing. Mechanistic within-host modelling of primaquine induced haemolysis in G6PD deficiency showed that it is theoretically possible to deliver a safe radical curative primaquine regimen over 20 days by inducing controlled haemolysis with gradually escalating doses (7.5, 15, 22.5 & 30 mg). A Phase 1 study in G6PD deficient healthy volunteers has commenced to test and refine this predicted "optimal" primaquine regimen. Optimal is defined both in terms of the absolute and relative reductions in haemoglobin concentrations and the daily rate of haemolysis. In total 20 healthy volunteers will be recruited in two sites in Thailand. The trial design is adaptive, with rigorous pre-specified alterations in the administered regimen, depending on the observed outcomes. Recruitment in Bangkok started in December 2018 and should finish in June 2019. The safety of the initial regimen has been demonstrated in 5 volunteers (baseline haemoglobins ca. 14 to 16 g/dL) with one of three common G6PDd mutations: Mahidol, Viangchan, and Canton. Fractional haemoglobin falls ranged from 15 to 25%. These early preliminary results provide proof-of-concept of the safety of ascending doses primaquine. The final analysis, using our prior developed mechanistic model, will identify an

optimal ascending dose primaquine regimen that will be subsequently field tested for safety and efficacy in G6PD normal and deficient patients with *P. vivax* infection.

1588

EFFECT OF DIHYDROARTEMISININ-PIPERAQUINE AND ARTEMETHER-LUMEFANTRINE WITH AND WITHOUT PRIMAQUINE ON *PLASMODIUM VIVAX* RECURRENCE: A SYSTEMATIC REVIEW AND INDIVIDUAL PATIENT DATA META-ANALYSIS

Robert J. Commons[1], on behalf of the WWARN Vivax ACT Recurrence Study Group[2]

[1]*Menzies School of Health Research, Red Hill, Australia,* [2]*WorldWide Antimalarial Resistance Network, Oxford, United Kingdom*

Artemisinin-based combination therapy (ACT) is recommended for uncomplicated *Plasmodium vivax* malaria in regions with emerging chloroquine resistance. This study aimed to determine the risk of recurrent *P. vivax* following dihydroartemisinin-piperaquine (DP) and artemether-lumefantrine (AL) with or without primaquine. Clinical efficacy studies of uncomplicated *P. vivax* treated with DP or AL and published between January 2000 and January 2018 were identified. Individual patient data from available eligible studies were pooled using standardised methodology. The effect of mg/kg dose of piperaquine/lumefantrine, ACT administered, and primaquine on the rate of *P. vivax* recurrence between days 7 and 42 after starting treatment were investigated by Cox regression analyses. Secondary outcomes were the risk of recurrence assessed on days 28, and 63. 2,017 patients from 19 studies were included. The risk of recurrent *P. vivax* at day 42 was significantly higher in 384 patients treated with AL alone (44.0% [95%CI 38.7-49.8]) compared to 812 patients treated with DP alone (9.3% [7.1-12.2]); adjusted hazard ratio (AHR) 12.63 [95%CI 6.40-24.92], p<0.0001. A higher dose of piperaquine was associated with decreased rates of recurrence at days 42 and 63; AHRs [95%CI] for every 5 mg/kg increase 0.63 [0.48-0.84], p=0.0013 and 0.83 [0.73-0.94], p=0.0033 respectively. In patients with symptomatic recurrence after AL the mean haemoglobin increased 0.13 g/dL [95%CI 0.01-0.26] for every five days that recurrence was delayed; p=0.0407. Co-administration of primaquine reduced substantially the rate of recurrence at day 42 after AL (AHR=0.20 [0.10-0.41], p<0.0001), and at day 63 after DP (AHR=0.08 [0.01-0.70], p=0.0233). The risks of *P. vivax* recurrence at day 42 are lower following treatment with DP compared with AL, reflecting a longer duration of post-treatment prophylaxis. These risks are reduced substantially by co-administration with primaquine. Delaying *P. vivax* recurrence is associated with a small improvement in haemoglobin. This highlights benefits of radical cure and prolonged post-treatment prophylaxis.

1589

PHARMAKOCINETICS, EFFICACY AND SAFETY OF ARTEMETHER-LUMEFANTRINE DISPERSIBLE TABLET FORMULATION (1:12) IN THE TREATMENT OF ACUTE UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN NEONATES AND INFANTS <5 KG BODY WEIGHT

Cornelis Winnips[1], Jay Prakash Jain[2], Guoquin Su[3], Celine Risterucci[1], Marc Cousin[1], W. Lin[3], Katalin Csermak Renner[1]

[1]*Novartis Pharma AG, Basel, Switzerland,* [2]*Novartis Institutes for Biomedical Research Inc., Emeryville, CA, United States,* [3]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States*

In neonates/infants <5 kg of body weight (BW) with uncomplicated *P. falciparum* malaria, WHO recommends artemisinin-based combination therapy (ACT) at the same mg/kg BW as in those ≥5 kg, but no ACT is currently approved for this population. In a recent trial in infants <5 kg BW and >28 days, Coartem dispersible (AL), at 20mg artemether:120mg lumefantrine BID for 3 days yielded artemether exposures whose safety was not previously established. This open-label, single-arm, multicenter study in Sub-Saharan Africa will assess a new formulation of AL with a 1:12 ratio, in infants <5 kg, at a starting dose of 5mg:60mg (bid for 3 days) based on Physiologically based Pharmacokinetic modeling. It will use a staggered approach by enrolling inpatients in two sequential cohorts of 20 infants each: age >28 days (Cohort 1) and age ≤28 days (Cohort 2). Exposure will be checked in a few patients prior to completing each cohort with or without dose adjustment. An independent data monitoring committee will review efficacy and safety data on an ongoing basis, and at completion of Cohort 1, recommend whether to proceed to Cohort 2. Exclusion criteria include severe malaria, signs and symptoms of a critical condition, hepatic or renal abnormality, and major neurological malformation. The main objectives are to evaluate PK (e.g. artemether C_{max}), efficacy (e.g. PCR-corrected parasitological cure up to day 43; time to parasite clearance), safety and tolerability of the new AL tablet. Neurodevelopment status will be checked at Day 4 and at 12 months of age. Use of antipyretics and rescue medication per local guidelines is allowed. Protocol approval is sought from ethics committees in Switzerland and in participating countries. Written informed consent will be obtained from all parents/guardians. Results are expected in 2022.

1590

COHORT EVENT MONITORING STUDY OF 8572 MALARIA CASES TO EVALUATE, IN REAL-LIFE SETTING, THE SAFETY AND TOLERABILITY OF THE FIXED-DOSE COMBINATION THERAPY PYRONARIDINE-ARTESUNATE FOR THE TREATMENT OF UNCOMPLICATED MALARIA

Michael Ramharter[1], Gaston T. Lutete[2], Ghyslain Mombo-Ngoma[3], Serge-Brice Assi[4], Jude D. Bigoga[5], Felix Koukouikila-Koussounda[6], Pierre-Michel Ntamabyaliro Nsengi[2], Francine Ntoumi[6], Mirjam Groger[1], Diane Egger-Adam[7], Matthias Karnahl[7], Jorge Liz[8], Robert M. Miller[9], Sarah Arbe-Barnes[9], Jangsik Shin[10], Peter G. Kremsner[7], Isabelle Borghini-Fuhrer[8], Stephan Duparc[8]

[1]*Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany,* [2]*University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [3]*CERMEL, Lamabrene, Gabon,* [4]*Institut Pierre Richet / Institut National de Santé Publique, Bouaké, Côte D'Ivoire,* [5]*University of Yaounde, Yaounde, Cameroon,* [6]*FCRM, Brazzaville, Republic of the Congo ,* [7]*Institut für Tropenmedizin, Tübingen, Tübingen, Germany,* [8]*Medicines for Malaria Venture, Geneva, Switzerland,* [9]*Artemida Pharma Limited, Stevenage, United Kingdom,* [10]*Shin Poong Pharmaceutical Co., Ltd., Seoul, Republic of Korea*

Pyronaridine-artesunate (Pyramax™, PA) has received a positive opinion under article 58 by EMA and is approved in African and Asian countries for the treatment of uncomplicated vivax and falciparum malaria. PA is highly efficacious and is well tolerated apart from, in a small number of patients, asymptomatic, transient rises in liver transaminases. This large clinical Phase IIIb/IV study has evaluated the safety of PA in a real-life setting including hitherto underrepresented patient populations such as children <1 year. The study was conducted in Cameroon, Democratic Republic of Congo, Gabon, Ivory Coast and the Republic of Congo. Patients above 5kg bodyweight presenting with uncomplicated malaria at local health facilities were included. The primary objective was to evaluate any hepatic safety events in a subgroup of patients enrolled with asymptomatic transaminases >2xULN from blood taken immediately prior to treatment. PA was given according to the label information as a once daily dose for 3 days; the first dose under supervision by the health care provider and patients were seen again on D7 and D28 at home by a community health worker. Further liver function testing was performed if there were any hepatic signs or symptoms. Between June 2017 and March 2019, 8,572 uncomplicated malaria episodes including 142 with elevated baseline liver enzymes and 147 in children <1 year of age, were treated with PA. No episode of clinically apparent drug induced liver injury was detected. 9 mostly mild (0.1%) hypersensitivity reactions occurred. 33 (0.4%) serious adverse events occurred in the course of this study of which only 3 (0.03%) events were judged as related to PA. D28 crude and PCR corrected cure rate will be presented. PA has confirmed its very good safety and efficacy profile for the treatment of uncomplicated malaria in

Africa in this unselected patient population. This includes patients with raised liver enzymes at baseline, children below one year of age and patients with comorbidities.

1591

A PHASE 1A, FIRST-IN-HUMAN, DOSE-ESCALATION STUDY OF M5717: A FIRST-IN-CLASS INHIBITOR OF *PLASMODIUM FALCIPARUM* EUKARYOTIC TRANSLATION ELONGATION FACTOR 2

James McCarthy[1], Oezkan Yalkinoglu[2], Arnand Odedra[1], Rebecca Webster[1], **Claude Oeuvray**[3], Aliona Tappert[2], Deon Bezuidenhout[4], Justin Wilkins[5], Akash Khandelwal[2], Wilhelmina Bagchus[6]

[1]*QIMR Berghofer Medical Research Institute, Heston, Australia,* [2]*Merck KGaA, Darmstadt, Germany,* [3]*The Global Health Institute of Merck, Eysin, Switzerland,* [4]*Merck PTY, Modderfontein, South Africa,* [5]*Occams, Werl, Germany,* [6]*Merck Institute for Pharmacometrics, Lausanne, Switzerland*

M5717 is a first-in-class inhibitor of the *Plasmodium falciparum* translation elongation factor 2. Preclinical data predicting good oral bioavailability, potent antimalarial activity, and favorable safety profile prompted the conduct of a phase 1a, first-in-human, safety and pharmacokinetic (PK) study in healthy adult volunteers (ClinicalTrials.gov Identifier: NCT03261401). The study is a randomized, placebo-controlled design, employing dose escalation with an adaptive component allowing for modifications to the dose increments based on PK and safety data. Currently (April 2019), seven doses have been tested in fasted volunteers (50 - 1250 mg); typical cohort size was six active and two placebo volunteers. M5717 was well tolerated, with no serious adverse events (SAEs), severe adverse events (AEs), or clinically significant electrocardiogram findings noted. All AEs were mild or moderate and transient, and mostly considered unrelated to M5717. Exposures following single oral doses of M5717 were non-linear across the dose range. The most parsimonious model describing M5717 PK was two-compartmental, with a recirculation component to describe secondary peaks; central volume of distribution (V2/F) and absorption rate constant (ka) were strongly inversely correlated with the administered dose. The median time to maximum concentration (t_{max}) was 2.9 hours (range 1-7), and the median terminal half-life ($t_{1/2}$) was over 6 days and appeared independent of dose. None of the volunteers receiving 1250 mg M5717 exceeded the exposure threshold area under the curve (AUC) of 318,200 hr*ng/mL defined from the no-observed-adverse-effect-level (NOAEL) in pre-clinical toxicology studies in rats. In summary, results to date show that M5717 is well tolerated and has favorable PK enabling single oral dose administration. These results have prompted the initiation of a phase 1b study in which healthy volunteers were inoculated with blood-stage *P. falciparum* parasites and dosed with M5717 to investigate its antimalarial activity.

1592

SAFETY OF *SIPHONOCHILUS AETHIOPICUS* (AFRICAN GINGER) FOR THE TREATMENT OF TANZANIAN ADULTS AGED 18 TO 45 YEARS BY USING CONTROLLED HUMAN MALARIA INFECTION (CHMI)

Florence Milando

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

Malaria is a key public health challenge occurring mostly in the Africa region and causes significant morbidity and mortality. According to the WHO 2018 report, an estimated 219 million cases of malaria occurred worldwide in the year 2017. The scientific investigation of antimalarial herbal remedy to prove its efficacy and safety may be of benefit to the worldwide agenda of malaria control and elimination.This will be the first time such an approach is used in a controlled clinical trial setting for evaluation of herbal remedies for malaria and hence open up the possibility of testing many more malaria products in Africa. The object of this study is to evaluate the safety and tolerability of *Siphonochilus aethiopicus* (African Ginger) given as preventive or curative medicine among Tanzanian healthy adult aged 18 to 45 years by using the Control Human Malaria Infection model. The study design of the trial will be single center phase IIb and open label clinical trial with a population of 18 healthy participants aged 18 to 45 years residing in Bagamoyo District or nearby districts. The participants will be divided into two subgroups of 9 participants each. The first subgroup (G1) will receive a malaria herbal remedy 2 day before the CHMI to evaluate its preventive efficacy (liver stage activities of antimalarial). The second subgroup (G2) will be treated with an antimalarial herbal remedy as soon as diagnosed positive with blood slide after CHMI to evaluate its curative efficacy (blood stage activities of the herbal remedy). The safety and tolerability will be evaluated through assessment of the following;(i) Clinical significance abnormal values of laboratory tests during the follow up period of 42 days (ii) Significant changes in physical examination results comparing to baseline during the follow up period of 42 days (iii) AEs during the follow up period of 28 days or serious adverse events (SAE) during the follow up period of 42 days. The study will be commenced in June 2019 and the complete monitored data will be available for presentation in October 2019.

1593

EFFICACY OF *SIPHONOCHILUS AETHIOPICUS* (AFRICAN GINGER) FOR THE TREATMENT OF TANZANIAN HEALTHY ADULTS AGED 18 TO 45 YEARS BY USING CONTROLLED HUMAN MALARIA INFECTION (CHMI)

Kamaka Ramadhani Kassimu

Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

Malaria is a disease of poverty and still a major global health problem especially in Africa. Almost all African countries are located in a malaria endemic area. It was estimated that 219 million cases of malaria occurred worldwide in 2017. The scientific investigation of antimalarial herbal remedy to prove its efficacy and safety may be of benefit to the worldwide agenda of malaria control and elimination. The objective of this study is to evaluate the parasitic suppression activities and protective efficacy of *Siphonochilus aethiopicus* (African Ginger) given as preventive or curative medicine among healthy Tanzanian adults aged 18 to 45 years by using the Control Human Malaria Infection (CHMI) model. The study design of the trial will be single center phase IIb and open label clinical trial with a population of 18 healthy participants aged 18 to 45 years residing in Bagamoyo District or nearby districts. The participants will be divided into two subgroups of 9 participants each. The first subgroup (G1) will receive a malaria herbal remedy 2 day before the CHMI to evaluate its preventive efficacy (liver stage activities of antimalarial). The second subgroup (G2) will be treated with an antimalarial herbal remedy as soon as diagnosed positive with blood slide after CHMI to evaluate its curative efficacy (blood stage activities of the herbal remedy). The efficacy will be evaluated through ;(i) Early Treatment Failure (ETF) (ii) Asexual parasite clearance time (PCT). (iii) Adequate Clinical and Parasitological Response (ACPR) for treatment at 28 days and 42days after PCR correction of reinfection (ACPR 28 and 42 after PCR correction of reinfection (iii) Proportion of participants from group 1 with development of *Pf* parasitemia by TBS following CHMI. The study will be commenced in June 2019 and the complete monitored data will be available for presentation in October 2019.

1594

PHARMACOLOGICAL PROPERTIES OF PIPERAQUINE IN HEALTHY VOLUNTEERS WITH INDUCED BLOOD-STAGE *P. FALCIPARUM* MALARIA INFECTION: A MECHANISTIC MODELLING APPROACH

Thanaporn Wattanakul[1], Richard Hoglund[1], Joerg Möhrle[2], James McCarthy[3], **Joel Tarning**[1]

[1]*Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*Medicines for Malaria Venture, Geneva, Switzerland,* [3]*QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Dihydroartemisinin-piperaquine is a recommended first-line therapy for malaria. Piperaquine is also under consideration for other drug combinations. The aim of this study was to develop a semi-mechanistic pharmacokinetic-pharmacodynamic (PK/PD) model describing the parasite dynamics in healthy volunteers in the induced blood stage *P. falciparum* model. The PK/PD model developed was used to predict treatment failures in the presence of multidrug resistant infections, as well as optimal dosing regimens for these infections. 24 volunteers participated in the study. Each participant was inoculated with a total of 1,800 viable *falciparum* infected erythrocytes (ACTRN12613000565741). Parasite densities and piperaquine levels were measured by qPCR and LC-MS, respectively. Nonlinear mixed-effect modelling was used to characterise the PK properties of piperaquine and the *in vivo* parasite dynamics in response to piperaquine. Piperaquine PK was well described by a three-compartment disposition model. A semi-mechanistic parasite dynamics model was developed, including maturation of parasites, sequestration of mature parasites, synchronicity of infections and multiplication of parasites, as described in natural infections with *falciparum* malaria. Piperaquine-associated parasite killing was estimated using an E_{MAX}-function. The final PK/PD model described parasite dynamics adequately, with simulations predicting a higher probability of treatment failures when parasites were resistant to piperaquine alone compared to dihydroartemisinin alone (3.38% vs 1.69%). Modelling and simulation predicted that the ideal additional drug candidate in novel triple-combination therapies should have a 48h parasite reduction ratio of $\geq 10^3$, with ≥3 week duration of action, to combat multidrug resistant infections. In conclusion, a semi-mechanistic model describing *falciparum* parasite dynamics was successfully developed and implemented using nonlinear mixed-effects modelling. This will be a highly useful tool to assess novel antimalarial drug combinations including piperaquine, and its effect on multidrug resistant infections.

EXTENDED DURATION ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF MALARIA IN HIV-UNINFECTED CHILDREN IN UGANDA: THE EXALT RANDOMIZED CONTROLLED PK/PD STUDY

Mwebaza Norah[1], Whalen Meghan[2], Francis Orukan[1], Kacey Richards[3], Martina Wade[3], Were Moses[1], Liusheng Huang[2], Richard Kajubi[1], Francesca Aweeka[2], Sunil Parikh[3]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*University of California San Francisco, San Francsisco, CA, United States,* [3]*Yale School of Public Health, New Haven, CT, United States*

Artemether-lumefantrine (AL) is the most widely used artemisinin-based combination therapy. Recent data, including a comprehensive meta-analysis, suggest that lumefantrine (LR) exposure is lower in young children and that absorption is dose-limited. We are conducting a prospective PK/PD study of extended duration AL in children ages 6 months-17 years in a high transmission area in Uganda. Children with uncomplicated *P. falciparum* infection are randomized to 3-day (standard 6-dose) or 5-day (10 dose) AL with intensive or population PK sampling for artemether, DHA, and LR quantification by LC MS/MS out to day 21 and clinical follow-up to 42 days. Thus far, n=349 children have been screened, n=167 enrolled (median age 5 years, range 1-14), and n=7 withdrawn. The targets for enrolment are n=100 and n=120 episodes for intensive and population PK sampling, respectively. Outcome data for n=84 participants (3-day (n=47) and 5-day (n=37)) are presented. Thus far, 28-day treatment outcomes in the 3-day (n=47) versus 5-day (n=37) are as follows: ACPR (38% vs 70%), LPF (51% vs 19%), LCF (11% vs 11%), respectively. At 42-days, 3-day vs 5-day treatment outcomes in the 3-day (n=47) versus 5-day (n=37) are as follows: ACPR (28% vs 38%), LPF (51% vs 32%), LCF (21% vs 30%). PK parameters for n=18 children have been completed thus far (n=9 each arm). Terminal LR concentrations were significantly increased in the 5-day versus 3-day regimen on days 7,14, and 21 (1090, 186, 91.5 ng/mL vs 321, 118, 62.2 ng/mL; all p-values <0.005). LR area under the concentration-time curve (AUC) measured from the time of the last dose over 21 days indicates a geometric mean $AUC_{0\text{-infinity}}$ of 322 ug*h/ml and 255 ug*h/ml (p =0.20) for the 5-day and 3-day regimens, respectively. Preliminary results demonstrate that twice daily AL over 5 days significantly enhances terminal LR concentrations out to day 21 with modest increases in $AUC_{0\text{-infinity}}$. Changes in PK exposure coincide with a reduced risk of malaria at 28 days, with risk reduction appearing to diminish by 42 days in our high transmission setting. Enrollment began in February 2018 and completed PK/PD and safety data are expected in Fall 2019.

1596

MOLECULAR EPIDEMIOLOGICAL STUDY OF MULTIDRUG-RESISTANT FALCIPARUM MALARIA IN THE CENTRAL HIGHLANDS OF VIETNAM IN 2018-2019

Huynh H. Quang[1], Marina Chavchich[2], Nguyen T. Trinh[1], Nguyen D. Manh[3], Michael D. Edstein[2], Kimberly A. Edgel[4], Nicholas J. Martin[4]

[1]*Institute of Malariology, Parasitology and Entomology, Quy Nhon, Vietnam,* [2]*Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia,* [3]*Military Institute of Preventive Medicine, Hanoi, Vietnam,* [4]*U.S. Naval Medical Research Unit TWO, Singapore, Singapore*

Dihydroartemisinin-piperaquine (DHA-PPQ) used to treat *Plasmodium falciparum* in Vietnam is now failing at a rate of >50% in Binh Phuoc province. This is due to the spread of resistant parasites, particularly those containing mutation C580Y in the Kelch 13 propeller gene responsible for artemisinin resistance combined with amplification of plasmepsins 2 and 3, which is implicated in piperaquine resistance (i.e. KEL1/PLA1 clade). Furthermore, mutations in the *Pfcrt* gene responsible for resistance to chloroquine may also be contributing to the successful spread of these "super-resistant" parasites. It is of utmost importance to evaluate if KEL1/PLA1 parasites are spreading north of Binh Phuoc province and to consider alternative treatment options to avoid selection of highly resistant parasites and future treatment failures. To characterize the markers of drug resistance, we conducted a survey of symptomatic malaria in several provinces of the central highlands of Vietnam from June 2018 to March 2019. Of the 102 *P. falciparum* patients recruited so far, 33 were from Dak Nong, 46 from Dak Lak, 7 from Gia Lai, and 16 from Kon Tum province. *P. falciparum* malaria was confirmed in all samples by blood film microscopy and HRP2-3 based rapid diagnostic testing, indicating absence of *hrp2-3* deletions in these samples. Sequencing of the Kelch 13 gene revealed that the C580Y mutation was present in the majority of the samples (73.5%, 75/102) and only two participants had parasites containing the I539T mutation. Twenty three (22.5%) of the participants had parasites with amplification of plasmepsins 2 and 3. KEL1/PLA1 parasites were present in 27.3% (9/33) of participants' samples from Dak Nong, 6.5% (3/46) from Dak Lak, 42.9% (3/7) from Gia Lai, and 6.3% (1/16) from Kon Tum province. Characterization of other markers including Exo415, *Pfcrt* and *Pfmdr1* genes is ongoing. These preliminary findings suggest that the KEL1/PLA1 parasites are now present in Dak Nong province and in the central highlands of Vietnam. These data, collected jointly with Vietnamese public health officials, will inform future malaria treatment guidelines.

1597

ASSESSMENT THE QUALITY OF ROUTINE MALARIA DATA IN MADAGASCAR

Solo Harimalala Rajaobary

National Malaria Control Program, Antananarivo, Madagascar

The availability of quality data is critical for informed decision-making. By 2018, more than 7% of inconsistencies were found in centrally transmitted reports. This study's objective is to evaluate the quality of the data transmitted between different levels of the health system. This study was a routine data analysis of monthly activity reports (RMAs) from January to June 2018 in 20 health facilities (HF), 8 health districts, 2 health regional directorates and the central level. The Routine Data Quality Assessment (RDQA) tool was used for the review. The reported results audit focused on the accuracy of the data transmitted, the promptness of reporting, the completeness and availability of reports. A recount was performed to assess the quality of the positive rapid diagnostic test (RDT +) indicator. Quality data is determined by an accuracy between 95% and 105%, and discrepancy by the difference between the cases reported and the cases recounted by the recounted cases. Overestimation occurs when the ratio of recounted data to reported data is less than 95%. At the health facility level, data verification showed accuracy between 95 to 105% and overestimation to less than 70%. The source documents were 80% complete and 75% available. An overestimate of 91% was observed at the district level, and 84% at the regional level. The promptness of reporting was 90% with availability of 92% at this level. At the regional level, these rates were respectively 78% and 89% and an overestimate at 84% was observed. At the central level, promptness was at 38% and availability at 96%. A 7% discrepancy was reported at the HF level, 8% at the health district level and 41% at the regional level. Between the HF level and the central level, an 8% discrepancy was observed for the 20 HF supervised. The data quality anomalies identified at HF level were reflected at different levels of the health system. The availability of quality data remains a challenge for the Ministry of Health.

1598

HOUSEHOLD MEMBERS OF PERSONS WITH MALARIA IN HIGHLAND KENYA AREAS OF UNSTABLE TRANSMISSION ARE AT INCREASED RISK OF DEVELOPING CLINICAL MALARIA WITHIN 30 DAYS

George Ayodo[1], Lindsey B. Turnbull[2], Veronicah Knight Adhiambo[1], Chandy C. John[2]

[1]*Kenya Medical Research Institute, Kisumu, Kenya,* [2]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States*

The national malaria strategy in Kenya is that only microscopy- or RDT-confirmed cases of malaria are treated with anti-malarial drugs. Screen and treat studies suggest that individuals in the household of a person with malaria may be at higher risk of subsequent malaria than individuals in malaria negative households. In the present prospective case-control study, we assessed whether clinical malaria was more frequent in individuals living in households with compared to without a person with microscopy confirmed malaria within the past 30 days. From 2007-2017, all persons from Kipsamoite and Kapsisiywa, two highland Kenya areas of unstable malaria transmission who came to site health centers with symptoms of fever or headache were tested for malaria by microscopy. Individuals who visited the health center and had microscopy-confirmed malaria were designated cases. Individuals who visited the clinic in the same week as a case for symptoms of malaria, but were microscopy negative were designated controls. Visits by household members of cases or controls within 30 days of the case or control visit were assessed for the presence of microscopy-confirmed malaria. The analysis was thus limited to encounters whereby multiple household members visited the clinic within a 30-day period. Of 7098 total visits, 70 cases and 516 controls were identified. 87 health center visits within 30 days of the case/control visit were from case households and 599 were from control households, of which 40 (46.0%) and 39 (6.5%) were microscopy positive respectively. Persons in the household of a case had 12-fold increase in the odds of developing microscopy-confirmed malaria within 30 days of the index (case/control) health center visit compared to persons in a control household (OR 12.22, 95% CI 7.18, 20.81, p <0.0001). In this area of unstable malaria transmission, household members of individuals with confirmed malaria have a substantially increased risk of malaria within 30 days of the case illness. Future studies should assess whether anti-malarial treatment of household members of persons with confirmed malaria can decrease subsequent malaria incidence.

1599

POOR AGREEMENT BETWEEN FACILITY RECORD DATA, ROUTINE HEALTH INFORMATION SYSTEM DATA, AND EXIT INTERVIEW DATA DURING A HEALTH FACILITY SURVEY IN MOZAMBIQUE: CAUSE FOR CONCERN WITH REGARD TO ROUTINE DATA QUALITY?

Baltazar Candrinho[1], Mariana Da Silva[2], Guidion Mathe[2], Mercia Dimene[2], Ana Rita Chico[3], Ana Cristina Castel-Branco[3], Frederico Brito[4], Marcel Andela[3], Gabriel Ponce de Leon[5], Abu Saifodine[6], Rose Zulliger[7], Mathew Plucinski[5], James Colborn[3]

[1]*Baltazar Candrinho, Maputo, Mozambique,* [2]*National Malaria Control Program, Maputo, Mozambique,* [3]*Clinton Health Access Initiative, Maputo, Mozambique,* [4]*UNICEF, Maputo, Mozambique,* [5]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*United States Agency for International Development, Maputo, Mozambique,* [7]*Centers for Disease Control and Prevention, Maputo, Mozambique*

Malaria data reported through Mozambique's routine health management information system (HMIS) is the primary source of data for measuring transmission trends and evaluating program impacts. Previous studies showed major discrepancies between HMIS data and health facility record data; few studies exist that compare HMIS to a gold standard measure of case data. This study used data collected through a health facility survey conducted April-May 2018 in Maputo Province (low malaria burden), Cabo Delgado (moderate) and Zambézia (high). Facilities were stratified by type and randomly sampled. Data collection included exit interviews and clinical re-examinations of 20 randomly selected patients, comparison of exit interview data with health facility records, and routine data abstraction to compare with HMIS data. A total of 1,840 patients from 117 health facilities were included; 72% had fever / history of fever. Retrospective data abstracted from health facility registers aligned poorly with HMIS data from the same period. The absolute number of all-cause outpatients, suspect malaria cases, and confirmed malaria cases recorded in facility registries and reported through the HMIS were significantly different in all provinces; in all cases numbers were higher for HMIS than for facility registries. Specifically, 42,431 all-cause outpatient visits were abstracted from facility registers in Maputo Province, compared with 87,992 in the HMIS (difference=45,561). Factors associated with agreement between registry and exit interview data and RDT results were patients being under the age of 5 and clinicians testing and treating according to national treatment guidelines (p<0.01 for all provinces). Similarly, the presence / absence of fever was more likely to match when clinicians correctly tested and treated in Zambézia (p=0.04), and in smaller facilities in Maputo and Cabo Delgado (p<0.05). These results suggest care should be taken in assuming the accuracy of data reported through Mozambique's routine HMIS, and improving case management practices could potentially lead to concurrent improvements in the quality of malaria indicators.

THE ASSOCIATION BETWEEN *PLASMODIUM FALCIPARUM* INFECTION IN THE FIRST SIX MONTHS OF LIFE AND SUBSEQUENT INFECTION AMONG CHILDREN UNDER 24 MONTHS IN MALAWI, 2016-2018

Liana R. Andronescu[1], Andrea G. Buchwald[2], Andy Bauleni[3], Patricia Mawindo[3], Don P. Mathanga[3], Miriam K. Laufer[1]

[1]*Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*University of Colorado School of Public Health, University of Colorado, Denver, CO, United States,* [3]*Malaria Alert Center, University of Malawi College of Medicine, Blantyre, Malawi*

In high transmission settings, infants under six months comprise up to 10% of malaria-related hospitalizations in children under five years old. Despite the prevalence of malaria infection and disease in this age group, the epidemiology is not well understood and incidence is rarely assessed. In the first six months of life, infants may either have increased immunity to infection due to presence of maternal antibodies or increased susceptibility due to exposure *in utero*. The impact of early malaria infection on subsequent disease is unclear. We aimed to determine if *P. falciparum* infection in the first six months of life alters the risk of subsequent clinical malaria up to 24 months of age. To address this question, infants in Malawi were followed at two sites from birth until 24 months of age. Study participants were scheduled for clinic visits at three-month intervals and asked to visit the clinic between appointments in the event of illness. RDTs were performed at all scheduled appointments and if malaria signs and symptoms were present at sick visits. Positive RDTs were confirmed by microscopy. Preliminary data from one study site included 94 participants with a mean follow-up time of 21.48 (SD: 6.54) months and a mean of 2.37 (SD: 4.30) infections. In the first six months of follow-up, 27 infections were reported for an incidence rate of 5.1 *P. falciparum* infections per 100 person-months of observation. In the following 18 months, there were 207 infections for an incidence rate of 14.6 infections per 100 person-months. A Poisson model, adjusted for season of birth, indicates that for every infection occurring before six months, an additional 1.73 (95% CI 0.97, 3.07) infections may be observed between six and 24 months, suggesting early infection is associated with increased risk of subsequent infection. These results might be due to increased exposure to *P. falciparum* or an impact on immunity among infants who are infected in the first six months of life. Analysis of our final analysis will include data from both health centers and covariates for bed net use and village to assess exposure.

1601

SPATIAL MODELING OF CATCHMENT AREAS FOR ESTIMATING MALARIA INCIDENCE USING HEALTH FACILITY SURVEILLANCE DATA IN UGANDA

Adrienne Epstein[1], Victor Kamya[2], Sarah Staedke[3], Arthur Mpimbaza[2], Asadu Sserwanga[2], Jane Namuganga[2], James Kapisi[2], Isabel Rodriguez-Barraquer[1], Moses Kamya[2], Grant Dorsey[1], Bryan Greenhouse[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

High quality measures of malaria are essential to target populations at risk, measure changes in disease burden, and evaluate the impact of interventions. A recommended indicator in high transmission settings is incidence, or the number of cases divided by the population at risk. Quantifying this denominator is challenging using health facility data because catchment areas are not well defined. The aim of this analysis is to model catchment areas around Malaria References Centers supported by the Uganda Malaria Surveillance Project. Using outpatient data from 34 Malaria References Centers from January 2017 to March 2019 (n = 950,674 outpatient visits of which 247,487 were malaria cases), we estimated travel times from each patient's village of residence to the health facility. We specified Poisson generalized additive models to evaluate the relationship between travel time and attendance. The outcome was the count of outpatient visits for each unique village/facility pair. We included covariates accounting for travel times to competing facilities and random effects for sentinel facilities. We used the modeled relationships to estimate catchment area population sizes by determining the threshold beyond which attendance appreciably declined. Villages with travel times within this threshold were considered to be part of the health facility's catchment area. To calculate catchment area populations, we applied a correction factor to the village populations to account for the probability of attendance. Preliminary results suggest catchment sizes ranged from 1,464 individuals to 7,822 individuals. In addition to travel time, attendance was driven by the proximity of alternative nearby facilities; fewer facilities within a 1 hour travel time of a patient's village was positively associated with attendance. We used these population estimates to estimate malaria incidence, which ranged from 31/1,000 to 505/1,000 across the sites. We will next validate these estimates by comparing them to known incidences from cohort studies in 3 districts where Malaria References Centers are located.

1602

EPIDEMIOLOGY OF *PLASMODIUM VIVAX* IN DUFFY NEGATIVE INDIVIDUALS

Lauren Bradley, Guiyun Yan

University of California - Irvine, Irvine, CA, United States

Plasmodium vivax is the most common malarial species worldwide however, it is relatively rare in sub-Saharan Africa. In order to establish blood-stage infection *P. vivax* utilizes the Duffy antigen as the receptor for invasion. It has long been understood that Duffy negativity, or the lack of expression of the Duffy gene, yields resistance to blood-stage infection of *P. vivax*. Recently, however, studies have found cases of *P. vivax* infection in Duffy negative individuals in a number of countries in Africa and South America. Little is currently known about the extent of *P. vivax* infections and parasitemia in Duffy-negative people in the African community. This study aims to investigate the effect of Duffy genotypes on *P. vivax* prevalence and parasitemia, and whether the copy number of the Duffy binding protein gene has any impact on *P. vivax* parasitemia. It is possible that certain Duffy genotypes and phenotypes within the human population allows for increased infectivity by *P. vivax*. We are examining these questions using *P. vivax* samples from the cross-sectional survey and hospital-based passive case detection in a malaria epidemic and an endemic areas in Ethiopia.

1603

SPATIOTEMPORAL EPIDEMIOLOGY OF MALARIA IN SOUTHERN VENEZUELA: A CRITICAL *PLASMODIUM* HOT-SPOT IN LATIN AMERICA

Maria E. Grillet[1], Jorge Moreno[2], Jan E. Conn[3], Juan V. Hernandez[4], Maria F, Vicenti[5], Adriana Tami[6], Alberto Paniz-Mondolfi[7], Martin Llewellyn[8], Ananias A. Escalante[9]

[1]*Instituto de Zoología y Ecología Tropical, Universidad Central de Venezuela, Caracas, Bolivarian Republic of Venezuela,* [2]*Centro de Investigaciones de Campo "Dr. Francesco Vitanza," Servicio Autónomo Instituto de Altos Estudios, MPPS, Tumeremo, Edo Bolivar, Bolivarian Republic of Venezuela,* [3]*Wadsworth Center, New York State Department of Health, Albany, NY, United States,* [4]*University of Groningen, University Medical Center Groningen, Department of Medical Microbiology, Groningen, Netherlands,* [5]*University of Groningen, University Medical Center Groningen, Department of Medical Microbiology, Groningen, Groningen, Netherlands,* [6]*University of Groningen, University Medical Center Groningen, Department of Medical Microbiology, Groningen, Netherlands,* [7]*Infectious Diseases Research Incubator. Instituto de Investigaciones Biomédicas, Clinica IDB, Barquisimeto, Bolivarian Republic*

of Venezuela, [8]Institute of Biodiversity, Animal Health, and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, [9]Temple University, Philadelphia, PA, United States

Despite advances in malaria control worldwide, Latin America has undergone a setback mainly due to Venezuela. The Venezuelan cases represented 57% of the regional malaria burden in 2017, and the country was among those with the largest increases worldwide. Historically, the southeastern part of the country (near the Brazilian border), has accounted for ~70% of malaria. Thus, this study aims to describe the spatial variation of cases in the last decade, for *P. vivax* and *P. falciparum*, to detect the occurrence of hot spots, describe the spatial progression of the epidemic, and predict spread across the country. Venezuela reported around 1,207,348 malaria cases in the whole period, with overall incidence rates (per 1,000 person-years) ranging from 5.2 (2007) to 28 (2017). Overall, ~61% of the cases were in in the south. From 2012-2017, *P. vivax* malaria in that region increased from 25,843 to 146,885 (468%) with 496,847 cases and a mean ratio of *P. vivax*/*P. falciparum* of 3.04. Annual malaria incidence during the last 10 years mostly occurred in the eastern area of Bolivar state where two significant and persistent local clustering of *P. vivax* and *P. falciparum* were detected. Average malaria incidence within the cluster area was 5.2 times greater than outside the cluster. Since 2014, local malaria transmission has reemerged in new areas producing a significant change in the epidemiological landscape. The disease is now propagating across the country, increasing local transmission in the traditional endemic *foci* and re-emerging in northern urban and peri-urban landscapes. Massive increases in transmission in southern Venezuela are positively correlated with an increase in uncontrolled illegal gold mining and deforestation, exacerbated by the deterioration of public health care. Changes in migration, as a result of the Venezuelan economic collapse, have driven the malaria spillover into the rest of the country and Latin America, a global threat for the WHO Regional Technical Strategy for Malaria.

1604

ADAPTING MALARIA INDICATOR SURVEYS TO IMPROVE UPON TRAVEL DATA RELEVANT FOR MALARIA EPIDEMIOLOGY

Carlos A. Guerra[1], Daniel T. Citron[2], Olivier Tresor Donfack[3], David L. Smith[2], Guillermo A. Garcia[1]

[1]*Medical Care Development International, Silver Spring, MD, United States,* [2]*Institute for Health Metrics and Evaluation, Seattle, WA, United States,* [3]*Medical Care Development International, Malabo, Equatorial Guinea*

Malaria indicator surveys (MIS) are increasingly used for monitoring and evaluating the impact of malaria interventions and to provide input data for modeling malaria prevalence and indicators. Some MIS include questions about history of travel but only a few have been used to explore the relationships between human mobility, malaria prevalence and importation. A recent study on Bioko Island that used MIS data to characterize human mobility unveiled clear relationships between human travel to mainland Equatorial Guinea and odds of malaria infection, strongly suggesting that many who return to the island could be acquiring their infections during their travels. The study also revealed limitations of the MIS travel data and prompted modifications to the questionnaires. Here, we present preliminary analyses of the expanded travel information captured by the 2018 MIS on Bioko Island. Questions related to travel were modified to include more detail about travel, including pinpointing travel destination as well as frequency and duration of travel. The questionnaire was also expanded to record professional sector of adult interviewees in an attempt to identify high-risk groups of travelers. The data showed that 72.7% of travellers to mainland were bound to three out of thirteen districts and 47% to a single district, Bata. The level of detail of within-island travel improved significantly and provided new insights into human movement and its possible role in mixing parasites brought in to Bioko from mainland Equatorial Guinea. On average, travellers made 1.4 trips to mainland every 8 weeks and spent 18 nights away per trip. It was also possible to identify that 80.5% of travelers belonged to three job sectors. The new travel data have important implications for the design and implementation of strategies designed to reduce malaria importation rates to Bioko. We show that by implementing simple modifications and extensions to MIS travel questionnaires useful travel information can be improved substantially.

1605

REVEALING THE MALARIA MAP: USING SOFTWARE IN A NOVEL APPROACH TO GEOSPATIAL TARGETING OF MALARIA INTERVENTIONS AND SBC MESSAGING

Christina M. Riley[1], Frazer Bwalya[1], Todd Jennings[2], Derek Pollard[1], Anne C. Martin[1], Javan Chanda[2], Reuben Zulu[3], Emmanuel Kooma[3], John Miller[2], Anna M. Winters[1]

[1]*Akros, Lusaka, Zambia,* [2]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia,* [3]*National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia*

The Zambia Ministry of Health is aiming to eliminate malaria through an ambitious strategy emphasizing a scalable intervention package (SIP) that includes indoor residual spraying (IRS) and targeted mass drug administration (MDA). To optimize delivery of these interventions, accurate data on performance of service delivery teams, intervention uptake among community members, and focused Social Behavior Change (SBC) messaging is necessary. Operational service delivery information for census-type intervention campaigns was collected from 2017 to 2019 in Southern Province, Zambia using Reveal, an in-field spatial intelligence tool that plans and tracks delivery of field intervention activities down to household level. Information was combined with satellite-based household enumerations to develop dashboards of service delivery statistics and location information to understand coverage and to support targeted SBC messaging. In addition to improved SIP coverage at district and village level from 2017 to 2019, SBC messaging data among individuals present at the time of the MDA R2 campaign in 2019 (N=36,786) shows that approximately 90% of all individuals self-reported that they had heard malaria messaging in the previous year. More than 50% specifically reported having heard that malaria was dangerous, 33% recalled hearing messages on the importance of IRS and MDA in combatting malaria and 10% cited testing and treatment-seeking messaging in cases of fever. Individuals highly preferred health facilities (63%) and community health workers (55%) to village meetings (18%), radio (8%), or TV (3%) as their source for malaria information and messaging, supporting intervention service delivery for malaria messaging delivery method. Geospatial differences in messaging awareness and preferred source of messaging were observed. The Reveal platform continuously improved field team operational performance through regular review and data feedback. Using Reveal, geo-spatial differences uncovered in newly acquired malaria messaging data will be optimized in similar fashion to further improve impact of malaria SIPs.

1606

RISK FACTORS OF MALARIA INFECTION IN A LOW ENDEMIC DISTRICT WITH INTENSIFIED VECTOR CONTROL IN MAPUTO PROVINCE, SOUTH OF MOZAMBIQUE

Julia Montana Lopez[1], Wilson Simone[2], Beatriz Galatas[1], Caterina Guinovart[3], Fernando Laice[2], Arlindo Chidimatembue[2], Regina Rabinovich[4], Baltazar Candrinho[5], Francisco Saute[1], Pedro Aide[6]

[1]*Barcelona Institute for Global Health - Centro de Investigaçao em Saude de Manhiça, Manhiça, Mozambique,* [2]*Centro de Investigaçao em Saude de Manhiça, Manhiça, Mozambique,* [3]*Barcelona Institute for Global Health, Barcelona, Spain,* [4]*Barcelona Institute for Global Health - Harvard TH Chan School of Public Health, Boston, MA, Barcelona, Spain,* [5]*National Malaria*

Control Program, Ministry of Health, Maputo, Mozambique, [6]Centro de Investigaçao em Saude de Manhiça - National Institute of Health, Ministry of Health, Manhiça, Mozambique

Southern Mozambique is targeted by a regional malaria elimination initiative. In Moamba district, the NMCP led a universal coverage of vector control tools (VC) with distribution of long-lasting insecticidal nets (LLINs) in late 2017 and Indoor Residual Spraying (IRS) campaigns with Actellic in the dry seasons of 2015-2018. Incidence reported by Ministry of Health declined from about 256 malaria cases per 1000 in 2015 to 84 per 1000 in 2018. An age-stratified cross-sectional survey was carried out in Moamba district (Maputo province) in May-June 2018, to estimate malaria infection prevalence after the deployment of VC. Using a structured questionnaire, data on demographics, use of malaria control tools and travel history were collected from 2,919 individuals selected from 30 clusters using a two-stage cluster sampling method with probability proportional to size. A rapid diagnostic test (RDT) was done in all participants. Multivariable logistic regression models adjusting for clustering at the neighbourhood and household levels via random effects were used to identify the main risk factors associated with RDT positive malaria infections. Data presented are preliminary. Overall weighted malaria prevalence was 2.5% (95% CI 1.6%-3.8%), and most cases (41 of 68) clustered near Maputo. Under 5 prevalence was 1.5% (0.8%-2.7%), 3.9% (2.3%-6.4%) in 5-15 year olds and 2.0% (1.1%-3.4%) in >=15 year olds. 76% of participants reported sleeping under a bednet the previous night and 45% of households reported receiving IRS in the previous 12 months. The main risk factors for infection were travel to malaria endemic areas in Mozambique (OR=17.9 (1.3-249.6), p=0.03) and living near Maputo (OR=4.2 (1.4-12.8), p=0.01). No association was found between RDT positivity and VC variables (sleeping under a net, living in a sprayed household, both, or neither), age or gender. These findings suggest that importation from higher malaria transmission areas may hinder elimination in the south. The lack of impact of VC may be explained by insufficient coverage estimates or changes in the mosquito population and its behaviour as a result of intensified VC for years.

1607

COMPARATIVE EFFECTIVENESS TRIAL OF TWO COMMUNITY CASE MANAGEMENT TECHNIQUES FOLLOWING WITHDRAWAL OF INDOOR RESIDUAL SPRAYING IN NE UGANDA

Dorothy Echodu[1], Kathryn Colborn[2], Ronald Mulebeke[3], Thomas Eganyu[4], Humphrey Wanzira[3], Fred Bukenya[4], Richard Elliott[5], Joaniter Nankabirwa[6], Jimmy Opigo[7], Adoke Yeka[8]

[1]*Pilgrim Africa, Seattle, WA, United States,* [2]*University of Colorado Denver, Denver, CO, United States,* [3]*Pilgrim Africa, Kampala, Uganda,* [4]*Pilgrim Africa, Toroma, Uganda,* [5]*Boise State University, Boise, ID, United States,* [6]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [7]*National Malaria Control Program, Kampala, Uganda,* [8]*University of Makerere, Kampala, Uganda*

Vector control should be pursued and maintained as long as malaria transmission is ongoing. Budget constraints faced by high burden countries make this a challenge in the case of indoor residual spraying (IRS). We present the protocol of a prospective two year trial (2019-2021) evaluating alternative cost effective intervention combinations to maintain malaria reduction gains post IRS in a high burden setting. IRS with pirimiphos-methyl was implemented every 6-8 months in 55 villages in Katakwi District in Uganda from 2016-2018 to achieve malaria prevalence reduction below 10% after the last round of IRS. We will conduct a cluster-randomized effectiveness trial of the combination of PermaNet 3.0 deltamethrin- piperonyl butoxide (PBO) nets and either integrated community case management (iCCM) for malaria, pneumonia and diarrhea in children under 5, or proactive community case management (ProCCM). ProCCM includes active all ages malaria case detection and treatment, and active detection and treatment of pneumonia and diarrhea in children under 5. A total of 27 villages have been randomized to iCCM + PBO nets and 28 villages to ProCCM + PBO nets using covariate-constrained randomization. Malaria incidence data will be recorded weekly by community health workers in both arms using mobile devices, and also recorded on paper as per national guidelines. Community level cross-sectional Pf prevalence and serology surveys at baseline, midline and endline, and continuous HMIS monitoring from all public health facilities in the study area will be conducted. Entomological surveillance using CDC light-traps and pyrethrum spray catches is also planned. Primary study outcomes are all ages Pf prevalence measured in cross-sectional surveys, and annual parasite incidence in children under 5 at public health facilities. Secondary outcomes include changes in transmission indicators measured by entomology and serology, as well as incidence data from the intervention arms. Baseline prevalence data together with preliminary incidence and entomology data will be presented. This study is expected to provide evidence to guide sustainable IRS exit.

MALARIA AND OTHER PARASITIC INFECTIONS IN PREGNANCY IN GHANA: BURDEN AND EFFECT

Gifty D. Ampofo, Matilda Aberese-Ako, Harry Tagbor

University of Health and Allied Sciences, Ho, Ghana

Uptake of antenatal clinic (ANC) interventions to control malaria and anemia in pregnancy has improved in Ghana yet maternal anemia prevalence and low birth weight (LBW) incidence have remained the same over the past decade. It is known that intestinal helminths and schistosomiasis co-exist with malaria and may be contributing to the persisting maternal anemia and low birth weight but their specific contributions are not known. This study therefore sets out to determine the relative contributions of malaria, intestinal helminthiasis and schistosomiasis and/or co-infections to maternal anemia and low birth weight. A health facilities-based cohort study began in June 2018 and is on-going, in the Ashanti and Volta Regions of Ghana, to follow pregnant women from booking until delivery of 2500 live births. At recruitment, demographic, socio-economic, obstetric and medical histories are recorded. Blood, urine and stool samples are taken for a full blood count (FBC) and detection of parasitic infections. FBC and malaria parasitemia are measured again at subsequent visits. Stool and urine samples are taken again prior to delivery. All other morbidities that these women experienced are also recorded as are interventions delivered during ANC visits. At delivery, the birth weight and any adverse birth outcomes are recorded. Data is being captured electronically and STATA 15 is being used for data management and subsequent analysis. Currently, a total of 2461 women of all gravidity have been enrolled. Their mean age is 27.18 years (sd=6.59). At baseline their mean hemoglobin concentration, anemia and malaria parasitemia prevalence are 10.84g/dl (sd=1.53), 51.64% and 6.52% respectively. Only 61.48% have bednets and 47.18% slept under one the night prior to enrolment. Out of 454 live births, 419 have recorded birth weights. The mean birth weight is 3.0kg (sd=0.49) and 9.30% are low birth weight. Malaria parasitemia (at baseline) seems low while maternal anemia and LBW incidence appear high. Factors accounting for these findings will be understood at the end of the study.

1609

PREVALENCE OF MALARIA IN EARLY PREGNANCY AMONG NULLIPAROUS WOMEN IN THE DEMOCRATIC REPUBLIC OF THE CONGO, KENYA, ZAMBIA AND PAKISTAN

Sequoia I. Leuba[1], Melissa Bauserman[1], Carl L. Bose[1], Antoinette K. Tshefu[2], Waldemar A. Carlo[3], Musaku Mwenechanya[4], Edward A. Liechty[5], Fabian Esamai[6], Robert L. Goldenberg[7], Saleem Jessani[8], Elizabeth M. McClure[9], Jennifer J. Hemingway-Foday[9], Steven Meshnick[1]

Health and Paediatrics, Moi University School of Medicine, Eldoret, Kenya, [7]Columbia University, New York, NY, United States, [8]Aga Khan University, Karachi, Pakistan, [9]RTI International, Research Triangle Park, NC, United States

In malaria-endemic countries, an estimated 1 in 4 women are infected with malaria during their pregnancy, and this infection can cause maternal anemia, preterm birth, stillbirth, and low birth weight. However, likely due to the late enrollment of antenatal care in most malaria-endemic areas, few studies have examined malaria infection in early pregnancy. This is the first large multisite study of malaria in early pregnancy. This is an ancillary study, added to the Global Network's trial of low-dose aspirin in early pregnancy (ASPIRIN). At early pregnancy (i.e., 6-13 weeks), dried blood spots were obtained from 3261 pregnant women in four sites of the Global Network (Democratic Republic of the Congo (DRC), Kenya, Zambia, and Pakistan). These dried blood spots were subsequently analyzed for *Plasmodium falciparum* infection by qPCR. The prevalence of *P. falciparum* among nulliparous pregnant women ranged from 1.0% to 59.8%. The prevalence in the DRC was 59.8% (666/1113; 95% CI: 57.0%, 62.7%), in Kenya was 33.2% (220/663; 95% CI: 29.6%, 36.8%), in Zambia was 5.4% (31/572; 95% CI: 3.6%, 7.3%), and in Pakistan was 1.0% (4/411; 95% CI: 0.3%, 2.5%). Risk factors of *Plasmodium falciparum* infection in early pregnancy and associations with birth outcomes will be presented. These results show differing levels of malaria in early pregnancy depending on the location. Future steps include determining risk factors of malaria in early pregnancy and its effects on birth outcomes.

MULTIPLICITY OF INFECTION AND PARASITE DENSITY BY AGE IN SYMPTOMATIC MALARIA EPISODES IN SOUTHERN MALAWI

Alaina Halbach[1], Andrea Buchwald[1], Dominique Earland[1], Alick Sixpence[2], Mabvuto Chimenya[2], Milius Damson[2], Karl Seydel[3], Don Mathanga[2], Terrie Taylor[3], Miriam Laufer[1]

[1]*Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Malaria Alert Center, University of Malawi College of Medicine, Blantyre, Malawi, [3]College of Osteopathic Medicine, Michigan State University, East Lansing, MI, United States*

Malaria remains an important cause of morbidity and mortality worldwide despite improvements in public health interventions. Individuals repeatedly exposed to malaria over time can develop a state of semi-immunity with asymptomatic infections. While overall parasite density has been found to decrease with age, we hypothesize that in order for symptomatic disease to occur in adults who have developed this semi-immunity, their parasite burden, defined by parasite density (PD) and multiplicity of infection (MOI), must be higher than in children. This assessment is part of a 2 year longitudinal malaria cohort study in Mfera, Malawi with age stratified enrollment of 120 subject ages 1-50 presenting with uncomplicated *Plasmodium falciparum* malaria. Subjects presented for monthly follow-up visits as well as for sick visits. Blood smears and dried blood spots on filter paper were collected at all visits. PD (parasites/μL) was determined via smear and MOI was determined through MSP and GLURP genotyping from the dried blood spots. The PD and MOI for symptomatic episodes were compared across age groups. There were 459 symptomatic episodes from 110 subjects. The mean PD decreased significantly across age groups (7,581 parasites/μL in the adults compared to 65,499 and 48,322 in children under 5 years and children aged 5 to 15 years, respectively, p<.001). The mean MOI was significantly less in adults compared to the two younger age groups (1.88 clones detected per episode in adults compared to 2.51 and 2.58 clones per episode in children under 5 and children 5 to 15, respectively, p<.005). The decreased parasite burden among adults may be explained by their semi-immune responses that limit parasite density, even in symptomatic infections, thus reducing the overall parasite burden in adults. Alternatively, symptomatic infections may occur when novel parasite proteins are expressed.

PREVALENCE OF MICROSCOPIC AND SUBMICROSCOPIC *PLASMODIUM SPP.* INFECTIONS AND ASSOCIATED FACTORS IN INDIGENOUS AND NON-INDIGENOUS COMMUNITIES IN COLOMBIA

Jehidys Estella Montiel Ramos, Luisa F. Carbal Reyes, Veronica Sierra Cifuentes, Juan C. Perez, Gabriel J. Velez, Daniel C. Aguirre Acevedo, Lina M. Zuluaga Idarraga, Cesar H. Segura Latorre, Alberto Tobon Castaño, Ana M. Vasquez Cardona

Universidad de Antioquia, Medellín, Colombia

Prevalence of asymptomatic and submicroscopic infections (SI) by *Plasmodium* in Colombia has not widely explored. There is a great diversity of indigenous communities in Colombia living in endemic areas; however, the burden of infection in these populations has not extensively studied. The prevalence of *Plasmodium* infection and its associated factors in indigenous and non-indigenous population was explored in two endemic villages from Antioquia. A Community-based cross-sectional survey was conducted between Nov 2016-Nov 2017 in 7 villages of Turbo and El Bagre municipalities from Antioquia. All inhabitants of all ages that were willing to participate were included. Sociodemographic and clinical data from each subject were recorded as well as household information. Parasitological diagnosis was performed by microscopy and nested PCR. The prevalence of microscopy and SI was estimated and a adjusted GEE model was used to explore risk factors associated with parasitemia, taking into account the correlation between subjects at a household level. Among 713 participants enrolled, 60,1% were from indigenous communities. *Plasmodium* spp. was detected in 30 subjects (4,2%, CI 95% 2,9-5,9), from those 29 were in indigenous population. 47% of infections were afebrile and most of them submicroscopic (10/14). Microscopic and submicroscopic prevalence was 2,5% (CI 95% 1,6-3,9) and 1,7% (CI 95% 0,9-2,9) respectively. In El Bagre all infections occurred in indigenous participants (3,9%, CI 95% 2,2-7,1) and 81% were submicroscopic. By contrast, in Turbo the highest prevalence occurred in indigenous people (11,5%; CI 95%: 7,3-17,5) but 88,8% were microscopic. Living in an indigenous population increase the incidence rate of infection compare with non-indigenous population (IRR 19,4; CI 95% 2,3-166,7). Most of infections were detected in indigenous communities. Not only microscopic but also SI can contribute to malaria transmission. Thus, prevention and control strategies targeting to a particular reservoir such as indigenous population, rather than relying on passive detection of clinically malaria, might be essential to achieve elimination

1612

SUBCLINICAL *PLASMODIUM FALCIPARUM* INFECTION AMONG CHILDREN AND ADULTS RESIDING IN A HIGH MALARIA TRANSMISSION COMMUNITY

Tamaki Kobayashi[1], Matthew M. Ippolito[2], Jay Sikalima[3], James S. Lupiya[3], Mike Chaponda[3], William J. Moss[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Johns Hopkins University School of Medicine, Baltimore, MD, United States, [3]Tropical Diseases Research Centre, Ndola, Zambia*

Chronic, asymptomatic, and subpatent malaria are overlapping subclinical syndromes classified according to the extent or duration of parasitemia and the presence or absence of parasite-attributable pathology. Subclinical malaria is incompletely characterized in terms of its natural history, clinical consequences, and epidemiological contribution. We investigated demographic and clinical features of subclinical malaria to assess potential risk factors and elucidate its relevance to malaria control. Longitudinal and cross-sectional surveys were conducted between 2013 and 2017 in adults and children residing in a high malaria transmission area of northern Zambia (n=2,249). *Plasmodium falciparum* parasitemia was measured by polymerase chain reaction (PCR), microscopy, and rapid diagnostic test (RDT). Demographic, clinical data (temperature, hemoglobin, self-reported symptoms), bed net use, indoor residual spraying, and recent antimalarial treatment were recorded. Parasite prevalence was 31% by microscopy,

53% by RDT, and 55% by PCR. Participants were stratified according to PCR, microscopy, and RDT results: patent (+/+/+), subpatent (+/-/-), recent (-/-/+), and no (-/-/-) parasitemia. Among PCR-positive individuals, 66% (n=816) had subclinical malaria defined as temperature <38°C and no self-reported fever, chills, headache, vomiting, diarrhea, or cough within the prior 48 hours. Participants with patent (n=592) or recent (n=183) parasitemia tended to be younger (median age = 10 y, IQR 5-20) than those with subpatent (n=253) or no parasitemia (n=762) (25 y, IQR 10-41). Participants with patent or recent parasitemia were more likely to have anemia compared to no parasitemia (OR=1.8, 95%CI 1.5, 2.2). Those with no parasitemia were more likely to report sleeping under a bed net compared to those with patent, subpatent or recent parasitemia (OR=2.5, 95%CI 1.7, 2.5). This study identified a high prevalence of subclinical malaria in a holoendemic area. Characterization of this diverse group will inform public health and clinical approaches to malaria control in similar transmission settings.

1613

SEVERE MALARIA SURVEILLANCE IN A RURAL DISTRICT HOSPITAL IN NORTHERN ZAMBIA

Matthew M. Ippolito[1], Jean-Bertin Kabuya[2], James S. Lupiya[2], Luc Kambale Kamavu[3], Jay Sikalima[2], Mike Chaponda[2], Proscovia Miiye Banda[3], William J. Moss[4]

[1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [2]*Tropical Diseases Research Centre, Ndola, Zambia,* [3]*St. Paul's General Hospital, Nchelenge, Zambia,* [4]*Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States*

Severe malaria surveillance is routinely performed in Zambia by hospital-based Health Management Information System (HMIS) personnel. HMIS surveillance relies on information aggregated from ward registers. Supplementation of HMIS data with hospital- and patient-level data from additional sources may provide greater resolution of severe malaria clinical epidemiology. To assess hospital-based methods of severe malaria surveillance, we conducted a single center study that evaluated four data collection approaches over the period June 2017 to March 2019. Aggregate data were collected from HMIS records and central pharmacy artesunate inventories. Individual-level data were collected from artesunate administration records and laboratory blood transfusion logbooks. Means and standard deviations of cases per month were calculated and compared using Student's *t* test and one-way analysis of variance. The HMIS monthly case estimate (79 ± 40) was systematically greater than estimates based on artesunate inventory (56 ± 38), artesunate treatment courses (54 ± 32), and pediatric blood transfusions (45 ± 18) (P=0.02). Age was similar between artesunate-treated patients and transfused patients (median 24 months, interquartile range 14-43) and similar across years of surveillance. Partial or complete blood product stockouts were recorded for 95 days over the 667-day surveillance period (14%). Accurate accounting of severe malaria case burden can help focus resources in a timely and effective manner. Shifts over time in case volume, age distribution, and allocation of blood transfusion may reveal underlying changes in local malaria epidemiology. Alternative data sources can supplement existing register-based HMIS surveillance.

PRELIMINARY FINDINGS AND LOGISTICAL CHALLENGES FROM AN INTENSIVE LONGITUDINAL COHORT STUDY OF MALARIA TRANSMISSION IN A PRE-ELIMINATION SETTING IN SOUTHERN ZAMBIA

Jessica Schue[1], Japhet Matoba[2], Jennifer C. Stevenson[2], Harry Hamapumbu[2], Ben Katowa[2], Michael Musonda[2], Tamaki Kobayashi[1], Timothy Shields[1], Andre Hackman[1], Philip E. Thuma[2], William J. Moss[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Macha Resarch Trust, Choma, Zambia*

The Southern Province has the lowest *P. falciparum* prevalence in children under 5 years in Zambia and is targeted for malaria elimination. An intensive cohort was designed to understand how malaria transmission is sustained in a near-elimination setting. The study is a longitudinal cohort of geographically clustered households in Choma District, Zambia. Households are visited monthly for up to two years and all persons over 3 months of age are eligible. Blood is collected at each visit and qPCR targeting *Pfcyt-b* is performed. Passive case detection occurs at the rural health center and all persons who test positive by RDT are eligible. Data collection began in October 2018. As of March 2019, 171 households were enrolled and 9 refused to participate. In the enrolled households, there were 845 eligible persons of which 795 (94%) consented. The median household size was 5 (range:1-17) and 83% of households own at least one bed net. Each person has a median number of 4 visits, with 264 completing all visits in the first 6 months. Bed net usage the previous night ranged from 38% in October 2018 to 49% in March 2019. On average, 27.7% (range: 12.6-42.6) participants traveled in the previous 4 weeks. Bed net use declined during travel, 75.9% of all travelers reported not using a bed net. Laboratory results through mid-February identified 29 qPCR positive samples, for a parasite prevalence of 2.2% within the cohort. Eight confirmed cases were enrolled at the health center. Public events in the area impacted monthly sampling targets. Sampling members has been a challenge, especially for school age children and farmers. Community mobilization and monthly dissemination meetings of aggregated results help to maintain high levels of acceptance. Data collection continues through September 2020. *Pfcyt-b* positive samples will be genotyped to determine the proportion resulting from local transmission vs. importations. The longitudinal genetic data and the travel information will be used to construct a malaria transmission network. Risk factors for malaria at the household and individual level will be identified.

1615

WHEN FEVERS REIGNITE: AN ASSESSMENT OF *PLASMODIUM VIVAX* RECURRENCES IN PANAMA

Carmela M. Jackman[1], Bernardo Garcia Espinosa[2], Madeline E. Baird[2], Nicholas Presley[2], Darlene Bhavnani[2], Lizbeth Cerezo[1]

[1]*Ministerio de Salud de la República de Panamá, Panama City, Panama,* [2]*Clinton Health Access Initiative, Boston, MA, United States*

Panama is committed to eliminate malaria by 2020. Over the last five years, malaria cases have become increasingly concentrated in indigenous *Comarca* regions yet reduction of national cases has stalled in this period. A successful elimination campaign will tailor activities to the species makeup of the local context but while *Plasmodium vivax* accounts for all local cases in Panama, little is known about the burden of relapses. To address this gap, this study sought to quantify *P. vivax* recurrences and describe the population in which they occur. Currently, Panama's malaria case data is stored in free-text files without validation or unique ID numbers. This retrospective cohort study compiled annual data and applied Jaro-Winkler distances on patient names to identify individuals with multiple malaria incidents. Per national guidelines, cases are confirmed by microscopy and followed up with a control blood slide for nine months. Recurrences were defined as successive episodes of *P. vivax* malaria in this timeframe. To assess risk factors related to recurrence, odds ratios (OR) were calculated from patient demographics. Of the 2,168 *P.*

vivax cases reported from January 1, 2016 to December 31, 2018, 11.0% were identified as recurrences. This proportion increased over time, yielding 5.8% in 2016 to 16.2% in 2018. Median time to recurrence was 118 days (IQR: 71-173 days). Among cases detected in the Guna Yala *Comarca*, 13.8% were recurrences, the highest proportion versus other endemic regions where this figure ranged from 3.5% to 12.3%. Highest odds of recurring were found in males (OR: 1.36; 95% CI: 1.04 - 1.77), and in those aged 0 - 4 years (OR: 1.65; 95% CI: 1.09 - 2.51) when compared to individuals over 40 years old. Trends observed in this study coincide with efforts toward strengthening reporting and case detection through improved community case management in the 2016-2018 period. This work highlights the importance of quantifying recurrence and assessing its contribution to ongoing transmission. As Panama approaches elimination, this study provides evidence on *P. vivax* recurrences to describe progress toward this goal and inform case management strategies.

1616

PLASMODIUM SPECIES FREQUENCY AT BANCOUMANA, A MALARIA VACCINE TESTING CENTER IN MALI

M'Bouye Doucoure[1], Amatigue Zeguime[1], Sintry Sanogo[1], Moussa B. Kanoute[1], Bourama Samake[1], Aissata Doumbia[1], Drissa Dembele[1], Aly Togora[1], Mahamadoun H. Assadou[1], Boubacar Traore[1], Jordyn Manucci[2], Agnes Mwakingwe-Omari[3], Jen C.C. Hume[3], Patrick E. Duffy[3], Issaka Sagara[1], Ogobara Doumbo[1]

[1]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Division of Intramural Research, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

Malaria transmission blocking vaccines (TBVs) that target the sexual stages of the parasite in the mosquito host have emerged as a potential tool for malaria elimination. Recent phase 1 TBV clinical trials have shown promising activity, prompting further evaluation in phase 2 trials. In support of such trials, we initiated a study in Bancoumana, Mali, a rural and malaria-endemic site 60 km south of Bamako, to characterize community-specific malaria epidemiology. Here, we present first year data (Feb 2018 to Jan 2019) on *Plasmodium* species frequencies and parasite infection prevalence. A total 873 volunteers stratified into three age groups (0-4 years, 5-14 years and 15-65 years) were recruited and followed monthly for clinical and laboratory assessment (i.e. clinical exam, blood smears and hemoglobin level). As expected, *P. falciparum* (*Pf*) was most prevalent at 11.3% (1092/9634) with 3.5% (335/9634) gametocyte carriers; for *P. malariae* and *P. ovale,* the annual prevalence was 0.64% (62/9634) and 0.15% (14/9634) respectively. *Pf* prevalence was significantly higher in Feb [19.4% (162/836)] compared to transmission season in Oct [13.2% (105/794), p=0.001] and Nov [13.3% (106/796), p=0.001]. The lowest prevalence was observed in Jan [6.3% (49/775)]. *P. falciparum* gametocyte carriage rates (GCR) peaked in Feb [7.7% (64/836), while *P. malariae* and *P. ovale* GCRs varied between 0% and 1.8% throughout the year. Overall, malaria prevalence was lower in 2018-2019 compared to previous assessments in Oct 2011 [21.5% (50/233)] and Oct 2012 [38.2% (26/68)] (Assadou et al). *Pf* was most prevalent in 5-14 year olds [7.7% (744/9634) with a GCR of 2.29% (221/9634)], followed by participants 15-65 years [3.0% (291/9634) with a GCR of 0.94% (91/9634)] and 0-4 years [0.59% (57/9634) with a GCR of 0.24% (23/9634)]. *Pf* density ranged between 40 to 409,320 parasites/µl. *Pf* coinfected with *P. malariae* in 0.29% (28/9634) of cases, and with *P. ovale* in 0.03% (3/9634) of cases. Prevalence and parasite density were highest among children aged 5-14, and *P. falciparum* gametocyte carriage throughout the year enables continual transmission.

1617

CHARACTERIZATION OF ENDEMIC YEAR-ROUND MALARIA TRANSMISSION IN THE CHITTAGONG HILL TRACTS OF BANGLADESH
