In Bangladesh, 18 million people live in malaria endemic regions. Most malaria cases occur in the remote Chittagong Hill Tracts on the eastern border. Surveillance in this area has relied on both facility-based and field-based detection which is likely incomplete from limited access to hard to reach areas. Accurate incidence estimates could improve elimination plans. Using data from community-based malaria surveillance, we estimated incidence and described demographic, temporal, and geographic heterogeneity. During Sep 2010 - Oct 2013, United Nations Development Programme and Hill District Council staff regularly visited remote communities in 70 unions and tested people with febrile illness for malaria using either slide microscopy or rapid diagnostic test. We collected health register data from mobile clinics and community health workers and calculated incidence rates using the expected annual number of cases and population estimates from the 2011 Bangladesh Census. Among 43,783 patients tested, 10,334 were diagnosed with malaria. Overall, the incidence rate was 4.3 cases per 1000 person-years [PY]) while the median case age was 14 (IQR: 6 - 28.5). Individuals <5 years had significantly higher incidence rates (6.4 cases per 1000 PY) than those 5 - 14 years and ≥15 years (5.5 & 3.6 cases per 1000 PY). For those ≥15 years, men had higher incidence rates than women (4.0 vs 3.0 cases per 1000 PY), but not significantly so. Monthly incidence remained ≥1 case per 1000 PY throughout the entire study period. Among 70 unions, the median incidence was 2.8 cases per 1000 PY (IQR: 1.2 - 5.5); the three unions with the highest incidence (48, 28 & 28 cases per 1000 PY) also had the most cases. In the Hill Tracts, malaria maintains a robust, year-round transmission cycle afflicting both sexes and all age groups, with a higher burden borne by children. Most unions sustain high transmission as defined by the WHO (≥1 case per 1000 PY) with some having rates comparable to parts of sub-Saharan Africa. Elimination in Bangladesh will require sustained control strategies for all ages while targeting geographic areas of highest incidence.

1618

QUANTIFYING THE ROLE OF AGE AND *PLASMODIUM FALCIPARUM* INFECTION TO ANEMIA PREVALENCE AMONG CHILDREN IN UGANDA

John M. Henry[1], David L. Smith[1], Moses Kamya[2], John Rek[3], Bryan Greenhouse[4], Isabel Rodriguez-Barraquer[4], Grant Dorsey[4]

[1]*University of Washington, Seattle, WA, United States,* [2]*Makerere University, Kampala, Uganda,* [3]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [4]*University of California San Francisco, San Francisco, CA, United States*

The link between malaria infection and anemia is well established, but the mechanisms of interaction between the human host and protozoan parasite which lead to anemia are complex and noisy. In particular, those mechanisms may depend on a wide variety of factors including the age and exposure history of the host. This makes determining the relative contribution of malaria infection to the burden of anemia difficult. Using hemoglobin concentration measurements and *P. falciparum* parasite counts from children under 10 years old obtained from the Program for Resistance, Immunology, Surveillance, and Modeling (PRISM) study currently underway in Uganda, we have found strong evidence for the existence of an age- and infection status-dependent pattern in hemoglobin concentration. Applying the known statistical properties of the data-fitted Ornstein-Uhlenbeck process to determine the probability an individual is below the hemoglobin levels which categorize anemia

conditioned on infection status, we estimated the impact of malaria infection on anemia. After correcting for age, we show that *P. falciparum* infection accounts for an average drop of approximately .835 g/dl in girls and .651 g/dl in boys, which accounted for age-specific differences in the prevalence of mild, moderate, and severe anemia. In this population, the model suggests *P. falciparum* increased odds of anemia by a factor of about 1.54 for girls and 1.42 for boys. Further study is needed for individuals during and after adolescence and in locations that may have different baseline levels of nutrition and elevation, as these are also strong drivers of hemoglobin concentration. Improving these estimates may have programmatic implications in evaluating the relative impact of different public health interventions focused on reducing the burden of malaria and anemia.

1619

EVALUATION OF A LINK BETWEEN MALARIA AND HYPERTENSION IN THE UNITED STATES: A CROSS-SECTIONAL POPULATION-BASED COHORT ANALYSIS

Morgan Birabaharan, Andrew Strunk, Amit Garg, Stefan Hagmann

Donald and Barbara Zucker School of Medicine, Hempstead, NY, United States

Malaria has growing recognition for its association with hypertension (HTN). Low birth weight, malnutrition and chronic inflammation in the setting of malaria in malaria-holoendemic areas have been discussed as possible patho-mechanisms. We aimed to assess if predominant singular or sporadic malaria infection in the context of travel exposure in a population residing in a malaria non-endemic country also shows an association with HTN. A cross-sectional analysis was performed using Explorys, a large database with US patients seen in the inpatient and outpatient settings (63 million unique lives, 27 healthcare organizations, all census regions and insurance types represented). The analysis included adult patients with an active status in the database during April 2014-April 2019 and had demographic data on age, gender, race, and body mass index. The Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT) of 'malaria' and 'essential hypertension' were used to identify patients with malaria and HTN. We assessed overall HTN prevalence among patients with and without past malaria infection, and within demographic subgroups. A total of 4,670 malaria patients were compared with the control cohort of approximately ~18 million non-malaria patients. The prevalence of HTN in the malaria-cohort was 43.6% (2,080/4,670) compared to 38.2% (6,897,190/18,062,810) in the general population. Patients with malaria were more likely to be male (57.0% vs 43.4%), >65 years of age (41.3% vs 28.9%), African American (25.9% vs 12.6%), and diabetic (18.4% vs 14.9%), but were less likely to be a smoker (22.1% vs 29.3%), obese (41.2% vs 45.9%), or an alcoholic (3.2% vs 3.9%). In subgroup analysis, the prevalence of HTN was highest among patients who were male, >65 years of age, and white. Patients with history of malaria and one modifiable risk factor had higher prevalence of HTN than the general population with the same modifiable risk factor; obese (58.8% vs 50.1%), tobacco smoker (61.1% vs 46.0%), diabetic (87.2% vs 82.3%), and alcoholism (73.3% vs 54.2%). In this observational study we observed a higher prevalence of HTN among those with a history of malaria infection. As most individuals in the U.S. diagnosed with malaria suffer from travel-associated malaria, our findings suggest that even singular or rare exposure to malaria may be associated with higher odds of also having HTN. Further investigation of the malaria-HTN link should also include travel-associated malaria cases.

1620

EPIDEMIOLOGIC AND CLINICAL PROFILE OF SEVERE MALARIA CASES TREATED AT THE BEFELATANANA UNIVERSITY HOSPITAL, MADAGASCAR FROM JANUARY 2018 TO FEBRUARY 2019

Hitsy A. Razafindrazaka[1], Jocelyn Razafindrakoto[2], Volatiana Andriananja[1], Mihaja Raberahona[1], Rajaonarison Mahan[1], Laurent Kapesa[2], Mamy Randria:[1]

[1]*Department of Infectious Diseases, Befelatanana University Hospital, Antananarivo, Madagascar,* [2]*USAID/PMI, Antananarivo, Madagascar*

Madagascar has five malaria transmission zones, based on transmission length and the intensity. In general, the central highlands (CHL) has low malaria transmission and the coastal areas have high malaria transmission. Malaria is the 4th leading cause of hospital mortality in 2017. We described the epidemiologic and clinical profile of severe malaria cases admitted to the Befelatanana University Hospital, situated in the CHL. We conducted chart abstractions of all severe malaria cases from January 1, 2018 to February 28, 2019. Cases were defined as a person admitted at with positive malaria Rapid Diagnostic Test (RDT) and at least one WHO-defined severe malaria symptom. Data were captured and analyzed using EPI-INFO 7.0, and the P-value and OR were calculated by Fisher›s exact test. A total of 73 patients were admitted to the analysis: 19 were female (26%) and 54 (74%) male. The mean age was 35 years (range 10-50). Sixty-four (88%) cases were residents of the CHL, and reported having travelled to high transmission zones. None of them took malaria chemoprophylaxis. Two cases were autochthonous and seven cases were not specified. During their travel, 13 cases worked as masons (18%), 13 as seasonal farmers (18%), 11 as street vendors (15%), 10 drivers (13 %), and 17 unspecified. All 64 cases developed severe malaria after returning to the CHL. The symptoms were fever in all of them, shaking in 37 cases (51%), sweat in 32 cases (45%) and headache in 30 cases (41%). The main symptoms of severity were prostration (71%), confusion (67%), kidney failure (16%), and coma (12 %). The treatment was injectable Artesunate in 63 cases (86.3%) and injectable quinine in 10 cases (21.92%), which was followed by ACT treatment. Median time to discharge was 4.33 days. The parasitemia was negative at Day 3 in 29 out of 31 cases (94%) who tested by microscopy. Eight cases died: 2 women and 6 men. The majority of cases were CHL residents travelling to high transmission zones. This suggests that they should be sensitized on prevention such as consistent use of LLIN. Clinicians in the low transmission also CHL should be regularly targeted to refresher training on malaria case management.

1621

EVALUATING GUIDELINES FOR COMMUNITY HEALTH WORKER PROTOCOLS IN ZAMBIA BASED ON DATA FROM TRIALS AND ROUTINE REPORTING

Caitlin A. Bever[1], Reine Rutagwera[2], Hannah Slater[3], John Miller[2], Kammerle Schneider[3], Thom Eisele[4], Edward Wenger[1]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*PATH, Lusaka, Zambia,* [3]*PATH, Seattle, WA, United States,* [4]*Tulane University, New Orleans, LA, United States*

The Zambian National Malaria Elimination Centre has rolled out a vast community health worker (CHW) program to improve access to timely malaria diagnosis and treatment in rural areas. In addition to addressing primary cases, CHW duties include conducting reactive follow-ups, in which those living in the vicinity of a primary case are tested, and treated if positive. The original guidelines for CHWs mandated that reactive follow-ups include all neighbors within 140m of the index household but the routine reporting data has shown that this is an unachievable standard in regions where the transmission intensity, and therefore primary caseload, is high. A revised set of recommendations dictated that in these high transmission intensity regions, CHWs should still attempt to perform at least five follow-ups per month for maintenance of skills and

continued awareness within the community. In this work, we set out to further improve the regional CHW guidelines by balancing the operational difficulties faced by each CHW with the epidemiological benefits expected from a given number of reactive follow-ups. Using data from a large-scale mass drug administration trial conducted in Southern Province from 2011-2016 as well as routine reporting data collected by CHWs from 2014 until now, we determine the expected number of infections treated per follow-up as a function of local transmission intensity and population distribution. These results are weighed against previously observed CHW performance to recommend achievable protocols that can be adjusted in response to major changes in transmission. Finally, we identify those health facility catchment areas where it is expected that the current allotment is insufficient for the local population and suggest specific placement for additional CHWs.

MALARIA TRANSMISSION MONITORING IN LAGOS STATE, NIGERIA

Ndukwe Ukoha[1], Ify Aniebo[1], Kelechi Ohiri[1], Wellington A. Oyibo[2]

[1]*Health Services Delivery Foundation, Abuja, Nigeria,* [2]*ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine, University of Lagos, Lagos, Nigeria*

Malaria prevalence in Nigeria in the last 15 years has seen successive decline in prevalence from the Malaria Indicator Survey conducted in 2010 and 2015 from 42% in 2010 to 27% in 2015. Indeed in 2015, the prevalence of malaria was 0% in Lagos State. This prompted the use a surrogate measurement in elucidating the transmission of malaria in Lagos. The objective of this transmission intensity monitoring was to provide a snapshot on malaria transmission using antigens. Samples for this study was obtained from asymptomatic individuals in communities in Lagos. A sub-set of the Lagos MIS samples were tested by indirect ELISA for total immunoglobulin (Ig)-G Ab against a chimeric *Pf* antigen. In a sub-set of 142 asymptomatic samples from which ELISA was conducted to measure *Plasmodium falciparum* antibodies, 7 of the individuals were positive (4.9%) by microscopy but the Pf ELISA detected antibodies in 80 persons with antibody prevalence of 56.3%. High antibody levels were expressed in children less than 15 years compared with the older age groups and this indicated that malaria transmission occurred more at the younger population. Our antibody results provided several significant indicators of transmission in Lagos and this was also evident in the high levels of Pf antibody in Ikorodu, an area identified as a high malaria transmission area when compared to the urban areas where transmission is low. These results demonstrated that malaria transmission is ongoing in Lagos.

1623

EPIDEMIOLOGY OF MALARIA IN KT ZONE, SOUTHERN ETHIOPIA: A FIVE YEAR DATA ANALYSIS, 2011-2015

Abraham Lere Keshabo, **Adamu Addissie Nuramo**

Addis Ababa University, Addis Ababa, Ethiopia

Between 2000 and 2015, the number of malaria cases declined by 42% while the malaria death rate declined by 66% in the African Region. However, Malaria is a major public health challenge in Ethiopia, contributing 4% of all cases in Africa. It makes approximately 68% of the population the country at risk. Therefore, this surveillance data analysis needed to analyze magnitude, trends, and geographical distribution of the disease in Kembata-Tembaro Zone from 2011 to 2015. A descriptive study was employed for analysis of data on malaria indicators from the Integrated Disease Surveillance and Response System database for the years 2011-2015. The surveillance data were analyzed to show incidence, trends and variation in risk by reporting woredas by using charts, graphs and tables. In the Zone, the average estimated annual incidence of reported total malaria in the overall population was 69 per 1000 persons and confirmed malaria were 54 per 1,000 per year over the five years (2011 to 2015). As of the calendar years 2011-2015, the annual incidence of total malaria report dropped from 119/1000 to 9/1000 and reported malaria in-patient admissions and deaths dropped from 1.7/1000 to 0.9 per 1,000 per year and 1.3/100,000 to 0.4/100,000 respectively. In addition, laboratory test increases from 60% in 2011 to 90.2% in 2015. We conclude that the magnitude of Malaria in Kembata Tembaro Zone declined (dropped significantly from 119/1000 to 9/1000) from 2011-2015. From all woredas, kedida woreda is most frequently affected woreda in the Zone. Even though different malaria control strategies were designed to roll back to its minimum level in Kembata Tembaro Zone, still malaria cases were not decreased as expected. Therefore, the zonal health department should maintain such reduction in both morbidity and mortality due to malaria.

1624

IDENTIFICATION OF EXPRESSED *VAR*S IN WHOLE BLOOD CLINICAL SAMPLES WITH A CUSTOM CAPTURE ARRAY VERSUS RNA ENRICHMENT METHODS

Emily M. Stucke[1], Antoine Dara[2], Ankit Dwivedi[1], Theresa Hodges[1], Drissa Coulibaly[2], Abdoulaye K. Kone[2], Karim Troaore[2], Boureima Guindo[2], Bourama Tangara[2], Amadou Niangaly[2], Modibo Daou[2], Issa Diarra[2], Youssouf Tolo[2], Mody Sissoko[2], Albert E. Zhou[1], Matthew B. Laurens[1], Amed Ouattara[1], Bourema Kouriba[2], Ogobar K. Duombo[2], Shannon Takala-Harrison[1], David Serre[1], Mahamadou A. Thera[2], Christopher V. Plowe[3], Mark A. Travassos[1], Joana C. Silva[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*University of Sciences, Techniques and Technologies, Bamako, Mali,* [3]*Duke University, Durham, NC, United States*

The *var* gene family encodes *Plasmodium falciparum* erythrocyte membrane protein-1 (PfEMP1) antigens. These highly diverse antigens are displayed on the surface of infected erythrocytes and play a critical role in immune evasion and sequestration. Studies of *var* expression using non-leukocyte-depleted blood are challenging due to the predominance of host genetic material and lack of conserved *var* segments to allow primer anchoring and sequence amplification. To address these barriers, we compared two enrichment methods for parasite RNA extracted from whole blood clinical samples—globin and rRNA depletion followed by polyA selection *vs.* a custom capture array based on Roche's SeqCap EZ Enrichment System. The capture array was designed with probes covering the 3D7 reference genome and an additional >4,000 full-length *var* gene sequences. We tested each method on the same samples from Malian children with severe or uncomplicated malaria infections, and sequenced using Illumina. *Var*-like transcripts were identified from the *de novo* assembly of non-human reads and annotated. For each sample, we compared transcript length and number of unique transcripts generated from each enrichment method. To determine if each method yielded identical *var* sequences, we compared sequences generated by each method. We then quantified *var* expression to determine if expression correlated between methods. Depletion of the most abundant human RNAs followed by polyA selection produced transcripts with greater median length in samples with the highest parasitemias compared to the capture method. The capture array produced the longest maximum length and largest numbers of transcripts for each sample, particularly for samples with low parasitemia (<2,000 parasites/μL). The capture method produced more unique fragments, including up to 20 distinct acidic terminal sequence domains per sample. The two methods produced different quantitative *var* profiles. Further evaluation will include expression analyses of samples with known *var* repertoires to determine the method best suited to analyze *var* expression in studies with both low and high parasitemia samples.

1625

GLOBAL GENETIC DIVERSITY AND POPULATION STRUCTURE OF *PLASMODIUM FALCIPARUM* TRANSMISSION VACCINE TARGETS PFS47, PFS48/45 AND PFS230

Ankit Dwivedi[1], Alvaro Molina-Cruz[2], Giovanna Carpi[3], Kara Moser[1], Carolina Barillas-Mury[2], Joana C. Silva[1]

[1]*Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States,* [3]*Department of Biological Sciences, Purdue University, West Lafayette, IN, United States*

The *Plasmodium falciparum* (*Pf*) protein Pfs47 has been shown to mediate evasion of the mosquito complement-like immune system, enabling parasite survival and transmission. Pfs47 is a potential target of interventions aimed at preventing malaria transmission, as are Pfs48/45 and Pfs230, other 6-cystine family members expressed during the sexual stage of the parasite life cycle. Population genetics and experimental transmission studies, using multiple *Pf* strains and mosquito species, suggest that *P. falciparum* adaptation to local mosquito populations has led to regional selection at the *Pfs47* locus. Less is known about genetic diversity and selection on *Pfs48/45* and *Pfs230* locus. In this study we analyze whole genome sequence data of ~710 parasite samples originating from 8 geographical locations in South America, Africa, SE Asia and Oceania, which differ in intensity of malaria transmission and *Anopheles* mosquito vector species. We investigate genetic differentiation at all sexual stage 6-cys protein family *loci* between global populations based on nucleotide diversity (ϖ), haplotype diversity (*Hd*) and fixation index (F_{ST}). Genetic differentiation at *Pfs48/45* and *Pfs230* is higher than expected by chance, as observed in the case of *Pfs47*. Furthermore, haplotype diversity networks of these 6-cys *loci* show strong geographic structure with varying diversity in local populations. We also investigated potential functional association of other *loci* with *Pfs47* based on linkage disequilibrium (LD) statistics (*r2*). We generated a list of *Pf loci* in LD with *Pfs47*, which includes other sexual stage 6-cys protein family *loci*. Further investigation of functional processes and metabolic pathways associated with the *loci* in LD with *Pfs47* is underway. These genes could be functionally associated with *Pfs47* and/or potentially involved in survival of the parasite in the mosquito vector, representing potential targets for transmission-blocking strategies. The genetic diversity and population structure observed in Pfs47, Pf48/45 and Pfs230 *loci* could be important for the successful design of transmission blocking vaccines based on these targets.

1626

THE APOLIPOPROTEIN E3/E3 GENOTYPE IS ASSOCIATED WITH PROTECTION FROM SEVERE MALARIA IN UGANDAN CHILDREN

Giselle Lima-Cooper[1], Benson J. Ouma[2], Andrea L. Conroy[1], Katrina Co[1], Dibyadyuti Datta[1], Robert O. Opoka[3], Chandy C. John[1]

[1]*Ryan White Center for Pediatric Infectious Diseases and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Department of Microbiology, Makerere University, Kampala, Uganda,* [3]*Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda*

Apolipoprotein E (APOE), a protein involved in the transport and metabolism of lipids and brain injury repair, has been implicated in the pathogenesis of experimental cerebral malaria, but there is conflicting data on whether the APOE alleles (E2, E3, E4) or genotypes are associated with increased risk of severe malaria in humans. We investigated associations between APOE polymorphisms and disease severity in two cohorts of Ugandan children enrolled in prospective studies of severe malaria pathogenesis. The first cohort consisted of children ages 5-12 years with cerebral malaria (CM, n=92) or uncomplicated malaria (UM, n=94), and asymptomatic community children (CC, n=108). Children with UM or CC had not had severe malaria, so were combined as a "protected" comparator group to CM. Children with the APOE E4 allele or the APOE E3/E4 genotype had an increased risk of CM (odds ratio (OR) [95% confidence interval (CI)], 1.71 [1.03, 2.84] and 1.85 [1.09, 3.14], respectively), while children with the APOE E3/E3 genotype had decreased risk of CM (OR [95% CI], 0.57 [0.33, 0.98]). The second cohort consisted of children ages 18 months - 12 years with CM (n=269) or severe malaria anemia (SMA, n=233), and asymptomatic community children (CC, n=216). In this cohort, children with CM and SMA had similar frequencies of APOE alleles and were combined into a single severe malaria group. Children with the APOE4 allele or APOE4/E4 genotype had a higher risk of severe malaria (OR [95% CI], 1.68 [1.16, 2.44] and 11.25 [1.51, 83.60], respectively), while children with the APOE E3 allele or APOE E3/E3 genotype had a decreased risk of severe malaria (OR [95% CI], 0.43 [0.22, 0.84], and 0.54 [0.37, 0.78], respectively). Children with the APOE E4/E4 or E3/E3 genotypes also had significantly increased or decreased risks, respectively, for CM alone. In two independent cohorts of Ugandan children, APOE E3/E3 was associated with protection from severe malaria and APOE4 with increased risk for severe malaria. Future studies should confirm these associations in other populations, and if confirmed, determine the mechanisms by which APOE E3/E3 may protect from severe malaria.

1627

MALARIA IN VENEZUELA: CHANGES IN THE COMPLEXITY OF INFECTION REFLECTS THE INCREMENT IN TRANSMISSION INTENSITY

M. Andreina Pacheco[1], David A. Forero-Peña[2], Melynar Chavero[3], Angel Gamardo[4], Luisamy Figuera[3], Leopoldo Villegas[5], María E. Grillet[6], Kristan Schneider[7], Ananias A. Escalante[1]

[1]*Temple University, Philadelphia, PA, United States,* [2]*Escuela de Ciencias de la Salud, Universidad de Oriente, Núcleo Bolívar, Ciudad Bolívar, Bolivarian Republic of Venezuela,* [3]*Departamento de Medicina Interna, Complejo Hospitalario Universitario "Ruíz y Páez", Ciudad Bolívar, Bolivarian Republic of Venezuela,* [4]*Biomedical Research Institute and Therapeutic Vaccines, Ciudad Bolívar, Bolivarian Republic of Venezuela,* [5]*Asociación Civil Impacto Social (Tumeremo, Venezuela) and Global Development One, Silver Spring, MD, United States,* [6]*Instituto de Zoología y Ecología Tropical, Universidad Central de Venezuela, Caracas, Bolivarian Republic of Venezuela,* [7]*University of Applied Sciences Mittweida, Mittweida, Germany*

Malaria incidence has reached staggering numbers in Venezuela in a matter of years. Historically, Bolivar State has accounted for approximately 70% of the Venezuelan cases with many clustered in the Sifontes municipality, a region characterized by an extractive economy including gold mining. It has been proposed that changes in migration to this area, as a result of the Venezuelan economic crisis, drove a malaria spillover to the rest of the country and the region. Here, we studied *Plasmodium falciparum* (*Pf*) and *Plasmodium vivax* (*Pv*) populations from the municipality of Sifontes. Samples collected in 2018 were compared with samples from 2003 (106 *Pf* and 104 *Pv*). A total of 77 *P. falciparum* and 94 *P. vivax* isolates from 2018 were genotyped by using eight standardized microsatellite *loci*. In addition, mutations linked to drug resistance (*Pfdhfr*, *Pfdhps*, and *Pfcrt*) and the *Pfk13* gene associated with artemisinin delayed parasite clearance in *P. falciparum* were analyzed. Consistent with the increase in transmission, polyclonal infections raised from 1.9% in 2003 to 39% in 2018 in *P. falciparum* and from 15.4% to 68% in *P. vivax*. Although the circulating *P. falciparum* parasites still harboring drug-resistant mutations in *Pfdhfr*, *Pfdhps*, and *Pfcrt*; mutations associated with artemisinin delayed parasite clearance was not found in the *Pfk13* gene. Interesting, for both parasites, the genetic diversity (He: 0.98 for *P. falciparum* and He: 1.0 for *P. vivax*) increased in 2018. The samples from 2003 and 2018 have several alleles per locus in common but do not share multi-locus genotypes. Bayesian clustering using the Structure v2.3.4 software yield two populations linked to the time of sampling showing that the parasites populations temporarily changed. Whereas the situation on mutations linked with drug resistance in *P. falciparum* seems to remain stable, all other observations are consistent with an increase in

transmission. These parasite genetic data will support studies directed to test the hypothesis that the outburst of malaria in Venezuela originated in Sifontes as a malaria hotspot.

1628

DEMOGRAPHIC AND EVOLUTIONARY INSIGHTS FROM RECENT LARGE-SCALE WHOLE-GENOME SEQUENCING EFFORTS OF *PLASMODIUM FALCIPARUM* IN SOUTH AMERICA

Angela M. Early[1], Pablo Cardenas Ramirez[2], Manuela Carrasquilla[3], Horace Cox[4], Luana C. Mathieu[5], Aimee R. Taylor[3], Caroline O. Buckee[3], Angelica Knudson[6], Lise Musset[5], Socrates Herrera[7], Julian C. Rayner[8], Daniel E. Neafsey[3], Vladimir Corredor[6]

[1]*Broad Institute, Cambridge, MA, United States,* [2]*Massachusetts Institute of Technology, Cambridge, MA, United States,* [3]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [4]*Guyana Ministry of Public Health, Georgetown, Guyana,* [5]*Institut Pasteur de la Guyane, Cayenne, French Guiana,* [6]*National University of Colombia, Bogota, Colombia,* [7]*Institute of Immunology, Cali, Colombia,* [8]*Wellcome Sanger Institute, Hinxton, United Kingdom*

Genomic diversity in *Plasmodium falciparum* is undercharacterized in many parts of South America, considering the significance of local disease burden, challenges to disease elimination, and the propensity for the *de novo* emergence of drug resistance mutations in this region. Here, we report the first whole-genome sequencing-based survey of *P. falciparum* from the Pacific coast of Colombia, a regional hotspot for malaria transmission that is estimated to account for 25% of the *P. falciparum* malaria cases in the Americas. Of the 151 clinical samples sequenced, only a small proportion of infections (0.1) are multiclonal. There is also a high degree of relatedness among parasites. Parasite pairs have a median identity-by-descent (IBD) rate across their genomes of 0.20, with 14% showing strong evidence of clonality (IBD > 0.75). This high clonality and low number of multiclonal infections suggest that recombination between unrelated lineages is low, allowing a small number of distinct clonal lineages to persist. Despite the low genetic diversity in the population, we observed multiple segregating haplotypes at known drug resistance genes including *pfcrt*, *pfdhps*, *pfdhfr*, and *pfmdr1*. We compared these Colombian results with those from the only other South American region with extensive population-level genomic data: the Guiana Shield. There is sufficient population structure to largely differentiate parasites from the two regions allowing infections to be flagged as potentially imported and placing directionality on parasite migration. The joint analysis of these data sets demonstrates how genome-wide sequencing and targeted molecular surveillance across the Americas is increasing our ability to (1) detect the early emergence of drug resistance, (2) track regional parasite movement, and (3) measure declines in diversity that could mark successful intervention strategies. These data, however, are only a first step. Continued dense sampling across the continent is needed to detect the potential spread of the *pfkelch13* C580Y mutation from Guyana and to monitor the expected increase of exported parasites from Venezuela.

1629

COMPARATIVE TRANSCRIPTOMICS OF *PLASMODIUM FALCIPARUM* IN NORMAL AND SICKLE-TRAIT ERYTHROCYTES USING RNA SEQUENCING

Joseph W. Saelens, Jens E. Petersen, Betsy Freedman, Steve B. Haase, Steve M. Taylor

Duke University, Durham, NC, United States

Sickle-trait hemoglobin (HbAS) confers near-complete protection from severe, life-threatening falciparum malaria in African children, but the molecular mechanisms by which HbAS confers these protective phenotypes remain incompletely understood; our preliminary data suggest that HbAS allows normal erythrocyte invasion and maturation, but disrupts the structured transcriptional program of the parasite. To further investigate this, we performed time-series comparative transcriptomic analyses of the asexual stage of *Plasmodium falciparum* in normal (HbAA) and HbAS erythrocytes using RNA sequencing. In separate experiments, late schizonts of *P. falciparum* reference strains 3D7 and FUP were isolated using Percoll gradients and inoculated into parallel cultures in HbAA and HbAS erythrocytes. Newly-invaded rings were purified using sorbitol, and over 48 hours parasites from each independent culture were sampled for light microscopy and RNA isolation every 3 hours. RNA from each timepoint was sequenced on the Illumina NovaSeq6000, generating ~120 million 150bp paired-end reads for each of 16 timepoints over the asexual cycle. We quantified transcripts using STAR and modeled differential expression of parasite transcripts between HbAA and HbAS erythrocytes with DESeq2. We identified periodic gene expression using persistent homology, Lomb-Scargle, JTK-CYCLE, and de Lichtenberg algorithms, and measured the impact of HbAS on *P. falciparum's* periodic gene expression using the Characterizing Loss of Cell Cycle Synchrony (CLOCCS) software. We then analyzed our time series data using the Local Edge Machine (LEM) software to infer *P. falciparum's* periodic regulatory networks that are disrupted in sickle-trait. These analyses reveal HbAS broadly disrupts the highly-structured gene expression of *P. falciparum,* suggesting that sickle-trait confers its protective effect by neutralizing the transcriptional programs that underlie the parasite's pathogenic mechanisms. Understanding these aberrant effects on parasites of HbAS will help to identify new targets for therapeutic and preventive malaria measures.

EVOLUTION AND EXPANSION OF MULTI-DRUG RESISTANT MALARIA IN SOUTHEAST ASIA

William L. Hamilton[1], Roberto Amato[1], Rob W. van der Pluijm[2], Arjen M. Dondorp[2], Dominic P. Kwiatkowski[1], Olivo Miotto[2], MalariaGEN Community Project[3], GenRe-Mekong Project[3], TRACII collaborations[3]

[1]*Wellcome Trust Sanger Institute, Hinxton, United Kingdom,* [2]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand*

The evolution of drug resistant malaria poses a major challenge to elimination efforts. A multidrug resistant co-lineage of *Plasmodium falciparum* malaria, named KEL1/PLA1, spread across Cambodia 2008-2013, causing high treatment failure rates to the front-line therapy. Through the MalariaGEN Community Project, we have analysed whole genome sequencing data from >1,600 *P. falciparum* clinical samples collected 2008-2018 from across Southeast Asia to investigate the epidemiology of multi-drug resistance emergence, evolution and expansion. We found that KEL1/PLA1 parasites spread rapidly from 2015 into all of the regions surrounding Cambodia, maintaining a high level of genetic relatedness reflecting their common origin. However, several genetic subgroups have recently emerged within this lineage with diverse geographical distributions. Some of these KEL1/PLA1 subgroups carry recently emerging mutations in the chloroquine resistance transporter (*crt*) gene, which arise in association with a constellation of other mutations that have accumulated over decades in Southeast Asia. Our findings highlight both the utility of pathogen genomics for revealing large-scale processes in evolutionary biology, and the need for ongoing surveillance and rapid public health responsiveness in the face of continual parasite evolution.

1631

CHARACTERIZING *PLASMODIUM FALCIPARUM* GENETIC DIVERSITY IN TWO VILLAGES OF MALI BOUGOULA-HAMEAU AND FALADJE

Aoua Coulibaly[1], Aminatou Kone[1], Antoine Dara[1], Abdoulaye Djimde[1], Nicola Mulder[2], Olivo Miotto[3]

[1]*University of Science, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*University of Cape Town, Cape Town, South Africa,* [3]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand*

The genetic diversity of *P. falciparum* populations is a major factor in the parasites ability to adapt to changes in its environment, enabling the

development of drug resistance and the evasion of host immune system. Therefore, characterizing the genetic diversity and understanding the main drivers of the genetic diversity and differentiation would be critical in implementation of new strategies for malaria control programs. Studies have demonstrated markedly lower level of population structure in West African parasite populations, and given the difficulties in separating populations by geographical origin using current tools, it is necessary to develop new methods that can discriminate *P. falciparum* populations from West African countries. The aim of this study is to identify genetic variations that can discriminate between parasite populations in two villages of Mali, Bougoula-Hameau and Faladje. Overall 433 dried blood spots samples from both villages were subjected to DNA extraction. DNA was amplified using sWGA and sequenced on Illumina platform. In total, 1000000 SNPs were identified from the dataset. Series of filtering steps were conducted on the potential SNPs and samples, to eliminate artifacts and produce a list of high quality SNPs and samples. Population genetic analysis was performed including population structure and inter population differentiation. Principal component analysis (PCA) was done on all samples, and neighbor joining trees were constructed for all samples. The parasite populations showed a low genetic differentiation (Fst<0.02). When performing the same analyses after selecting a set of SNPs with higher Fst, we observed a remarkable separation between the groups. Analyses are ongoing to qualify how stable the differentiating SNPs are using a larger dataset, and higher resolution data.

WHOLE TRANSCRIPTOME IDENTIFICATION OF MICRORNAS ASSOCIATED WITH SEVERE MALARIAL ANEMIA IN KENYAN CHILDREN

Qiuying Cheng[1], Caroline Ndege[2], Samuel B. Anyona[2], Christophe G. Lambert[1], Douglas J. Perkins[1]

[1]*University of New Mexico, Albuquerque, NM, United States,* [2]*University of New Mexico-Kenya Global Health Programs, Kisumu, Kenya*

Molecular mechanisms that mediate the development of pediatric severe malarial anemia (SMA, Hb<5.0g/dL) are only partially defined. MicroRNAs (miRs), a group of non-coding RNAs ~22 nucleotides in length, have been shown to modulate host gene expression profiles. Thus, we utilized whole-transcriptome analysis of peripheral blood to compare miR levels in children (6-36 months of age) with non-SMA (Hb>5.0g/dL, n=43) and SMA (n=17) from a holoendemic *Plasmodium falciparum* transmission region of western Kenya, Siaya. Transcriptome measurements were performed using the HumanHT-12 v4 expression BeadChip kit (Illumina®) which covers 228 distinct human miRs. Here, we present the results for miRs which potentially target immune response genes known to be important in the pathogenesis of SMA. The preliminary findings presented highlight the potentially important role of miRs in the pathogenesis of SMA.

1633

PIPERAQUINE RESISTANCE IS ASSOCIATED WITH DIFFERENTIAL VACUOLAR ACCUMULATION AND PEPTIDOMIC PROFILES IN *PLASMODIUM FALCIPARUM*

John Okombo[1], Sachel Mok[1], Edward Owen[2], Zbynek Bozdech[3], Manuel Llinas[2], David Fidock[1]

[1]*Columbia University, New York City, NY, United States,* [2]*Pennsylvania State University, Pennsylvannia, PA, United States,* [3]*Nanyang Technological University, Jurong West, Singapore*

Recent reports document treatment failures with the first-line therapy combination of dihydroartemisinin plus piperaquine (PPQ) in Cambodia and emerging resistance in French Guiana. The absence of effective alternative malaria treatments underlines the need to define the molecular interactions linked to PPQ resistance (PPQ-R) to curb its spread. Analysis of genome-edited lines complemented by whole-genome sequence data and phenotypic studies recently revealed that novel mutations in the *Plasmodium falciparum* chloroquine resistance transporter (PfCRT) can mediate PPQ-R. Since PfCRT mutations conferring resistance to chloroquine (CQ), an antimalarial with a common putative mode of action, have previously been implicated in altered drug transport kinetics and changes in hemoglobin metabolism. The aim was to use peptidomics, gene expression studies, vacuolar drug accumulation assays and a heme fractionation protocol on isogenic *P. falciparum* lines expressing wildtype ($Dd2^{Dd2\ GCO3}$) and mutant pfcrt alleles ($Dd2^{Dd2}$, $Dd2^{Dd2\ F145I}$, $Dd2^{Dd2\ G353V)}$ to gain insight into phenotypes associated with mutations that modulate PPQ activity. Preliminary data suggest that lines harboring PfCRT mutations differ in peptidomic profiles compared to their isogenic parent. In addition, microarray-based transcriptomics reveal an upregulation of genes involved in the protein export pathway and hemoglobin digestion, possibly to offset defects in peptide transport. The PPQ-R $Dd2^{Dd2\ F145I}$ and $Dd2^{Dd2\ G353V}$ lines accrued [^{3}H] CQ to higher levels compared to $Dd2^{Dd2}$ but exhibited only marginal ablation in [^{3}H] PPQ accumulation relative to the PPQ-sensitive $Dd2^{Dd2\ GCO3}$, implying potential contribution of other physiological interactions – possibly binding to PfCRT at higher PPQ concentrations eliciting conformational changes that permit drug expulsion. Fractionation studies on the tested lines showed that PPQ inhibited heme detoxification in a manner not dissimilar to CQ. Our results provide evidence that changes in peptide levels, gene expression, drug accumulation and possible involvement of binding to PfCRT play a role in the PPQ-R phenotype.

1634

HIGH THROUGHPUT PHENOTYPIC SCREEN UNRAVELS *PLASMODIUM FALCIPARUM* GENES ESSENTIAL TO MALARIA TRANSMISSION

Jyotsna Chawla

University of South Florida, Tampa, FL, United States

Transmission to new hosts which is crucial to a parasite's life cycle is mediated by sexual stages, called gametocytes in the deadly *Plasmodium falciparum.* Circulating in the human host mature gametocytes are picked up during a blood meal and are primed for survival and development in the mosquito vector. Critical, yet neglected with no drugs targeting this stage, gametocytes propagate through the population unchecked, making it a prime target to block malaria transmission. Previous work in our laboratory achieved a saturation level mutagenesis of *P. falciparum* by creating random insertions of *piggyBac* transposon elements to generate >38,000 mutants. In this study, we characterized genes dispensable for asexual development for their likely importance in sexual stage development. These genes are characterized for their expression patterns, GO pathways, conservation with other *Plasmodium spp.* and other identifiable features. Our next goal is to validate mutant phenotype and define significance in gametocyte formation. Through this study, we anticipate closing an important gap in the *P. falciparum* life cycle and lay the foundation for new antimalarial intervention strategies.

1635

LONGITUDINAL GENOTYPING USING AMPLICON DEEP-SEQUENCING TO DESCRIBE RESIDUAL PARASITEMIA IN THE SETTING OF RAPIDLY DECLINING TRANSMISSION IN NAGONGERA, UGANDA

Jessica Briggs[1], Noam Teyssier[1], Joaniter Nankabirwa[2], John Rek[2], Emmanuel Arinaitwe[2], Moses Kamya[2], Grant Dorsey[1], Isabel Rodriguez-Barraquer[1], Bryan Greenhouse[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda*

Characterizing the reservoir of asymptomatic parasitemia that persists following effective malaria control interventions is critical for designing strategies to sustain gains and eventually eliminate malaria. In Nagongera, Uganda, 2 rounds of LLIN distribution and 6 rounds of IRS over 4 years have reduced the incidence of malaria from 2.29 cases per person-year (ppy) to 0.05 cases ppy. Despite this dramatic reduction in malaria incidence, in a cohort of participants (n=448) followed monthly over one

year from October 2017-October 2018, 26% of the participants were parasitemic by ultrasensitive *var*ATS quantitative PCR (qPCR) at one or more timepoints. To investigate the reservoir of parasitemia in this cohort, we performed qPCR monthly and genotyped all positive samples using an amplicon-based deep sequencing method targeting a highly variable region of *P. falciparum* apical membrane antigen-1. Of 782 available positive qPCR samples, we successfully genotyped 717 (92%). We then designated clones seen in the first three months as baseline infections and any clone seen afterwards a new infection. Three skips were allowed before calling the same clone in an individual new, to allow for imperfect detectability. Molecular force of infection (mFOI) was calculated as the number of new infection events divided by person time. At the cohort level, the proportion of participants with infections persistent from baseline declined from 15.4% to 4.7%. There were only 10 episodes of malaria; therefore, the majority of these infections cleared without antimalarials. All episodes of malaria occurred in the setting of acquiring a new infection within the last 28 days. Overall mFOI was 0.21 events ppy compared to an incidence of malaria of 0.05 cases ppy; thus mFOI was able to capture additional transmission events not reflected by malaria incidence. We show that amplicon deep sequencing of longitudinal samples can successfully be used to characterize asymptomatic parasitemia; in our cohort, declining prevalence of parasitemia is primarily driven through clearance of old infections.

1636

ACCURATE ASSEMBLY OF MULTIGENE FAMILIES AND OTHER REGIONS OF HIGH DIVERSITY IN *PLASMODIUM FALCIPARUM* FROM WHOLE GENOME SEQUENCING WITH NOVEL ASSEMBLER PATHWEAVER

Nicholas J. Hathaway[1], Jeffrey A. Bailey[2]

[1]*University of Massachusetts Medical School, Worcester, MA, United States,* [2]*Brown University, Providence, RI, United States*

Plasmodium multigene families play key roles in facilitating infection and host immune evasion but due to their interrelated and highly diverse nature have been a challenge to study and fully characterize using standard whole-genome sequencing and analysis methods. While other technologies such as long read sequencing can be used the greater cost and more cumbersome sample requirements have inhibited their adoption. Thus the vast majority of genomic studies of *Plasmodium* have relied on short read sequencing data. To leverage this wealth of data, we have developed a novel local assembler, PathWeaver, which after standard reference alignment takes shotgun whole genome sequencing data from specific genes or gene families and optimally de novo reconstructs the genes of interest. The algorithm can iteratively recruit mismapped and unmapped reads overcoming limitations of the reference genome. On control genomes, it was able to accurately assemble the VAR, RIFIN, STEVOR, and SURFIN gene families. In comparison to other metagenomic assemblers, metaSPAdes, MEGAHIT, savage and MetaVelvet), PathWeaver was showed improved performance on both multigene families as well as other highly variable genes including AMA1, CSP, and TRAP. PathWeaver was then used on all currently publicly available whole genome sequencing data which contained 4054 field samples that spanned across South America, Africa, and South East Asia and 33 lab isolates. This enabled the more fully characterization of the number and diversity of VAR, RIFIN, STEVOR, and SURFIN genes.

1637

HOST AND PARASITE TRANSCRIPTOMIC CHANGES UPON SUCCESSIVE *PLASMODIUM FALCIPARUM* INFECTIONS IN MALIAN CHILDREN

In malaria-endemic regions, children have to overcome successive encounters with *P. falciparum* parasites before developing immunity, first against severe disease and later against uncomplicated malaria. Understanding cellular and molecular interactions between host and parasites during infections can provide critical insights on processes underlying this stepwise acquisition of immunity, as well as to how parasites adapt to more "malaria-experienced" hosts. Here, we describe joint analyses of host and parasite gene expression from blood samples collected from five consecutive *P. falciparum* symptomatic infections in three Malian children. We generated and sequenced 15 polyA-selected RNA-seq libraries after globin reduction to simultaneously characterize host and parasite transcriptomes. Unsupervised clustering analysis revealed that host gene expression profiles primarily clustered by individual, while the parasite gene expression profiles differentiated early vs. late infections. This pattern was also supported by gene-by-gene analysis that revealed that a greater number of host genes were differentially expressed according to the individual rather than by the number of prior malaria episodes experienced (4,581 vs. 1,042, FDR=0.2), while more parasite genes were differentially expressed according to the number of prior infections (0 vs. 68). Gene co-expression analysis highlighted more than 1,000 human/parasite gene pairs whose expression co-vary across infections (R^2>0.8), revealing potential host/pathogen interactions throughout the course of the infections. We also showed that the dual RNA-seq data enable statistical assessment of the proportions of i) the different white blood cell subsets and ii) the parasite developmental stages. Finally, we leveraged the read sequences generated to analyze allelic variations in transcribed regions and rigorously assess the polyclonality of each infection. Overall, our findings suggest complex interactions between the host's acquisition of immunity and the parasite's escape mechanisms over successive infections.

1638

GLOBAL STRUCTURE OF THE *VAR* GENES ENCODING THE MAJOR VARIANT SURFACE ANTIGEN OF *PLASMODIUM FALCIPARUM*

Gerry Tonkin-Hill[1], Shazia Ruybal-Pesántez[1], **Kathryn E. Tiedje**[1], Virginie Rougeron[2], Sedigheh Zakeri[3], Tepanata Pumpaibool[4], Pingchai Harnyuttanakorn[4], OraLee H. Malaria remains a major public health problem in many countries. Unlike influenza and HIV, where diversity in immunodominant surface antigens is understood geographically, relatively little is known about the global population structure of PfEMP1, the major variant surface antigen of the malaria parasite *Plasmodium falciparum.* The extreme diversity of the *var* genes that encode PfEMP1 has so far hindered efforts to understand their population structure. A Jumping Hidden Markov Model (JHMM) that considers *var* gene recombination was used to reconstruct each sequence in the dataset as an imperfect mosaic of donor sequences. By leveraging this approach that we designed specifically for the analysis of *var* genes and applying it to a global dataset of *var* sequences from ten countries, we describe *var* gene population structure at a global scale for the first time. The sensitivity of the approach allowed for the comparison of the global dataset to ape samples of other *Plasmodium* species. Using the JHMM method, we were able to distinguish all countries within the global data set. We describe multiple sub-populations in South America consistent with the "Out of Africa" hypothesis where *P. falciparum* was introduced into South America from Africa, likely due to the transatlantic slave trade. We provide compelling evidence for *var* population structure within Africa with Uganda, Ghana and Gabon showing distinct proportion profiles using the JHMM method. Additionally, we identify a number of highly conserved *var* types that are present globally and have previously not been well characterized. These findings will inform efforts in potential vaccine design and suggest that the analysis of *var* genes is a promising tool in the surveillance of the rapidly evolving transmission dynamics of *P. falciparum*.

IN SILICO CAPTURE AND ASSEMBLY OF HIGHLY VARIABLE LOCI

Theresa K. Hodges[1], James Matsumura[1], Ankit Dwivedi[1], Kara A. Moser[1], Andrea A. Berry[2], Shannon Takala-Harrison[3], Jonathan Crabtree[1], Joana Carneiro Da Silva[1]

[1]*Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*University of Maryland School of Medicine, Baltimore, MD, United States,* [3]*Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States*

The reconstruction of highly variable protein-coding genes in *Plasmodium falciparum* remains challenging, despite recent advances in DNA sequencing technologies and whole genome assembly algorithms. In particular, genes with length polymorphisms and low complexity regions are difficult to assemble. Many of these genes contribute to antigenic variability in the parasite and are potential targets for vaccine design. We present a novel pipeline to reconstruct the sequence of target gene(s) from whole genome sequencing (WGS) data from new pathogen isolates. The first step involves the recruitment of WGS reads from targeted genes by using GSNAP to map read data to one or more reference allelic sequences from the *loci* of interest and retaining successfully map reads and their mate pairs. For each targeted gene, de novo assembly of all recruited reads is performed using SPAdes and the resulting assembly is assessed by aligning it back to the reference genome. Assembly is further improved by *de novo* assembling the recruited reads using Hierarchical Genome Assembly (HGA) and Scaffold Builder, based on user-defined thresholds. These steps are repeated for recruited reads that remain unassembled, using the SMALT aligner and/or iterative rounds with different assembly parameter values, until no further improvements can be made to the assembly, at which point the assembled fragment(s) is considered final. The pipeline was validated using short read WGS data from four *P. falciparum* strains from different continents, including 3D7 and NF166 from Africa, 7G8 from South America and NF135 from SE Asia. PacBio-based reference for each strain were used as positive control and confirmed the accurate reconstruction of >95% of all protein-coding *loci* over 90% of their length. Subsequently, we used this pipeline to reconstruct 228 malaria vaccine antigens from 459 *P. falciparum* isolates from seven different geographic areas, using short read WGS data for each isolate. Of these, 210 *loci* were fully reconstructed from >350 strains. Total amount of starting DNA material is a critical factor in the successful reconstruction of allelic sequences for target *loci*.

MOLECULAR EPIDEMIOLOGY OF MALARIA UNDER SHIFTING AGRICULTURAL PRACTICES IN AFRICA

Elizabeth Hemming-Schroeder[1], Daibin Zhong[1], Amanda Chie[1], Harrysone Atieli[1], Andrew Githeko[2], Guiyun Yan[1]

[1]*University of California Irvine, Irvine, CA, United States,* [2]*Kenya Medical Research Institute, Kisumu, Kenya*

Africa bears a disproportionate amount of the global malaria burden, accounting for roughly 90% of worldwide malaria cases and deaths. At the same time, millions of sub-Saharan African residents are also afflicted by chronic hunger, food insecurity, and famine. To help combat food insecurity, investments in dams and irrigation in sub-Saharan Africa have increased substantially over the past decade. However, it is not clear if water resource development will have unforeseen consequences for malaria control. Therefore, the objective of this study is to assess the impacts of shifting agricultural practices on malaria epidemiology by measuring differences in population genetic diversity and infection complexity across irrigation zones. To achieve this objective, we collected malaria parasites from 30 clusters in three irrigation zones in Homa Bay, Kenya. Malaria parasites were sequenced on the Illumina Miseq (2x300 bp read length) at four polymorphic genes (*pfmsp1*, *pfcsp*, *pfama1*, and *pfcpmp*) and four genes associated with drug resistance (*pfk13, pfmdr1, pfdhfr,* and *pfdhps*) to measure population level spatial genetic structure and within-host genetic diversity. A pilot test of 8 PCR reactions were successfully amplified, sequenced, and joined for the four polymorphic genes. An average of 22653 reads per sample passed quality filtering, 27931 reads for *pfcsp,* 11737 reads for *pfama1,* 24792 for *pfmsp1,* and 26151 for *pfcpmp.* These methods will be implemented, with the addition of drug resistance markers to compare population and within-host diversity across irrigation zones. This study will inform how the construction of irrigation schemes and shifting agricultural practices modulates malaria epidemiology and risk. As population growth is expected to continue in Africa, water resource development is also expected to help meet food security demands. Understanding the interactions between these development activities and malaria epidemiology is critical to maintaining effective malaria control strategies.

1641

EPHRIN B LIGANDS REGULATE HUMORAL IMMUNE RESPONSE TO *PLASMODIUM* PARASITE

Adesola C. Olatunde[1], Patrice N. Mimche[1], spencer O. Seely[1], Taryn P. Stewart[1], Franklin Maloba[2], Balotin Fogang[2], Lawrence Ayong[2], Tracey J. Lamb[1]

[1]*University of Utah, Salt Lake City, UT, United States,* [2]*Centre Pasteur du Cameroun, Yaounde, Cameroon*

Malaria remains one of the infectious diseases that cause high morbidity and mortality worldwide. Despite several attempts to induce protective immune responses against *Plasmodium* parasites that cause malaria, sterile immunity against this pathogen through vaccination is yet to be achieved. Generation of protective humoral immunity, characterized by a high affinity and long-lived antibody response, against any pathogen relies on robust germinal center (GC) reactions orchestrated by follicular helper T (Tfh) cells. The molecular and cellular mechanisms that prevent the development of a long-lived protective humoral response specifically in the case of *Plasmodium* are poorly understood. Emerging data have demonstrated that ephrin B1, a ligand for the Eph B receptor tyrosine kinase subfamily, is involved in Tfh cell recruitment, retention and contact-dependent interaction with GC B cells. Here we show an upregulation in the expression of Ephrin B ligands on both Tfh and GC B cells that peak

at day 17 post infection of wild type mice with non-lethal *P. yoelii* XNL. Selective deficiency of Ephrin B1/B2 on B cells ($CD19^{cre+}$Ephrin $B1/B2^{fl/fl}$ mice) led to lethality in some mice infected with an otherwise non-lethal *P. yoelii* XNL infection. We observed an increase in the expression of Ephrin B on peripheral Tfh cells from human with both severe and cerebral malaria. Therefore we investigated the role that Tfh-expressed ephrin B ligands may play in generating an efficacious antibody response to *Plasmodium* infection. Unlike $CD19^{cre+}$Ephrin $B1/B2^{fl/fl}$ mice, $CD4^{cre+}$Eprhin $B1/B2^{fl/fl}$ mice were able to control this infection. Our data show a requirement for EphrinB/EphB signaling for development of *Plasmodium* humoral responses with B cell expression of ephrin B1/B2 ligands a requirement in mice for generating a protective response against primary acute *Plasmodium* infection

1642

MALIAN CHILDREN WITH SEVERE MALARIA EXHIBIT DISTINCT PFEMP1 ANTIBODY PROFILES THAT DIFFER BY BLOOD TYPE

Albert E. Zhou[1], Paul Han[1], Andrea A. Berry[1], Drissa Coulibaly[2], Emily M. Stucke[1], Amed Ouattara[1], Biraj Shrestha[1], Matthew B. Laurens[1], Rie Nakajima[3], Aarti Jain[3], Omid Taghavian[3], Joshua M. Obiero[3], Li Liang[3], Algis Jasinskas[3], Amadou Niangaly[2], Bourema Kouriba[2], Abdoulaye Kone[2], Ogobara K. Doumbo[2], J. Alexandra Rowe[4], Shannon Takala-Harrison[1], Kirsten E. Lyke[1], Christopher V. Plowe[5], Philip L. Felgner[3], Mahamadou A. Thera[2], Mark A. Travassos[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Bamako, Mali,* [3]*Vaccine Research and Development Center, Department of Physiology and Biophysics, School of Medicine, University of California Irvine, Irvine, CA, United States,* [4]*Centre for Immunity, Infection and Evolution, Institute of Immunology and Infection Research, School of Biological Sciences, University of Edinburgh, Edinburgh, United Kingdom,* [5]*Duke Global Health Institute, Duke University, Durham, NC, United States*

Severe malaria caused by *Plasmodium falciparum* primarily affects children in sub-Saharan Africa. Severe malaria pathogenesis is poorly understood but likely involves deep tissue sequestration and rosetting of infected erythrocytes. ABO blood type and *P. falciparum* erythrocyte membrane protein-1 (PfEMP1) variant surface antigen expression appear to play critical roles in rosetting. Depending on blood type, parasites infecting subjects may express certain subsets of PfEMP1s, such as DBLα1 domains, associated with severe disease pathogenesis. For each blood type, we predicted that Malian children with severe malaria would demonstrate a unique PfEMP1 serological profile that reflects the lack of antibody responses to PfEMP1s potentially involved in pathogenesis. We also predicted that severe malaria cases would have less recognition of and lowered seroreactivity to a subset of PfEMP1 protein fragments than controls with uncomplicated malaria. We probed a custom protein microarray populated with reference strain and field-derived PfEMP1s associated with severe malaria pathogenesis with sera from a 2000-2003 Malian severe malaria case-control study. Our findings suggest that sera from children with severe malaria differed in the number of PfEMP1s recognized depending on the blood type: sera from blood type A severe malaria cases (n=27) recognized 91.6% of PfEMP1 fragments, sera from blood type AB cases (n=7) recognized 21.8% of PfEMP1 protein fragments, and sera from blood type O cases (n=13) recognized 81.6% of PfEMP1 protein fragments. In addition, sera from blood types A, AB, and O severe malaria cases reacted less intensely to 67, 12, and 34 PfEMP1s fragments, respectively, than uncomplicated malaria sera. Analyses investigating the differential serological responses to DBLα1-PfEMP1s are currently ongoing. These findings may inform our understanding of severe malaria pathogenesis and the design of vaccines to protect individuals from severe malaria.

IMMUNOMODULATION OF PREGNANCY-ASSOCIATED MALARIA AND ITS EFFECT ON INFANT IMMUNE RESPONSE AGAINST VACCINE ANTIGENS

Eliana M. Arango Florez[1], Catalina Alvarez Larrotta[1], Olga M. Agudelo Garcia[1], Amanda Maestre[1], Stephanie K. Yanow[2], Jaime Carmona Fonseca[1]

[1]*Universidad de Antioquia, Medellin, Colombia,* [2]*University of Alberta, Edmonton, AB, Canada*

Pregnant women have an increased risk of plasmodial infections. Submicroscopic plasmodial infections (SPI) are a very common finding in pregnant women living in low malaria transmission setting areas. SPI are considered chronic because they are usually asymptomatic and undiagnosed by routine tests (thick blood smear-TBS). In chronic infections, there is persistence of the antigenic stimulus that changes the expression of immune mediators. This promotes constant regulation, including increases in regulatory T cells, which can suppress unrelated immune responses in a non-antigen-specific manner, and cause T cell exhaustion, less robust effector functions and alteration in memory T cell differentiation. This study aimed to evaluate the immunomodulatory effect of plasmodial infection during pregnancy and its association with immune responses generated in infants against five vaccines included in the Colombian immunization plan (tetanus toxoid, hepatitis B, BCG, rotavirus, and pneumococci). Three groups of pregnant women and their infants (6 months old) were evaluated: 1) with SPI at delivery (n=15); 2) with a history of malaria during pregnancy (n=17); and 3) without malaria infection during pregnancy or at delivery (n=25). Malaria infection was diagnosed by quantitative real-time PCR (qPCR) and TBS. The relative expression of mediators associated with inflammation, anti-inflammation, regulation and co-stimulation of the immune response were quantified in peripheral blood of women and infants and placental tissue by qPCR (using the $\Delta\Delta$CT method). The infant serum levels of IgG anti-the five vaccines and of IgA anti-rotavirus were quantified by ELISA. Compared with the uninfected group, SPI at delivery increased the expression of FOXP3 in maternal peripheral blood, of IL10 and IL13 in placental tissue, and of IL10, IL13, FOXP3, TNFRII, and CD163 in infant peripheral blood. Malaria infections at delivery (submicroscopic) and during pregnancy (microscopic) were associated with decreased expression of CD40 in placenta and infant blood, as well as decreased levels of IgG anti-tetanus, rotavirus and pneumococci in 6 month old infants

1644

MATERNAL TRANSFER OF IMMUNOGLOBULIN G AND ITS IMMUNITY AGAINST *PLASMODIUM FALCIPARUM* INFECTION AMONG CHILDREN ENROLLED IN A UGANDAN BIRTH COHORT

Erick Okek

Makerere University, Kampala, Uganda

Pregnant mothers from malaria endemic areas transfer immune IgG to their babies. This paper estimates the efficiency of transfer of the IgG and associates the effects of maternal exposure to amount transferred. To estimate the efficiency of transfer, we ran a total of 583 maternal and cord blood pair using luminex. Each Magpix plate contained 40 pairs of cord and maternal samples. IgG response against a sixteen panel of common *Plasmodium falciparum* antigens were estimated; antigens were coupled with beads in the U.K.Each bead region was pooled in a buffer, mixed with samples to allow binding, several washings done, mixed and incubated with secondary IgG. Amount of antigen-antibody complex was determined by a Magpix machine. Positive control were obtained from adult individuals with history of malaria episodes, negative controls obtained from six Caucasians from the U.K .To determine the effects of maternal malaria incidence, maternal malaria prophylaxes, gravidity and child sex on amount of IgG transfer ,we did multivariate analyses in STATA using data from the mother study. To determine whether the amount of IgG transferred has any association to child malaria incidence,

we did spearman rank and found weak correlation. IgG against PfAMA1 is the most efficiently transferred at about 95%-100%. IgG transfer against most malaria antigens (GLURP, Etramp, MSP, RH5 and EBA) varies between 40% to 100% irrespective of maternal exposure. Children whose mothers had placental malaria had higher IgG response against Etramp, had very little malaria incidence during the first year of life. Maternal malaria prophylaxis, gravidity and sex had very little effects on the amount of IgG transferred. On average, it took a minimal of 3 months for a child to develop the first episode of malaria.PfAMA1 antigens are formed at earlier stages of *P. falciparum* infections thus most individuals will make robust antibodies against it thus facilitating its efficient transfer. This birth cohort was in malaria endemic area meaning almost all participants were exposed to malaria accounting for little effects of malaria incidence during pregnancy on IgG transfer.

CHARACTERIZATION OF DIFFERENCES IN HOST IMMUNE GENE EXPRESSION PROFILE IN MALARIA-PROTECTED AND MALARIA-SUSCEPTIBLE CHILDREN

Gillian Mbambo, Ankit Dwivedi, Kirsten E. Lyke, Joana C. Silva

University of Maryland School of Medicine, Baltimore, MD, United States

Individuals in malaria endemic regions differ in the level of susceptibility to clinical *Plasmodium falciparum* infection, despite comparable exposure. We hypothesize that children with lower susceptibility to malaria exhibit a higher expression of genes involved in the activation of an immune response, or genes that play a role in immune effector function, in response to malaria infection, when compared with more susceptible children. To address our hypothesis, we used Peripheral Blood Mononuclear Cells (PBMCs) collected from Malian children (4-6 years of age) who participated in the control arm of an AMA1-based blood-stage vaccine efficacy study. PBMCs were collected over a transmission season, with samples from the beginning of the malaria season (Day 0), peak malaria season (Day 90) and the end of malaria season (Day 150). Children who experienced no clinical malaria episodes over the course of the malaria season were classified as "protected" whereas age-matched children that experienced two or more clinical malaria episodes were classified as "susceptible". PBMCs were stimulated with *P. falciparum* schizonts (Pfsz), *Staphylococcus aureus* enterotoxin B (SEB) as a positive control, and media as a negative control. We used mass cytometry to quantify phenotype and cytokine production post-antigen stimulation and identified a subset of children with T cell effector response including any combination of TNFα, IL-2, IFNγ transcriptional master cell regulators (Tbet and RORγt). This subset of subjects with cells with malaria antigen recognition is being used to identify differences in gene expression profiles that are associated with patterns of protective immune responses to malaria in malaria-protected vs. malaria-susceptible children. Characterizing differentially expressed genes between protected and susceptible individuals will help identify genes important for protection against malaria infections and further our understanding of the host's immunological response throughout a transmission season.

CHARACTERIZATION OF NATURALLY-ACQUIRED HUMAN ANTIBODIES TO *PLASMODIUM VIVAX* RETICULOCYTE BINDING PROTEIN 2B (PVRBP2)

Christopher L. King[1], Li-Jin Chan[2], Lenore Carias[1], Melanie Dietrich[2], Camila Franca[2], Sebastian Menant[2], Wai-Hong Tham[2]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Walter and Eliza Hall Institute, Melbourne, Australia*

The *Plasmodium vivax* reticulocyte binding protein 2b (PvRBP2b) has recently been identified to play a critical role in restricting parasite invasion into reticulocytes and is a potential vaccine candidate for *P. vivax* malaria. Naturally acquired immunity (NAI) protects against malaria in individuals residing in endemic areas and the passive transfer of antibodies from malaria immune individuals confers protection. A successful vaccine often models an effective immune response by natural infection. Previous studies have shown antibodies to PvRBP2b correlate with protection against clinical vivax malaria. Here we show that *P. vivax* exposed individuals acquire antibodies that block PvRBP2b binding to reticulocytes and monoclonal antibodies (mAbs) obtained from such individuals with NAI replicate this blocking activity. We also report the structure of PvRBP2b in complex with these inhibitory mAbs and identify the blocking epitopes by X-ray crystallography. These studies reveal that naturally acquired human mAbs target PvRBP2b at the binding interface with both human transferrin receptor and transferrin. Studies are currently underway to evaluate whether these human mAbs have evolved to engage polymorphic variants of PvRBP2b, whether these mAbs can block *P. vivax* invasion of reticulocytes, correlate with protection *in vivo*, and if the epitopes recognized by these mAbs are broadly conserved. A compendium of globally conserved epitopes of neutralizing human antibodies enhances the ability to develop strain-transcending RBP- and other Pv invasion ligand-based vaccines and therapeutics against *P. vivax*.

CEREBRAL MALARIA, SICKLE CELL DISEASE AND BURKITT LYMPHOMA: TH1/TH2 CYTOKINE EXPRESSIONS AND CELL ADHESION MOLECULES

Olakunle O. Kassim[1], Muheez A. Durosinmi[2], Samuel K. Martin[3], Gail Hollowell[1], Kwashie A. AkoNai[2]

[1]*Howard University College of Medicine, Washington, DC, United States,* [2]*Obafemi Awolowo University, Ile-Ife, Nigeria,* [3]*Walter Reed Army Research Institute, Washington, DC, United States*

Plasmodium falciparum (Pf) plays a major role in the pathogenesis of cerebral malaria (CM), sickle cell disease (SCD) and Burkitt lymphoma (BL).

We sought to determine the prevalence of immunological factors that are common to all three diseases. Our three study groups consisted of children with CM, SCD and BL who were enrolled at Obafemi Awolowo University Teaching Hospital (OAU) in Ile-Ife, southwestern Nigeria. For these groups and the matched controls, we determined and compared the serum concentrations of endotoxin (LPS), Th1/Th2 cytokines (TNF-α, IL-1, IL-6, IL-10), cell adhesion molecules (ICAM-1 and VCAM-1), EB-VCA and EBNA-1 IgG antibodies and anti-malaria IgG, IgM, IgA and IgG subclasses to a Pf ring stage antigen. Similar determinations were done for serum iron, transferrin, α-1 antitrypsin and α-2 macroglobulin which are protease inhibitors. We analyzed the results for associations between the LPS and Th1/Th2 levels and between EBNA/EB-VCA/Pf antibodies and BL. Results showed that IgM antibodies to the malaria antigen were significantly elevated in BL, SCD and CM. But all the four IgG subclasses were decreased in SCD, BL and SCD. While Th1 and Th2 cytokine levels were 3-10X higher in CM, SCD and BL children than in controls, the highest values came from children with CM. Total serum iron, transferrin and iron binding capacity were significantly decreased in BL and SCD, but with highest decrease in SCD. While there were no differences in EBV-VCA levels for BL and control children, anti-EBNA-1 IgG antibodies were significantly elevated in BL. On the other hand, both ICAM-1 and VCAM-1 levels were twice as elevated in children with BL, SCD and CM. Odds ratio determinations showed an increased risk for BL with combined elevated anti-malaria and EBNA1 IgG antibodies. Dose response curves showed significant correlations between serum LPS and Th1/Th2 cytokines and between TNF-α and ICAM-1 and VCAM-1. The results elucidate the distinct immunological interactions in each of the malaria-associated diseases.

1648

THE EFFECT OF KILLER IMMUNOGLOBULIN-LIKE RECEPTOR GENOTYPE ON MALARIA INCIDENCE AND PARASITEMIA

Jean Digitale[1], Isabel Rodriguez-Barraquer[1], Perri Callaway[1], John Rek[2], Emmanuel Arinaitwe[2], Grant Dorsey[1], Moses Kamya[3], Margaret E. Feeney[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*Makerere University College of Health Sciences, Kampala, Uganda*

Killer cell immunoglobulin-like receptors (KIR) are expressed by malaria-specific effector T cells, and may influence the immune response to malaria. KIR genotypes are highly heterogeneous; little is understood about their relationship to antimalarial immunity. We evaluated the association of KIR genotypes with measures of immunity to malaria. Data were collected from Ugandan subjects enrolled from randomly selected households at 3 East Africa ICEMR sites with a range of malaria transmission. These analyses included 658 children aged 6 months to 10 years and 234 adults with immunogenetic and clinical data. KIR genotypes were determined by sequencing. Outcome data were obtained via routine quarterly follow-up of participants and care-seeking at study clinics when ill. Exposures of interest were KIR haplotype (A vs. B), number of activating KIR genes, and the presence of 9 KIR genes. Outcomes of interest were parasitemia (presence/absence and level, at both routine and ill visits), malaria incidence rate, and probability of symptoms if infected. We estimated multi-level models with random effects at the individual level, controlling for age group and sex. In models of malaria incidence and risk of parasitemia, we also controlled for household mosquito exposure levels. Future planned analyses will incorporate household random effects and HLA class I ligands for each KIR, and will control for multiple testing using the false discovery rate approach. 34% of respondents had Haplotype A; the mean number of activating KIR was 2.19 (SD=1.35). Each additional activating KIR was associated with an 8.5% decrease in parasite density at active malaria visits (95% CI: -16.2%, -0.11%), but not at routine quarterly visits, and did not appear to affect malaria incidence or the probability of symptoms if infected. *KIR2DS1* was protective against malaria incidence (incidence rate ratio: 0.81, 95% CI: 0.68, 0.96, p=0.02), with no effect on other outcomes. The presence of other KIR genes and haplotype (A vs. B) had no effect on any outcomes. The number of activating KIR and presence of *KIR2DS1* may impact parasitemia levels and malaria incidence rate, respectively.

A SERINE PROTEASE HELPS CYTOTOXIC LYMPHOCYTE LYSE INFECTED RBCS AND MANAGE PARASITE DEATH

Gunjan Arora, Javier Manzella-Lapeira, Eric O. Long

National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, Rockville, MD, United States

The morbidity and mortality caused by the malaria parasite *Plasmodium falciparum* occur during the blood-stage of infection. Antibodies acquired through years of exposure to *P. falciparum* can limit parasite replication and protect from malaria symptoms. A potential mechanism for inhibition of *P. falciparum* growth in RBCs is antibody-dependent cellular cytotoxicity (ADCC) by natural killer (NK) cells, which are activated by FcγRIIIa binding to IgG. We have shown that IgG isolated from malaria-exposed Malian adults induced lysis of infected RBCs by primary human NK cells, and inhibited parasite growth. Antibody-dependent NK cell-mediated lysis of RBCs was highly selective for infected RBCs in a mixed culture with uninfected RBCs. The *P. falciparum* antigen PfEMP1, which is expressed on the surface of infected RBCs, was a dominant target of antibodies that promoted NK cell-dependent lysis of infected RBCs and inhibition of *P. falciparum* growth. A human monoclonal antibody to the *P. falciparum* antigen RIFIN, also expressed on the RBC surface, stimulated lysis of RIFIN+ infected RBCs by NK cells, provided the RIFIN antibody carried an intact Fc receptor-binding segment. Cytotoxic granules released by NK cells contain Granzyme B, a potent protease that can effectively lyse infected RBCs and mediate death of intracellular parasite. Lysis of infected RBCs and parasite death can be prevented by inhibiting Granzyme activity. Importantly, ADCC was dependent on Granzyme but not Caspase activation. These results implicate acquired immunity through ADCC by NK cells towards *P. falciparum*-infected RBCs, antibody-based vaccine strategies that target blood-stage malaria parasites should consider this new mechanism of action.

GENERATING LONG-LIVED EFFECTOR/MEMORY T CELLS WITH MOUSE CYTOMEGALOVIRUS VACCINATION TO PROLONG MALARIA IMMUNITY

Komi Gbedande[1], Samad A. Ibitokou[1], Florentin Aussenac[1], Mariapia degli Esposti[2], Michael G. Brown[3], Robin Stephens[1]

[1]*Department of Internal Medicine, Division of Infectious Diseases, University of Texas Medical Branch (UTMB), Galveston, TX, United States,* [2]*Centre for Experimental Immunology, Lions Eye Institute, Nedlands, Western Australia, Australia,* [3]*Department of Medicine, University of Virginia, Charlottesville, VA, United States*

Malaria represents a challenge for vaccine development in part because long-lived T cell responses are required to maintain immunity. Immunity to infection with *Plasmodium spp.* is known to decay; and in mouse models, this decay correlates with loss of malaria-specific T cells. Various effective whole parasite vaccines have been proposed, but long-term protection has been elusive. Our recent work has identified effector T cells (Teff), such as those generated by persistent and recurring *Plasmodium* infections, to provide the best protection from malaria. However, Teff are short-lived; explaining the decay of natural immunity seen on emigration from an endemic area. The aim of the current study is to design a system allowing us to prolong generation of protective Teff. Cytomegalovirus (CMV) is the most successful T cell-inducing vaccine vector to date; and as a chronic virus, it can function as a vector for persistent expression of pathogen epitopes. Therefore, the goal of our novel contribution is to prolong protection by live-attenuated malaria vaccine strategies using chronic vaccination with a mouse cytomegalovirus (MCMV). Our preliminary data shows that MCMV infection protects against *P. chabaudi,* and also activates T cells driving them to an effector phenotype similar to that seen

in response to *P. chabaudi* infection. When we expressed the *P. chabaudi* MSP-1 epitope B5 as an MCMV immediate early gene, (MCMV-B5), we could see proliferation of B5 TCR Tg T cells, which is maintained by MCMV-B5 infection. We are currently testing the MCMV-B5 as a boosting strategy for vaccines that are effective, but shorter-lived in order to prolong immunity to malaria by promoting survival and cytokine production of protective effector T cells. Using MCMV as adjuvant to prolong generation of *Plasmodium*-specific effector T cells, we will also be able to study mechanisms of generation and protection.

1651

TH1 DIFFERENTIATION, BUT NOT ANTIBODY PRODUCTION, CORRELATES WITH PROTECTION FROM REINFECTION IN *PLASMODIUM* INFECTION, AND IS REGULATED BY STAT3 IN T CELLS

Victor H. Carpio[1], Florentin Aussenac[1], Kyle D. Wilson[1], Alexander Dent[2], **Robin Stephens**[1]

[1]*Department of Internal Medicine, Division of Infectious Diseases, University of Texas Medical Branch, Galveston, TX, United States,* [2]*Department of Microbiology and Immunology, Indiana University School of Medicine, Indianapolis, IN, United States*

In response to infection with *Plasmodium spp.*, IFN-γ^+ T helper-1 (Th1) cells drive control of parasite by phagocytosis, while IL-21$^+$ T follicular helper (Tfh) cells promote clearance by antibodies. Our data show that rather than separate subsets, many effector T cells maintain a hybrid Th1/Tfh phenotype (IFN-γ^+IL-21$^+$CXCR5$^+$) throughout infection. Although the germinal center appears with delayed kinetics, a small but stable fraction of GC-Tfh (CXCR5^{hi}PD-1^{hi}) is present, supporting reports that Tfh in malaria are less functional due to inflammatory cytokines. Persistence of parasite drives the hybrid phenotype, as early drug-cure reduced the hybrid Th1/Tfh phenotype, increasing Th1-like cells (IFN-γ^+IL-21$^-$CXCR5$^-$). We investigated the molecular regulation of Th1/Tfh T cells and found that CD4-intrinsic Bcl6, Blimp-1 and STAT3 coordinately regulate T-bet expression. Upon infection of mice deficient in the Th1 master regulator, T-bet, CD4 T cells made very little IFN-γ, and 40% of the animals died. Although Bcl6 can bind T-bet, bcl6 and Blimp-1 mainly regulate the level of CXCR5 on hybrid T cells. T cell specific deficiency of Tfh-promoting transcription factor, STAT3 (STAT3 TKO) had a more profound effect. Infected STAT3 TKO mice showed a decrease in the hybrid Tfh/Th1 phenotype, with a concomitant increase in Th1 cells. Strikingly, and despite reduced antibody production, STAT3 TKO mice were completely protected from reinfection. T-bet deficient mice, which had no Th1 memory differentiation, took longer to control parasite re-challenge; reinforcing the interpretation that the improved Th1 response was protective in re-challenge. In summary, the data demonstrate that T cell intrinsic STAT3 regulates the plastic differentiation state of mixed-lineage Th cells in persistent infection, and can determine the outcome of infection. While the host cytokine response to *Plasmodium* infection is surely highly evolved to optimize outcomes for both the parasite and the host, this mechanistic knowledge suggests the feasibility of manipulating immune responses towards better outcomes in malaria.

Transmission blocking vaccines (TBV) for malaria provide an additional tool to limit the spread of malaria. Pfs25 and Pfs230 are among the two leading antigens that have been used to make conjugate vaccines and are the only TBVs to have been tested in malaria endemic countries using either Alhydrogel® or AS01 as the adjuvant. Both vaccines induce functional antibodies that can prevent development of Pf in the mosquitoes. Efficient antibody production by B cells requires interaction with a specialized subset of CD4 T cells called T follicular helper (Tfh) cells that produce IL-21 and can be identified by their expression of the homing marker CXCR5. The current study explored the dynamics of circulating Tfh cells during a small pilot study in healthy Malian adults that were vaccinated with either conjugated Pfs25-EPA/AS01, Pfs230-EPA/AS01, both Pfs25-EPA/AS01 and Pfs230-EPA/AS01 vaccines or a comparator vaccine at a 0, 1 and 6 month schedule. The levels of circulating Tfh cells were measured in real-time with a simple whole blood *ex vivo* assay using flow cytometry. Circulating Tfh cells were defined as CD4 T cells that co-expressed CXCR5 and PD1. The results showed that the levels of circulating Tfh cells were similar in subjects that received either the Pfs25, Pfs230 or both vaccines.

HOSPITAL-DERIVED ANTIBODY PROFILES OF MALARIA PATIENTS IN SOUTHWEST INDIA

Apoorva Venkatesh[1], Aarti Jain[2], Huw Davies[2], Ligia Periera[3], Jennifer Maki[3], Edwin Gomes[4], Phillip L. Felgner[2], Sanjeeva Srivastava[1], Swati Patankar[1], Pradipsinh K Rathod[3]

[1]*Indian Insitute of Technology, Mumbai, India,* [2]*University of California Irvine, Irvine, CA, United States,* [3]*University of Washington, Seattle, WA, United States,* [4]*Goa Medical College and Hospital, Bambolim, India*

Naturally acquired immunity to malaria across the globe varies in intensity and protective powers. In Asia, particularly in India, there are unique opportunities for exploring and understanding malaria immunity relative to host age, co-occurrence of *Plasmodium falciparum* and *P. vivax* infections, varying travel history, and varying disease severity. A US NIH ICEMR (South Asia) team examined the level of immunity in an Indian malaria patient population at a tertiary care hospital in Goa, India. Sera from 200 patients of different ages, in different seasons, infected with *P. falciparum* or *P. vivax* or both species, and with different clinical severity were applied to an established protein array system with over 1,000 *P. falciparum* and *P. vivax* antigens. Differential binding of patient IgG to different antigens was measured. IgG reactivity towards *P. falciparum* antigens was very strong. Of 248 seropositive *P. falciparum* antigens, the strongest were VAR, MSP10, HSP70, PTP5, AP2, AMA1, and SYN6. In *P. vivax* patients, ETRAMPs, MSPs, and ApiAP2, sexual stage antigen s16, RON3 were the strongest IgG binders. Both *P. falciparum* and *P. vivax* patients also revealed strong binding to new antigens with unknown functions. Seropositives showed antigens unique to the young (HSP40, ACS6, GCVH) or to non-severe malaria (MSP3.8 and PHIST). Together, these studies confidently help define antigens for surveillance and possibly for disease protection, in many different parts of India and the world.

1654

PROTECTION-ASSOCIATED IMMUNE RESPONSES FOLLOWING VACCINATION WITH RADIATION-ATTENUATED *PLASMODIUM FALCIPARUM* SPOROZOITES

Nina Hertoghs[1], Katharine V. Schwedhelm[2], Ying Du[1], Fergal Duffy[1], Stefan H. Kappe[1], M. Juliana McElrath[2], Stephen C. De Rosa[2], Kenneth D. Stuart[1]

[1]*Seattle Children's Research Institute, Seattle, WA, United States,* [2]*Fred Hutchinson Cancer Research Center, Seattle, WA, United States*

Vaccines that prevent malaria infection would be valuable tools in the effort to eliminate and eradicate malaria, a disease that each year results in over 200 million cases and approximately 400,000 deaths. Radiation-attenuated sporozoites (RAS) have been established to confer sterilizing protection, although the mechanism behind this protection is incompletely understood. *In vivo* animal studies have provided some mechanistic insight into how anti-malarial immunity is achieved, although some of these mechanisms are challenging to study in humans. This project aims to understand protective anti-malarial immunity in humans and in this way, aid the development of a malaria vaccine. To this end, we performed immunological analyses of samples from clinical trials in which volunteers were vaccinated with *Plasmodium falciparum* RAS and whose protection from malaria infection was assayed by controlled human malaria infection (CHMI). Blood samples collected at multiple timepoints during the immunization schedule and after CHMI were analyzed to compare immune responses between protected and non-protected volunteers using whole blood RNAseq and flow cytometry on PBMCs. The RNAseq analysis includes responses of at least 13,000 genes at each time point and identified vaccine induced changes in the expression levels of numerous genes of which a proportion correlated with protection. Furthermore, three flow cytometric staining panels were developed, and an existing panel was optimized by using BD FACSymphony technology which can analyze up to 28 markers in each panel. Together, these four panels cover all major arms of the immune system and give a unique opportunity to broadly characterize vaccine-induced immune responses and how these develop over time. Additionally, these data help to assess whether the transcriptomic changes reflect changes in the immune cell composition of the blood due to cell trafficking or proliferation. The flow cytometric and RNAseq data are being integrated to provide insights into specific cell types and processes that are involved in the vaccine-induced protection and to guide further malaria vaccine development.

1655

PROTECTIVE ANTIGENS AND ANTIBODIES DURING THE PRE-ERYTHROCYTIC STAGE OF MALARIA

Rahwa A. Osman, Suzanne McDermott, Kenneth D. Stuart

The Centre for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States

Malaria causes over 200 million cases and 445,000 deaths globally every year. A highly efficacious vaccine that prevents infection is an urgently needed tool to combat this situation. Immunization with liver-stage arresting, radiation-attenuated *Plasmodium falciparum* sporozoites (PfRAS) confers sterilizing protection. In addition, high anti-malaria antibody titers have been previously shown to be important for protection. These findings indicate that adaptive immune responses induced by malaria antigens during the pre-erythrocytic (PE) stage of the *P. falciparum* life cycle are suitable targets for better vaccine design. However, the protective antigens and antibodies associated to this protection are still unknown. To identify these elusive antibodies and cognate PE antigens, we are using samples from PfRAS vaccine trials in which protection was determined by Controlled Human Malaria Infection (CHMI) in combination with state-of-the-art molecular immunological approaches. We are identifying and characterizing B-cell receptor repertoires that are associated with protection using next generation sequencing of single chains as well as natively paired heavy and light chains. We expect these studies will identify protective antibodies, and clonal diversity and frequency associated with protection following malaria vaccination. To identify protective antigens, we are generating yeast antigen display libraries that comprehensively represent the *P. falciparum* proteome. We will screen these libraries with serum samples from protected individuals following PfRAS immunization and CHMI. Thus, our work will inform and improved vaccine design approaches and expand our knowledge of protective malaria antigens and host antibodies, as well as providing important tools to further malaria research.

ENSEMBLE MODELING FOR PRECLINICAL ANTIMALARIAL DRUG DEVELOPMENT: PROVIDING MECHANISTIC INSIGHTS INTO PARASITE-HOST BEHAVIOR

Lydia Burgert[1], Matthias Rottmann[1], Sergio Wittilin[1], Andreas Krause[2], Nathalie Gobeau[3], Joerg Moehrle[3], Melissa Penny[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*Idorsia Pharmaceuticals Ltd, Basel, Switzerland,* [3]*Medicines for Malaria Venture, Geneva, Switzerland*

Emerging drug resistance and late stage drug attrition fuel the need to search for new antimalarial compounds to be used in combination therapies. Host-parasite dynamics and their interactions with drugs are important to understand throughout the antimalarial drug development process to facilitate meaningful translation of results between and within clinical stages and thereby speed up the development process. Using an ensemble of mechanistic within-host parasite growth and antimalarial action models we assessed host-parasite interactions in the two main preclinical drug testing systems of murine parasite: *P. berghei* in normal mice and human parasite *P. falciparum* in immunodeficient NOD $^{scidIL\text{-}2R'c\text{-}/\text{-}}$ (SCID)-mice. Control and treatment data of four different antimalarials (ACT451840, Chloroquine, MMV390048 and OZ439) from three different laboratories were used to compare drug action between pre-clinical experimental systems. We identified changes in the ability of the parasite to infect erythrocytes as a driver of differences in parasite growth patterns observed between experiments and laboratories. We found that properties of the host-parasite system such as growth, clearance characteristics and resource availability are mainly driving *P. berghei* infection. In contrast, experimental set-up in SCID mice (e.g. human erythrocyte injections) replaces many host functions and therefore influences *P. falciparum* behavior and thus drug action. A comparison of drug efficacy parameters between host-parasite systems did not allow a direct translation of drug action between experimental systems. Additionally, we identified the importance of understanding parasite recrudescence behavior following non-curative treatment and elucidate potential pitfalls for human equivalent dose prediction. We conclude that additional parasite behavior such as parasite dormancy or changes in growth behavior might play an important role in explaining observed parasite recrudescence patterns. Taken together, our findings demonstrate the need of assessing the clinical relevance of gained mechanistic insights for human dose prediction.

1657

DEFINING MINIMAL TARGET PRODUCT PROFILES OF NEW MALARIA INTERVENTIONS: A MODELLING STUDY

Melissa A. Penny[1], Guojing Yang[1], Flavia Camponovo[1], Nakul Chitnis[1], Ewan Cameron[2], Monica Golumbeanu[1]

[1]*Swiss Tropical and Public Health Insitute, Basel, Switzerland,* [2]*Big Data Institute, Oxford, United Kingdom*

Delivery strategies and profiles of new malaria interventions for control and elimination will necessarily differ from those of existing interventions. Modelling and simulation provides understanding of how interventions interact to reduce malaria in different epidemiological settings without the need to test all combinations of interventions in the field. However, models to date have generally only been used at specific stages of development, rather than in generating evidence for decision-making along the whole development pathway. We present a new approach to use models and machine learning to identify key determinants of intervention impact

and thus aid decision making and more efficient resource allocation in the development of new interventions. Our framework 1) provides a new approach for using complex models to answer questions for product development; 2) guides thinking on operational, health system, or intervention factors determining impact and thus define the minimal profile of interventions for different settings; and 3) provides a way to iterate the precision of optimal profiles of new interventions as further detail becomes available. We applied our framework to many novel malaria interventions currently in development targeting different parasite and/or vector targets for a range of follow-up time points and delivery modalities. We found that at very low transmission, increasing levels of effective case management with existing or new interventions is likely to be core for facilitating further burden reduction. Conversely, for all other settings, coverage, rather than intervention efficacy, is the main driver of impact. While for some interventions high coverage deployment, or increasing efficacy, might be difficult or impossible to achieve, our analysis shows that this can be alleviated through deployment of interventions in combination, targeting different parts of the parasite or vector life-cycle. In addition, increasing the frequency of deployments can dramatically decrease the minimum coverage or minimum target product profile required in order to achieve different health goals.

PLASMODIUM VIVAX LACTATE DEHYDROGENASE IN INDUCED BLOOD STAGE MALARIA INFECTION: UNDERSTANDING BIOMARKER DYNAMICS FOR THE PURPOSE OF MALARIA ELIMINATION

Sumudu Britton[1], Lachlan Webb[1], Deborah Akinlotan[1], Ihn K. Jang[2], Bridget Barber[1], Ellie Sherrard-Smith[3], Kim Piera[4], Anstey Nicholas[4], Gonzalo J. Domingo[2], McCarthy S. James[1]

[1]*QIMR Berghofer Medical Research Institute, Brisbane, Australia,* [2]*PATH, Seattle, WA, United States,* [3]*Imperial College London, London, United Kingdom,* [4]*Menzies School of Health Research, Darwin, Australia*

Current rapid diagnostic tests (RDTs) based on lactate dehydrogenase (LDH) lack sufficient sensitivity to reliably diagnose *Plasmodium vivax* infection. A model of biomarker dynamics would inform optimisation of this assay as well as the development of new biomarkers for improved *P. vivax* RDTs for malaria elimination. We aimed to measure key assay parameters to develop a mathematical model of the dynamics of LDH during *P. vivax* infection. Eight malaria-naïve subjects from a *P. vivax* induced blood stage malaria study had blood samples collected at inoculation, and at sequential time-points up to and following treatment with chloroquine. Parasite density was measured by 18S qPCR; *P. vivax* LDH (PvLDH) was measured using the Quansys ELISA twice-daily to 3 days post treatment, and then daily until 5 days post treatment. We used data from 7 subjects who had sufficiently measurable levels of PvLDH to calculate a log-linear decay rate of LDH, and then converted this rate into an elimination half-life. The mean elimination half-life of PvLDH was 16 hours (range 12.6- 19.8). The correlation between parasitemia and PvLDH was 0.89 (95%CI 0.84-0.93). The observed level of PvLDH at any given time point was 0.37 pg/parasite (95% CI 0.346-0.398). Parasitemia and PvLDH appeared to follow out-of-phase 48-hour patterns. When a 24-hour lag was introduced to PvLDH in order to better model, the time pattern, the correlation between parasitemia and PvLDH was stronger ($r = 0.94$, 95%CI 0.91-0.96), which suggests a stage-specific or time-dependent relationship that will require explanation. Our study found a shorter PvLDH elimination half-life than previously described, which may contribute to the poor sensitivity of RDTs as a result of rapid clearance. We also found a strong correlation between parasitemia and PvLDH. We are now using key parameters identified in this study (half-life of PvLDH and the correlation between parasitemia and PvLDH) to develop a mathematical model to describe the dynamics of within-host parasite growth, and PvLDH production and decay over the course of a *P. vivax* infection.

PREDICTING MALARIA ELIMINATION USING MATHEMATICAL MODELLING AND MACHINE LEARNING

Theresa Reiker, Monica Golumbeanu, Munir Winkel, Emilie Pothin, Nakul Chitnis, Thomas A. Smith, Melissa Penny

Swiss Tropical and Public Health Institute, Basel, Switzerland

Over the last decade, malaria transmission has decreased in many settings, and for some countries the strategic aim has shifted to elimination. An open question in planning is how to predict the probability of elimination in a given setting with a given set of interventions. Modelling and simulation provide crucial guidance in understanding potential intervention impact and determining optimal strategies. With recent computational advances, most applied modelling work is based on complex computer simulations. Nonetheless, predicting the probability of elimination for a specific strategy remains difficult, as this is inherently based on model and intervention assumptions as well as population sizes. Elimination is a binary, highly stochastic event and when many possible interventions are considered, elimination probabilities are difficult to derive. Here, we propose adding machine learning methods to current methods of simulation as an additional step in predicting disease progression and the impact of interventions. Specifically, we discuss definitions of elimination in the presence of importation and the implication for predictions/ interpretations, sampling approaches (full factorial; Latin hypercube; adaptive), and the use of, and performance of different machine learning emulators (especially Gaussian Processes) on top of simulation results to convert binary outcomes into probabilities. We provide a general framework to assist in setting up a modelling study and incorporating machine learning methods for predicting elimination of malaria. This framework is also applicable to other infectious diseases.

COST ANALYSIS OF MALARIA CONTROL AND ELIMINATION ACTIVITIES IN HETEROGENEOUS MALARIA TRANSMISSION AREAS OF MYANMAR

Kyaw Myint Tun[1], Ann Levin[2], Zaw Tun Win[1], Bo Bo Thet Ko[1], Thant Zin Aung[1], Sway Minn Htet[1], May Aung Lin[1], Taylor Price[3], Hala Jassim AlMossawi[3], Sara Oliphant[3], Zaw Wutt Hmone[1], Neeraj Kak[3]

[1]*University Research Co., Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar,* [2]*Levin & Morgan, LLC., Bethesda, MD, United States,* [3]*University Research Co., LLC, Chevy Chase, MD, United States*

PMI's Defeat Malaria project is being implemented in 31 townships of 3 States/Regions and has contributed to a significant decline of malaria incidence through the implementation of proven interventions. The resulting epidemiological picture is becoming increasingly heterogeneous, ranging from nearly malaria-free zones to *foci* of persistent transmission, thus requiring the deployment of both control as well as elimination activities. The cost analysis of malaria control activities, with considerations for potential elimination activity costs, is important for projecting resource requirements of interventions in heterogeneous malaria transmission settings. For this purpose, both financial and economic costs of Defeat Malaria were estimated, separated into recurrent and capital costs, and micro-costing and sensitivity analysis were conducted. The cost estimates were based on current project costs and case scenarios of initial malaria elimination activities conducted in low transmission areas. The estimated annual financial and economic direct costs in 2017 per Defeat Malaria output - cost per village malaria worker (VMW), per person tested, and per person treated - were $1,276 and $1,633 per VMW, $14 and $18 per person tested, and $710 and $909 for person treated, respectively. The annual cost for malaria control per VMW ranged from $1,146 to $2,282, considering the costs of training, supervision, monthly meetings, and incentives. The main cost drivers were monitoring/supervision and surveillance (i.e. monthly township meetings and data analysis), comprising over 40% of the total costs, followed by diagnosis, treatment, and

training. Sensitivity analysis revealed that the cost per VMW declines as more VMWs are added to the program, since there are several fixed costs associated with the program. Some approaches to lowering the cost of monthly meetings were examined. The findings from this study will serve as a baseline analysis for estimating the costs of malaria elimination activities, and developing an investment case showing the benefits of investing in malaria control and elimination compared to counterfactual scenarios

MODELING *PLASMODIUM FALCIPARUM* INFECTION IN AN IMMUNOCOMPROMISED JUVENILE MOUSE MODEL

Jeanine A. Ursitti[1], Biraj Shrestha[2], Amed Ouattara[2], Matthew Adams[2], Christopher V. Plowe[3], Mark A. Travassos[2], Steven A. Fisher[1]

[1]*Departments of Medicine and Physiology, University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States,* [3]*Duke Global Health Institute, Duke University, Durham, NC, United States*

Cerebral malaria, caused by infection with *Plasmodium falciparum*, leads to the deaths of hundreds of thousands of children under the age of 5 years, predominantly in Africa, each year. Binding of infected erythrocytes to the endothelial protein C receptor (EPCR) and other putative receptors, with subsequent sequestration of parasites in the brain vasculature, has been proposed as critical to pathogenesis. The limitations of current *in vivo* models, however, have hindered testing this hypothesis and developing new therapies. The goal of our experiments is to develop a novel model to specifically study the blood stage of *P. falciparum* malaria by injecting *P. falciparum* infected RBCs (iRBCs) into immune deficient juvenile mice (NBSGW, NOD.Cg-*KitW-41J Tyr* $^{+}$ *Prkdcscid Il2rgtm1Wjl*/ThomJ). Control (CON) and *P. falciparum* infected human RBCs (iRBCs; strain HB3var03) were cultured and labeled with the fluorophore CFDA-SE just prior to injection. Juvenile mice, at postnatal day 12-14, were injected intraperitoneally with a single aliquot of CON and iRBCs (100 µl, 7% parasitemia) and assayed at 4h and 24h post-injection. qPCR of blood samples showed that this approach yielded significant levels of HuRBCs in the blood (HBB gene; n=11 with n=6 positive, average= 0.09% human RBC hematocrit and range=0.001-0.296) and detectable parasitemia at 4h and 24h (Plasmepsin IV gene; n=11 with n=6 positive, average=0.031% and range=0.004-0.07). Histological assays showed aggregates of the fluorescently labeled iRBCs in brain and lung blood vessels of mice treated with iRBCs, but such aggregates are considerably lower in samples from CON injected mice. We conclude that IP injection of *P. falciparum* iRBCs into immunocompromised juvenile mice results in significant and persistent "blood humanization" and parasitemia. This technique may provide a novel model by which to test *P. falciparum*-genotype/disease-phenotype correlations using field samples as well as to study the pathogenesis of cerebral malaria and new therapies. We are continuing to test additional aspects of this model including humanization of the immune system.

ANTIMALARIAL DRUG-RESISTANCE EVOLUTION DURING AND AFTER MASS DRUG ADMINISTRATION

Maciej F. Boni, Thu N-A Tran, Tran Dang Nguyen

Pennsylvania State University, University Park, PA, United States

Mass drug administration (MDA) of antimalarial drugs in malaria-endemic areas may be critical for helping near-elimination regions reach elimination. One concern in MDA implementation is insufficient participation of residents in a given transmission area, which may result in incomplete elimination and a subsequent rebound of malaria prevalence. A second potential concern (addressed here) is that MDA may have unexpected or detrimental effects on drug-resistance evolution. Using a previously developed individual-based stochastic mathematical model for *P. falciparum*, we evaluate certain drug-resistance consequences when dihydroartemisinin-piperaquine (DHA-PPQ) is used for MDA in populations of 40,000 and 300,000 individuals, with approximately 80% population participation in the MDA. The first-line drug for uncomplicated falciparum malaria in this population is assumed to be artemether-lumefantrine. We highlight three results from our study. First, MDA creates a genetic bottleneck, which introduces a large amount of unpredictability for genotype frequencies associated with drug resistance. This bottleneck tends to promote genotypes resistant to DHA-PPQ, but real-world results in small populations like this will always be stochastic and highly variable. Second, importation of artemisinin-resistant *kelch13* genotypes is associated with MDA failure. With low importation of *kelch13* resistant genotypes, the bottleneck effect is weak and MDA can succeed in low-transmission regions; with high levels of importation, *kelch13* mutants tend to fix in the period immediately following the bottleneck, leading to scenarios with 100% fixation of artemisinin-resistant genotypes. Third, the simplest solution to avoiding uncertainty during the post-MDA bottleneck is to repurpose the public health infrastructure put into place for the MDA and increase treatment access for the general population post-MDA. With increased treatment access (ITA), the probability of local elimination of *P. falciparum* increases in low-transmission regions ($PfPR_{2-10} < 2\%$); this result holds under high and low drug-resistance importation scenarios.

1663

THE ROLE OF DRUG QUALITY IN THE EMERGENCE AND TRANSMISSION OF ANTIMALARIAL RESISTANCE

Aleisha Brock[1], Joshua V. Ross[1], Adrian Esterman[1], Sunil Parikh[2]

[1]*University of South Australia, Adelaide, Australia,* [2]*Yale School of Public Health, New Haven, CT, United States*

The emergence and transmission of antimalarial resistance is hampering malaria eradication efforts and shortens the useful therapeutic life of currently available antimalarials. Drug selection pressure has been identified as a contributing factor; in particular, the population treatment coverage and subtherapeutic concentrations of active pharmaceutical ingredient (API) in the bloodstream. Poor quality antimalarial medicine can be a source of subtherapeutic doses of antimalarial API(s). The aim of this research was to investigate the impact of poor-quality antimalarial treatments and non-recommended quality assured monotherapies on the (i) emergence and/or (ii) transmission of the double *dhfr* mutant, associated with low-to-moderate levels of pyrimethamine resistance. Deterministic mathematical models were developed, with sensitivity analyses and validation methods used to test the models. The use of full and half dose pyrimethamine were used as a proxy to represent poor quality antimalarial use, and artemether-lumefantrine was used as a proxy to represent good quality antimalarial use. Key findings identified that the use of poor quality antimalarials provide a favourable environment for the emergence of resistance, and increase its transmission. The shortest time to the emergence of resistance occurred with the exclusive use of half dose pyrimethamine 193 days after the introduction of pyrimethamine treatment - a 54% reduction compared to baseline. The largest impact on the transmission of resistance was identified with the exclusive use of full dose pyrimethamine, resulting in 777% more malaria cases and an increase in the proportion of resistant infections by 18%, compared to baseline. In comparison, the exclusive use of half dose pyrimethamine resulted in 559% more malaria cases and 14% more resistant infections, compared to baseline. Findings for the triple *dhfr* mutant will additionally be presented. These models are the first to explore the impact of poor-quality antimalarial medicines on the emergence and transmission of resistance, providing insight into this important area of malaria control.

QUANTIFYING MALARIA ACQUIRED DURING TRAVEL AND ITS ROLE IN MALARIA ELIMINATION ON BIOKO ISLAND

Daniel T. Citron[1], Carlos A. Guerra[2], Guillermo A. García[2], Sean L. Wu[3], Su Yun Kang[4], Katherine E. Battle[4], Harry S. Gibson[4], David L. Smith[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Medical Care Development International, Silver Spring, MD, United States,* [3]*University of California, Berkeley, CA, United States,* [4]*University of Oxford, Oxford, United Kingdom*

Over the past fifteen years, malaria burden on Bioko Island in Equatorial Guinea (EG) has decreased significantly. Despite extensive ongoing control and elimination efforts on Bioko, further progress towards elimination appears to have slowed in recent years. This includes apparently persistent malaria in the capitol city of Malabo, an urban area with few viable vectors. Past studies have shown that people traveling from mainland EG to Bioko are infected at a significantly higher rate than people traveling from Bioko to mainland EG, suggesting that infections acquired off-island may be an important factor explaining the persistence of malaria on Bioko. Beginning with data assembled from four island-wide malaria indicator surveys conducted in 2015-2018, we used a combination of mapping methods and mechanistic models to estimate the geographical distribution of malaria infections; estimate the influence of infections acquired during off-island travel; and investigate whether deploying additional interventions could reduce on-island prevalence to zero. We first mapped malaria prevalence and its relationship with recent off-island travel using a Bayesian geostatistical framework, discovering an elevated malaria risk among those who had recently traveled to mainland EG. We supplemented this initial analysis with a mechanistic model of malaria transmission to quantify the influence of off-island transmission. We discovered that infections occurring off-island were sufficient to explain a large fraction of cases mapped on Bioko, particularly among the residents of Malabo. Lastly, we used a simulation model of malaria transmission and human travel behavior, calibrated to the survey data and geostatistical maps, to evaluate the potential impact of adding mass treatment or vaccination to the current package of interventions on Bioko Island. We found that the influence of off-island transmission was too strong for additional on-island treatments to be effective in further reducing malaria prevalence, but that interventions to reduce off-island transmission could be more effective in the long term.

1665

THE ECONOMIC IMPACT OF SUBSTANDARD AND FALSIFIED ANTIMALARIAL MEDICATIONS IN NIGERIA

Sarah Laing[1], Sarah Beargie[1], Colleen Higgins[1], Daniel Evans[2], Daniel Erim[3], Sachiko Ozawa[1]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*Duke University, Durham, NC, United States,* [3]*RTI International, Durham, NC, United States*

Nearly 20% of antimalarials in low- and middle-income countries (LMICs) have been found to be substandard or falsified (SF). SF antimalarials can have a detrimental impact on health, with the potential to contribute to antimalarial resistance (AMR) and impose adverse economic burden on patients and the health system. Nigeria has the highest burden of malaria in the world, accounting for 19% of malaria mortality largely among children. We estimated the health and economic impact of SF antimalarials on children under five in Nigeria by developing an agent-based SAFARI (Substandard and Falsified Antimalarial Research Impact) model. The model simulated children with background characteristics, malaria infections, patient care-seeking, disease progression, treatment outcomes, and estimated their incurred costs. Model inputs for Nigeria were informed by epidemiologic, demographic, cost, and pharmaceutical data from the literature. We estimated the impact of SF malaria medicines, antimalarial resistance, as well as possible interventions and policy scenarios such as improving adherence, educating more people to seek care or removing stock-outs from different sectors. Our results demonstrated that SF antimalarials contribute to 16% (12,300) of malaria deaths and 11% (US $892 million) of annual costs in Nigeria. If AMR were to develop, we simulated that the burden of malaria could increase by 7,700 deaths (10%) and add $839 million (11%) in costs. In our regional analysis, both the health and the economic impact of SF medicines in the northern region (9,700 deaths, $698 million) were more than triple that of the southern region (2,700 deaths, $193 million). Interventions that produced the greatest cost-savings were the elimination of stock-outs in all sectors ($1.1 billion) and removing SF antimalarials ($892 million). The results highlight the significant health and economic burden of poor quality antimalarials in Nigeria. In order to reduce the burden of malaria and prevent antimalarials from developing resistance, policymakers and donors must recognize the threat and implement interventions to combat the impact of SF antimalarials.

SPATIAL COVARIATE-BASED CONSTRAINED RANDOMIZATION OF MALARIA INTERVENTIONS

Kathryn Colborn[1], Thomas Eganyu[2], Humphrey Wanzira[2], Ronald Mulebeke[2], Fred Bukenya[2], Richard Elliot[3], Adoke Yeka[4], Dorothy Echodu[2]

[1]*University of Colorado Denver, Aurora, CO, United States,* [2]*Pilgrim Africa, Kampala, Uganda,* [3]*Boise State University, Boise, ID, United States,* [4]*Makerere University, Kampala, Uganda*

A two-year cluster-randomized comparative effectiveness trial of two different community case management interventions in NE Uganda employs a novel technique for cluster randomization of spatially constrained areas. The potential for contamination of treatments due to spatial proximity of villages and the potential for vector flight between different intervention areas required us to develop a spatially explicit cluster randomization methodology for this study. We describe a design framework for randomizing 55 villages in a rural area of Uganda to one of two interventions, proactive integrated community case management (ProCCM) or integrated community case management (iCCM). We first assigned villages to geographically contiguous clusters that could then be randomized to receive either the ProCCM or iCCM intervention using *k*-means clustering. We used the sum-of-squares of Euclidean distances between the village centroids to determine the ideal number of clusters. This yielded 8 total clusters, which resulted in 70 possible randomizations. We then applied the covariate-based constrained randomization (CCR) of clusters methodology described by Moulton *et al*. CCR restricts the choices of randomizations to those that yield acceptable balance between the two arms with respect to important cluster-level confounders. The confounders we considered in this randomization included: baseline malaria prevalence by microscopy, household density, population density, whether or not the cluster bordered lake Bisina, and sub-county (there were 2 sub-counties in this study area). We used a cut-off of the top 12 randomizations according to balance scores and chose one of these randomizations at random. This randomization achieved high balance with respect to baseline confounders across the arms. We are exploring other types of spatial clustering methods for this framework as well as optimizing CCR using variable weighting. This methodology is important for spatially correlated outcomes, such as vector-borne disease prevalence, where human and vector mixing could potentially contaminate the interventions.

Tumeremo, Bolivarian Republic of Venezuela, [4]Global Development One, Silver Spring, MD, United States, [5]Universidad Central de Venezuela, Caracas, Bolivarian Republic of Venezuela

Coincident with accelerating economic decline, the incidence of malaria in Venezuela has risen sharply over the last decade, from approximately 50,000 cases in 2010 to more than 500,000 cases in 2017. As a result of internal migration to the Bolívar state for subsistence illegal gold mining and emigration to neighboring countries for better economic opportunities, the malaria crisis in Venezuela threatens to destabilize and reverse regional progress towards malaria elimination. Although incidence patterns themselves are clear about the severity of this situation, it is unclear what these patterns imply about the feasibility of reversing the dramatic rise of this epidemic. To provide a quantitative basis for the development of plans to confront this epidemic, we used a dynamic transmission model to estimate the reproduction number of the disease, *R*, over time and across space. The effect size–1/*R*–provides an estimate of the level of effort required to push *R* below 1 and the parasite toward local elimination. To characterize the trend in *R* and the effect size over time and across space, we fitted our transmission model to weekly incidence data in each municipality of the Bolívar state from 1995 to 2018. After accounting for effects of seasonality, human mobility and migration, and recrudescing and relapsing infections, our fitted model estimated that *R* has risen only slightly above 1 over the 24-year time period, despite the sharp increase in incidence. The relatively high effect sizes in Bolívar state, which is the epicenter of the epidemic, suggest that appropriately targeted control efforts could result in a proportionally large reduction in transmission. Based on this data-driven approach, our results indicate that the malaria epidemic in Venezuela can be reversed, should the resources and effort to confront this crisis be mobilized in a timely manner.

Chan School of Public Health, Cambridge, MA, United States, [7]Harvard University, Cambridge, MA, United States*

In the last decade, the availability of new genetic data, driven both by advances in sequencing technology and surveillance from operational efforts, has greatly furthered our understanding of the evolutionary processes and transmission dynamics exhibited by *Plasmodium falciparum*. We combine genomics with epidemiology in a mechanistic model designed to both simulate changes in diversity at the population level and to track the movement of individual strains. We apply this model to genetic data obtained from malaria infections in Thiès, Senegal, over the past 11 years to evaluate spatial and temporal changes in infections. Thiès is a malaria-endemic setting that has seen an overall decline in malaria incidence since 2006 from > 100/1000 to < 10/1000. We corroborate previous results and extend the model to incorporate GPS data and timestamps. The model is calibrated via approximate Bayesian computation, using a kernel density estimator that allows us to evaluate non-Gaussian likelihoods. We analyze the simulations to extract spatiotemporal features that can inform intervention strategies. In particular, we show that a decline in the complexity of infection over a season is a natural consequence of the seasonal variation in transmission. We also use principal component analysis to reveal spatiotemporal correlations between related infections and show that there is a characteristic speed at which strains can propagate in an endemic city. These two insights indicate that iterative and targeted genetic surveillance can greatly increase the informational content of resource-limited data. We build on these results to construct a new model for malaria in Senegal at the national scale and across multiple levels of transmission, which will enable us to identify potential gaps in surveillance strategies. Furthermore, through this work, modeling transmission dynamics and patterns of parasite infections will facilitate intervention stratification and targeting toward malaria elimination.

1669

A METHOD FOR SELECTIVE ENRICHMENT OF *PLASMODIUM FALCIPARUM* GENOMIC DNA FROM DRIED BLOOD SPOTS OF PATIENTS WITH MALARIA INFECTIONS FROM THE PERUVIAN AMAZON

Andry Mavila[1], Paulo Manrique[2], Juan Carlos Castro[3], Christopher Delgado-Ratto[4], Dionicia Gamboa[5], Oscar Nolasco[2]

[1]*Centro de Investigaciones de Recursos Naturales de la Amazonía (CIRNA), Iquitos, Peru, [2]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Centro de Investigaciones de Recursos Naturales de la Amazonía (CIRNA)/Departamento Académico de Ciencias Biomédicas y Biotecnología, Facultad de Ciencias Biológicas, Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [4]Global Heath Institute, University of Antwerp, Antwerp, Belgium, [5]Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía/Instituto de Medicina Tropical "Alexander von Humboldt," Universidad Peruana Cayetano Heredia, Lima, Peru*

Malaria is one of the most important public health problems in Peru specially in the Loreto region which encloses most of the cases (97% of all malaria cases in 2016). Current malaria control efforts are challenged to the high prevalence of asymptomatic and sub-microscopic infections (low parasitemia not detectable by microscopy). Infections with low parasitemia are commonly missed by current gold standard (light microscopy) and even using molecular approaches. The objective of this work was to standardize a method for selective enrichment of *P. falciparum* genomic DNA retrieved from dried blood spots of malaria patients. Genomic *P. falciparum* DNA samples with variable range of parasitemia were enriched through the selective whole genome amplification (SWGA) method using the phi29 polymerase and sets of primers 6A and 8A. Through SWGA, the initial DNA of *P. falciparum* in simulated clinical samples was increased ~126 times (>5,000 molecules/μL). Using the *Fsp*EI enzyme the whole human genome DNA was eliminated and the parasitic genomic DNA was increased ~38 times. Furthermore, in clinical samples of parasitized patients the *P. falciparum* genomic DNA was increased ~ 29,126 times (from > 60,000 molecules/μL). In conclusion, the SWGA method produces the selective enrichment of *P. falciparum* genomic DNA in a wide range of concentrations, from simulated clinical samples and clinical samples of patients with malaria. Hereby, we provide a useful strategy to improve malaria research involving low parasitemia isolates.

1670

FROM PILOTS TO AN ELIMINATION PROGRAM: HOW MUCH DO MALARIA INTERVENTIONS COST

Katya Galactionova[1], Mar Velarde[1], Thomas A. Smith[1], John Miller[2], Melissa A. Penny[1]

[1]*Swiss Tropical and Public Health Institute; University of Basel, Basel, Switzerland, [2]Malaria Control and Evaluation Partnership in Africa (MACEPA), PATH, Lusaka, Zambia*

Countries with areas of very low malaria transmission require evidence on how best to achieve elimination given the limited resources available. Malaria elimination pilots in Ethiopia, Zambia, and Senegal generated evidence on costs and effectiveness of different intervention strategies. To inform decisions at country level there is a need to generalize these findings to implementation by programs. Using a standardized methodology we produced costs for a fixed setting and under an implementation modality representative of programs in Africa for

interventions recommended as part of an elimination strategy. We first evaluated intervention costs within the pilots. We then extrapolated from trial to program by revising implementation assumptions with expert opinion from MACEPA teams, country programs, and the literature. For each intervention we developed a prospective costing model around the reference implementation. Informed with the operational insight, translation of trial implementation to programmatic mode entailed imputing resource requirements at above district level, scaling down intensity of training and supervision, updating partner wages with those of the program, and scaling down incentives at community level. For the reference implementation and setting we estimated cost of RR at $0.18, cost RACD at $0.84, cost of MDA at $4.44, and cost of IRS at $5.42 per person per year. Here we illustrate a strategy to overcome the limited transferability of the costing data and highlight the scope for implementation science research and economic evaluation of scalable intervention models for malaria elimination. We show that differences in costs between the pilot sites were primarily driven by differences in intervention design and implementation of interventions. Differences in prices were a minor driver. Generalizing from pilots to program requires a careful re-assessment of resource requirements across the delivery pathway. As supportive activities and incentives are scaled-down outside the pilot, reflecting capacity constraints on the ground, implications for effectiveness of the tools should be further re-examined.

CHANGES IN VENDOR MOUSE GUT MICROBIOTA HINDERS EXPERIMENTAL REPRODUCIBILITY

Rabindra K. Mandal[1], Joshua E. Denny[2], Morgan L. Duff[1], Nathan W. Schmidt[1]

[1]Indiana University, Indianapolis, IN, United States, [2]University of Louisville, Louisville, KY, United States

An inability to reproduce previous experiments has a tremendous impact on the biomedical enterprise, at both the individual and corporate level. Many factors contribute to this growing concern that has garnered attention both within, and outside of, the scientific community. While using the murine model of malaria, a profound and lasting change in the severity of disease was noted within mice obtained at different time points from a specific commercial vendor. Based on our prior work we hypothesized a change in gut microbiota composition contributed to the temporal change in severity of malaria. Using 16S rRNA gene sequencing and analysis, we identified a distinct and lasting shift in gut microbiota from mice obtained over time within a defined production suite from the commercial vendor, which impacted reproducibility of two infectious disease model systems. Germ-free mice colonized with cecal content from mice within the same production suite before and after this discrete change followed by *Plasmodium yoelii* infection provided a direct demonstration that the change in gut microbiota profoundly impacted the severity of malaria. We also observed differences in fecal bacterial burden following acute *Salmonella enterica* serovar Typhimurium infection. Given the growing recognition that gut microbiota affect diverse states of health and disease, this change in gut microbiota likely impacted experimental reproducibility of diverse research groups. These results also demonstrate the need for commercial vendors to frequently monitor gut microbiota within production rooms, and provide that information to the scientific community.

1672

USING BEHAVIORAL ECONOMICS TO UNDERSTAND THE DETERMINANTS OF PROVIDER ADHERENCE TO MALARIA CASE MANAGEMENT GUIDELINES

[1]Breakthrough ACTION, ideas[42], Washington, DC, United States, [2]Breakthrough ACTION, ideas[42], New York, NY, United States, [3]Breakthrough ACTION, Johns Hopkins Center for Communications Programs, Baltimore, MD, United States, [4]Breakthrough ACTION, ideas[42], Abuja, Nigeria, [5]Breakthrough ACTION, Johns Hopkins Center for Communication Programs, Abuja, Nigeria, [6]President's Malaria Initiative and United States Agency for International Development, Abuja, Nigeria

Testing and treating fevers appropriately is critical to reducing child mortality and morbidity in Nigeria, where the prevalence of malaria parasitemia in children under 5 years (CU5) of age is 27%, according to microscopy data (2015 Nigeria Malaria Indicator Survey [NMIS]). When patients seek care for fever in health facilities, health providers may not test, diagnose, and treat malaria cases appropriately. To understand the determinants of health providers' fever case management practices, we conducted a formative research study using behavioral economics (BE) theory to identify potential factors. BE draws on social psychology, microeconomics, and other social sciences to understand how context shapes behavior, and why, for example, providers may know the national treatment guidelines, yet do not comply. From Oct-Nov 2018, Breakthrough ACTION Nigeria conducted site visits and interviews with 31 providers and 24 clients in 12 primary and secondary health facilities in Akwa Ibom (NMIS CU5 malaria prevalence: 23%), Kebbi (NMIS CU5 malaria prevalence: 64%), and Nasarawa (NMIS CU5 malaria prevalence: 36%) states. Results were coded and analyzed using BE theories and segmented by cadre and facility type. 74% (23/31) of providers indicated that they distrusted RDTs, citing various shortfalls or malfunctions. 42% (13/31) of provider responses suggest that they operate under a "scarcity" mindset, in which inadequate resources (including time) may cause providers to "tunnel," or intently focus, on seeing as many clients as possible instead of following protocol; compliance is further impeded by hassles (such as coordination with other departments). Providers additionally exhibited "base rate neglect," where they overestimated the probability of severe malaria and malaria in general compared to other potential causes of fever, and they seemed to view tests as tools designed to complement their own opinions, tending to favor their own clinical experience/judgment when tests appeared to contradict initial suspicions. BE provides a useful lens for identifying barriers related to fever case management in Nigeria.

1673

USE OF MALARIA SERVICES AND DATA QUALITY IMPROVEMENT TOOL IN CASCADED SUPERVISION APPROACH IMPROVED QUALITY OF MALARIA SERVICES: EXPERIENCE FROM MWANZA REGION, TANZANIA

Emmanuel Lesilwa[1], Goodluck Tesha[1], Jasmine Chadewa[2], Agnes Kosia[3], Zahra Mkomwa[1], Bayoum Awadhi[3], Rita Noronha[3], Dunstan Bishanga[3], Frank Chacky[4], Abdallah Lusasi[5], Ally Mohamed[5], Chonge Kitojo[6], Erik Reaves[6]

[1]USAID Boresha Afya Lake and Western Zone - PATH, Oyster Bay, Dar Es Salaam, United Republic of Tanzania, [2]USAID Boresha Afya Lake and Western Zone -Jhpiego, Oyster Bay, Dar Es Salaam, United Republic of Tanzania, [3]USAID Boresha Afya Lake and Western Zone -Jhpiego, Oyster Bay, Dar Es Salaam, United Republic of Tanzania, [4]National Malaria Control Programme, Dar Es Salaam, United Republic of Tanzania, [5]National Malaria Control Programme, Oyster Bay, Dar Es Salaam, United Republic

of Tanzania, [6]US President's Malaria Initiative/United States Agency for International Development, Oyster Bay, Dar Es Salaam, United Republic of Tanzania

Poor quality of malaria data is the challenges that National Malaria Control Program (NMCP) in Tanzania is addressing by innovations. In 2017, NMCP developed malaria services and data quality improvement (MSDQI) tool to guide supervisors. The tool comprises of seven modules addressing performance of Malaria Case Management with indicators weighed against a standard score. Facilities scoring below 50% of the overall score was deemed poorly performing, 50%-75% moderate and above 75% good performance. The supervisor provides mentorship, on job training (OJT) to poor performing facilities during supervision and develops action plan for improvement. The supervision was conducted through cascaded supervision approach where supervisors from high levels supervised lower level facilities using MSDQI tool. The project in collaboration with NMCP trained 190 supervisors selected from hospitals and health centers in Mwanza Region on malaria case management and data quality. After the training, the supervisors conducted supervision using the cascaded approach. Overall 207 facilities were assessed and 50 (24%) were classified as poor performers. Mentorship and OJT was provided to 430 health care providers with knowledge and skill gaps, between July and September 2018. Performance scores showed improvement in the percentage of providers demonstrating compliance to case management testing guidelines and adherence to treatment results. Cases tested for malaria rose from 75% in 2016 to 88% in 2018. There was a decline in proportion of malaria cases treated without a confirmatory diagnostic test from 1.5% in 2016 to 0.02% in 2018. Provision of IPTp2 (37.6%) and IPTp3 (37.6%) in 2016 rose to 72.4% for IPTp2 and 48.4% for IPTp3 in 2018. Issuing of bed nets to pregnant women increased from 4.9% 2016 to 75.6% in 2018, and from 2.9% 2016 to 65% in 2018 for infants according to DHIS2. During the period, the prevalence of malaria has decreased from 14% in 2016 to 8.1% in 2018 in Mwanza. Cascaded supervision approaches appeared to have contributed to improved quality of malaria service provision and hence improved malaria indicators.

1674

IMPROVEMENT OF HEALTHCARE PROVIDER ATTITUDE TOWARDS DOCUMENTATION THROUGH ON-SITE TRAINING AND SUPPORTIVE SUPERVISION OTSS AND CASE MANAGEMENT TRAINING IN OSUN STATE, SOUTHWEST NIGERIA

Victoria Erinle[1], Chinedu Chukwu[1], Faith Benebo[1], Isaac Adejo[1], Adeyinka Onikan[1], Thomas Hall[2], Mariah Boyd-Boffa[3], Bala Mohammed Audu[4], Shekarau Emmanuel[4], Nnenna Ogbulafor[4], Sonachi Ezeiru[5]

[1]*Management Sciences for Health (MSH), Abuja, Nigeria,* [2]*Management Sciences for Health (MSH), Arlington, VA, United States,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*National Malaria Prevention Program, Abuja, Nigeria,* [5]*Catholic Relief Services, Abuja, Nigeria*

One of the key issues identified in Nigeria regarding malaria case management is the lack of adherence to national guidelines in respect to proper documentation of individual cases by frontline health workers, leading to frequent unconfirmed diagnosis and misuse of antimalarial medicines. In collaboration with the National Malaria Elimination Program and with funding from Global Fund, Management Sciences for Health carried out on-site training and supportive supervision (OTSS) and case management training in the 30 local government authorities (LGAs) in Osun state, southwest Nigeria between July and November 2018. The purpose of this study was to compare percentages of unclassified malaria diagnoses and proper documentation of cases before and after OTSS and case management training. National and state level experts facilitated a three days' case management training of 887 frontline health workers in 821 public health facilities in the state. An OTSS team comprising of subject matter specialists from the national, state, and LGA levels visited 120 public health facilities twice using a national OTSS checklist to assess case management practices and to mentor health workers on proper malaria case management and documentation according to national guidelines. A total of 120 health facilities (comprising 95% public primary healthcare and 5% secondary) were visited by the OTSS team and 600 case notes from the health facilities were reviewed by the OTSS team for documentation of signs and symptoms, evidence of parasitological test, and definitive diagnosis. After OTSS and case management training, unclassified diagnosis of malaria in patient case notes decreased from 61% to 36%, and satisfactory documentation improved from 27% to 32%. The quality of documentation improved following the case management training and the OTSS visits in Osun state. It is important that this is sustained so as to contribute to the national goal of pre-elimination of malaria as contained in the National Malaria Strategic Plan 2014-2020.

1675

UTILITY OF MALARIA CASE CLASSIFICATION CALCULATOR FOR CASE CLASSIFICATION AND RESPONSE

Saw Naung Naung, Ye Hein Naing, Phyoe Yarzar, Thant Zin Aung, Ei Ei Win Aung, Hein Htet Linn Nyan, Kyaw Myint Tun

University Research Co., Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar

In January 2018, the PMI-supported Defeat Malaria project began working with the Myanmar National Malaria Control Program to pilot elimination activities in 3 Townships of Rakhine State. A malaria case classification calculator (MC3) was developed as an innovative tool to improve case investigation and response. This paper-based tool collects several types of information including date of onset of fever, history of previous malaria infections and blood transfusions, treatment completion according to national guidelines, and other relevant epidemiological linkages for appropriate classification of malaria cases. By using the MC3 to classify malaria cases, investigators can quickly identify the appropriate response and reduce the need for an expert epidemiologist or medical doctor's review. From April to September 2018, Defeat Malaria assessed the ease of use and effectiveness of MC3 through 7 key informant investigator reports, and reviewed 61 malaria case records from 41 out of 241 villages of Toungup Township. All key informants agreed that the MC3 tool was easy to use and helpful, in particular because it led to higher confidence and independence in case classification and calculation of appropriate timing for response, due to visualization of objectively verifiable epidemiological information. However, the application of the tool to mixed infections was more difficult. Of 61 malaria cases investigated, 58 (95%) were classified without difficulty (28 imported, 29 locally contracted, and 1 relapsed); only 3 cases (5%) could not be classified due to asymptomatic malaria, because the appearance of fever is a key starting point for the calculator utilization. MC3 has potential for classifying malaria cases and guiding appropriate timing for response, but it is not useful in classifying asymptomatic cases. Based on success thus far, the MC3 tool will be expanded to a mobile platform and introduced to other partners through the national malaria program.

KNOWLEDGE, ATTITUDES AND PRACTICES OF MALARIA IN STABLE COMMUNITIES IN THE INTERIOR OF SURINAME

Roxana M. Hijlaard, Reana Burke, Bianca Jubitana, Edward van Eer

Medical Mission Primary Health Care, Paramaribo, Suriname

The malaria situation in the interior of Suriname has changed significantly over the last decades reaching near elimination levels in 2009. Both the absence of malaria and decreased interaction of health services for malaria interventions in stable populations might have changed the communities' perceptions and practices towards malaria. To inform future intervention strategies, this study aimed to determine and compare the current level of knowledge, attitudes and practices of malaria in stable communities with a variety of malaria exposure levels. A total of 567 households were included in a community based cross-sectional survey between January and March

2018 in selected villages in the interior of Suriname. The study area was categorized into low versus high annual parasite index (API) according to malaria transmission intensity history and currently being at risk of malaria transmission versus not at risk. Descriptive and analytical statistics were used to summarize data. Respondents from areas at risk of malaria had significant more knowledge about malaria transmission (84%) than areas not at risk (56%). When comparing knowledge regarding malaria transmission between areas with high and low API, significant differences were found (75% in high API and 61% in low API). A positive attitude to the use of mosquito net use was observed without significant differences between areas. Sleeping under a mosquito net was perceived as the best malaria prevention method and used by 80% in total. Mosquito net use was significantly lower in areas current not at risk (71%), compared to areas current at risk (84%). 20% of all respondents were exposed to malaria information messages in the past 5 years, exposure to malaria information was significantly higher in areas current at risk of malaria compared to areas not at risk. Although the study population has fair knowledge about malaria, misconceptions still occur. Poor practices in terms of protection against mosquitoes can stagnate the elimination of malaria. This suggests the need of health education incorporated in comprehensive behavior change interventions to raise the community's awareness.

1677

IMPROVING THE QUALITY OF MALARIA CASE MANAGEMENT AND PREVENTION DURING PREGNANCY IN PUBLIC HEALTH FACILITIES IN BURKINA FASO

Thierry Ouedraogo, Ousmane Badolo, Mathurin Dodo, Bonkoungou Moumouni, Youssouf Sawadogo, Blami Dao, Stanislas Nébié

Jhpiego, Ouagadougou, Burkina Faso

In 2017, malaria was the leading cause of medical consultation (43.34%), of hospitalization (44.05%) and of death (16.13%) in Burkina Faso. The disease mostly kills children under five years and pregnant women. One objective of the National Malaria Control Program (NMCP) is to contribute to improving the health of the population by reducing malaria burden by 2020. In order to achieve that, the NMCP revised the malaria treatment guidelines in 2014 and conducted training in primary health care. NMCP implemented a one-day orientation training in district and regional hospitals with the support of the PMI Improving Malaria Care Project. A cross-sectional study was conducted in 2015 to assess the quality of malaria prevention and treatment during pregnancy in public health facilities. Data were collected in all 13 health regions from 28 primary health centers, 12 district hospitals, 8 regional hospitals and 2 university teaching hospitals (UTHs). A total of 2,282 patient records were randomly selected and reviewed and 208 providers were interviewed. The assessment focused on the prevention, diagnosis, treatment and reporting of malaria data. A comparative analysis of 2015 and 2017 data was done to understand trends and to identify challenges in program performance. The results showed an increase in the provision of adequate care in 2017 versus 2015 at all levels of the health system, particularly at UTHs. Provision of adequate care at primary health care facilities was 64% in 2015 and 67.1% in 2017. Likewise, adequate care increased at district hospitals from 39.9% in 2015 to 43% in 2017 and from 50% in 2015 to 62.5% in 2017 in regional hospitals. Finally, UTHs showed an increase from 31% to 64% in 2015 and 2017 respectively. Despite the existence of some challenges like lack of central and regional regular supervision, improvement in the quality of care and prevention of malaria in pregnancy have been observed in the health facilities in Burkina Faso between 2015 and 2017. It is important to carry out regular quality assessment or analysis to identify the causes of persistent problems in diagnosis, treatment and prevention of malaria during pregnancy.

1678

RETENTION OF TECHNICAL AND TRAINING KNOWLEDGE AND SKILLS BY MASTER AND GENERAL TRAINERS IN THREE STATES/REGIONS IN MYANMAR

Ni Ni Aye

Jhpiego, Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar

The NMCP of Myanmar aims to achieve malaria elimination through equitable and universal access to effective preventive and curative services to all at-risk populations in coordination with communities, national and international non-governmental organizations and other stakeholders. The PMI-funded Defeat Malaria project supports the National Strategic Plan's objective to reduce the malaria burden and contribute to elimination in part through capacity development of integrated community malaria volunteers (ICMVs), a new type of cadre introduced in 2017. Defeat Malaria aims to improve this new cadre's knowledge and skills in malaria epidemiology, prevention, and case management through a community-based intervention approach. Seventeen State/Regional (S/R) level master trainers (MTs) were trained from Kayin and Rakhine States and Taninthary Region, 13 of whom then trained 55 general trainers (GTs) in the same S/Rs. The GTs then trained 776 ICMVs. In order to assess MTs and GTs retention of knowledge and skills related to malaria and training methodology, and thus their ability to adequately train ICMVs, in December 2018 Defeat Malaria supported an evaluation of 11 MTs at 9 months after completion of their training using standardized tools in 2 of the 3 S/Rs. Forty-five percent of MTs achieved a passing score on knowledge of malaria technical areas (passing is defined as a score of ≥80% on knowledge and skills assessments). Twenty-seven percent achieved ≥80% on knowledge of training methodology. Regarding training skills, 73% of MTs achieved a passing score on facilitation skills, 82% on demonstration skills and 36% on coaching skills. All MTs achieved ≥80% on skills related to patient history taking, RDT use and treatment of malaria. In addition, 19 GTs were assessed for retention of training skills from 2-7 months after training. Thirty-one percent scored ≥80% on facilitation skills, 42% on demonstration skills and 10% on coaching skills. This evaluation will inform efforts to improve the curriculum, provide continuous mentoring of all trainers after training, especially to the GTs who train and provide supportive supervision to ICMVs.

HOW ACCURATE ARE HOUSEHOLD SURVEYS IN ESTIMATING INDOOR RESIDUAL SPRAYING COVERAGE?

Olivier Tresor Donfack[1], Charity Okoro Eribo[1], Liberato Motobe[1], Wonder P. Phiri[1], Carlos A. Guerra[2], Guillermo A. Garcia[2]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Medical Care Development International, Silver Spring, MD, United States*

Indoor residual spraying (IRS) and malaria indicator surveys (MIS) have been conducted every year since the start of the Bioko Island Malaria Control Project (BIMCP). All households on Bioko Island have been uniquely identified and geo-referenced and this database represents the backbone for all malaria interventions on the island. During IRS rounds, sprayed households are tagged accordingly so that true IRS coverage can be accurately estimated. Households surveyed during MIS are also linked through the same unique identifier and the survey questionnaire enquires whether the house had been sprayed in the last round. Based on this information, we assessed the performance of the MIS in estimating spray coverage relative to the IRS data. To this end, households surveyed during the 2018 MIS were matched to those targeted for IRS in the round earlier in the same year to assess the sensitivity, specificity and accuracy of the survey responses. Out of 4,774 households that were surveyed during the MIS, 1,772 belonged to communities that were targeted during the corresponding IRS round. Only 1,557, however, provided an unambiguous response to the question (*i.e.* "yes" or "no") and were included in the analyses. Amongst these, 1,339 (86%) were sprayed during the IRS round. The MIS responses identified 1,277 true positives (95.4%), 127

true negatives (58.7%), 90 false positives (41.3%) and 62 false negatives (4.6%). Thus, the sensitivity and specificity of the MIS to determine IRS coverage were estimated at 95.4 and 58.7%, respectively. Though the overall accuracy was 90.2%, the high proportion of false positive responses rendered the MIS an unreliable source for estimating true IRS coverage. Our findings raise concern on the use of household surveys for this purpose. Similar assessments are recommended for other settings to improve the understanding of the reasons for response biases.

1680

IMPROVING BIMONTHLY MALARIA LOGISTICS DATA REPORTING ACROSS 459 HEALTH FACILITIES SUPPORTED BY THE GLOBAL FUND: A CASE STUDY OF STRENGTHENING COORDINATION AND GOVERNANCE SYSTEMS IN JIGAWA STATE, NORTHWESTERN NIGERIA

Melis Esi[1], Danny Camlavi[1], Thomas Hall[2], Isaac Adejo[1], Mariah Boyd-Boffa[3], Emmanuel Nfor[2], Olumide Elegbe[1], Bala Mohammed Audu[4], Mohammed Shaibu[4], Olukayode John[4], Sonachi Ezeiru[5], Chukwudi Uche[5]

[1]*Management Sciences for Health (MSH), Abuja, Nigeria,* [2]*Management Sciences for Health (MSH), Arlington, VA, United States,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*National Malaria Elimination Program, Abuja, Nigeria,* [5]*Catholic Relief Services, Abuja, Nigeria*

Bimonthly facility stock reporting (BFSR) is a major component of the Nigeria health system, facilitating the timely and accurate resupplying of key, life-saving commodities, including those for malaria. Prior to 2018, facility staff in Jigawa state had received no training on stock reporting and there was inconsistent follow up from the local government authority (LGA) level, contributing to stock outs of key malaria commodities. Across 459 health facilities, the reporting rate was below 80% in 2017, including late submissions, leading to inaccurate Last Mile Delivery (LMD) plans. Management Sciences for Health in collaboration with the Global Fund, Catholic Relief Services and the National Malaria Elimination Program (NMEP), strengthened the Jigawa state and LGA logistics coordination units by training them to use onsite training and supportive supervision (OTSS) to build facility-level capacity to complete and submit timely and accurate BFSR. This technical assistance was coupled with support to reinforce the coordination platform called the Malaria Procurement and Supply Chain Technical Working Group. To facilitate this capacity building process, the NMEP and partners established new reporting and planning timelines, developed tools including a BFSR checklist used by both supervisors and facilities, and an OTSS form used during supervisory visits to facilities, while BFSR validation rules were used during BFSR review meetings and LMD plan generation. After the introduction of this method, the BFSR reporting rate increased to 94% in April 2018 and improved to 100% in each of the reporting periods since, up to March 2019, leading to the generation of timely and accurate LMD plans and allowing for timely resupply of malaria commodities in all 459 health facilities. Provision of technical assistance to state and local logistics management units to strengthen coordination, supportive supervision, and constructive feedback to facilities during bi-monthly review meetings improve reporting rates and planning, leading to improved resupply of malaria commodities and greater potential for proper management of malaria cases.

1681

WHAT DOES SELF-REPORTED BEDNET USE MEAN? EVIDENCE FROM REMOTE ADHERENCE MONITORING IN UGANDAN HOUSEHOLDS

Paul Joseph Krezanoski

University of California San Francisco, San Francisco, CA, United States

Long-lasting insecticide treated bednets (LLINs) have contributed to the decrease in malaria illness in recent decades, but new evidence suggests LLINs may not be as effective as previously. One critical component of LLIN effectiveness is how LLINs are used. Only recently have remote electronic LLIN use monitors been developed that can provide a more accurate and precise quantification of real-life LLIN use compared to traditional methods like self-reported use. In 2017, our group deployed electronic LLIN use monitors for 6 weeks each in 10 households in rural Uganda. We have previously used this data to develop new metrics of LLIN use such as duration of use, nights missed and times of use. In this study, we focus on how self-reported use might correlate with LLIN use measured by a remote adherence monitor. To achieve this, we used the electronic record to simulate 100 LLIN use assessments by self-report. Self-reported use was defined as nights where the electronic record detected at least 15 minutes use. Each assessment trial consisted of randomly chosen nights, one each from the 10 households. Self-reported use was high across the simulations, an average of 96%. According to the electronic record, average adherence between 0000-0600 hours was also high at 95%, and duration of use was 10 hours per night. However, coverage from 2100 to 0600 hours was 11% lower than self-reported use (85%), and 12% of households used their LLINs less than 5 hours per night. These findings demonstrate the imprecision of self-reports: even high self-reported LLIN use may harbor a wide variation in intra-night LLIN use behaviors with risk for malaria exposure. Combining this with findings of social desirability bias in self-reports, estimated at 13% in a recent paper, LLINs may be used less than surveys based on self-reports suggest. Given the remarkable impact of LLINs on malaria incidence, LLINs may be even more effective than previously thought. In conclusion, more studies using these tools for understanding how LLINs are used in real-life are indicated so that we can better understand the optimal role of LLINs in malaria prevention.

1682

HEALTH SYSTEM STRENGTHENING SUPPORT TO NATIONAL MALARIA PROGRAM ON DATA MANAGEMENT LEADS TO IMPROVEMENT IN THE QUALITY OF DATA REPORTED INTO THE NATIONAL HEALTH MANAGEMENT INFORMATION SYSTEM DATABASE (DHIS2) IN TARABA STATE, NORTHEAST NIGERIA

Chinedu Chukwu[1], Jerry Mbaka[1], Isaac Adejo[1], Adeyinka Onikan[1], Thomas Hall[2], Mariah Boyd-Boffa[3], Nnaemeka Onugu[4], Sonachi Ezeiru[4], Perpetua Uhomoibhi[5], Bala Mohammed Audu[5]

[1]*Management Sciences for Health (MSH), Abuja, Nigeria,* [2]*Management Sciences for Health (MSH), Arlington, VA, United States,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*Catholic Relief Services, Abuja, Nigeria,* [5]*National Malaria Elimination Program, Abuja, Nigeria*

Management of health data is a significant challenge in Nigeria, impacting the performance of health providers, quality of care and the overall health system. Health care providers and data managers in Taraba have not received any training or consistent supervision in over five years, leading to weak adherence to data management guidelines. Though there is routine data submission to the state from the facility and local government authority (LGA) levels, these reports are frequently sent with "zero data elements", or data entry errors, and thus no malaria indicator performance measures. In collaboration with the Global Fund in Nigeria, Management Sciences for Health, in partnership with the National and State Malaria Elimination Programs, builds capacity of state-level data managers and health care providers on malaria services documentation and indicator reporting according to national guidelines. Capacity is built by providing trainings and by linking the state level with the most up-to-date tools, leading to improved analyses and use of malaria data for decision making. Capacity and performance are reinforced with routine, onsite supportive supervision and with the introduction of data validation meetings at the LGA level. In Taraba, this intensive support led to a 6% improvement in data quality, demonstrating a reduction in the number of data entry errors. The data quality rate improved each quarter in 2018, from 87% at baseline in the first quarter to 93% by the end of the year in the fourth quarter. Building capacity and knowledge in data management, indicator definitions, and national DHIS2 reporting requirements, with regular supportive supervision, are key to data quality improvement, and improved analysis and use of data for decision making.

1683

MALARIA DURING PREGNANCY AND NEWBORN OUTCOME AMONG INPATIENTS IN NON CRITICAL OBSTETRIC UNITS OF PUBLIC HOSPITALS OF THE PERUVIAN AMAZON

Priscilla Magno-Muro[1], Freddy Valera-Gallegos[2], Nataly Atarama[1], Raul Chuquiyauri[3], Wilma Casanova[4], Stalin Vilcarromero[5]

[1]*Sociedad Científica de Estudiantes de Medicina de la Amazonia Peruana (SOCIEMAP), Universidad Nacional de la Amazonia Peruana (UNAP), Iquitos, Peru,* [2]*Sociedad Cientifica de Estudiantes de Medicina de la Amazonia Peruana (SOCIEMAP), Universidad Nacional de la Amazonia Peruana (UNAP), Iquitos, Peru,* [3]*Sanaria Inc., Rockville; Medical Care Development International, Silver Spring, Malabo, Mexico,* [4]*Universidad Nacional de la Amazonia Peruana (UNAP), Iquitos, Peru,* [5]*Sociedad Científica de Estudiantes de Medicina de la Amazonia Peruana (SOCIEMAP), Medical Care Development International, Department of Medicine, Division of Infectious Diseases, Stony Brook University, Stony Brook, NY, United States*

Annual malaria incidence in the Peruvian Amazon increased by 21.5% from 2013 (43744 cases) to 2017 (53163 cases), and its impact among pregnant women has not been well described. We aimed to describe the clinical and epidemiological characteristics of pregnant women hospitalized in non-critical care units and its implications on the fetus or newborn. We reviewed the clinical charts of all pregnant women with malaria diagnosed by thick smear from 2010-2016, along with the clinical charts of their newborn. Cases admitted in critical care were not included. A total of 131 pregnant women met the criteria, and according to WHO criteria: 42 (30.4%) of the women were considered to have severe malaria, and 78 (56.5%) and 13 (9.4%) were 16-25 and <16 years old respectively. 71 (51.4%) lived in urban and peri-urban settings, 71 (51%) were in their third trimester, 120 (87%) reported no previous history of malaria and perception of temperature elevation (109, 79%), headache (93, 68%) and chills (66, 47.8%) were the most common symptoms. Only four were asymptomatic. The vast majority (126, 91.3%) were housewives, and only 47% (65) studied elementary school or less. For 61.6% (85) of women, this was their first or second pregnancy. *Plasmodium falciparum* was the most common species identified (78, 56.5%), and 73% (101) harbored parasite densities less than 3+. The most frequent maternal complications were anemia (74.6%, 106) and thrombocytopenia (46.4%, 58). 43.5% (62) received only oral therapy. Artesunate and Clindamycin were the most commonly prescribed medication. Only in 62 cases (45%) was it possible to obtain the newborn's clinical data. 83.9% (52/62) of the neonates presented an adequate weight at birth, 8% (11/62) were premature, 7.2% (10/62) were small for the gestational age, 4.3% (6/62) intrauterine growth restriction and 7/62 were considered congenital malaria (6 asymptomatic). The high sensitivity of WHO guidelines may explain why severe malaria cases were managed in a non-critical care setting. Despite malaria being endemic to rural communities, this data shows how impactful it is to urban/peri-urban settings.

1684

PILOTING A CASE-BASED SURVEILLANCE TOOL TARGETED AT PHARMACEUTICAL PRIVATE PROVIDERS (PSPS) IN LAGOS, NIGERIA.

Tayo Olaleye[1], Olukunle Adewusi[1], Luke Baertlein[1], Chizoba Fashanu[1], Omotayo Giwa[1], Abimbola Osinowo[2], Deepa Pindolia[3], Owens Wiwa[1]

[1]*Clinton Health Access Initiative (CHAI), Abuja, Nigeria,* [2]*Lagos State Malaria Elimination Program, Lagos, Nigeria,* [3]*Clinton Health Access Initiative (CHAI), Nairobi, Kenya*

Nigeria's 2015 malaria indicator survey confirms malaria prevalence in Lagos state to be 0% and ~2%, based on microscopy and mRDTs respectively. Prevalence however remains heterogeneous within the state. The private sector, specifically the Patent and Proprietary Medicine Vendors and Community Pharmacists collectively called PSPs, is the first point of care providing treatment for up to 67% of care-seeking fever cases. However, reliable data on diagnosis and treatment practices is lacking, preventing informed resource planning and effective government oversight. The scale-up of a surveillance system could contribute to efficient programming and providing a wholesome view of true malaria prevalence in Lagos; thus accelerating progress towards elimination. An innovative case-based surveillance system was developed and piloted in 387 PSPs across Lagos in March 2019. The system included configuration of DHIS2 data collection tool for mobile reporting and a retail private sector specific DHIS2 instance for hosting and analysis of reported data. The trained PSPs use a case-based reporting system via a mobile app; the data is presented in analytics to support decisions on case management practice and supportive supervision. On average, each month, 42% of the trained PSPs reported at least once. Case management indicators, such as test uptake and adherence, are calculated and displayed in dashboards and routine reports used by government officers and PSP supervisors to target supervision visits based on PSP performance. Data review meetings are held routinely to facilitate the use of the data for program and supervision planning. By July 2019, 111 targeted supervision visits using PSP-specific reported data, were conducted. Although reporting rate is low, this pilot clearly indicates that the retail private sector can collect and report malaria-specific case-based data which can be used to guide state malaria programming and operations. Routine reporting in this manner, scaled up to all the PSPs in the state, region and country, will provide a more representative data of malaria diagnosis and treatment practices in the private sector.

1685

MALARIA PREVENTIVE PRACTICES AMONG UNDER-FIVES IN RIVERS STATE, NIGERIA

Nsirimobu Ichendu Paul, Omosivie Maduka, Chijioke Adonye Nwauche, Ibinabo Laura Oboro, Terhemen Kasso, Lucy Eberechukwu Yaguo-Ide, Abimbola Temitayo Awopeju, Godly Otto, Ifeyinwa Nwogo Chijioke-Nwauche, Carol Iyalla

University of Port Harcourt, Port Harcourt, Nigeria

Malaria is a life threatening protozoan infection especially in under 5 children and strong malaria preventive practices is key to reducing its associated mortality. The study assessed malaria preventive practices among under-five children in Rivers State, Nigeria. This was a cross sectional study in public and private health facilities in Rivers state. Ethical approval for the study was obtained from the Research and Ethics committee of the University of Port Harcourt Teaching Hospital, while an informed written consent was obtained from the parents or caregivers of the participants. Stratified sampling method was used to select the health facilities and the subjects for the study. A pretested interviewer administered questionnaire was used to harvest relevant information on socio demographic characteristics of the subjects and informants and malaria preventive practices. Obtained data was analysed using SPSS version 22. A total of 1138 children participated in the study constituting of 613 (53.9%) male and 525(46.1%) female Mean age of participants was 1.74±1.08 years. Mothers, accounted for majority 1012 (88.9%) of the informants. Most of the informants had tertiary degree; 605 (53.4%) and 697 (61.8%) among mothers and fathers respectively. Among the occupations of fathers, public servants, civil servants and the self-employed were more represented, constituting 242 (21.4%), 200 (17.7%) and 149 (13.2%) respectively. Traders/business women, the self-employed and civil servants were most represented among the occupations of mothers in the study and these accounted for 444 (39.7%), 181 (16.2%) and 137 (12.3%) respectively. Malaria preventive practices included protective window nets, bed nets, indoor residual spraying and use of drugs which constituted 970 (85.2%), 605 (53.2%), 483 (42.4%) and 133 (11.7%) respectively. Protective window net use rate was high (85%) among children in Rivers state. Health education on the integrated approach to malaria prevention is advocated.

1686

KNOWLEDGE, ATTITUDES, AND PRACTICES REGARDING MALARIA TRANSMISSION AND PREVENTION AMONG THE MAIJUNA COMMUNITY: A QUALITATIVE STUDY IN THE PERUVIAN AMAZON

Kathryn M. Hogan[1], Michael von Fricken[1], Michael Gilmore[1], Graziella Pagliarulo McCarron[1], Brian Griffiths[1], Guillermo Garcia[2]

[1]*George Mason University, Fairfax, VA, United States,* [2]*Medical Care Development International, Silver Spring, MD, United States*

Over 90% of incident malaria cases in Peru are localized in the Department of Loreto, and many who reside there live in rural, subsistence farming communities that are geographically isolated from existing healthcare services. Therefore, the emphasis on preventive behaviors as well as early treatment seeking is vital to decreasing transmission in the area. The uptake of these behaviors is often dependent upon local malaria knowledge, beliefs, and overcoming the idea that malaria is embedded and unavoidable in society. The objective of this study was to explore the history of malaria transmission among the Maijuna people, an indigenous community of the Peruvian Amazon, and understand the impact that current knowledge and attitudes have on preventive behaviors in Sucusari. Knowledge, attitudes, and practices were assessed using semi-structured interviews, and CareStart Rapid Daignostic Tests were used to test for malaria. Individuals were sampled using purposive sampling, and each adult in the community was asked to take a malaria test. Thirty-four individuals were interviewed between January and April 2019, and 35 were tested for malaria out of a total 65 adults in the community. Themes emerged from interviews as follows: confusion about the transmission mechanism of malaria, the feeling that malaria is unavoidable, and the adoption of preventive behaviors as a direct results of local health programming. Following interviews, there was a community meeting to debrief and clarify any questions about transmission, prevention, and treatment. The results indicate that previous community-based programming may have been presented in a manner that was unclear to large portions of the community, or did not reach the whole intended audience. The results also show that while there was confusion about the mode of transmission of malaria, this was not directly related to the practice of preventive behaviors. Information from this study can act as a foundation for local health organizations to evaluate and alter community-based programming in indigenous communities in Sucusari, as well as other Peruvian indigenous communities.

ASSOCIATION BETWEEN PLACENTAL MALARIA AND THE INCIDENCE OF MALARIA IN INFANTS BORN TO HIV-UNINFECTED UGANDAN MOTHERS LIVING IN A HIGH MALARIA TRANSMISSION SETTING

Abel Kakuru[1], Sarah Staedke[2], Daniel Chandramohan[2], Richard Kajubi[1], Teddy Andra[1], Harriet Adrama Harriet Adrama[1], Miriam Nakalembe[3], Tamara D. Clark[4], Theodore Ruel[4], Diane V. Havlir[4], Moses R Kamya R. Kamya[3], Grant Dorsey[4], Prasanna Jagannathan[5]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Makerere University College of Health Sciences, Kampala, Uganda,* [4]*University of California San Francisco, San Francisco, CA, United States,* [5]*Stanford University, San Francisco, CA, United States*

Although placental malaria (PM) has been associated with adverse birth outcomes, data on the effect of PM on the incidence of malaria during infancy remain inconclusive. We evaluated associations between PM and other maternal factors on the incidence of malaria during the first year of life in a birth cohort of 611 infants born to HIV-uninfected mothers. The study was conducted in Busia, Uganda, an area with high malaria transmission intensity. Mothers were enrolled during the second trimester of pregnancy, and PM was categorized based on the proportion of high-power fields with malaria pigment seen by histology as none (n=348); mild (<10%, n=135); moderate (10-<30%, n=100); and severe (30-60%, n=28). A total of 1008 episodes of malaria were diagnosed in infants (incidence 1.84 episodes per person year.) We observed significant effect modification between several maternal factors and infant sex, and therefore report stratified analyses. Among male infants, those born to mothers with severe PM had a higher incidence of malaria compared to those born to mothers with no PM (aIRR 1.87, 95% CI 1.03-3.37, p=0.04). Male infants born to a gravida ≥3 mother (aIRR 1.65, 95% CI 1.25-2.18, p<0.001) and those with either submicroscopic or microscopic parasitemia at enrollment (aIRR 2.56, 95% CI 1.73-3.81, p<0.001) had a higher incidence of malaria during infancy compared with those born to a gravida ≤2 mother or those without parasitemia at enrollment, respectively. Among female infants, only those born to mothers with submicroscopic or microscopic parasitemia at enrollment (aIRR 1.89, 95% CI 1.33-2.69, p<0.001) had a higher incidence of malaria during infancy. Together, these data suggest that the association between second trimester parasitemia and incidence of malaria during infancy reflects a shared exposure to malaria transmission. However, infant sex may modify associations between PM, gravidity and infant malaria incidence, resulting in important, sex-specific consequences of *in utero* malaria exposure in male, but not female, infants.

1688

MAINTAINING UNIVERSAL COVERAGE OF LONG LASTING INSECTICIDAL NETS THROUGH DISTRIBUTIONS IN SCHOOLS IN UGANDA

JohnBaptist Bwanika[1], Ruth Kigozi[1], Emily Godwin[1], Patrick Bukoma[1], Peter Thomas[2], James Tibenderana[3], Sam Siduda[1], Gloria Sebikaari[4], Belay Kassahun[4]

[1]*USAID's Malaria Action Program for Districts, Kampala, Uganda,* [2]*US President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, USA, Kampala, Uganda,* [3]*Malaria Consortium, London, United Kingdom,* [4]*US President's Malaria Initiative, US Agency for International Development, Kampala, Uganda*

There is strong evidence that regular use of a long lasting insecticidal net (LLIN) substantially lowers one's risk of contracting malaria. Mass distribution campaigns seek to achieve universal coverage (a net for every 2 individuals), an outcome that may be improved by distributing additional LLINs in schools. More data are needed on whether continuous distribution via this channel can improve universal coverage of LLINs in a general population. To evaluate this question, the US President's Malaria Initiative Malaria Action Program for Districts piloted a school distribution program in June 2018. LLINs were distributed in schools in 26 Ugandan districts that had below 70% LLIN coverage (intervention arm), and longitudinal data were collated - before distribution and six months after - from two representative population samples of 2,420 households in the intervention arm and 550 households in the control arm. To control for possible confounding, the proportion of pregnant women who received LLINs during ANC was checked and ascertained not to be significantly different at 65.2% (95%CI: 63.2%, 67.3%) in intervention and 63.1% (95%CI: 60.7%, 65.5%) in control areas. Households' socio-demographic and net ownership data were collected and analyzed; LLIN coverage was assessed by asking heads of households about the number of resident individuals and LLINs present in their households. Analysis revealed that the proportion of households with universal coverage of LLINs was maintained from 68.5% (95%CI: 66.6%, 70.4%) to 70.7% (95%CI: 68.5%, 72.9%) in the intervention arm, and fell, significantly, from 78.2% (95%CI: 75.3%, 81.1%) to 69.6% (95% CI: 65.0%, 74.1%) in the control arm. Households from the highest wealth quintile were more likely to have universal coverage than those from the lowest wealth quintile (OR 1.40, 95% CI 1.10-1.78). Likewise, households whose heads had university education were more likely to have universal coverage than those with household heads with no formal education (OR 2.08, 95% CI 1.39-3.11). These findings suggest that LLIN replenishment through schools can sustain universal coverage in the general population.

1689

EFFECT OF FOUR YEARS OF SEASONAL MALARIA CHEMOPREVENTION ON THE ACQUISITION OF ANTIBODIES TO *PLASMODIUM FALCIPARUM* ANTIGENS IN OUELESSEBOUGOU, MALI

Almahamoudou Mahamar[1], Djibrilla Issiaka[1], Ahamadou Youssouf[1], Sidi Mohamed Niambele[1], Harouna M. Soumare[1], Oumar Attaher[1], Amadou Barry[1], David L. Narum[2], Patrick E. Duffy[2], Brian Greenwood[3], Michal Fried[2], Alassane Dicko[1]

[1]*Malaria Research and Training Center (MRTC), Bamako, Mali,* [2]*Laboratory of Malaria Immunology and Vaccinology (LMIV), National Institute of Allergy and Infectious Diseases (NIAID), National Institutes of Health (NIH), Rockville, MD, United States,* [3]*London School of Hygiene & Tropical Medicine (LSHTM), London, United Kingdom*

More than 200 million people live in areas of highly seasonal malaria transmission, where seasonal malaria chemoprevention (SMC) with SP and AQ was recommended in 2012 by WHO. The strategy is now widely implemented and protecting more than 17 million children in 2018. We previously reported that SMC reduced seropositivity to MSP-1_{42} and CSP (but not AMA1), and the duration of SMC did not further reduce seropositivity. In this study we assessed the impact of four years of SMC on the acquisition of antibodies to malaria antigens. A cross-sectional survey was carried out one month after the last dose of SMC in 2017 in children aged 4-5 years randomly selected from areas where SMC was given for 2 or 4 years during the malaria season. Antibody extracted from dry blood spots was used to measure IgG levels to CSP, MSP-1_{42} and AMA1 by ELISA. The prevalence of antibodies to MSP-1_{42} were similar in children who received SMC for 4 years when compared to those who received SMC for 2 years (85.1 vs 86.0%, p = 0.80). The prevalence of antibodies to AMA-1 and to CSP were not lower in children who received SMC for 4 years compared to those who received SMC for 2 years (95.3 vs 88.8%, p = 0.01 for AMA-1; 91.2 vs 81.9%, p =0.001 for CSP). Similarly to the seropositivity prevalence, the anti-MSP-1_{42} IgG median levels did not significantly differ between children that received SMC for four or two years (0.88 IQR: 0.64-1.15, 0.95 IQR: 0.68-1.15; p = 0.15) and anti-AMA-1 and anti-CSP IgG median levels were not inferior in children who received SMC for four years vs. two years (1.45 IQR: 1.24-1.68, 1.41 IQR: 1.17-1.64; p = 0.02) and (1.30 IQR: 1.00-1.56, 1.17 IQR: 0.87-1.47; p = 0.0005) for AMA1 and CSP respectively. In this area of high seasonal malaria transmission, children who had received SMC for four years did not had higher seropositive and antibody titers to CSP and AMA1 compared to children who had received SMC for two years suggesting that children may not be at higher risk of malaria after the cessation of SMC.

1690

COMMUNITY-BASED APPROACH TO REACH MALNOURISHED INFANTS FROM 6 MONTHS TO 5 YEARS DURING A SEASONAL MALARIA CHEMOPREVENTION (SMC) CAMPAIGN IN REMOTE AREAS IN NIGER

Hortense Angoran-Benié[1], Dr Hadiza Jackou[2], Chrestien Yameni[1]

[1]*Catholic Relief Services, Baltimore, MD, United States,* [2]*MNCP program, Niamey, Niger*

Malaria & acute malnutrition are major public health problems in Niger and Children 3 - 59 months are mostly victim. In 2016 National Data showed malaria incidence rate at 120,75 case per 1 000 habitants and moderate and severe malnutrition at 12.53% and 9.56%. Both diseases coincide with the lean rainy season. Since 2016, The National Malaria Control program (NMCP) and the Nutrition Directorate decided to integrate nutritional screening by trained community health workers during SMC campaigns. Infants were reached in the communities using MUAC, scored card and daily summary sheets through fixed, mobile and door to door approaches. Community workers were identified, trained and equipped by the national nutritional Directorate and its partners. In addition to training received on SMC campaign, community workers were also trained on: carrying out interpersonal communication with the mothers; the infant classification based on the color observed screening of edema; filling out data tools and proper infant referrals (yellow and red). Joint planification, supportive supervision and data validation processes by both the NMCP and the Nutrition Directorate were conducted in the communities. For 2018, the national target for Malnutrition screening was 3,750,315 enfants. 3,514,747 were screened for malnutrition. 3,349,058 (95,29) were healthy (arm circumference >125mm); 131,508 (3,74%) were moderately malnourished (arm circumference between 115 and 125; and 34,181 (0,9%) were deemed severely malnourished (arm circumference <115mm with or without lower extremity edema). In conclusion, the integration of malnutrition screening into seasonal malaria chemoprevention campaign using community volunteers is possible and is cost effective in the fight against children under five years who are vulnerable to malaria and malnutrition in low income country. However, management of referred malnourished children remains a great challenge.

IMPROVED UPTAKE OF MALARIA IN PREGNANCY INDICATORS: A CASE FROM USAID LAKE AND WESTERN ZONE, TANZANIA

Zipporah Wandia[1], Jasmine Chadewa[2], Agnes Kosia[2], Goodluck Tesha[1], Lusekelo Njoge[2], Zahra Mkomwa[3], Dunstan Bishanga[2], Rita Noronha[2], Bayoum Awadhi[2], Gaudiosa Tibaijuka[2], Chonge Kitojo[4], Erik Reaves[4], Abdallah Lusasi[5]

[1]*Jhpiego, Dar es Salaam, United Republic of Tanzania,* [2]*USAID Boresha Afya Project -Jhpiego Tanzania, Dar es Salaam, United Republic of Tanzania,* [3]*USAID Boresha Afya Project –Path Tanzania, Dar es Salaam, United Republic of Tanzania,* [4]*President's Malaria Initiative/United States Agency for International Development, Dar es Salaam, United Republic of Tanzania,* [5]*National Malaria Control Program-Tanzania Ministry of Health, Community Development, Gender, Elderly and Children, Tanzania, Dar es Salaam, United Republic of Tanzania*

Malaria in pregnancy (MiP) has been recognized as a major public health concern contributing to poor maternal and newborn health outcomes. In Sub-Saharan Africa, up to 20% of stillbirths are attributable to MiP and contributes to an estimated 10,000 maternal deaths and 100,000 infant deaths. Tanzania implements a three-pronged approach to prevent the adverse effect associated with MiP as recommended by WHO: use of long lasting insecticide-treated bed nets (LLINs), intermittent preventive treatment of malaria in pregnancy (IPTp) with sulfadoxine-pyrimethamine, and prompt diagnosis and treatment. Tanzania has improved uptake of IPTp and MiP indicators in seven regions supported by the USAID Boresha Afya Project in collaboration with the National Malaria Control Program and regional and council health management teams. The supported regions used the malaria data dashboard, a platform where all malaria data are displayed for easy access by all malaria stakeholders, to identify health facilities with low uptake of MiP indicators and poor documentation in Health Management Information System Book 6, the antenatal care (ANC) register used in Tanzania's health facilities. The project completed quarterly follow-up and mentorship for health care workers at ANC between 2016 and 2018 in 1817 (100%) health facilities. IPTp2 increased from 49% to 74% and IPTp3 increased from 2% to 49%, both approaching the national targets of 80% for IPTp2 and 60% for IPTp 3 in all seven regions. ANC visits <12 weeks increased from 14% to 37% and ANC 4th visits increased from 39% to 62%, pregnant women tested for malaria at 1st ANC visit increased from 68% to 98%, and ferrous folic supplementation uptake increased from 68% to 78%. The improvements in MiP indicators in the supported regions may be attributed to commitment among health care workers, mentorship, and proper documentation. Continued and expanded mentorship to reinforce proper documentation and use of the malaria data dashboard might further increase IPTp uptake, thereby reducing maternal and neonatal deaths associate with malaria in pregnancy.

1692

ACCEPTABILITY AND USE OF LONG-LASTING INSECTICIDAL NETS (LLIN) AND TOPICAL REPELLENTS AMONG FOREST-GOERS INVILLAGES OF TANINTHARYI REGION AND KAYIN STATE IN MYANMAR

Kaung Myat Thu[1], Nay Min Shein[1], Feliciano Monti[2], Zar Ni Htun[1], Bo Bo Thet Ko[1], Htin Lin Thaw[3], Sway Minn Htet[1], Kyaw Myint Tun[1]

[1]*University Research Co., Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar,* [2]*United States Agency for International Development, Yangon, Myanmar,* [3]*American Refugee Committee, Yangon, Myanmar*

One of the malaria elimination challenges in Myanmar is that the disease primarily affects marginalized populations such as forest-goers. In 2018, Defeat Malaria project implemented a pilot intervention to explore the acceptability and utilization of preventive measures among forest-goers in 9 villages in 4 townships of Tanintharyi Region and Kayin State. In November-December 2017, about 950 forest-goers received a prevention kit comprised of a long-lasting insecticidal net (LLIN) and a 100g tube of a topical mosquito repellent, replaceable on demand, containing 12% N, N-diethyl-benzamide. The acceptability, utilization and perceived usefulness of both LLINs and repellent were assessed after 6 months, in June-July 2018, by reviewing activity data, interviewing beneficiaries with a structured questionnaire, and conducting focus group discussions. All forest-goers who received the kit were invited to participate in the assessment; 286 engaged in structured interviews, and 6 focus group discussions were conducted. Seventy eight percent of the forest-goers were male, with median age 41 years, an average monthly income of 60 USD, with 45% having an income of less than 1 USD/day. The most common types of forest-related work were farming (91%), followed by bamboo cutting/logging (41%), and hunting (22%). Sixty three percent worked at times from 6pm to 6am, while 85% of hunters hunted during the night. Although acceptability of LLINs was more than 90%, their utilization varied from 75% among farmers and wood cutters to 50% in hunters. The utilization of the repellent was very high among all types of forest-goers with 90% reported during the last night-time visit to the forest. Seventy eight percent reported using the repellent every night in the forest. According to the qualitative results, most of the forest-goers highly appreciated the usefulness of the repellent in reducing mosquito bites. Although acceptability of LLINs was high, their utilization during night was difficult. The high use of repellent is encouraging and warrants conducting further studies on its effectiveness in reducing malaria transmission among forest-goers.

1693

HEARING TO UNDERSTAND: ASSOCIATIONS BETWEEN HEARING MALARIA HEALTH MESSAGING AND MALARIA KNOWLEDGE, AWARENESS AND PRACTICE OF PREVENTATIVE MEASURES IN THE 2018 MALARIA INDICATOR SURVEY FOR BIOKO ISLAND, EQUATORIAL

Tammy Cavanzos[1], Matthew Rossheim[1], Olivier Tresor Donfack[2], Wonder P. Phiri[2], Guillermo A. Garcia[3], Michael E. von Fricken[1]

[1]*Department of Global and Community Health, George Mason University, Fairfax, VA, United States,* [2]*Medical Care Development International, Malabo, Equatorial Guinea,* [3]*Medical Care Development International, Silver Spring, MD, United States*

The Bioko Island Malaria Control Project (BIMCP) started in 2004 to reduce morbidity and mortality caused by malaria on Bioko Island. A Malaria Indicator Survey (MIS) is conducted annually to measure the impact of the project. This study uses the MIS household data to examine the associations between individual's reception of the malaria communication messaging with knowledge of malaria preventative measures and practice of malaria preventative measures. The sample size of this analysis is 4,444. 50% of the population heard a malaria message within 6 months. The use of Indoor Residual Spraying (IRS) was among the most popular malaria messages heard (10% recalled hearing it) while 9% recalled hearing the need to eliminate breeding sites/clean up trash. Messages regarding LLIN use were recalled by less than 1%. Household knowledge of preventive measures was 77% for using LLINs, 18% for using IRS, and 6% for prophylaxis. 58% of the population slept under an LLIN the night before and 43% received IRS within 12 months. After adjusting for potential confounders, the only factor associated with sleeping under an LLIN was knowledge of IRS as a preventative measure (OR=0.77, 95% CI: 0.65, 0.90). After adjusting for potential confounders, factors associated with indoor residual spraying within 12 months included knowledge of mosquito nets as a preventative measure (OR=0.64, 95% CI: 0.55, 0.74) and hearing a malaria-related message regarding sleeping under an LLIN (OR=0.78, 95% CI: 0.67, 0.91). Health-related messages are reaching the population. However, improvements are needed to increase malaria knowledge regarding preventative measures, as this affects acceptance and use of preventive measures.

1694

THE EFFECT OF EDUCATION ON MALARIA PREVENTION BEHAVIOR

Kevin Croke

Harvard T.H. Chan School of Public Health, Boston, MA, United States

Health-seeking behavior by individuals and improved socioeconomic status are key contributors to successful malaria control programs, and both may be affected by education levels. Yet there is relatively little causal evidence of impact of education on malaria prevention behavior and ownership of preventive commodities. We leverage education policy changes that induced plausibly exogenous shifts in cohort-level educational attainment in several Sub-Saharan African countries to examine the impact of increased education on bednet ownership and usage, and on treatment seeking behavior for children. We find that increases in education lead to significant increases in bed net ownership and usage, especially when it is female household members who gain additional education. Impact on treatment seeking behavior for febrile illness is more limited.

1695

INCREASING COVERAGE AND USE OF INSECTICIDE-TREATED NETS IN ZAMBIA: RESULTS FROM THE ZAMBIA MALARIA INDICATOR SURVEY 2018

Maya Fraser[1], Caterina Guinovart[2], Busiku Hamainza[3], Elizabeth Chizema-Kawesha[3], Kafula Silumbe[4], Mercy Mwanza-Ingwe[3], Hawela Moonga[3], Anthony Yeta[3], Mutinta Mudenda[3], Fred Masaninga[5], John M Miller[4]

[1]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States,* [2]*PATH/ISGlobal, Barcelona, Spain,* [3]*National Malaria Elimination Centre, Lusaka, Zambia,* [4]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia,* [5]*World Health Organization, Lusaka, Zambia*

Universal coverage of vector control, defined as every household having adequate coverage of insecticide treated nets (ITNs) or indoor residual spraying (IRS), is a key piece of Zambia's National Malaria Strategic Plan for 2017–2021. From 2017–2018, in support of this goal, a mass distribution campaign of more than 10 million total nets was conducted across all provinces. The Zambia National Malaria Indicator Survey (MIS) 2018, a nationally representative household survey designed to assess key malaria indicators, was conducted in April–May of 2018 during peak transmission season, and provided an opportunity to assess coverage and usage of ITNs following mass distribution. The 2018 MIS was a two-stage cluster sample of 4,475 households selected from 179 standard enumeration areas, with 4,177 completed household interviews. Household members were asked a series of standardized questions about malaria interventions, including vector control. A net roster module listed each net that households owned, and which family members slept under it. Results showed that nationally Zambia achieved 80% coverage of at least one ITN per household. Eight of ten provinces had greater than 80% coverage.

Increases in coverage were especially notable in rural areas, where the household ownership of at least one ITN increased from 78% in 2015 to 87% in 2018. Forty-five percent of households reported having at least one ITN for every two household members (up from 42% in 2015), a measure of full coverage of ITNs within households. Among all household members, 65% reported using an ITN the previous night. For those in households with at least one ITN, 84% reported usage the previous night. Among children under age five and pregnant women, these figures were 69% and 71%, respectively. These findings show an increase among most all ITN indicators since 2015 and indicate that usage is high among those who have access to nets. Further results will be presented on the characteristics of households who did not receive ITNs and of individuals in households with nets that did not use them.

1696

COMMUNITY APPROACH TO FIGHT AGAINST MALARIA THROUGH THE USE OF DIGITAL HEALTH IN THE HEALTH DISTRICT OF NIORO DU RIP (SENEGAL)

Malick Anne[1], **Abdoulaye Ndione**[1], Diarga Mballo[1], Ibrahima Diankha[1], Mouhamed Gueye[1], Youssoupha Ndiaye[2]

[1]*Senegal Health Ministry and Social Action, Kaolack, Senegal,* [2]*Senegal Health Ministry and Social Action, Dakar, Senegal*

Worldwide, 219 million cases of malaria were recorded in 2017 and 435,000 deaths. Nearly 90% of malaria cases and 92% of deaths occur in sub-Saharan Africa. In Senegal, the evolution of parasite prevalence from 2009 to 2015 still ranks Senegal among the countries of sub-Saharan Africa (SSA) where malaria is endemic and constitutes a health problem. However, this burden dropped significantly by more than 50% between 2009 and 2015. The health district of Nioro, thanks to the numerous actions to fight against malaria and especially the indoor sprinkling, experienced a decrease in the incidence of malaria that increased from 2014 to 2017 from 34 ‰ to 3 ‰. In the drive to maintain this incidence of pre-elimination of malaria, the district has put in place a strategy in 2018 whose goal is to get communities to engage in the fight against malaria through the use of social networks with the concept group "Zero Malaria". A descriptive study of this strategy was carried out and the choice of villages was reasoned based on the incidences of malaria recorded in the health structures. The initiative is based on the mentoring of young volunteers named "ambassador of fight against malaria" who through the network whatsapp carry out activities of awareness and mobilization against the malaria at the level of their village. Thus 20 cine buses were made and 20 "zero malaria" groups created. 200 ambassadors had to carry out awareness activities against malaria by sharing audio and video made by the ambassadors via whatsapp. 3340 people were sensitized including 2461 women and 879 men. The strategy has strengthened knowledge about malaria and increased community ownership of malaria.

1697

PHARMACOKINETIC/PHARMACODYNAMIC MODELING TO IDENTIFY OPTIMAL DIHYDROARTEMISININ-PIPERAQUINE INTERMITTENT PREVENTIVE TREATMENT REGIMENS FOR YOUNG UGANDAN CHILDREN

Erika Wallender[1], Emma Hughes[1], Abel Kakuru[2], Prasanna Jagannathan[3], Mary Kakuru Muhindo[2], Bishop Opira[2], Meghan Whalen[1], Moses Kamya[4], Grant Dorsey[1], Francesca Aweeka[1], Philip J. Rosenthal[1], Rada M. Savic[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*Stanford University, Palo Alto, CA, United States,* [4]*Makerere University, Kampala, Uganda*

Intermittent preventive treatment (IPT) with dihydroartemisinin-piperaquine (DP) is highly protective against malaria in young children, but concerns remain about optimal dosing, toxicity, and selection for drug resistance. We use pharmacokinetic/pharmacodynamic (PKPD) modeling to identify the optimal DP IPT regimen for Ugandan children as young as 2 months of age by describing the PK in this population and quantifying relationships between piperaquine pharmacokinetics and protective efficacy, toxicity, and markers associated with drug sensitivity. Clinical data, PQ concentrations ([PQ)]), and *P. falciparum* genotypes associated with decreased PQ sensitivity in Africa (*pfmdr1* 86Y, *pfcrt* 76T) were obtained longitudinally from Ugandan children randomized to receive standard dosing of DP as IPT every 12 weeks (n=184) or every 4 weeks (n=96) from age 2-24 months. We developed a population PK model using nonlinear mixed effects modeling and used logistic regression to evaluate the relationship between [PQ] and probability of parasitemia. From 280 children, 4,509 [PQ]s (3,627 troughs, 882 intensive), 120 ECGs, 142 malaria episodes, and 82 asymptomatic parasitemia episodes were analyzed. Median [PQ] was lower for children compared to adults, lower at age 24 months compared to 3 months (2.0 vs 4.2 ng/mL 12-week DP, 4.4 vs 4.9 ng/mL 4-week DP), and lower with asymptomatic parasitemia compared to not detected (1.3 vs 2.6 ng/mL). With symptomatic malaria the median [PQ] was 3.7 ng/mL (below the limit of quantification-12.5 ng/mL; 2.5-97.5% percentile). After allometric scaling, age-dependent enzyme maturation and weight for age z-score were significant covariates for PQ clearance: older or malnourished children had faster PQ clearance, thus require higher DP doses. PKPD analysis revealed a significant [PQ]-effect relationship, with 10 ng/mL PQ associated with 95% protection from parasitemia. Ongoing analysis is evaluating the relationships between PK and ECG QTc length and resistance markers. The similar protective [PQ] identified for children and pregnant women in Uganda is a key target to guide DP IPT optimization.

1698

MIDLINE RESULTS FROM A MALARIA INTENSIFICATION PLAN IN HIGH BURDEN AREAS OF CAMBODIA

Dr. Siv Sovannaroth[1], Michelle Pahl[2], Kimhong Gove[2], Chelsea Hanlon[2]

[1]*National Center for Parasitology, Entomology and Malaria Control in Cambodia., Phnom Penh, Cambodia,* [2]*Clinton Health Access Initiative, Phnom Penh, Cambodia*

Malaria cases increased in Cambodia by 289% between January and March 2018, compared to the same period in 2017. 80% of all reported cases were concentrated in 10 out of 21 Operational Districts (ODs), with over 90% occurring in the forested areas among migrant and mobile populations (MMP) and forest goers. In response, the Cambodia National Center for Parasitology, Entomology and Malaria Control (CNM) and partners established an Intensification Plan (IP) to accelerate the prevention of malaria infection and improve case management by health centers (HCs) and village and mobile malaria workers (VMWs/MMWs) for September 2018 - August 2019. CNM analysed cases reported through the Malaria Information System at all points of care to identify the 30 highest burden HCs in 10 target ODs. CNM conducted a mass screen and treat exercise in 4 villages per HC to identify transmission hotspots and at-risk populations. The first IP objective aimed to strengthen a core package: case management, commodity tracking, and data-driven supervision with HC and VMWs. The second objective aimed to dramatically reduce cases and increase testing by MMP by recruiting 95 MMWs to conduct active case detection twice per month, introduce behaviour change activities, and provide services 24 hours. CNM launched monthly Data Review and Action meetings with all partners to track key indicators and solve operational challenges. Success at the midpoint is due to rapid implementation of the two objectives and a collaborative M&E and problem solving process. In February 2019 there were 2,478 total cases in the IP areas, a 28% drop in total cases and a 60% drop in Pf cases compared to this time the prior year. 15,102 total tests were conducted in February 2019 in the 10 IP ODs (average 16% positivity rate), compared to 6,512 tests (average 53% positivity rate) in February 2018. Launching an IP required strong coordination between partners and within multiple units at CNM. Through this coordination and data-driven decision-making, impact on case burden has been demonstrated. CNM continues to implement and track the IP to determine its full effects at endline and potential for expansion.

BUILDING AN EVIDENCE BASE FOR COMMUNITY ENGAGEMENT DURING URBAN MALARIA OUTBREAKS: A QUALITATIVE STUDY IN SANTO DOMINGO, DOMINICAN REPUBLIC

Hunter Keys[1], Gregory Noland[2]

[1]*University of Amsterdam, Amsterdam, Netherlands,* [2]*The Carter Center, Atlanta, GA, United States*

Community engagement (CE) is considered vital to disease control and elimination. Haiti and the Dominican Republic (DR), which share the Caribbean island of Hispaniola, aim to eliminate malaria by 2020. In the DR, malaria has shifted from a rural to a mostly urban disease: the capital Santo Domingo accounted for 73% of all cases nationwide in 2018. Concurrent to these outbreaks, a policy of decentralization transferred primary responsibility for malaria control from the national to the local level. Malaria's changing epidemiology, the vulnerability of poor, peri-urban populations, and the need to strengthen local capacity have highlighted the need for effective CE, yet there has been no formal investigation of current CE practices in this setting. Using grounded theory, this qualitative study examined CE processes and outcomes in areas of Santo Domingo recently affected by malaria. Interviews and observational data were collected from July 2017 to March 2019 among national malaria program staff, local field teams, community members, and malaria patients. Findings suggest two predominant themes. First, while decentralization seeks to "empower the periphery" by training and supervising community volunteers, decision-making and knowledge-production are concentrated in sites of political and scientific power, creating missed opportunities for dialogue. Second, understandings of malaria's root cause and its elimination differ between public health and community spheres. Partly to avoid appearing too political, the malaria program focuses on the biological basis of disease: the parasite and its vector. In communities, however, malaria is understood to result from social, economic, and infrastructural inequalities: stagnant water, healthcare obstacles, and ineffective or corrupt institutions. These results reveal a disconnect in understanding between public health agencies and affected communities, and suggest that effective CE will likely require a more ground-up, politically-engaged approach.

DEVELOPING AND PILOTING A SUITE OF DIGITAL SOLUTIONS FOR MALARIA ELIMINATION

Vivek Agrawal[1], Anne Liu[1], Lakshmi Balachandran[1], Pedro Pagalday Olivares[1], Sameen Babur[1], Juan Manuel Acosta[2], Jose Garcia Munoz[2], Karoline Tufte Lien[2], Marta Vila[2], Rodolfo Melia[2], Derek Treatman[3], Pierre Dane[3], Anna Winters[4], Annie Martin[4], Matt Berg[5], Craig Appl[5], Abdisalan Noor[6], Mwalenga Nghipumbwa[6], Arnaud Le Menach[1]

[1]*Clinton Health Access Initiative, Boston, MA, United States,* [2]*University of Oslo, Oslo, Norway,* [3]*Vital Wave, Palo Alto, CA, United States,* [4]*Akros, Lusaka, Zambia,* [5]*Ona, Burlington, VT, United States,* [6]*World Health Organization, Geneva, Switzerland*

The Digital Solutions for Malaria Elimination project commenced in 2017, by identifying gaps in existing malaria surveillance systems across three regions - Greater Mekong Sub-region, Sub-Saharan Africa and Mesoamerica. The identified gaps produced software requirements that could improve information systems geared towards strengthening surveillance systems - including more user-friendly mobile interfaces in areas of low connectivity, integrated dashboards for decision support across levels, support for resource allocation and task management, and targeted visualizations of case and *foci* data on maps. Since then, a suite of tools and tool enhancements have been developed to cater to these requirements. These include enhancements to the DHIS2 Web platform (the de-facto malaria information system in many countries), which has expanded its data model to now accommodate relationships between different records (e.g. cases to *foci*), and mapping functionality to draw and update geographic boundaries and color code cases. A new Case Notification, Case Investigation and Focus Investigation application, powered by the DHIS2 Android Application, has been built to register cases and record field investigation data through an intuitive user interface with offline functionality. A new Focus Investigation and Response Intervention application, powered by a mobile tool named "Reveal", has also been built to conduct focus investigation and record field intervention data, through a map-based interface for effective tracking and analysis. Finally, a set of common goods have been developed to be accessible by any digital tool, including geospatial tools to improve accuracy and access to geographic data, a data dictionary to provide a standard set of definitions for malaria data, and an implementation guide for supporting digital tool operationalization. The various tools are in the process of being field-tested across ten focus countries, in the form of structured pilots with actual users. User feedback from these pilots will be incorporated into future software development. A full-fledged roll-out is expected to commence in late 2019.

MAPPING MALARIA HOTSPOTS IN OUTBREAKS FOR TARGETING INTERVENTIONS IN CAMBODIA IN 2018

Pengby Ngor[1], Siv Sovannaroth[2], Lisa J. White[1], Po Ly[2], Richard J. Maude[1]

[1]*Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*National Centre for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia*

Cambodia aims to eliminate malaria using a phased approach stratified by province for *P. falciparum* by 2020 and *P. vivax* by 2025. Efforts to achieve these targets are threatened by recent outbreaks with a 42% increase in reported malaria cases from 2017 to 2018, with a 28% reduction in *P. falciparum* and 137% increase in *P. vivax*. The Cambodia National Center for Parasitology, Entomology and Malaria Control (CNM) has adopted an intensification plan in 7 provinces which have around 80% of the cases. There is a need to identify areas within these provinces to target with additional resources to interrupt transmission during the outbreaks whilst minimising costs of implementation. To help with this, detailed maps of malaria hotspots were produced at village level using routine surveillance data from the CNM malaria information system (MIS) for 2018. The MIS in Cambodia includes individual level reports from all health facilities and village malaria workers in the country with data collected via a combination of paper and smartphone based reporting. In order to ensure maximum accuracy and completeness of the maps, locations of villages in the highest incidence provinces were verified, corrected and, where needed, collected by local healthcare workers using a combination of satellite images and field visits. These locations were then incorporated into the MIS and the maps produced using ArcGIS software. This poster will describe the process of collecting the data, producing the maps and give up to date information on how the results are helping CNM to plan the targeted delivery of interventions.

1702

REDUCTION IN MALARIA PREVALENCE IN SENTINEL POPULATIONS FOLLOWING INTRODUCTION OF A PACKAGE OF INTERVENTIONS FOR MALARIA ELIMINATION: RESULTS FROM EASY ACCESS GROUP SURVEYS IN 2017 AND 2018, GRANDE-ANSE (HAITI)

Thomas Druetz[1], Gillian Stresman[2], Vena Joseph[1], Ruth Ashton[1], Matt Worges[1], Lotus van den Hoogen[2], Bernadette Fouche[3], Eric Rogier[3], Michelle A. Chang[3], Jean F. Lemoine[4], Chris Drakeley[2], Thomas P. Eisele[1]

[1]*Tulane University, New Orleans, LA, United States,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Programme national de lutte contre la malaria, Port-au-Prince, Haiti*

In 2017, a total of 8,627 confirmed malaria cases were reported in the Grande-Anse Department - about 45% of all confirmed cases in Haiti. While incidence was approximately 1.8 cases per 1,000 at the national level, it was ten times higher in Grande-Anse. Thus, aggressive interventions are necessary to achieve malaria elimination in this Department. In a pilot area of 5 communes, the following interventions were implemented in the latter half of 2018: improved surveillance using case based reporting, mobilization of communities to help eliminate malaria, community case management, and indoor residual spraying (IRS) and mass drug administration (MDA), using single-dose sulfadoxine-pyrimethamine + primaquine, targeted to the 12 highest transmission *foci* only. A pre-post study using easy access groups surveys was used to assess changes in malaria prevalence in the 5 target communes before and after implementation of the intervention package. Surveys were conducted in November-December 2017 and 2018 (pre- and post-intervention, respectively) in the same venues - 25 primary schools selected in 2017 by stratified random sampling, and all 16 functioning health facilities in the area. In each venue type, 2,500 participants were sampled each year. Participants were administered a questionnaire to assess self-reported exposure to IRS and MDA. Participants were tested for a current *Plasmodium falciparum* infection using an HRP2-based rapid diagnostic test and for previous malaria exposure by screening for a panel of antibodies by Luminex. A total of 614 households reported having been sprayed, and 834 individuals reported having received MDA (acceptance rate: 90% and 85%, respectively). Preliminary results suggest a reduction in the overall RDT-based malaria prevalence following the piloted interventions (from 6.8% in 2017 to 1.4% in 2018). Declines were observed both in schools (from 3% to 0.4%) and in health facilities (from 10.5% to 2.5%). Difference-in-differences estimators will be used to assess the effectiveness of the intervention package to reduce malaria transmission, and ultimately to inform the national elimination strategy.

TIME SERIES ANALYSIS OF MALARIA IN BOTSWANA TO FORECAST FUTURE CASES

Refilwe Y. Senyatso[1], Erica P. Berlin[2], Tjantilili Mosweunyane[1], Mooketsi Molefi[3]

[1]*Botswana National Malaria Programme, Gaborone, Botswana,* [2]*Clinton Health Access Initiative, Westport, CT, United States,* [3]*University of Wits, Gaborone, Botswana*

Botswana is one of the countries that are targeted for malaria elimination by year 2020 by the World Health Organization E2020 Initiative and the Southern African Development Community Elimination 8 (SADC E8) Initiative. Botswana reoriented its malaria program towards elimination in 2010 due to a drastic reduction in confirmed malaria cases from 8056 in 2000 to 885 in 2009. The country has been recording incidence of less than 1 per 1000 population since 2011. However, upsurges of cases and incidence during outbreaks in 2014 and 2017 prevented Botswana from reaching earlier elimination targets in 2015 and 2018. This study uses ARIMA models to gain insight into which factors contribute most to driving malaria case trends in Botswana. Routine district level data on malaria cases, rainfall, temperature and Indoor Residual Spraying coverage were collected from January 2010-May 2018. We seek to find the impact these variables have on the number of malaria cases. We also aim to make projections to determine when Botswana will have zero local malaria cases to assess the feasibility of the 2020 elimination target. Preliminary analysis of the data of malaria cases compared with IRS coverage is not conclusive. This indicates that the changes on the number of cases are not affected by one variable. Notwithstanding this, further analysis indicates that malaria cases are declining beyond 2017. The findings of the study will inform strategies for accelerating malaria elimination in Botswana.

ESTIMATING MALARIA PARASITE MOBILITY IN MOZAMBIQUE USING MOBILE PHONE RECORDS

Jessica R. Floyd[1], Pedro Rente Lourenço[2], Nick W. Ruktanonchai[1], Andrew J. Tatem[1], Nuria Oliver[2]

[1]*University of Southampton, Southampton, United Kingdom,* [2]*Vodafone Research, London, United Kingdom*

Despite large reductions in burden, malaria remains one of the primary causes of death in Mozambique. Human-mediated parasite movement combined with spatial and seasonal changes in transmission threatens the success of interventions by reintroducing parasites to areas targeted for elimination. This is a particular concern in southern Africa, where relatively high transmission in Mozambique poses a challenge for the low-transmission countries nearby. Call detail records (CDRs) provide a unique insight into human movements in real time and have previously been used to identify sinks and sources of malaria in other countries. In this study we used pseudonymized and aggregated call detail records (CDRs) from a sample of over 8.5 million subscribers of a mobile phone operator in Mozambique to quantify human movements for four months in 2017. We combined these data with high-resolution malaria prevalence maps to calculate parasite importation and exportation rates and to identify potential net sinks and sources of malaria across districts. We used a community structure algorithm to explore the connectedness of provinces in Mozambique through human mobility, and we calculated parasite mobility between urban and rural areas at a high spatial resolution. We identified seasonal differences in parasite mobility between the months, with parasite exportation and importation rates varying in certain districts from month to month. We found that the districts in southern Mozambique are more connected to each other through human mobility than to districts in northern Mozambique, suggesting that current efforts to eliminate malaria from the southernmost provinces of Mozambique by 2020 could have lasting effects on reducing the risk of cross-border exports into neighbouring countries. We also observed differences in parasite mobility between rural and urban areas of the country. This work will help provide evidence to inform malaria elimination strategies regionally. Controlling malaria at parasite sources would benefit both the populations living in the source areas and the populations that suffer from malaria exported from those areas.

1705

IMPROVING MALARIA ELIMINATION PLANNING BY ACCOUNTING FOR SEASONAL POPULATION DENSITY AND MOBILITY

Nick Warren Ruktanonchai[1], Victor Alegana[2], Elisabeth zu Erbach-Schoenberg[1], Andrew Tatem[1]

[1]*University of Southampton, Southampton, United Kingdom,* [2]*Kenya Medical Research Institute-Wellcome Trust Research Programme, Nairobi, Kenya*

In malaria elimination settings, programmatic activities are often focused on targeting likely high transmission areas and at-risk populations before transmission ramps up. In many cases, however, population, mobility, and risk data used to plan elimination are often either based on the period data collection took place (such as the census period, for movement or population densities), or an annual average (for risk). In reality,

demography and mobility can vary seasonally. This means disease spread and the population densities that determine exposure and intervention effort can differ between high and low transmission seasons. New data, including call detail records (CDRs) from mobile phones, could help quantify how population densities and mobility varies between seasons, and therefore help optimize intervention effort each month. Here, we present an analysis of seasonal mobility and population densities in Namibia, linked with seasonal maps of malaria transmission. We quantify how connectivity of Namibia changes each month, and how high risk locations and exportation rates change when seasonal estimates are used. Within an R Shiny-based interface, we demonstrate how this relates to intervention effort, by optimizing community health worker travel to simulated settlements across malaria-endemic regions of Namibia. We find that optimal travel paths and community health worker catchment areas change significantly when accounting for seasonal mobility and risk, and in some areas, catchment areas varied dramatically from one month to the next during the early high transmission season of Namibia. We also find that transmission dynamics themselves change dramatically when using a seasonal picture of transmission and risk, implying significantly different maps of sources and sinks nationwide compared to a model where the annual average of mobility and risk is used. These results underscore the importance of using data from the appropriate month when dealing with seasonally-variable diseases like malaria, as important factors such as human mobility can vary as well as the intrinsic rates of infectious risk by month.

GENETIC RELATEDNESS OF MALARIA INFECTIONS IN SENEGAL REVEALS DISTINCT TRANSMISSION PATTERNS

Sarah K. Volkman[1], Stephen F. Schaffner[2], Rachel F. Daniels[1], Timothy Farrell[2], Yaye Die Ndiaye[3], Awa B. Deme[3], Aida S. Badiane[4], Fatou Ba Fall[5], Medoune Ndiop[5], Alioune Badara Gueye[5], Ibrahima Diallo[5], Yakou Dieye[6], Caterina Guinovart[7], Bronwyn MacInnis[2], Daniel L. Hartl[8], Doudou Sene[5], Daouda Ndiaye[4], Dyann F. Wirth[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Broad Institute, Cambridge, MA, United States,* [3]*Dantec Teaching and Research Hospital, Dakar, Senegal,* [4]*Cheikh Anta Diop University, Dakar, Senegal,* [5]*Senegal National Malaria Control Program, Dakar, Senegal,* [6]*PATH MACEPA, Seattle, WA, United States,* [7]*PATH MACEPA/ISGlobal Collaboration, Barcelona, Spain,* [8]*Harvard University, Cambridge, MA, United States*

Genetic analysis detected highly related Sénégal *Plasmodium falciparum* infections across time and space in both high burden and pre-elimination settings. We hypothesized that genetic signatures of parasite relatedness reflect transmission patterns and can be useful for targeting intervention and evaluating impact. We genotyped 4,397 malaria clinical samples collected from 2006 to 2018 representing distinct and dynamic transmission settings, including: Richard Toll (< 1/1000), Thiès (from > 100/1000 to < 10/1000), Kédougou (> 450/1000), and additional sentinel sites (n = 730). We analyzed data from 24 independent, high minor-allele-frequency single-nucleotide polymorphisms for relatedness using identity by descent (IBD) and identity by state (IBS). Only samples with a pairwise relatedness (IBD or IBS) of > 0.95 were included. Analysis revealed (1) significant temporal declines in IBS > 0.95, (2) persistent parasite lineages across geographic and temporal space, and (3) parasite relatedness that distinguished local from imported infections. In Thiès (n = 2,190) we detected 60 distinct parasite lineages persisting for more than one transmission season and up to 11 years duration. Epidemiological modeling of genetic patterns revealed transmission declines and rebounds, with significant differences ($p = 0.001$) in the fraction of IBS > 0.95 from 2006 to 2018. In Kédougou (n = 714) we observed increases in IBS > 0.95 and emergence of highly related and clonal parasites. In Richard Toll (n = 649), we found evidence for imported infections, with more than 21% of parasites sharing a genotype with a parasite from Thiès, as well as local infections with 10 parasite lineages persisting over multiple transmission seasons and highly related infections predominantly found within households of nontravelers ($p = 0.01$). Modeling spatiotemporal connectivity and simulations of parasite movement using genetic signatures of relatedness and gene flow are now being used to reveal patterns of malaria transmission to assess intervention strategies, stratification, and implementation.

1707

REDUCTIONS IN MALARIA BURDEN THROUGH THE USE OF A SCALABLE INTERVENTION PACKAGE (SIP) IN ACCORDANCE WITH THE ZAMBIA NATIONAL MALARIA ELIMINATION STRATEGIC PLAN 2017-2021: THE CASE OF MULOBEZI DISTRICT IN WESTERN PROVINCE

Kafula Silumbe[1], Javan Chanda[1], Ketty Ndhlovu[2], Marie-Reine Rutagwera[1], Busiku Hamainza[2], Anthony Yeta[2], Mutinta Mudenda-Chilufya[2], John M Miller[1]

[1]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia,* [2]*National Malaria Elimination Centre, Lusaka, Zambia*

The Zambian Ministry of Health's National Malaria Elimination Strategic Plan (NMESP) 2017-2021 calls for a package of malaria interventions to reduce malaria transmission through the use of proven vector control tools, expanding access to malaria treatment through case management, clearing parasites through selective use of mass drug administration (MDA), and improved surveillance including at both facility and community levels. Mulobezi District in Western Province, Zambia, is one of the few districts that has received the full scalable intervention package (SIP) as prescribed by the NMESP across all 13 health facility catchment areas (HFCA) within the district. Insecticide-treated nets were distributed to all households in January 2018 as part of a national mass distribution and indoor residual spraying campaigns have been conducted consistently since 2016; in addition, the roll out of surveillance activities in communities that utilize community health workers who follow up cases has been conducted since June 2016. To complement these interventions, four rounds of MDA were carried out in Mulobezi from late 2017 to early 2019. With the deployment of this SIP, a marked reduction in malaria incidence has been noted in the district. Reviewing the data across the months of February from 2017 to 2019, passive confirmed cases have reduced from 65% (Feb 2017) to 43% (Feb 2019). Active confirmed cases have also exhibited a downward trend from 1,707 (Feb 2017) to 152 (Feb 2019). The parasite reservoir is largely characterized by afebrile infections and with previous studies carried out noting that nearly half of the parasite reservoir consistently resides in children age 5 to 14 who are essentially school-age children. More targeting with parasite-clearing-specific activities is essential to address, the parasite reservoir. Therefore, data driven timely deployment of interventions is key in maintaining parasite-free communities. Ensuring adequate coverage of vector control and treatment combined with surveillance will enable optimal malaria burden reduction and help this district achieve its targets.

1708

FEASIBILITY AND ACCEPTABILITY OF A PEER NAVIGATOR-LED MALARIA FOCAL TEST AND TREAT INTERVENTION TARGETING HIGH-RISK POPULATIONS IN SOUTHERN LAO PDR

Emily Dantzer[1], Andrew A. Lover[2], Bouasy Hongvanthong[3], Khampheng Phongluxa[4], Francois Rerolle[1], Sophia Hocini[5], Rattanaxy Phetsouvanh[6], Adam Bennett[1]

[1]*University of California San Francisco, Malaria Elimination Initiative, San Francisco, CA, United States,* [2]*Department of Biostatistics and Epidemiology, School of Public Health and Health Sciences, University of Massachusetts, Amherst, MA, United States,* [3]*Lao PDR Centre for Malariology, Parasitology, and Entomology (CMPE), Vientiane, Lao People's Democratic Republic,* [4]*National Institute of Public Health/Lao Tropical Public Health Institute, Vientiane, Lao People's Democratic Republic,* [5]*University*

of California Los Angeles, Los Angeles, CA, United States, [6]Department of Communicable Disease Control (DCDC), Ministry of Health, Lao PDR, Vientiane, Lao People's Democratic Republic

Populations at higher risk (HRPs) of malaria in southern Lao PDR share similar occupational, behavioral, and social characteristics that increase their exposure to outdoor-biting mosquitoes. Based on a series of formative assessments in Champasak Province, shared characteristics include routine forest- and field-based work, sleeping outdoors, and frequent travel to local worksites. To engage these often hard-to-reach populations and improve their access to care, we implemented a focal test and treat (FTAT) intervention using peer navigators to target and test HRPs in forests and rice fields. The FTAT intervention comprised a demographic and malaria risk factor survey, testing using standard and ultra-sensitive RDTs, dried blood spot collection, treatment of positive cases, malaria IEC/BCC, and GPS tracking of HRP movement patterns. Peer navigators conducted FTAT continuously from March-November 2018 as part of a larger randomized controlled trial assessing the effectiveness of different targeted test and treat strategies to reduce *Plasmodium falciparum* transmission among village residents and HRPs in 14 health center catchment areas in Champasak. A mixed-method design was used to assess the capacity, feasibility, and acceptability of peer navigators to implement FTAT over time. Data collection methods included key informant interviews (KIIs) and focus group discussions (FGDs) with a diverse set of stakeholders including HRPs, peer navigators, formal health staff, and national and local malaria officials, as well as direct observations of peer navigators conducting all related FTAT tasks. A total of 4 FGDs, 38 KIIs, and 20 peer navigator observations were conducted over the course of the study, and both qualitative and quantitative findings generally support that FTAT is feasible, acceptable, and capable of being implemented by peer navigators. As more countries progress towards elimination, identifying evidence-based, community-led strategies to target HRPs and improve their access to malaria services is a priority, and if found to be effective, feasible, and acceptable, FTAT represents one such approach to bridging this gap.

1709

A SURVEY OF COMMUNITY HEALTH WORKERS CONDUCTING MALARIA COMMUNITY SURVEILLANCE IN ZAMBIA

Travis Porter[1], Elizabeth Chiyende[2], Todd Jennings[2], Marie-Reine Rutagwera[2], Christopher Lungu[2], Michael Hainsworth[3], Busiku Hamainza[4], Thomas P. Eisele[1], John M. Miller[2]

[1]*Tulane University, New Orleans, LA, United States, [2]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, [3]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States, [4]National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia*

As the burden of malaria has continued to decline in the southern regions of Zambia, the National Malaria Elimination Center (NMEC) has begun to further emphasize steps needed for achieving sub-national elimination. The National Malaria Elimination Strategic Plan calls for improved surveillance, community case management, and reactive case investigation to uncover remaining sources of transmission, in addition to vector control and other interventions that have been shown to substantially reduce malaria prevalence. To improve community access to malaria services and the health system's capacity to follow-up individual malaria cases, the NMEC began introduction of malaria focused community-based volunteer health workers (CHWs) in 2012. A community-led, decentralized recruitment approach has been instrumental in successfully expanding this network of CHWs across Southern and into Western and Central provinces, with over 3,400 CHWs introduced as of late 2018. However, little is known about the background, motivations, or support needs of this workforce which could help to improve program performance and sustainability, as well as ensure CHWs are receiving support needed to carry out their duties. We designed a cross-sectional survey to assess the professional experience, workload, perceptions of health system and community support, job satisfaction, and motivation of CHWs. In February and March of 2019, questionnaires were administered over the phone to a random sample of 480 CHWs—stratified by years of experience and province—operating within Southern, Western, and Central provinces. Early results from 351 completed questionnaires show that average scores on overall motivation and job satisfaction were high among program CHWs (4.2 and 4.6 out of 5, respectively), despite 40.7% reporting that CHW duties at least sometimes interfered with income earning or household responsibilities. Further analysis will explore associations between health system and community support and motivation on CHW performance, as well as the composition and predictors of motivation and job satisfaction among CHWs.

WINDBORNE LONG-DISTANCE MIGRATION OF MOSQUITOES AND PATHOGENS: IMPLICATIONS FOR MALARIA ELIMINATION

Tovi Lehmann[1], Alpha Yaro[2], Zana Lamissa[2], Samake Djibril[2], Moussa Diallo[2], Ousman Yossi[2], Diana L. Huestis[1], Yvonne M. Linton[3], Reed Mitchell[4], Ben Krajacich[1], Roy Faiman[1], Laura Veru[1], Jason W. Chapman[5], Don R. Reynolds[6], David Weetman[7], Martin J. Donnelly[7], Adama Dao[2]

[1]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [2]Malaria Research and Training Center (MRTC)/Faculty of Medicine, Pharmacy and Odonto-stomatology, Bamako, Mali, [3]Walter Reed Biosystematics Unit, Smithsonian Institution Museum Support Center, Suitland, MD, United States, [4]Smithsonian Institution - National Museum of Natural History, Suitland, MD, United States, [5]Centre for Ecology and Conservation, and Environment and Sustainability Institute, University of Exeter, Cornwal, United Kingdom, [6]Natural Resources Institute, University of Greenwich, Kent, United Kingdom, [7]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Mosquitoes are potent spreaders of some of the most impactful human diseases as is exemplified by malaria and dengue. Over the last century the most effective tools for combatting these diseases have targeted the vector. Long distance migration has been dismissed in mosquitoes since evidence for it has remained anecdotal and infrequent. To assess the potential for long distance mosquito migration, we sampled insects flying between 40 and 290 m above ground level in four Malian villages over three years using sticky nets mounted on tethered helium-filled balloons. Approximately 3,000 mosquitoes were collected amongst half a million other insects, and control nets confirmed that the insects were not captured near the ground. Over forty mosquito species, including members of the genus *Anopheles, Aedes,* and *Culex* were intercepted. Ten species, including primary and secondary malaria vectors were identified among >200 anophelines. Importantly, females accounted for >80% of all mosquitoes., and of these, 90% had taken a blood meal before their migration. This implies that pathogens will be transported by migrating females. The likelihood of capturing Anopheles increased with altitude and during the wet seasons. Simulated trajectories of mosquito flights indicated mean nightly travel of up to 300 km for 9-hour flight durations. Annually, the estimated number of mosquitoes at altitude crossing a 100 km line perpendicular to the winds were 6x10^6, and 4.4x10^7, for the vector species *An. coluzzii* and *An. squamosus*, respectively. These results provide compelling evidence that millions of previously blood-fed, malaria vectors frequently migrate over hundreds of kilometers across Mali, and thus almost certainly spread malaria over such distances. Malaria elimination success may, therefore, depend on whether sources of migrant vectors can be identified and controlled.

1711

EVALUATION OF COMMUNITY CASE MANAGEMENT AND REACTIVE CASE DETECTION (COMPONENT D) ON *PLASMODIUM FALCIPARUM* PARASITE PREVALENCE IN WESTERN PROVINCE, ZAMBIA

Travis Porter[1], Maya Fraser[2], Kafula Silumbe[3], Busiku Hamainza[4], Hawela Moonga[4], Joshua O. Yukich[1], Adam Bennett[5], Caterina Guinovart[6], Kammerle Schneider[2], Michael Hainsworth[2], Laurence Slutsker[2], John M. Miller[3], **Thomas P. Eisele**[1]

[1]*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States,* [2]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Seattle, WA, United States,* [3]*PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia,* [4]*National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia,* [5]*Global Health Sciences, University of California San Francisco, San Francisco, CA, United States,* [6]*Barcelona Institute for Global Health, Barcelona, Spain*

Zambia's current National Malaria Strategic Elimination Plan (NMESP) calls for high coverage with a comprehensive package of interventions to achieve malaria elimination. In addition to vector control and improved surveillance, the NMESP calls for improved access to malaria diagnosis and treatment through community case management (CCM). The CCM strategy enlists trained volunteer community health workers (CHWs) to provide malaria diagnosis and case management in their communities, and to report confirmed cases into the surveillance system. When feasible, CHWs also perform household testing and treatment for malaria infections around index cases within their community (aka, reactive case detection). Following successful scale-up of CCM in Southern Province by the end of 2014, the Zambia National Malaria Elimination Centre began a non-randomized district-level rollout of CCM in Western Province, starting with 7 districts in 2016, followed by 4 additional districts in 2017, 2 in 2018, with the remaining 3 districts slotted to receive CCM in the latter half of 2019. To evaluate the effectiveness of CCM at reducing *Plasmodium falciparum* parasite prevalence (*Pf*PR) in children <10 years old, 3 cross-sectional household surveys (2-stage cluster sampling design, proportional to cluster size) were conducted in Western Province during the peak malaria transmission seasons (April-May) in 2017-2019. Each survey was stratified by district to capture both those with and those yet to receive CCM. Preliminary results from the 2017 and 2018 surveys show *Pf*PR to have declined from 51.3% to 33.7% in districts which received CCM, while *Pf*PR declined from 40.6% to 24.9% over this period in districts absent CCM; 90.2% of households reported at least one form of vector control. A difference-in-difference estimator from random effects logistic regression showed the decline in *Pf*PR to be greater, although not statistically significantly, in the CCM districts as compared to non-CCM districts. Full results will be presented on the effect of CCM on *Pf*PR and confirmed malaria case incidence through mid-2019, with the inclusion of data from the ongoing 2019 survey.

A COORDINATED EFFORT: THE INTEGRATION OF MALARIA SURVEILLANCE FOR ELIMINATION INTO THE NATIONAL ELECTRONIC COMMUNICABLE DISEASE REPORTING SYSTEM IN VIETNAM

Thanh Duong Tran[1], Van Hoang Ho[2], Thanh Dong Le[3], Quang Thieu Nguyen[1], Quy Anh Nguyen[1], Huu Toan Trinh[2], Thi Yen Nguyen[3], Thi Thanh Thuy Cao[4], Jillian Dunning[4], Charlene Chinda Barina[4], Ha Le Phan[4], Quang Tan Dang[5]

[1]*National Institute of Malariology, Parasitology, and Entomology (NIMPE), Hanoi, Vietnam,* [2]*Institute of Malariology, Parasitology, and Entomology (IMPE), Quy Nhon, Vietnam,* [3]*Institute of Malariology, Parasitology, and Entomology (IMPE), Ho Chi Minh City, Vietnam,* [4]*Clinton Health Access Initiative, Boston, MA, United States,* [5]*General Department of Preventive Medicine, Hanoi, Vietnam*

Vietnam is committed to achieving malaria elimination by 2030 and has experienced a 70% reduction in the number of confirmed malaria cases since 2015, reporting a total of 4,813 in 2018. Elimination requires enhanced efforts toward timely and complete case-based surveillance and rapid response. The largest reporting system is the Ministry of Health's electronic communicable disease system (eCDS), a national platform used for 43 notifiable diseases. Several reportable communicable diseases have standalone systems that do not integrate with the larger reportable disease requirements, though sustainability requires close integration with systems that will continue to be maintained over time. The Malaria Management System (MMS), an electronic case-based reporting system capturing information on malaria diagnostics, case management, and epidemiology, is the first effort to integrate any reportable disease management system with the eCDS. Under the combined leadership of the General Department of Preventive Medicine (GDPM), the National Institutes for Malariology, Parasitology, and Entomology (NIMPE), Institutes of Malariology, Parasitology and Entomology (IMPE) in Quy Nhon and Ho Chi Minh City, and Viettel, Vietnam's largest mobile network operator, a surveillance roadmap for system integration was developed, costed, and approved by all. This was followed by a process to operationalize national surveillance guidelines, coordinate a user-centric approach to developing the electronic system based on user needs at multiple levels, and provide a comprehensive, scalable implementation plan with multiple international donors' support. The MMS pilot trained 80 staff in three provinces that represent 60% of Vietnam's malaria case burden, and results showed 97% of all reported cases(n=147) were classified, identifying local cases at the commune level. This integrated systems approach involved innovative coordination efforts that provide critical insights for other countries' efforts towards malaria elimination, and provides an example of surveillance management in elimination settings that is efficient and sustainable.

Malaria Transmission Blocking Vaccines (TBV) that target mosquito-stage development of the *Plasmodium* parasite by passive immunization of mosquitos during the blood meal from a vaccinated human, can play a significant role in malaria eradication. Pfs230 is a gametocyte and gamete surface antigen currently being evaluated as a TBV candidate. Chemical conjugation of subunit antigens to carrier proteins has been shown to be a good strategy to improve the immunogenicity of poorly immunogenic antigens. A 22kDa N-terminus domain of Pfs230 conjugated to a carrier protein EPA enhances its immunogenicity and this conjugate is currently under evaluation in clinical trials. Here, we assessed Outer Membrane Protein Complex (OMPC), a membrane vesicle derived from *Neisseria meningitidis*, as a carrier for Pfs230. We have synthesized Pfs230-OMPC conjugates with different levels of antigen load and examined their immunogenicity in mice. Chemical conjugation of Pfs230 to OMPC enhanced immunogenicity and functional activity of Pfs230 antigen, and OMPC conjugates achieved 2-20-fold higher antibody titer than Pfs230-EPA/ AdjuPhos® at different doses. OMPC conjugates were highly immunogenic even at low dose in mouse immunogenicity studies, suggesting a dose sparing effect. EPA conjugates generated an IgG subclass profile biased towards Th2 response in mice whereas OMPC

conjugates gave a strong Th1 biased immune response with high levels of IgG2, which can benefit Pfs230 functional activity that depends on compliment activation. OMPC appears to be a promising carrier for Pfs230 vaccines.

Chimeric rodent malaria parasites where the gene encoding circumsporozoite protein (CSP) has been replaced with different *csp* genes from the human malaria parasites, *Plasmodium falciparum* or *P. vivax*, are being actively used as pre-clinical tools to evaluate CSP vaccines *in vivo* in mice. In addition, chimeric rodent parasites expressing *P. falciparum* CSP have been evaluated as a whole sporozoite (Wsp) vaccine in preclinical studies. We have shown that these chimeric rodent parasites produce sporozoites in *Anopheles stephensi* mosquitoes, which are capable of infecting rodent and human hepatocytes. The availability of comparable chimeric *P. falciparum* parasites expressing *P. vivax* CSP would not only open up possibilities to test *P. vivax* CSP vaccines in small scale clinical trials using controlled human malaria infections but also to examine immune responses to heterologous antigens expressed by genetically attenuated WSp vaccines. We will describe the creation using CRISPR/Cas9 methodologies of several different chimeric *P. falciparum* parasites where either the *csp* gene has been replaced by one of the two major *P. vivax csp* alleles, VK210 and VK247, or these *P. vivax* alleles have been introduced into the genome as additional copy genes. We will present data on sporozoite production in *An. stephensi* mosquitoes, CSP expression and infectivity and immunogenicity of these chimeric *P. falciparum* sporozoites expressing *P. vivax* CSP.

Transmission blocking vaccines prevent mosquito infections but require durable functional antibody responses for malaria elimination. A phase 1 double-blind, 1-1 randomized, comparator-controlled trial (NCT02942277) in Mali assessed safety, tolerability, and functional immunogenicity of Pfs230D1M conjugated to ExoProtein A (EPA) and formulated with GSK's AS01 adjuvant vs. comparator ENGERIX-B. In March 2017, 236 healthy 18-50 yo volunteers from Bancoumana and Doneguebougou villages started doses on Days 0, 28, 168, and booster on Day 476. Volunteers received three full doses (40μg Pfs230D1M, n=56) or two full plus a third fractional dose (8μg Pfs230D1M, n=61), followed by full dose booster (n=82). Comparators received 3 ENGERIX-B doses then Menactra® on Day 476. Most AEs were mild injection site pain, headache and pyrexia (38-38.4°C). A single serious AE not related to vaccine occurred in ENGERIX-B group. Local reactogenicity was higher in Pfs230 arms (full dose n=111, fractional dose n=90) compared to comparator ENGERIX-B (n=42), $p<0.0001$, although mostly grade 1 (mild). After booster dose, 50/82 (61%) participants experienced local reactogenicity vs. 13/81(16%) comparators ($p = 0.0001$). Frequency of solicited systemic reactions was not significantly more frequent in the full (n=10) vs. fractional dose arm (n=4, $p= 0.1406$). A fraction (12.7%) of subjects had pre-existing antibodies to Pfs230D1M. ELISA titers post-dose 3 were significantly higher after the full (geometric mean= 1471.7 EU) vs. fractional dose (geometric mean=560.5 EU) , $p<0.0001$, then increased after the booster (4^{th}) but did not significantly differ between full and fractional arms. Standard membrane feeding assays (SMFA) 2 weeks post dose 3 showed significant functional activity ($p<0.0001$) in TBV arms (Median TRA 95.8; CI: 92.7, 97.4) versus comparator (53.6; 46.9, 62.3), while TRA after full dose Pfs230D1M (96.9; 94.1, 98.8) vs. fractional dose Pfs230D1M (93.6; 82.6, 97.3) did not differ ($p=0.2$). Detailed data on safety, immunogenicity, and functional activity by SMFA as well as by direct skin mosquito feeding (DSF) assays will be presented.

A malaria transmission-blocking vaccine is considered a vital tool for malarial eradication. Pfs230 expressed on the surface of gametes is one of the promising transmission-blocking vaccine antigens, as antibodies against Pfs230 have been shown to inhibit parasite development in mosquito midguts by standard membrane-feeding assay (SMFA). Since Pfs230 is a large protein consisting of 14 cystein motif (CM) domains which have hampered its production as an intact protein, most studies focused on the region including the first CM domain at the N-terminal. In this study, we aimed to screen all possible domains in Pfs230 that efficiently elicit transmission-blocking antibody response. Recombinant proteins containing single-CM-domain, 2-CM-domain, or 4-CM-domain were produced by the wheat germ cell-free system to obtain specific mouse antibodies. Western blotting and indirect immunofluorescence assay demonstrated that about half of the mouse antisera against Pfs230 fragments specifically recognized parasite Pfs230. Their transmission-blocking activity was evaluated by SMFA using *P. falciparum* NF54 strain. Of the antibodies, only those against protein fragments containing the CM domain 1 showed strong transmission-blocking activity. The results strongly support the concept that future Pfs230-based vaccine development should focus on the Pfs230 CM domain 1.

COMPARATIVE ANALYSIS OF THE PARASITE NEUTRALIZING ACTIVITY OF ANTIBODIES RAISED AGAINST REGION II AND REGION III-V OF THE *PLASMODIUM FALCIPARUM* ERYTHROCYTE BINDING ANTIGEN-175

Kritika Chaddha[1], Gaurav Anand[1], Syed Yusuf Mian[1], Enna Dogra Gupta[2], Deepak Gaur[1]

[1]*Jawaharlal Nehru University, New Delhi, India,* [2]*Indian Council of Medical Research, New Delhi, India*

Blood-stage malaria vaccine development has focused on targeting critical ligand-receptor interactions that mediate RBC invasion by *Plasmodium* merozoites. In this receptor blocking approach, the goal has been to identify the RBC binding regions of different parasite ligands & analyze the invasion inhibitory activity of Abs raised against these binding regions. In this regard, the receptor binding domain, Region II of EBA-175 was one of the first Ags to attract attention. The binding of EBA-175 to Glycophorin A is mediated by RII. Recently, the non-binding region III-V has been reported to induce potent strain-transcending parasite neutralizing Abs that suggests a structural or functional role that is yet not fully elucidated. In order to validate the vaccine potential of the different regions of EBA-175, we conducted a head to head comparative analysis of the invasion inhibitory activity of Abs raised against RII & RIII-V individually & in combination with Abs against other essential antigens (PfRH5, CyRPA) that constitute a crucial multiprotein complex. The invasion inhibitory activity of the Abs were evaluated by standard FACS based growth inhibition assays (GIA). In head to head comparison of the GIA activity of RII & RIII-V Abs, we found RIII-V Abs to be significantly more potent than RII Abs (RIII-V 80% vs RII 30%) consistent with previous reports. Importantly, only RIII-V Abs exhibited strain transcending invasion inhibition further confirming previous reports. We further evaluated & compared the efficacy of RII & RIII-V Abs in combination with Abs against other essential merozoite Ags (RH5 & CyRPA). In all combinations, RIII-V outperformed RII, with RIII-V based dual combination (RIII-V+CyRPA) & triple combination (RIII-V+CyRPA+RH5) inhibited invasion by 80-90% in a synergistic/additive manner. Our study establishes Region III-V of EBA-175 as a more potent & efficacious vaccine target compared to Region II. Thus, our study endorses a paradigm shift to malaria vaccine research by validating the vaccine potential of a non-binding region of EBA-175 & supports its inclusion in a multi-component malaria vaccine against *P. falciparum*.

1718

CLINICAL SAFETY AND PROTECTIVE EFFICACY AFTER IMMUNIZATION WITH GENETICALLY MODIFIED *PLASMODIUM BERGHEI* SPOROZOITES EXPRESSI*NG P. FALCIPARUM* CIRCUMSPOROZOITE PROTEIN IN A FIRST-IN-HUMAN PHASE1/2A TRIAL

António M. Mendes on behalf of the PbVac consortium

Instituto de Medicina Molecular - Universidade de Lisboa, Lisboa, Portugal

Highly efficacious immunization strategies against malaria are needed that elicit high level and durable protection against infection by Plasmodium parasites. Whole-parasite vaccination approaches employing attenuated Pf sporozoites appear as a promising alternative to subunit vaccine candidates, but are still in relatively early stages of clinical development. We have recently established the pre-clinical proof-of-concept of a new immunization strategy based on the use of rodent P. berghei (Pb) parasites genetically engineered to express antigens of their human-infective counterparts. Here, we describe the first-in-human phase $^{1}/_{2}$a clinical evaluation of PbVac, the first malaria vaccine candidate of this type, consisting of Pb parasites that express the Pf circumsporozoite protein. Vaccine administration by infected mosquito bites was safe and well-tolerated by a total of ^{24} healthy trial participants. The vaccine elicited cross-species cellular immune responses and functional PfCS-dependent antibody responses, which can efficiently inhibit Pf sporozoite invasion of liver cells. Although sterile protection against a Pf challenge was not observed, the vaccine displayed a clear biological effect in all immunized individuals. A significant delay in patency as measured by qPCR and a marked decrease in parasite density at the onset of parasitemia were observed in all vaccinated volunteers, which translates into a > ^{90}% reduction in their liver Pf burden, relative to non-immunized controls. This study supports the proof-of-concept of a new paradigm in malaria vaccination.

LOWER VACCINE DOSE ASSOCIATES WITH ANTI-CSP ANTIBODY DURABILITY AND FUNCTION: PHASE I TRIALS OF R21/MATRIX-M IN EUROPE AND AFRICA

Georgina Bowyer[1], Navin Venkatraman[1], Alfred B. Tiono[2], Duncan Bellamy[1], Daniel Silman[1], Amy Flaxman[1], Mehreen Datoo[1], Shahid M. Khan[3], Jenny M. Reimer[4], Sodiomon B. Sirima[5], Adrian V. Hill[1], **Katie J. Ewer**[1]

[1]*The Jenner Institute, University of Oxford, Oxford, United Kingdom,* [2]*CNFRP, Ouagadougou, Burkina Faso,* [3]*Leiden University Medical Centre, Leiden, Netherlands,* [4]*Novavax, Uppsala, Sweden,* [5]*Groupe de Recherche Action en Santé (GRAS), Ouagadougou, Burkina Faso*

R21 is a virus-like particle (VLP)-based vaccine displaying the immunodominant repeat region of the circumsporozoite protein (CSP) of *Plasmodium falciparum*. We assessed R21/Matrix M in Phase I clinical trials in malaria-naïve volunteers to assess the immunogenicity of different doses of vaccine and determine the effect of a fractional third dose of vaccine on the quality of the immune response. R21 is novel in that CSP epitopes cover the particle surface, in contrast to RTS,S where surface-exposed HBsAg epitopes predominate, and R21 induces a comparable titre of anti-CSP antibodies with a 5-fold lower dose. When decreasing doses of R21 were compared, lower doses elicited more durable antibody responses and induced a qualitatively different phenotype of peripheral memory T follicular helper cells. A fractional third dose regime (50,50,10) was compared with three fractional doses (10,10,10), and durability of antibody response was significantly improved in the group receiving three reduced doses. Lower doses also induced a larger memory B cell population, including switched memory B cells, and increased the proportion of IgG+ cells within the memory B cell pool. Persistence of antibody responses at 3 months after vaccination was associated with the proportion of switched memory B cells, suggesting that dose optimization is important for induction of durable immunity. We also characterized functional activity in an inhibition of sporozoite invasion assay employing transgenic *P. berghei* parasites encoding the *P. falciparum* CSP antigen, demonstrating these antibodies are capable of binding the sporozoite and potently blocking infection *in vitro*. In a subsequent Phase I study in a holo-endemic region of Burkina Faso, we observed significant boosting of naturally-acquired anti-CSP antibody levels and, importantly, substantial boosting of low-dose vaccine-induced antibody responses after the malaria season. Optimal deployment of CSP-based malaria vaccines may require careful dose optimization with the associated benefit of reduced costs using dose-sparing regimes.

1720

PRIOR EXPOSURE TO BLOOD STAGE MALARIA IMPAIRS PROTECTIVE EFFICACY OF A *PLASMODIUM YOELII* 17XNL PRE-ERYTHROCYTIC VACCINE CANDIDATE

Miranda S. Oakley, Pallavi Malla, Winter A. Okoth, Victoria Majam, Sanjai Kumar

Food and Drug Administration, Silver Spring, MD, United States

Immunogenicity and efficacy of pre-erythrocytic malaria vaccine candidates, such as RTS,S and radiation attenuated sporozoites (RAS), has been shown to be severely compromised in clinical trials conducted in endemic regions compared to the United States. In this study, we measured the effect of prior exposure to blood stage malaria on pre-erythrocytic vaccine efficacy using a circumsporozoite surface protein (*Py*CSP) vaccine candidate in the *Plasmodium yoelii* 17XNL murine model of malaria. Immunization with *Py*CSP delivered in Montanide ISA

51 adjuvant induced antibody-dependent sterilizing immunity against sporozoite challenge in C57BL/6 mice. However, prior exposure of *Py*CSP vaccinated mice to blood stage malaria resulted in a significant increase in intrahepatic parasite burden after sporozoite challenge demonstrating that blood stage malaria impaired the protective efficacy of *Py*CSP. This loss of vaccine efficacy caused by prior exposure to blood stage malaria was accompanied by a threefold reduction in IgG1 antibody titers. Results of an ELISpot assay performed 14 weeks after vaccination indicate that prior exposure to blood stage malaria causes a significant contraction of the memory B cell response to *Py*CSP. This model can be used to identify novel immune regulatory pathways induced by blood stage malaria that compromise pre-erythrocytic vaccine efficacy.

1721

IDENTIFICATION AND CHARACTERIZATION OF A NOVEL ANTIGEN PFCDPK5 AS A MALARIA VACCINE

Dipak K. Raj, Brett Sherman, Anup Jnawali, Gerald Cham-Kpu, Jonathan D. Kurtis

Brown University, Providence, RI, United States

Malaria is among the leading causes of mortality in children under five years of age worldwide, with most of these deaths resulting from *Plasmodium falciparum* infection. Despite decades of research, no vaccine candidate has been shown to confer significant protection to children. In an ongoing antigen discovery studies, we pioneered a high-throughput differential whole proteome screening method to identify targets of antibodies that protect children from severe malaria or malaria-specific mortality and identified Schizont Egress Antigen-1 (Raj et al. Science 2014). In a parallel screening experiment, We identified antibodies against several clones of PfCDPK5 protein only in malaria resistant children's sera. The immediate goals of this study are to gain an immunological understanding of anti-PfCDPK-5 antibodies in preventing parasite maturation and egress. The localization study and growth inhibition activity were evaluated as per our published methods. The immunoblot shows PfCDPK5 expressed in ring and schizont stage of parasites. Immunolocalization studies demonstrate that the protein localization on the plasma membrane of ring stage parasite and on the merozoite of the rupturing schizont. The polyclonal antibodies generated by recombinant PfCDPK5 by protein or DNA vaccine shows significant growth inhibition activity in *in vitro* growth inhibition assay. Immunization of full length PbCDPK5 the mice orthologs of human malaria parasite gene (PfCDPK5) shows significant protection from parasitemia and survival against a lethal parasite strain. In the present study, we validate a rationally identified vaccine candidate; PfCDPK-5 using integrated translational approaches that harness high-throughput molecular techniques and *in vitro* and *in vivo* functional assays.

1722

Evaluation of the PfSPZ Vaccine has been conducted in Equatorial Guinea (EG) since 2015. Phase I and II trials have been completed. The EG Malaria Vaccine Initiative (EGMVI) team is planning to conduct a Phase III trial next year in Bioko Island, EG. Vaccine coverage is at the cornerstone for a malaria vaccine deployment in mass administration campaigns. This study is an overall assessment of the proportion of potential study volunteers who are excluded from enrollment based on the selection criteria set for the Phase II EGSPZV3 study. We aimed to analyze the causes of 'screening failures' in volunteers in the ongoing trials for PfSPZ Vaccine in Equatorial Guinea with the purpose of identifying potential obstacles for volunteer's enrolment. From a total of 376 participants that were screened for EGSPZV2 and EGSPZV3 studies, there were 142 (37.8%) among them that were screen failures according to the protocol eligibility criteria. The main causes of screen failures in both studies were: problems related to a functional/available phone 32(8.5%), hepatitis B virus infection 28(7.4%), hepatitis C virus infection 6(1.6%), other medical history 27(7.2%), pregnancy 11(2.9%), abnormal ECG 3(0.8%), travel history 7(1.9%), abnormal body mass index 16(4.3%), high risk of tuberculosis 3(0.8%), HIV infection 4(1.1%), and not willing to use depoprovera 5(1.3%). These EGSPZV trials invited subjects who considered themselves as being healthy. To explore the reasons for screening failures is important and allowed us to identify baseline health profile of the targeted study population. Scattered evidence is suggesting that these screening failures, which are costly and can delay the onset of the trial, can be easily prevented by our screening tests but the rate of viral hepatitis infections is a major concern for reviewing current operational challenges for vaccination coverage and health promotion activities.

1723

STRUCTURAL BASIS FOR DEVELOPMENT OF A *PLASMODIUM FALCIPARUM* TRANSMISSION BLOCKING VACCINE TARGETING THE 6-CYSTEINE RICH PFS230 OR THE PFS230-PFS48/45 PROTEIN COMPLEX

Kavita Singh[1], Martin Burkhardt[2], Raul Herrera[2], Apostolos Gittis[1], Sofia Nakuchima[2], Olga Muratova[2], Emily Higbee[2], Karine Reiter[2], Margery Smelkinson[3], Bruce J. Swihart[4], Baoshan Zhang[5], Richard Shimp[2], Vu Nguyen[2], Nicholas J. MacDonald[2], Patrick E. Duffy[2], David Garboczi[1], David L. Narum[2]

[1]*Structural Biology Section, Research Technologies Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [2]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [3]*Biological Imaging Section, Research Technologies Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [4]*Biostatistics Research Branch, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [5]*Vaccine Research Center, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

A transmission blocking (TB) malaria vaccine would lessen the burden of human disease. Two vaccine candidates from *Plasmodium falciparum* are derived from the sexual-stage proteins Pfs230 and Pfs48/45, which together form a membrane-bound complex on gametes. Currently, the leading TB vaccine employs the first cysteine rich domain (D1) of Pfs230 and induces TB antibodies in humans. However, little is known about Pfs230(D1) with regards to its structure, subcellular arrangement, functional epitope(s), role of complement or benefit of a combination vaccine targeting both proteins. Here, we present the crystal structure of the recombinant domain 1 of Pfs230 (Pfs230D1M) in complex with a recombinant Fab fragment of a TB monoclonal antibody (mAb) 4F12

which binds Pfs230D1M using mainly hydrophilic interactions. Using mAb 4F12 and a panel of four new mAbs, we characterized their binding to Pfs230, their capacity to block transmission, and further evaluated the role of complement in TB activity. With confocal microscopy we observed that the structural arrangement of Pfs230 on the surface of macrogametes differed from that on microgametes and that some Pfs230 appeared to be uncomplexed with Pfs48/45. Studies using an *ex vivo* feeding assay demonstrated that mixing mAbs against different epitopes of Pfs230D1, or against Pfs230D1 and Pfs48/45 domain 3 (D3 also identified as Pfs48/45 6C) significantly increased TB activity compared to single mAbs alone. These structure and function studies provide insight on the mechanism of action of the Pfs230D1M vaccine, model the functional activity induced by a polyclonal antibody response and support the continued development of TB vaccines targeting Pfs230 and the Pfs230-Pfs48/45 protein complex.

1724

MANUAL DISSECTION OF MOSQUITO SALIVARY GLANDS WITH SHORTENED TRAINING TIMELINES

Alyssa Arnheim, Urvashi Rai, Hajar Hazime, Stephen L. Hoffman, B. Kim Lee Sim, Sumana Chakravarty

Sanaria Inc., Rockville, MD, United States

Plasmodium falciparum (Pf) Sporozoite (SPZ)-based vaccines are the only malaria vaccines to have demonstrated >90% protective efficacy against controlled human malaria infection. All PfSPZ products use the stage of the malaria parasite that is transmitted from mosquitoes to humans. Therefore, in Sanaria's manufacturing process, the mosquito behaves as a bioreactor, from which parasites are then extracted by microdissection of the insects' salivary glands ensuring several thousand-fold purification away from irrelevant mosquito constituents. The extraction of salivary glands by microdissection of mosquitoes involves four distinct steps performed by skilled personnel a) mosquito alignment b) decapitation c) gland extrusion and d) gland collection. In earlier iterations all steps in dissection were performed by individual trained dissectors, whereas in late 2015, altered configurations led to increases in efficiency and throughput of fully manual dissection, adding at least 100 mosquitoes to the average rate of dissection per hour within just 2 months of being instituted, and a 2-3 fold increase in the total number of mosquitoes processed in a single day. In addition, ergonomic set up of the work stations reduced dissector fatigue and allowed longer working hours. Sanaria is currently in the process of scaling up production to meet the needs of upcoming Phase 3 clinical trials which is very feasible with the manual dissection setup. We have implemented a new training program that brings on part-time dissectors to participate in GMP dissection for manufacturing. Over the course of six months, we have developed and implemented this program, and finalized 12 trainees from a pool of 82 applicants. In the past three months, we have trained two cohorts of dissectors and are prepared to bring on a third. Each dissector spends an average of 4 hours and 50 minutes training per day and on average, trains four days a week. Though the dissectors had minimal prior experience with dissection and microscopy, they are on track to be fully trained within three months.

CHALLENGES FACING NATIONAL MALARIA CONTROL PROGRAM VECTOR SURVEILLANCE

Tanya Russell[1], Robert Farlow[2], Tom Burkot[1]

[1]*James Cook University, Cairns, QLD, Australia,* [2]*R Farlow Consulting LLC, Burkeville, TX, United States*

Further gains in controlling malaria will require preserving the effectiveness of our present recommended vector control interventions while integrating new control strategies based on the susceptibility of local vectors to specific interventions. As the number of recommended interventions expands, the need for vector surveillance will grow to enable selection of appropriate interventions based on the ecology and biology of the vectors in specific epidemiological contexts. In order to assess the current status of vector surveillance by National Malaria Control Programs, an online survey gathered information from 35 national malaria control programs or their partner organizations. Few countries collected all the World Health Organization recommended surveillance data, and the underlying weaknesses that compromise national programs to implement fully effective vector surveillance are analyzed. The national programmatic limitations/weaknesses of vector surveillance self-identified by respondents all fell into three broad categories: lack of capacity, weak strategic planning and poor techniques. Overwhelmingly the countries provided responses that related to a lack of capacity within the Ministry of Health, with the main themes identified being limited spatial or temporal vector surveillance data, inadequate manpower and insufficient training opportunities. This has implications for the ability of National Malaria Control Programs to collect and utilize vector surveillance data that will support effective vector control and elimination.

The objective of this study was to assess the insecticidal durability of long lasting insecticidal nets (LLIN) (75 denier polyester and 100 denier polyester) 6 and 12 months after a mass bed net distribution campaign in southern Mali in December 2017. We conducted the study in two sites that participated in the campaign. Random samples of 30 campaign nets were collected from the two districts Kenieba (Site 1) and Kita (Site 2) and we collected information about bed net use and washing practices. We used the World Health Organization (WHO) cone bioassay to assess the insecticidal effectiveness of the LLINs. A laboratory colony of *Anopheles gambaie* Yaounde was used to conduct the bio-assay following the recommendation of WHO for phase III testing of LLIN. The bio efficacy assessment is underway. Preliminary results indicate similar bed net usage patterns in the two sites although there was a tendency toward less usage in site 1. The proportion of bed nets used the night before the survey was lower in Site 1 (57%) than in Site 2 (90%). Similarly, the bed nets were used during both the rainy and dry seasons 53% of the time in Site 1 and 73% of the time in Site 2. The proportion of nets washed was similar in Sites 1 (70%) and 2 (83%) although the mean number of washings over the last 6 months (if washed) was 4.5 times in Site 1 in contrast to 2.9 times in Site 2. The mains soap used at both sites were detergent or bleach.

Liverpool, United Kingdom, [5]School of Medicine, College of Health Sciences, Makerere University, Kampala, Uganda, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

To achieve and maintain universal coverage of long-lasting insecticidal nets (LLINs), the World Health Organization (WHO) recommends that countries distribute nets free-of-charge through mass campaigns repeated every 3 years. However, a growing body of evidence calls the 3-year lifespan of LLINs into question. Together with the Ugandan Ministry of Health, we embedded a cluster-randomized trial to evaluate the impact of LLINs delivered in a mass distribution campaign in 2017-18. A total of 104 clusters (health sub-districts) in Eastern and Western Uganda were included, covering 48 of 121 (40%) districts. Using adaptive randomisation driven by the number of LLINs available, clusters were assigned to receive one of 4 types of LLINs, including 2 brands with PBO: (1) PermaNet 3.0 [n=32] and (2) Olyset Plus [n=20]; and 2 without PBO: (3) PermaNet 2.0 [n=37] and (4) Olyset Net [n=15]. We are conducting cross-sectional community and entomology surveys at baseline, and 6, 12, 18 and 24 months after LLIN distribution. Net survivorship will be assessed in the community surveys and net durability and bio-efficacy will be evaluated in nets withdrawn from households with replacement at 12 and 24 months. The 18-month follow-up surveys will be complete in September 2019. Our baseline survey highlighted the major problem of net attrition, with only 65.0% of households owning at least one LLIN and only 17.9% adequately covered (at least one LLIN per 2 residents) approximately 3 years after the last mass distribution campaign carried out in Uganda in 2013-14. We will present preliminary results from the first three follow-up surveys and discuss LLIN survivorship and attrition, and changes over time. The results of this innovative, large-scale trial embedded within a routine national distribution campaign will make an important contribution to malaria control policy in Uganda, and throughout Africa.

1728

LLIN EVALUATION IN UGANDA PROJECT (LLINEUP) - IMPACT OF LONG-LASTING INSECTICIDAL NETS WITH AND WITHOUT, PIPERONYL BUTOXIDE ON MALARIA INDICATORS IN UGANDA: A CLUSTER-RANDOMIZED TRIAL

Samuel Gonahasa[1], Moses R. Kamya[1], Grant Dorsey[2], Catherine Maiteki - Sebuguzi[3], Agaba Katureebe[1], Mary Kyohere[4], Adoke Yeka[1], Amy Lynd[5], Jimmy Opigo[3], Janet Hemingway[5], Martin Donnelly[5], Sarah G. Staedke[6]

[1]*Infectious Diseases Research Collaboration, Kampala, Uganda, [2]University of California San Francisco, San Francisco, CA, United States, [3]National Malaria Control Division - Ministry of Health, Kampala, Uganda, [4]Makerere University - John Hopkins University Research Collaboration, Kampala, Uganda, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom*

Long-lasting insecticidal nets (LLINs) that combine pyrethroids with piperonyl butoxide (PBO) are a promising new tool to reduce the impact of pyrethroid resistance on malaria control. The World Health Organization has issued a preliminary endorsement of PBO LLINs, but additional epidemiological evidence of the effect of PBO LLINs is urgently needed. Together with the Ugandan Ministry of Health, we embedded a cluster-randomized trial to evaluate the impact of LLINs delivered in a mass distribution campaign in 2017-18. A total of 104 clusters (health sub-districts) in Eastern and Western Uganda were included, covering 48 of 121 (40%) districts. Using adaptive randomisation driven by the number of LLINs available, clusters were assigned to receive one of 4 types of LLINs, including 2 brands with PBO: (1) PermaNet 3.0 [n=32] & (2) Olyset Plus [n=20]; & 2 without PBO: (3) PermaNet 2.0 [n=37] & (4) Olyset Net [n=15]. We are conducting cross-sectional community surveys in 50 randomly selected households per cluster (5200 households per survey) & entomological surveillance for insecticide resistance in up to 10 randomly selected households enrolled in the community surveys per cluster (1040 households per survey), at baseline, & 6, 12, 18 & 24 months after LLIN distribution; the 18-month follow-up surveys will be complete in September 2019. The primary trial outcome is parasite prevalence as measured by microscopy in children aged 2-10 years in the follow-up surveys. The results of this innovative, large-scale trial embedded within a routine national distribution campaign will make an important contribution to malaria control policy in Uganda, & throughout Africa, where pyrethroid resistance in malaria vectors has increased dramatically. We will present the preliminary results from the first three follow-up surveys & discuss the impact of PBO LLINs on malaria control. We will also highlight this study design as a model paradigm for future assessment of malaria control interventions.

1729

THE LONG ROAD TO A MAINSTREAMED NATIONAL ENTOMOLOGICAL SURVEILLANCE INFORMATION SYSTEM IN UGANDA

[1]*Ministry of Health, Kampala, Uganda, [2]World Health Oganisation, Kampala, Uganda, [3]PMI VectorLink, Kampala, Uganda, [4]Infectious Diseases Research Collaboration, Kampala, Uganda*

The Global Technical Strategy for malaria provides guidance to countries to ensure universal access to malaria prevention (Pillar 1) and transform malaria surveillance into a core intervention (Pillar 3) to accelerate progress towards malaria elimination. For the past decade, the Ministry of Health has embarked on programmatic scale up of vector control interventions mainly; the use of long lasting insecticidal treated nets and Indoor residual spraying aimed at reducing the vector density and preventing man-mosquito bites. The effectiveness of vector control tools is threatened by the development of insecticide resistance, inappropriate use of tools and poor quality of deployment. Furthermore, the scale up of vector control has contributed to reduction in malaria morbidity and mortality with increased likelihood of epidemics. In Uganda, entomological surveillance is conducted by partners, and entomological data is not routinely captured in the Health Management Information System (HMIS) to aide timely decision making. From 2016-2019, Uganda embarked on a systematic multifaceted approach to strengthen the national entomological surveillance information system to monitor the effectiveness of vector control tools, insecticide resistance, and for early epidemic detection. We present the processes of mainstreaming entomological surveillance. First, we conducted a situation analysis of the current entomological surveillance system. Findings guided the implementation phase including: Development of Integrated Vector Management strategy, guidelines, and Insecticide Resistance management plan; Capacity building at various levels; Inclusion of entomological indicators in the HMIS; and Development of an entomological surveillance framework. The framework spells out stakeholders roles and responsibilities, coordination mechanisms, surveillance methods, data management, flow, analysis, and use for decision making. Partners' were mapped to identify and define their activities and geographical scope. The accountability for decision-making and their follow-up will rest with the National Malaria Control Division.

The increase of pyrethroid-resistance in vectors of *Plasmodium falciparum* has become a threat to the vector control program using long-lasting insecticidal nets (LLINs). Olyset®Plus is a LLIN incorporating pyrethroid permethrin and piperonyl butoxide (PBO). PBO is a synergist inhibits the activities of the enzymes that metabolize the pyrethroid. We examined whether Olyset®Plus reduces *P. falciparum* infection in children aged between 0 to 10 years in Gambe East, western Kenya. The main vectors in this area are *Anopheles arabiensis* and *An. funestus* s.s that have developed resistance to pyrethroid insecticides. The study area was divided to 12 sub-areas, and Olyset®Plus was distributed to residents in randomly selected four sub-areas. Olyset®Net (permethrin only LLIN) was also distributed in randomly selected other four sub-areas for the control arm. The PCR based pre-intervention infection rates of *P. falciparum* were 61.0% in the area covered with Olyset®Plus and 59.0% in the Olyset®Net area. After six months, the rates were reduced to 30.6% and 44.8% in the Olyset®Plus area and the Olyset®Net area, respectively, and 34.7% and 46.6% after 12 months, respectively. The differences in the post-intervention rates were statistically significant (permutation test at 5% significant level after adjusting for the confounding factors). Olyset®Plus was more effective for reducing *P. falciparum* infection.

1731

SURVIVAL OF 8 LLINS TYPES 6, 12, 24 AND 36 MONTHS AFTER A MASS DISTRIBUTION CAMPAIGN IN RURAL AND URBAN SETTINGS IN SENEGAL

Mbaye Diouf[1], Roger Clément Tine[1], Demba Anta Dione[2], Olivier Briet[3], Babacar Thiendella Faye[4], Isma Sow[5], Abdoulaye Konate[1], Abdoulaye Kane Dia[1], El Hadji Diouf[1], El Hadji Amadou Niang[1], Lassana Konate[1], Ousmane Faye[1]

Long Lasting Insecticidal Nets (LLINs) are one of the core components of global malaria prevention and control. The lifespan of LLINs varies widely depending on the population, AND randomized studies are required to compare net types in households under different field condition. This study evaluated the survival of LLINs in Senegal. 12,608 LLINs were distributed in 5 regions each stratified by rural and urban setting. As part of the longitudinal follow-up, 2222 nets were randomly sampled and monitored from 6 to 36 months. Using random effects for households, Bayesian model were allowed to estimate independent survival by net type and by area (rural/urban) with a coefficient of variation superior to 0 in the 95%CI. The complement of survival, attrition and median survival time of each net type, was determined as those nets that were missing because they were reported destroyed AND thrown, or repurposed. Three net types had a proportion of survival above 80% after 24 months: Interceptor®87.8% (95%CI 80-93.4); conical PermaNet® 2.0 86.9% (95%CI 79.3-92.4) and LifeNet 85.6% (95%CI 75-93). At 36 months, conical PermaNet® 2.0 maintained a good survival rate, 79.5% (95%CI 65.9-88.8). The odds of survival was 2.5 times higher in rural settings than in urban settings (OR 2.5; 95%CI 1.7-3.7). The attrition due to redistributed nets showed that the two conical net types (PermaNet® 2.0 and Interceptor®) were more often retained by households AND their median survival time was well above three years(Tm=3.5 years for PermaNet® 2.0 and Tm=4 years for Interceptor®). Despite this good retention, Interceptor® had a weak physical integrity and its median survival due to wear and tear was below three years (Tm= 2.4 years). Differences in survival among LLINs types maybe driven by brand, shape or environmental setting. It appears that in Senegal, conical nets may survive longer. Conical nets also are retained longer by households due to shape preference and they also benefit from increased effective lifespan.

1732

LEVERAGING THE US PRESIDENT'S MALARIA INITIATIVE AND GLOBAL FUND RESOURCES TO IMPROVE THE OUTCOMES OF THE 2018 MASS CAMPAIGN OF LONG LASTING INSECTICIDE-TREATED NETS TO COMBAT MALARIA

Jocelyn Razafindrakoto [1], Hasina Harinjaka Ramiandrisoa[2], Soza Andriamarovesatra[3], Emery Nkurunziza[3], Laurent T. Kapesa[1], Aline Mukerabirori[4], Fanjanirina Randrianarivony[5], Mauricette Andriamananjara Nambinisoa[2], Cecilia Vitale[6]

[1]*USAID/PMI, Antananarivo, Madagascar,* [2]*Programme National de Lutte Contre le Paludisme, Antananarivo, Madagascar,* [3]*PSI, Antananarivo, Madagascar,* [4]*MSH, Antananarivo, Madagascar,* [5]*Consultant, Paris, France,* [6]*The Global Fund, Geneva, Switzerland*

Madagascar's National Malaria Control Program began instituting mass distribution campaign of long-lasting insecticide-treated nets (LLIN) since 2009, in an effort to combat malaria. Funding for these mass campaigns came primarily from the Global Fund (GF) and the US President's Malaria Initiative (PMI). During the 2009/2010, 2012/2013 and 2015 campaigns, each donor was assigned different implementation zones, and used different approaches and discordant timing based on funding availability, which resulted in coordination and reporting challenges. For the most recent 2018 mass campaign, implementation challenges became more profound, due to the transition from one Global Fund grant to another. Fifteen months prior to the campaign, the in-country Roll Back Malaria committee (RBM) including NMCP, PMI and GF agreed on unified campaign with one implementation plan, M&E plan and a strategy based on task attribution rather than on zonal attribution between donors. The decision was made to implement majority of campaign activities prior to June 30, 2018 with GF funds, while both GF and PMI funded activities between July-December 2018. Under this agreement, GF support to activities covered the pre-campaign census, development and reproduction of campaign register books, training of community agents training and transportation and storage of LLINs. PMI funds were used to support the campaign monitoring, training, training and stipends of data clerks, supervision, stipends for community health agents, and regional support teams. This task arrangement by donor enabled a cost savings, and allowed PMI to distribute an additional 745,000 GF-procured LLINs to cover gaps. In total, 13 million LLINs have been distributed to 5.9 million households by 103,000 community health agents through 7,701 distribution sites. Donor flexibility around resource mobilization and geographic areas of support, along with a unified and transparent mass distribution plan and budget contributed to the success of the distribution of 13 million of LLIN in Madagascar.

1733

INCREASED BITING RATE OF INSECTICIDE-RESISTANT *CULEX* MOSQUITOES AND COMMUNITY ADHERENCE TO IRS FOR MALARIA CONTROL IN URBAN MALABO, BIOKO ISLAND, EQUATORIAL GUINEA

Godwin Fuseini[1], Raul Ncogo Nguema[1], Wonder P. Phiri[1], Olivier Tresor Donfack[1], Carlos Cortes[1], Michael E. von Fricken[2], Jacob I. Meyers[3], Immo Kleinschmidt[4], Guillermo A. Garcia[5], Carl Maas[6], Christopher Schwabe[5], Michel A. Slotman[3]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Department of Global and Community Health, George Mason University,*

Sustaining high levels of indoor residual spraying (IRS) coverage (≥85%) for community protection against malaria remains a challenge for IRS campaigns. We examined biting rates and insecticide resistance in *Culex* species and *Anopheles gambiae* s.l., and their potential effect on community adherence to IRS. The average IRS coverage in urban Malabo between 2015 and 2017 remained at 80%. *Culex* biting rate increased 6.0-fold between 2014 and 2017, reaching 8.08 bites per person per night, whereas that of *An. gambiae* s.l. remained steady at around 0.68. Although *An. gambiae* s.l. was susceptible to carbamates and organophosphates insecticides, *Culex* spp. were phenotypically resistant to all four main classes of WHO recommended IRS insecticides. Similarly, the residual activity of the organophosphate insecticide used since 2017, ACTELLIC 300CS, was 8 mo for *An. gambiae* s.l., but was almost absent against *Culex* for 2 mo post-spray. A survey conducted in 2018 within urban Malabo indicated that 77.0% of respondents related IRS as means of protection against mosquito bites, but only 3.2% knew that only *Anopheles* mosquitoes transmit malaria. Therefore, the increasing biting rates of *culicines* in urban Malabo, and their resistance to all IRS insecticides, is raising concern that a growing number of people may refuse to participate in IRS as result of its perceived failure in controlling mosquitoes. Although this is not yet the case on Bioko Island, communication strategies need refining to sensitize communities about the effectiveness of IRS in controlling malaria vectors in the midst of insecticide resistance in non-malaria vector mosquitoes.

1734

EFFECTS OF POST INDOOR RESIDUAL SPRAYING ON MALARIA ENTOMOLOGICAL PARAMETERS OF MALARIA TRANSMISSION IN MALI

Moussa Keita, Ibrahim Sissoko, Sory Ibrahim Diawara, Drissa Konate, Sékou F. Traore, Seydou Doumbia, Nafomon Sogoba

West African International Center for Excellence in Malaria Research (ICEMR-WA), University of Sciences, Techniques and Technologies of Bamako, Mali), Bamako, Mali

In Mali, insecticide treated long lasting nets (LLINs) distribution and indoor residual spraying (IRS) in selected districts are the key interventions for vector control. Koulikoro has been one of the selected districts for IRS for about nine consecutive years (2008-2016). In 2016, the National Malaria Control Program (NMCP) decided to stop the IRS in Koulikoro district. In this study we are assessing the potential effect of post IRS on entomological parameters of malaria transmission in previous and No-IRS areas in the districts of Koulikoro and Banamba, respectively. Mosquitoes were collected using pyrethrum spray-catch. *An. gambiae s.l.* was morphologically identified. Enzyme-linked immunosorbent assay (ELISA) was used to determine sporozoite infection rates. Monthly entomological inoculation rates (EIR) were estimated by combining the PSC data mosquito sporozoite infection rates. *An. gambiae s.l.* was the only malaria vector collected in both areas. A total of 1787 specimen of *An gambiae s.l.* was collected previous IRS area after IRS stopping against 68 specimens during IRS period. In the No-IRS area 1438 specimen against 1040 were collected after stopping and during IRS period, respectively. The mean density of *An. gambiae s.l.* per room after stopping the IRS was 11.9 times (7.4/0.62) higher than during the IRS. In the No-IRS area and after stopping the IRS, the mean density was only 1.5 times lower (8.7/6.0) than during the IRS. During the IRS campaign in previous IRS area, data collected did not allow us to detect a transmission. During the post IRS in the same area we observed 3.86 infective bites person month. In No-IRS area the mean EIR was 0.17 infective bite person month during IRS against 1.58 after stopping IRS. There was an increase in both areas probably because of the inter-annual variation in transmission. But the magnitude in the increase in the previous IRS area is certainly due to the effect of stopping IRS. IRS reduces malaria transmission where it is implemented and also positively impact on neighborhood areas. Stopping IRS increase the risk of transmission in both areas with higher magnitude in the IRS area.

1735

A GOOD SPRAY: ENTOMOLOGICAL SURVEILLANCE RESULTS FROM A CLUSTER RANDOMIZED TRIAL TO EVALUATE THE IMPACT OF A THIRD GENERATION INDOOR RESIDUAL SPRAY PRODUCT ON MALARIA TRANSMISSION IN MOZAMBIQUE

Joseph Wagman[1], Aklilu Seyoum[2], Stephen Magesa[3], Kenyssony Varela[3], Rodaly Muthoni[3], Christelle Gogue[1], Kenzie Tynuv[1], Carlos Chaccour[4], Francisco Saute[5], Rose Zulliger[6], Abuchahama Saifodine[7], Baltazar Candrinho[8], Jason Richardson[9], Christen Forndel[9], Laurence Slutsker[10], Molly Robertson[1]

[1]*PATH, Washington, DC, United States, [2]Abt Associates, Bethesda, MD, United States, [3]Abt Associates, Maputo, Mozambique, [4]ISGlobal/Centro de Investigação em Saúde de Manhiça, Barcelona, Spain, [5]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [6]President's Malaria Initiative, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Maputo, Mozambique, [7]President's Malaria Initiative, US Agency for International Development, Maputo, Mozambique, [8]Programa Nacional do Controlo da Malaria, Maputo, Mozambique, [9]IVCC, Liverpool, United Kingdom, [10]PATH, Seattle, WA, United States*

The Mopeia District of Zambezia Province in Mozambique has a high malaria burden despite high levels of household coverage with long-lasting insecticidal nets (LLINs). In this context, a two-year, two-armed cluster-randomized trial (CRT) was conducted to evaluate the impact of indoor residual spraying (IRS) with a third-generation IRS product when combined with a 2017 mass LLIN distribution campaign. One study arm received pyrethroid-impregnated LLINs and the other arm received two annual rounds (late 2016 and again in late 2017) of IRS with a microencapsulated formulation of pirimiphos-methyl (Actellic®300CS) in addition to LLINs. After the 2017 mass distribution campaign, LLIN use measured in an active cohort of over 1500 children was consistently greater than 85% for 15 months across both study arms. Based on entomological surveillance, the primary vector species throughout all of Mopeia was *Anopheles funestus* s.s., though *An. gambiae* s.s. and *An. arabiensis* were also collected at much lower densities. Field-collected *An. funestus* populations demonstrated emerging resistance to multiple pyrethroids and to bendiocarb (between 80% – 90% mortality in standard WHO tube tests) but were 100% susceptible to pirimiphos-methyl. During the six months after each IRS campaign, monthly *An. funestus* densities were substantially reduced at sentinel sites in IRS clusters compared to non-IRS clusters: 63% fewer specimens were collected in indoor light traps after the 2016 campaign, and 85% fewer after the 2017 campaign. Similar reductions in the numbers of *An. funestus* landing on human landing collectors were also recorded from houses in IRS clusters, both indoors and outdoors, following each spray campaign. Taken together with concurrent significant reductions in malaria infection and case incidence rates in the IRS clusters during the trial, these vector surveillance results provide compelling evidence of the additional impact of combining a third generation IRS campaign with a universal LLIN coverage campaign in an area of high transmission, moderate pyrethroid resistance, and high LLIN usage rates (>85%).

1736

COULD REPORTING HOUSE-LEVEL INDOOR RESIDUAL SPRAY COVERAGE IN URBAN SETTINGS IN AFRICA BE MISLEADING?

Liberato Motobe[1], Lucas Ondo[1], Jordan M. Smith[1], Jose Antonio Mba Nlang[1], Wonder P. Phiri[1], Carlos Cortes[1], Godwin Fuseini[1], Carlos A. Guerra[2], Guillermo A. Garcia[2]

[1]*Medical Care Development International, Malabo, Equatorial Guinea,* [2]*Medical Care Development International, Silver Spring, MD, United States*

The effectiveness of indoor residual spraying (IRS) in providing community protection against malaria largely depends on achieving high coverage. The World Health Organization prescribes that ≥85% of all structures that are potential resting places for anopheline mosquitoes be sprayed. These include internals walls of structures, eaves, ceilings, doors/windows and furniture. A structure in this context is defined as a sprayable three or four walled space with a roof. Traditional housing in rural settings in Africa may or may not have wall partitions, hence a structure could be defined as an entire house. However, in urban areas, houses generally have multiple internal walls separating habitable spaces, some of which, like kitchens, are not sprayable. Reporting IRS coverage at house level could be misleading in urban settings if not all the structures in the houses are sprayed. We reviewed IRS data on Bioko Island where the average number of structures per house is five. From 2016 and 2018, it we found that between 78.6 and 82.0% of houses were sprayed. However, coverage based on number of structures sprayed was only between 75 and 77%. Our analyses aim to describe the discrepancy between the two methods of quantifying IRS coverage in an urban setting and to assess its implications on the effectiveness of this intervention at the community level.

1737

COMBINING LONG-LASTING INSECTICIDAL NETS (LLINS) WITH THIRD GENERATION-INDOOR RESIDUAL SPRAYING (IRS) PROVIDES SIGNIFICANT ADDED PROTECTION COMPARED TO LLINS ALONE IN CHILDREN UNDER FIVE YEARS OF AGE IN A HIGH-TRANSMISSION AREA OF MOZAMBIQUE

Carlos Chaccour[1], Rose Zulliger[2], Joseph Wagman[3], Aina Casellas[4], Abuchahama Saifodine[5], Baltazar Candrinho[6], Jason Richardson[7], Molly Robertson[3], Francisco Saute[8]

[1]*ISGlobal/Centro de Investigação em Saúde de Manhiça, Barcelona, Spain,* [2]*President's Malaria Initiative, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Maputo, Mozambique,* [3]*PATH, Washington, DC, United States,* [4]*ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain,* [5]*President's Malaria Initiative, US Agency for International Development, Maputo, Mozambique,* [6]*Programa Nacional do Controlo da Malaria, Maputo, Mozambique,* [7]*Innovative Vector Control Consortium, Liverpool, United Kingdom,* [8]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique*

The most recent World Malaria Reports suggest we are not on track to reach the WHO's 2030 global goals for morbidity and mortality reduction. However, new tools or better coverage with existing ones can help us get back on track. There is growing interest in combining indoor residual spraying (IRS) with long-lasting insecticidal nets (LLINs) as an insecticide resistance management strategy, and a pressing need for additional evidence on the public health impact and cost-effectiveness of this approach. A cluster-randomized trial comparing the impact of LLINs vs LLINs + IRS (Actellic®300 CS) was conducted in Mopeia, a district of Mozambique with high malaria transmission, over two consecutive transmission seasons (November 2016 to October 2018). The district also received a mass distribution of standard pyrethroid-only LLINs in June 2017. The main outcome was malaria infection incidence in a prospective cohort of 1500 children under five years of age. Secondary outcomes included malaria prevalence at peak of transmission season and confirmed malaria cases reported from health facilities with strengthened reporting. The incidence cohort showed a significantly lower malaria infection rates in the IRS+LLIN arm compared with the LLIN-only arm throughout the 2-year follow up - overall incidence rate ratio (IRR) 0.83 (95%CI: 0.79-0.86; p<0.001). A reduction in cases reported from health facilities was also observed - overall case IRR of 0.72 (0.71-0.73; p<0.001). No difference in prevalence between arms was found in the cross-sectional survey conducted at baseline in 2017 prior to the LLIN distribution, (OR 1.08: 0.82-1.43; p=0.585). In the 2018 survey a significantly lower prevalence was observed in the IRS+LLINs arm, OR 0.70 (95%CI: 0.53-0.93; p=0.015); this was most evident in the under-five population, OR 0.54 (95%CI: 0.36-0.8; p=0.002). In the high transmission setting of Mopeia, the combination of LLINs with IRS was associated with significantly lower malaria incidence than LLINs alone. These findings, along with ongoing cost-effectiveness analyses, provide additional evidence for guidance on combining vector control interventions.

1738

COST AND COST-EFFECTIVENESS OF COMBINING LONG-LASTING INSECTICIDAL NETS (LLIN) WITH THIRD-GENERATION INDOOR RESIDUAL SPRAYING (IRS) IN A HIGH-TRANSMISSION AREA OF MOZAMBIQUE

Rose Zulliger[1], Sergi Alonso[2], Carlos Chaccour[3], Baltazar Candrinho[4], Joseph Wagman[5], Abuchahama Saifodine[6], Molly Robertson[5], Francisco Saute[7]

[1]*U.S. President's Malaria Initiative and Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Maputo, Mozambique,* [2]*ISGlobal/Centro de Investigação em Saúde de Manhiça/Centre for Primary Care and Public Health, Barts and The London School of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom,* [3]*ISGlobal/Centro de Investigação em Saúde de Manhiça, Barcelona, Spain,* [4]*Programa Nacional do Controlo da Malaria, Maputo, Mozambique,* [5]*PATH, Washington, DC, United States,* [6]*U.S. President's Malaria Initiative, US Agency for International Development, Maputo, Mozambique,* [7]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique*

Indoor residual spraying (IRS) and long-lasting insecticidal nets (LLIN) are cornerstones of malaria prevention, but there are limited data on the cost-effectiveness of IRS in combination with LLINs. This cluster randomized controlled trial determined the costs of IRS with Actellic®300 CS and of malaria in a high burden area of Mozambique with high household coverage with standard LLINs to help calculate the incremental cost effectiveness of IRS. The direct (e.g. medical costs to family) and indirect (e.g. lost productivity) costs and burden of malaria were collected through a community cohort, cross-sectional surveys, health facility (HF) data and questionnaires on health system expenditures from 2016-18. All IRS costs were collected prospectively. Disability-adjusted life years saved will be modeled using the trial effect estimates to calculate incremental cost effectiveness ratios. In cross-sectional surveys (n=805) the median all-age household cost of uncomplicated malaria was US$3.46 (IQR $0.07–22.41) and of severe malaria was $81.08 ($39.34–88.38). Household costs for children (n=1536) were $1.63 (IQR $0.00–7.79) for uncomplicated malaria and $64.90 ($49.76–80.96) for severe. The median health system cost was $3.55 ($3.50–3.60) for uncomplicated malaria and $26.56 (IQR $18.03–44.09) for severe. Cohort LLIN use after a 2017 mass distribution campaign was consistently >85% in both study arms. The 2016 and 2017 IRS campaigns sprayed homes of 76,669 and 70,988 people at a total cost of $563,212 ($7.35/person protected) and $658,259 ($9.27/person protected), respectively. There were 960 fewer cohort infections in the IRS arm, a crude incidence rate ratio of 0.79 (CI_{95} 0.76-0.82; p=0.0007). Individuals from IRS clusters had 19% fewer HF visits and the protective effect was greater (27%) in children. Despite the provision of free malaria services, households incur important malaria expenses. While IRS was associated with substantial costs, it was also associated with significant reductions in malaria burden, underscoring the importance of considering both the effectiveness and costs of vector control interventions.

EFFICACY OF SUMISHIELD®50WG FOR INDOOR RESIDUAL SPRAYING AND SUSCEPTIBILITY OF *ANOPHELES GAMBIAE* S.L. TO CLOTHIANIDIN IN NORTHERN GHANA

Sylvester Coleman[1], Yemane Yihdego[1], Frank Gyamfi[1], Edem K. Obum[1], Lena Kolyada[1], Jon Eric Tongren[2], Kristen George[3], Jennifer Armistead[3], Sixte Zigirumugabe[4], Dominic Dery[4], Samuel Dadzie[5], Maxwell Appawu[5], Daniel Boakye[5], Daniel Szumlas[6], Dereje Dengela[7]

[1]*U.S. President's Malaria Initiative Vectorlink Project, Accra, Ghana,* [2]*U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Accra, Ghana,* [3]*U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States,* [4]*U.S. President's Malaria Initiative, U.S. Agency for International Development, Accra, Ghana,* [5]*Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana,* [6]*Armed Forces Pest Management Board, Silver Spring, MD, United States,* [7]*U.S. President's Malaria Initiative Vectorlink Project, Abt Associates Inc., Bethesda, MD, United States*

In 2018, the U.S. President's Malaria Initiative (PMI) VectorLink Ghana Project piloted indoor residual spraying (IRS) with SumiShield 50WG® (SS), a newly available insecticide product with clothianidin as an active ingredient, in Mamprugu Moaduri district. Six other districts were sprayed with Actellic 300CS® (AC), for which pirimiphos-methyl is the active ingredient. Clothianidin was introduced as a first step towards operationalization of an insecticide resistance management strategy through insecticide rotation with the aim of delaying potential emergence of pirimiphos methyl resistance after six years of spraying AC in PMI project districts. Using standard World Health Organization (WHO) cone wall bioassays, residual bio-efficacy of SS sprayed in Mamprugu Moaduri was compared with that of AC sprayed in two districts, West Mamprusi and Kumbungu. *Anopheles gambiae* s.l. susceptibility to clothianidin was assessed across 11 sentinel sites, eight that received IRS and three that did not, using Centers for Disease Control and Prevention (CDC) bottle assays. WHO tube assays were also conducted to measure the susceptibility of *An. gambiae* s.l. to pirimiphos methyl and clothianidin. Actellic 300CS® showed a residual life of 6-8 months on mud, cement and wood surfaces, when tested with *An. gambiae* Kisumu, and up to six months was recorded for wild *An. gambiae* s.l. after a 24-hour holding period. SumiShield 50WG® remained effective for eight months and seven months in cone assays with *An. gambiae* Kisumu and wild *An. gambiae* s.l. respectively, with >80% mortality, when mosquitoes were held for up to 3 days post exposure. The residual bio-efficacy of SS was comparable to that of AC. *An. gambiae* s.l. was susceptible (> 98% mortality) to clothianidin at all sites. The general susceptibility of the vector to clothianidin and the 6-8 months residual life of SS indicate that this insecticide is a potential option for rotation in subsequent IRS campaigns in Northern Ghana. Continuous field assessments of the susceptibility of the vector and monitoring of biomarkers for early detection of resistance is recommended.

1740

COVERAGE OF INDOOR RESIDUAL SPRAYING (IRS) AND IMPACT OF IRS IN *ANOPHELES* POPULATIONS IN SITES OF ELEVATED MALARIA TRANSMISSION IN GRANDE ANSE, HAITI

Daniel Impoinvil[1], Rodrigue Anagonou[2], Ffyona Patel[2], Djenam Jacob[2], Amber M. Dismer[1], Jean Baptiste Merilien[3], Karen E. Hamre[1], Kathleen Holmes[1], Willy Lafortune[3], Jean Frantz Lemoine[3], Michelle A. Chang[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Abt Associates Inc., Cambridge, MA, United States,* [3]*Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti*

Indoor Residual Spraying (IRS) for malaria control has not been used in Haiti for about 3 decades, despite the WHO recommendation that IRS be a core malaria intervention. The Malaria Zero Consortium included IRS in its pilot of a targeted interventions package to accelerate malaria elimination in Haiti. IRS with a capsule suspension formulation of pirimiphos-methyl was applied in 11 zones of elevated malaria transmission in the communes of Dame Marie, Anse d'Hainault and Les Irois. One round of IRS was done during the rainy season from 15 October to 2 November 2018. Entomological monitoring was done in sentinel sites in the 3 IRS areas and 3 non-IRS areas. Mosquitoes were collected using human landing catches, UV light traps and pyrethrum spray catches, morphologically identified to species, and assessed for parity. While, in total, 11,557 households with 35,469 people were enumerated in the 11 zones, spray teams identified 9,497 eligible for IRS; the operational coverage rate was 92% (8,709 of 9,497), while the total effective coverage rate was 75% (8,709 of 11,557). Reasons that eligible houses were not sprayed included refusals (34%), unmovable sick individuals (18%), closed houses (8%), head of household unavailable to consent (16%), and other reasons. Some specific reasons for refusals were concerns about insecticide smell or side effects, refusal to move furniture, or being busy. Using the WHO wall bioassay to assess insecticide residual activity, susceptible field-collected *Anopheles albimanus* exposed to sprayed walls monthly from October 2018 to January 2019 had a 100% mortality after 24 hours. Approximately 99.3% (2,230 of 2,246) of *Anopheles* collected across all six sentinel sites were identified as *A. albimanus*, 0.5% as *A. pseudopunctipennis* (n = 11) and 0.2% as *A. vestitipennis* (n = 5). *Anopheles* abundance fell by 85% following IRS (pre-spray: n = 1049; post-spray: n = 154) and by 7% in non-IRS areas (pre: n = 94; post: n = 87). Parity rates of *A. albimanus* decreased from 79% (pre) to 49% (post) in the IRS areas, but increased in non-IRS areas from 73% (pre) to 77% (post). IRS reduced *Anopheles* populations; IRS may be an important intervention to reduce malaria rates in Haiti.

1741

ANOPHELES DYNAMICS: BITING ACTIVITIES IN JABI-THENAN DISTRICT IN NORTHWESTERN ETHIOPIA

Alemnesh H. Bedasso[1], Habte T. Maasho[2], Sisay D. Lemma[1], Eliningaya J. Kweka[3]

[1]*Ethiopia Public Health Institute, Addis Ababa, Ethiopia,* [2]*Addis Ababa University, Addis Ababa, Ethiopia,* [3]*Division of Livestock and Human Disease Vector Control, Tropical Pesticides Research Institute, Tanzania, United Republic of Tanzania*

Distribution, abundance, feeding behavior and human-biting are among the medical entomological parameters evaluated when determining the vector capacity of mosquito species. Despite a tremendous expansion in the financing and coverage of malaria control tools provision that has led to a wide-scale reduction in malaria incidence and mortality, the disease continuous to be a global health threat. Generating evidence on the mosquito species composition, abundance, resting behavior, biting pattern is important in entomological studies monitoring disease vectors, especially in malaria endemic regions and helps to design effective malaria vector control strategy. From September 2016 to August 2017, adult mosquitoes were collected twice monthly using CDC light traps, pyrethroid spray catches (PSC), pit fall shelters (PFS) and human landing catches (HLC) in each village. During the 12-month sampling period, a total of nine thousand two hundred fifty-eight (9,258) *Anopheles* and *Culex* mosquitoes were using CDC, HLC, PSC and PFS methods. Overwhelming majority, 7,519(81.2%) was composed of *Culex spp* followed by *Anopheles gambiae* s.l. 1,183(12.8%), *An. pharoensis* 281(3%), *An. funestus* 151(1.6%) and *An. coustani* 124(1.3%). The mean density comparison of primary vector *An. gambiae* s.l. showed no significance difference between indoor and outdoor resting sites for both CDC and HLC collections. The peak biting time for major malaria vector *An. gambiae* s.l. was found to be between 22:00 to 00:00 hours with 54.8% of total collections were caught in the time interval. Malaria vectors from Jabi-Tenhan district showed both endophagic/exophagic and endophilic/exophilic behaviors. Thus, in addition to the indoor based interventions (LLINs and IRS) in place, additional vector control methods should be designed to address the problem of outdoor biting mosquitoes.

MORE RESOURCES REQUIRED FOR DEFINITIVE DIAGNOSIS OF CHOLERA IN UGANDA

Peterson stephen Kyebambe[1], Godfrey Bwire[2], Timothy Kiggwe[1], Stephen Alele[1], Francis Ongole[3], Douglas Kizito Makanga[1], Pross Ingabire[1], Julius Kabali Kuule[1], Robert Isabirye[1]

[1]*Naguru Referral Hospital, Kampala, Uganda,* [2]*Ministry of Health, Kampala, Uganda,* [3]*Uganda National Health Laboratory Services, Kampala, Uganda*

According to the World Health Organization, Cholera is entwined with consumption of contaminated water. In areas of the world where universal access to safe water has been achieved the disease has been eliminated but in Africa and parts of Asia as well as the Caribbean plus Latin America, it remains endemic. From early January to late February 2019 there was an outbreak of Cholera in Kampala,Uganda. A total of 51patients,26 male and 25 female, were admitted for treatment at the Naguru Hospital isolation unit.The first cases to be identified were residents of Rubaga,one of the five divisions of the city.Later on the disease spread to other areas. In an effort to get a definitive laboratory diagnosis for each case, we whenever possible, subjected their stool samples to the tests of *Vibrio cholera* Rapid Diagnostic Test (RDT), culture and Polymerase Chain Reaction(PCR). The tests were carried out at the national reference laboratory,UNHLS, in Butabika , Kampala.This undertaking met several challenges, mainly inadequate supply of test kits and reagents. Thirty two RDTs were done of which 9 were positive,23 negative and 19 were not tested. Thirty one had culture of which only 3 showed growth of V. Cholera. Of the 23 who were RDT and culture negative only 9 were subjected to PCR and of these 8 were positive indicating they were falsely identified as negative by the other two tests. There was one case of positive RDT but negative culture and PCR. The results indicate the need to scale up availability of cholera test facilities to enable definitive diagnosis, treatment and follow up of cases thus preventing mortality and propagation of the disease in the community as some sufferers of the illness end up becoming carriers of the bacterium and can contaminate more water sources.

TO COMPARE ENVIRONMENTAL SAMPLE COLLECTION POINTS FOR ACUTE FLACCID PARALYSIS (AFP) SURVEILLANCE FOR POLIO BURDEN VERSUS COLLECTION POINT FOR *SALMONELLA TYPHI* CULTURE POSITIVE CASES BURDEN STRATIFIED BY TOWNS IN KARACHI, PAKISTAN

Abdul Momin Kazi, Ayub Khan, Mohammad Tahir Yousafzai, Zabin Wajidali, Farah Naz Qamar

Aga Khan University, Karachi, Pakistan

Pakistan is currently facing Extensively Drug Resistant (XDR) *Salmonella typhi* epidemic with confirmed large outbreaks in Hyderabad and Karachi cities. In November 2016, the first case of ceftriaxone resistant bacillus was reported from Hyderabad. An outbreak investigation was then conducted to identify the determinants, burden and geo spatial distribution of the outbreak using GIS mapping analysis. Simultaneously there was spread of cases in all towns of Karachi. Since Nov 2016 to March 2019, 1801 *S. typhi* resistant culture positive cases have been confirmed by Aga Khan University Hospital main lab and collection point in Karachi and using geospatial mapping techniques location based GIS maps have been plotted according to all towns of Karachi. To order to understand the environmental factors for *S. typhi* resistant culture positive cases burden, water samples in Karachi are being taken from same points where polio AFP samples are being collected. However, comparing *S. typhi* resistant culture positive cases disease burden according to Karachi town versus AFP sample collection points are quite different. In this study we have shown high resolution maps comparing high risk areas for polio versus *S. typhi* resistant culture positive cases density areas where environmental samples are being collected. We identified that areas for XDR cases are not same as the areas from where polio AFP sampling is done according to disease burden from disease perspective. In conclusion, prevalence of *S. typhi* resistant culture positive cases is geographically different from polio AFP surveillance. Therefore, the location for environmental samples should be different according to disease burden.

MICROBE LITERACY: A NOVEL STRATEGY FOR INCREASING VACCINATION COVERAGE IN SINDH PAKISTAN

Farah N. Qamar[1], **Mohammad T. Yousafzai**[1], Sultan Karim[1], Hina Memon[1], Amber Kashif[1], Ed Higgins[2]

[1]*The Aga Khan University, Karachi, Karachi, Pakistan,* [2]*Microbe Literacy, New York, NY, United States*

According to the latest Pakistan Demographic Health Survey 2017-18, acceptance for all routine immunization offered through expanded program of immunization (EPI) was very low in Sindh (49%). In the recent outbreak response in Hyderabad using Typhoid conjugate vaccine (TCV), caregivers' stated reasons for refusing TCV as, unfamiliarity with infectious disease; knowledge of adverse effects of other vaccines, and rumours about vaccines. We believe that misconceptions about the infectious disease process are abstract to people with limited education. We piloted the effectiveness of a 2-hour microbe literacy (ML) workshop in improving vaccination coverage for TCV in Hyderabad. We did a cluster randomized trials in two locations in Hyderabad. Each cluster comprised of 40 households and 11 workshops on ML were conducted in the intervention clusters. Participants included caregivers, parents, grandparents, political leadership and religious stakeholders of the cluster. Opportunity was given to the participants to collect biological samples from their household and visualize on a LCD connected to a microscope. At the end of the workshop clear messages that diseases due to these microbes could be avoided by hand washing, boiling of water and vaccination. There were 11 clusters consisting of 420 households whose parents participated in the ML workshops. Of the 1265 children in the target age group for TCV, in the intervention cluster, 1235 agreed to receive TCV (98% acceptance). In the control cluster there were, 320 households of which 203 households accepted vaccination (63% acceptance). The ML workshop is a simple and novel strategy for improving vaccine acceptance in areas of low literacy.

1745

REDEFINING TYPHOID DIAGNOSIS: WHAT SHOULD A BETTER TEST LOOK LIKE, AND WHAT INNOVATIONS ARE AVAILABLE TO MEET THE NEEDS?

Richard Mather[1], Peter J. Dailey[2], Heidi Hopkins[1], **Sabine Dittrich**[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Foundation for Innovative New Diagnostics (FIND), Geneva, Switzerland*

Typhoid fever is a bacterial infection caused by *Salmonella enterica* serovar Typhi (*S.* Typhi*)*. It is a infectious disease, with ~10.9 million new cases worldwide and ~116,800 deaths in 2017. The disease is most common in Asia and sub-Saharan Africa, with children predominantly affected. Various aspects of *S.* Typhi biology make diagnosis challenging. While simple tests are available (e.g., Widal), a recent Cochrane review highlighted the poor diagnostic accuracy of currently available tools. These diagnostic deficiencies result in over- and under-estimations of disease prevalence, as well as over- and under-treatment of patients. An accurate typhoid test could reduce morbidity/mortality through faster diagnosis, improve targeting of antibiotic use, and support global vaccine strategies. In recent years, novel approaches have been described to develop typhoid diagnostics aiming to overcome the biological challenges. Building on the recent momentum around improved typhoid surveillance and potential advances in typhoid identification, a target product profile (TPP) was developed using a Delphi process with test users and key opinion leaders. The TPP contains 36 test characteristics scored by 19/40 stakeholders (48%), ranging from physicians/laboratory technologists working in endemic areas, to global health researchers and implementers. The final "optimal" scope focuses on a point-of-care test to improve care for *S.* Typhi and Paratyphi. In addition, to inform R&D, a detailed technology

landscape is being prepared to link possible innovations with technology solutions. This presentation will focus on the overall stakeholder vision for new tests, and the discordant Delphi process results that require additional discussion in targeted meetings. Mapping if and how recent advances in serological, molecular, metabolomic, proteomic, and transcriptomic research could be translated into product development efforts will be explored through a developer's lens. The TPP and the landscape will support the global typhoid agenda, and is a necessary step to support the roll-out of new vaccines and safeguarding of global antibiotics.

1746

NATIONAL FOOD SECURITY AND ANNUAL CHOLERA INCIDENCE RATE: A MULTI-DIMENSIONAL ANALYSIS OF 30 COUNTRIES FROM 2012-2015

Aaron Richterman[1], Andrew S. Azman[2], Georgery Constant[3], Louise C. Ivers[4]

[1]*Department of Medicine, Brigham and Women's Hospital, Boston, MA, United States,* [2]*Division of Infectious Disease Epidemiology, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Partners in Health/Zanmi Lasante, Cange, Haiti,* [4]*Center for Global Health, Massachusetts General Hospital, Boston, MA, United States*

Individual and household-level evidence suggests a relationship between food insecurity and cholera risk. The relationship between national food security and the size of cholera outbreaks is unknown. We performed an analysis from 2012-2015 estimating the relationship between national food security and annual cholera incidence rate. As our measure of food security we used components of the Global Food Security Index (GFSI), a composite measure of food security at the country level which is reported annually, incorporates 28 unique indicators, and allows for inter-dimensional and cross-national comparisons. We included countries with available GFSI reporting cholera during the study period, excluding high-income countries. We developed multivariable zero-inflated negative binomial models with cholera incidence rate as the outcome, GFSI components as the exposure of interest, fixed effects for country and year, and time-varying controls related to water, sanitation, and hygiene, oral cholera vaccine deployment, health care expenditure, conflict, and extreme weather. 30 countries were included, reporting 550,106 cases of cholera 2012-2015 with a median annual incidence rate of 3.1 cases per 100,000 people (IQR 0.3-9.9). Included countries were, in general, food insecure - among all countries with available GFSI, they had a median rank of 90 (IQR 77-103) out of 113 countries for Overall GFSI during the study period and included eleven of the thirteen most food insecure countries. We found an independent relationship between cholera incidence rate and Overall GFSI (IRR 0.57, 95% CI 0.43-0.78), GFSI-Availability (IRR 0.81, 95% CI 0.70-0.95), and GFSI-Affordability (IRR 0.76, 95% CI 0.62-0.92). In the context of prior evidence at the individual and household level, this suggests there is a linkage between food insecurity and cholera at the national level that should be further explored and considered when evaluating the risk and consequences of outbreaks. Food security is not currently considered in any programmatic guidance for cholera control, and the impact of cholera outbreaks on food security is rarely discussed.

1747

CLINICAL PREDICTORS FOR VIRAL ETIOLOGIES OF ACUTE DIARRHEA IN RESOURCE-LIMITED SETTINGS

Benjamin J. Brintz[1], Benjamin Haaland[1], Joel Howard[1], Andrew Pavia[1], Tom Greene[1], Dennis Chao[2], Joshua Proctor[2], Adam Levine[3], James Platts-Mills[4], Karen Kotloff[5], Daniel Leung[1]

[1]*University of Utah, Salt Lake City, UT, United States,* [2]*Institute of Disease Modeling, Seattle, WA, United States,* [3]*Brown University, Providence, RI, United States,* [4]*University of Virginia, Charlottesville, VA, United States,* [5]*University of Marland, College Park, MD, United States*

Non-laboratory methods to more accurately assess etiology are needed for appropriate management of pediatric diarrhea in low and middle income countries (LMICs). In LMICs, etiological diagnosis is rarely made, and a large number (up to 70%) of patients with acute diarrhea are prescribed antibiotics. With the goal of antibiotic stewardship, we use clinical and quantitative molecular etiologic data from the Global Enteric Multicenter Study (GEMS) to develop predictive models for etiology of diarrhea in young children. Given the lack of testing done in LMICs for infectious diarrhea, the attributable pathogen data from GEMS presents a unique opportunity to determine if a child's clinical information can help determine the etiology of the diarrhea. We aimed to build an implementable model of virus-only etiology for use in LMICs given the lack of efficacy of antibiotics in this context. In order to build a parsimonious model, we first screened potential clinical predictors from the GEMS survey via random forest variable importance. In addition to the clinical information, we constructed a season variable to represent rainy/dry and hot/cold weather patterns near the health centers, based on climate data from nearby weather stations. Variables predictive of virus-only etiology include age, vomiting, BMI, bloody diarrhea, breastfeeding, and season. We assessed performance using the receiver operating characteristic (ROC) curve and area under the curve (AUC) with 10-fold cross-validation of various parameter sizes for both random forest regression and logistic regression. Both the variable screening and model fitting were nested within the cross-validation. The cross-validation showed that with a small number of variables, both types of models can achieve AUCs of between .825 and .850. Results also show that the model will perform better in some locations than others and that location specific information is helpful. Our model's performance suggests that implementing a clinical prediction rule in LMICs can assist providers in managing infectious diarrhea treatment and reduce unnecessary and damaging prescription of antibiotics.

1748

DETECTION OF *SALMONELLA* TYPHI IN BILE BY QUANTITATIVE REAL-TIME PCR

Sharon M. Tennant[1], Ellen Higginson[1], Joseph Nkeze[1], Jasnehta Permala-Booth[1], Irene Kasumba[1], Rosanna Lagos[2], Juan Carlos Hormazabal[3], Gad Frankel[4], Myron M. Levine[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*Hospital de Ninos Roberto del Rio, Santiago, Chile,* [3]*Instituto de Salud Publica, Santiago, Chile,* [4]*Imperial College, London, United Kingdom*

Typhoid fever remains an important cause of febrile illness in many areas of Africa, Asia and Oceania. Short-cycle transmission of typhoid occurs via ingestion of food contaminated by short-term or chronic carriers of *Salmonella* Typhi who have lapses in personal hygiene (failure to wash hands with soap) after defecation. Chronic gallbladder typhoid carriers, who typically have gallstones, constitute the long-term reservoir of infection. One way to estimate the prevalence of chronic biliary carriers is to test bile collected at the time of cholecystectomy. Herein we describe detection of *S.* Typhi in bile by real-time PCR. A quantitative PCR protocol for bile is especially important where antibiotics are routinely given to patients just before cholecystectomy. We evaluated probesets that target *oriC* (all *Salmonella*), *viaB* (Vi-expressing *Salmonella*), *fliC*-d (*Salmonella* with Phase 1 flagellin type 'd'), STY0201 (*S*. Typhi only) and *stoD* (*S*. Typhi only). We evaluated sensitivity and specificity of each probeset. As expected, the *oriC* probeset was able to detect all *Salmonella* serovars tested, the *viaB* probeset was able to detect serovars that possess Vi capsule, the *fliC-d*, STY0201 and *stoD* probesets were specific for *S*. Typhi. The *oriC* probeset was the most sensitive followed by the STY0201 probeset. Using an optimized DNA extraction technique, we detected *S.* Typhi in spiked human bile samples down to a concentration of $7.4x10^2$ CFU/ml. Human bile samples were spiked with *S*. Typhi and cephalosporins. *S*. Typhi in suspensions as low as 10^2 CFU/ml were detectable by real-time PCR in samples containing cefazolin, cefotaxime or ceftriaxone but could only be detected by culture in samples containing cefazolin. This real-time PCR detection method for *S.* Typhi in bile is also useful where bile-containing duodenal fluid is obtained by string capsule

from household contacts of acute typhoid cases, in attempts to find chronic carriers. These techniques will be helpful for efforts to control typhoid disease in endemic regions.

1749

PRODUCTION OF THE FECAL INFLAMMATION MARKERS AFTER ORAL CHALLENGE WITH SHIGELLA SONNEI 53G IN A CONTROLLED HUMAN INFECTION MODEL

K. A. Clarkson[1], K. T. Lerner[1], R. W. Frenck[2], M. Dickey[2], A. E. Suvarnapunya[1], L. Chandrasekaran[1], M. McNeal[2], K. Detizio[3], S. Parker[2], A. Hoeper[2], C. K. Porter[3], N. Maier[4], A. Fix[4], A. L. Bourgeois[4], M. Venkatesan[1], R. W. Kaminski[1]

[1]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [2]*CCHMC, Cincinnati, OH, United States,* [3]*Naval Medical Research Center, Silver Spring, MD, United States,* [4]*PATH, Washington, DC, United States*

Shigella is a leading cause of diarrhea-associated morbidity and mortality in children under the age of 5 living in low to middle income countries (LMICs) where *Shigella* species are endemic. Repeated non-fatal enteric infections with pathogens such as *Shigella*reduces gut permeability, resulting in reduced intestinal absorption of nutrients. In children, the reduction in nutrient absorption contributes to a constant state of malnutrition manifesting as physical and cognitive stunting. Recently, a cGMP lyophilized strain of *S. sonnei,* 53G was produced and used in a Controlled Human Infection Model (CHIM) in North American adults to determine a dose that safely and reproducibly achieved a 60-70% attack rate. The *S. sonnei,* 53G CHIM was developed to provide a more standardized model for use in evaluating the efficacy of interventions, such as vaccines or immunoprophylactics. The model also provides a unique opportunity to investigate the intestinal inflammatory response post-infection. Fecal samples were collected prior to challenge and 3, 7 and 14 days post-challenge and the concentrations of calprotectin and myeloperoxidase were quantified by ELISA. Calprotectin and myeloperoxidase concentrations peaked 3 days post-challenge and returned to baseline by day 14. Both calprotectin and myeloperoxidase levels were highly correlated with multiple disease outcomes including diarrhea severity, disease severity score and dysentery. In addition, calprotectin and myeloperoxidase concentrations were predictive of the adaptive mucosal immune response in that subjects with high levels of fecal inflammatory markers also had robust *Shigella*-specific mucosal immune response, as measured by IgA secreting $\alpha4\beta7$ positive gut-homing B cells. These results suggest that the evaluation of intestinal inflammation markers may be used as an additional measure of vaccine efficacy to help further differentiate the impact of vaccination on *Shigella* disease.

1750

AN EVALUATION OF LOW-COST SPECIMEN PRESERVATION FOR CHARACTERIZATION OF ETEC AND SHIGELLA AMONG CHILDREN WITH DIARRHEA AND/OR DYSENTERY IN TWO REGIONS OF CAMEROON

Amanda K. Debes

Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Worldwide, more than 600,000 children under 5 years of age die annually from diarrheal diseases; nearly one-third of pediatric diarrheal deaths are due to Enterotoxigenic Escherichia coli (ETEC) and *Shigellae*. There is a need for information on the strains and serotypes in endemic areas which crucial to the development of effective vaccines targeting the most vulnerable populations. Classical microbiological methods are often not practical in resource constrained settings where future vaccine efficacy trials need to be conducted. We hypothesized that ETEC and *Shigellae* cause a large proportion of moderate-to-severe (MSD) diarrheal illnesses which may be controlled with vaccines currently being developed. We nested a pediatric cohort into on-going multi-site surveillance efforts in Cameroon. Children and adolescents <18 years of age were enrolled between 1/1/15 and 12/31/17 and were recruited based on >3 loose stools within 24hours, presence of dehydration and/or blood and/or mucus. A total of 3522 persons were enrolled, 2222 meet the enrollment criteria. 198 specimens were randomly selected and screened using the Taqman Array Card (TAC). We found 34.0% (N=67) ETEC positive, of which 35.8% (N=24) are LT-STh positive, and 10.4% (N=7) are LT-STp positive. 32.8% (N=22) of ETEC positive were in patients >5 years. CFs were found present in 41.8% of ETEC positive samples. 34.0% (N=67) of persons presenting with MSD and/or bloody and/or mucoid stool are IpaH positive, of which 31.3%(N=21) >5 years of age. 77 (85.6%) of 90 cases had one diarrhea-attributable pathogen detected and 13 (14.4%) cases had two or more. *Shigellae* and rotavirus are most strongly associated with diarrhea in children with mixed infections. The 5 most common attributable pathogens are *Shigellae*, rotavirus, ST-ETEC, *V. cholerae,* and Norovirus GII; accounting for 85.5% of all attributable diarrhea. This study identified areas where the rates of *Shigellae* and ETEC were higher than hypothesized, warranting the need for further research investigating these high-risk areas. Such research may identify potential field sites for evaluation of vaccine candidates being developed.

1751

TEMPORAL TRENDS IN NON-TYPHOIDAL *SALMONELLA* GASTROINTESTINAL INFECTIONS IN CHILDREN UNDER FIVE FROM THREE COUNTRIES IN SUB-SAHARAN AFRICA

Irene N. Kasumba, Helen Powel, Anna Roose, Sunil Sen, Shamima Nasrin, Jasnehta Permala-Booth, Sharon M. Tennant, VIDA Consortium

University of Maryland Baltimore, Baltimore, MD, United States

Non-typhoidal *Salmonella* (NTS), an etiologic agent of gastroenteritis, is a risk factor for morbidity and mortality in young children. The two most common serovars that cause gastroenteritis worldwide are *S*. Typhimurium and *S*. Enteritidis. Additionally, variants of these two serovars also cause invasive disease in infants in sub-Saharan Africa. We evaluated the serovars, antimicrobial sensitivity and genotypes of *Salmonella* isolated from stools of children < 5 years old with moderate-to-severe diarrhea (MSD) or matched community controls at sites in The Gambia, Mali and Kenya during the Vaccine Impact on Diarrhea in Africa (VIDA) study (2015-2018) and compared data to isolates from the Global Enteric Multicenter Study (GEMS; 2007-2010) and the follow-up study GEMS-1a (2011). Approximately, 44.7%, 1.1% and 54.2% of *Salmonella* spp. were recovered from VIDA stools collected from The Gambia, Mali and Kenya, respectively. The most common isolates were serogroup B (18.4%), serogroup C_2-C_3 (12.3%), serogroup F (11.7%) and G (11.2%). In comparison to GEMS, a lower frequency of *S*. Typhimurium (38.2% versus 5.0%) and a higher frequency of *S*. Enteritidis (6.3% versus 9.5%) isolates were recovered during VIDA. During VIDA, we observed that 80% of *S*. Typhimurium were multi-drug resistant (MDR) like GEMS and GEMS1a. However, MDR for *S*. Enteritidis decreased from 69% during GEMS to 14.3% during VIDA. Importantly, we detected pan-susceptibility to ceftriaxone and ciprofloxacin during GEMS, however, 10.5 and 33.3% of serogroup B and *S*. Typhimurium isolates, respectively, were resistant to ceftriaxone in VIDA. All 74 *S*. Typhimurium isolates from GEMS stools were sequence type (ST) 313. Out of seven *S*. Typhimurium from VIDA stools, five were ST313 and all were MDR (100%), and two were ST36 and were pan-susceptible. *S*. Typhimurium ST313, which is responsible for most NTS-related bacteremia in Africa, and the only genotype of *S*. Typhimurium from GEMS stools, was also the dominant genotype in VIDA stools from Kenya. Ongoing studies should monitor causes of the changing landscape of *S*. Typhimurium and *S*. Enteritidis in Africa.

1752

ISOLATION OF BACTERIOPHAGES FROM WATER SOURCES IN THE AMAZON RIVER BASIN OF PERU WITH LYTIC ACTIVITY AGAINST CLINICALLY RELEVANT MDR *ACINETOBACTER BAUMANNII*

Brian Drury[1], Dylan Stephens[1], Emma Baker[1], Alexandra de la plante[1], Dallas Hamlin[1], David Craft[1], James M. Regeimbal[2], Ricardo Abadie[2]

[1]*Pennsylvania State Milton S. Hershey Medical Center and College of Medicine, Hershey, PA, United States,* [2]*Naval Medical Research Unit No. 6, Lima, Peru*

The WHO classifies MDR bacteria as an imminent threat to human health. The reinvestigation of lytic bacteriophages is a promising therapeutic approach to treat these infections that requires tailoring therapeutic cocktails from diverse phage libraries. Here we continued to expand a clinically relevant library of phages obtained from sewage water in Iquitos, Peru. Clinically sourced MDR *Acinetobacter baumannii* (MDRAB) strains isolated in Iquitos hospitals between 2011-2017 were used to harvest and characterize newly isolated phages. Collected sewage water was used to generate 3% w/v TSB, and was subsequently left as TSB/waste water or 7.4% FBS v/v or 5% v/v sheep's blood (FBS/SB) were added. The 3% TSB/waste water was inoculated with 5 MDRAB strains and grown overnight at 37°C. The FBS/SB was inoculated with 5 MDRAB strains and grown overnight at room temperature (RT). All three supernatants were then cleared by centrifugation and sterile filtration. Serial dilutions were spotted onto individual lawns of the initial 5 MDRAB strains. 3% TSB lawns were incubated overnight at 37°C and FBS/SB lawns were incubat3ed overnight at RT. Agar plugs of well-isolated plaques were suspended in PBS and filter sterilized. Initial phage isolation steps were repeated using different MDRAB strains and sewage water sources. Phage host-ranges were evaluated against 20 clinical isolates of MDRAB using sport-plates across all growth conditions and temperatures. 21 lytic phages were isolated with only one phage demonstrating specificity beyond the original host strain. That phage demonstrated activity against four other MDRAB strains and in all three growth conditions. All other phage isolates demonstrated activity against the host strain only but showed activity in all growing conditions. As demonstrated in other studies, we found it difficult to harvest and isolate phages that exhibited a wide range of activity against multiple MDRAB strains. Future efforts will continue to explore method modifications to yield a more diverse library of phages with broad specificity that could be used as tailored cocktails for the therapeutic management of patients with MDR infections.

1753

MULTI-VALENT ORAL VACCINE AGAINST ENTEROTOXIGENIC *ESCHERICHIA COLI* AND ENTERIC FEVERS (ETEC)

Tint Wai[1], MingLin Li[1], Sumana Chakravarty[2], Eric R. James[2], Bruce Liberi[1], Weiping Zhang[3], David Sack[4], Stephen L. Hoffman[2], B. Kim Lee Sim[1]

[1]*Protein Potential LLC, Rockville, MD, United States,* [2]*Sanaria Inc., Rockville, MD, United States,* [3]*Kansas State University College of Veterinary Medicine, Manhattan, KS, United States,* [4]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

We aim to develop an oral, bivalent vaccine protective against enterotoxigenic *Escherichia coli* (ETEC) and *Salmonella* Typhi. ETEC is estimated to cause 2.8-4.0x10^8 diarrheal cases in children <5 years of age, 10^8 cases in children >5 years and >1.5x10^5 deaths annually, and infect nearly every child living in a developing country. Typhoid causes ~2.1x10^7 million clinical cases and >10^5 deaths annually. Our recombinant live oral ETEC vaccine (Ty21a-ETEC) is composed of Ty21a, the oral typhoid vaccine, expressing both heat-labile (LT) and heat stable enterotoxin (STa) and 7 adhesins [CFA/I, CFA/II (CS1-CS3) and CFA/IV (CS4-CS6)] that facilitate colonization of host intestines and binds GM1. Thus, our vaccine candidate targets ETEC's key virulence antigens, toxins and adhesion factors. Further, our 7 adhesins comprise a multi-epitope fusion antigen (MEFA) that has shown to have broad spectrum anti-adhesin activity. We report that our oral bi-valent vaccine candidate Ty21a-ETEC, expresses our target toxins, MEFA antigens as well as the O-antigen of *Salmonella* Typhi. Intranasal (IN) immunization of BALB/c mice, that mimicked a mucosal/oral route of immunization, induced antibodies against LTB and MEFA that blocked binding to GM1, showing the induction of anti-toxin activity. We further showed that antibodies induced by IN immunization induced antibodies that blocked adhesion of ETEC to Caco-2 cells. Further, Ty21a-ETEC is stabilized at room temperature by foam drying. This room temperature stable, orally administered vaccine has the potential to provide enormous public health benefits for residents of developing countries, protect travelers and deployed military personnel to developing countries, and potentially serve national biodefense programs against ETEC-mediated biowarfare and bioterrorism threats.

1754

EVALUATION OF THE ANTIMYCOBACTERIAL AND ANTIMYCOLACTONE EFFICACY OF KOMBUCHA TEA

Adiza Abass[1], Elizabeth Gyamfi[2], Regina Appiah-Opong[3], WSK Gbewonyo[2], Phyllis Addo[3], Lydia Mosi[2]

[1]*Tokyo Medical and Dental University, Tokyo, Japan,* [2]*University of Ghana, Accra, Ghana,* [3]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana*

Buruli ulcer is caused by mycolactone (toxin) produced by Mycobacterium ulcerans. The treatment of the disease and early diagnosis is hampered by the lipid nature of the toxin and emerging bacterial resistance to currently used antimycobacterials. Kombucha tea, a health drink consumed worldwide has been shown to exert some medicinal properties. This study was aimed at assessing the antimycobacterial and mycolactone inactivating potential of Kombucha tea. Probiotic microbial isolates from the tea were identified using culture dependent and independent methods for the identification and characterization of bacteria and yeasts, respectively. Phytochemical analysis was conducted on the tea to determine the active organic compounds, total phenolic content and antioxidant properties. Increasing concentrations of the tea were co-incubated with mycolactone for various time points to observe for toxin attenuation. The presence of intact or inactivated mycolactone was detected using TLC and cytotoxicity assays on cultured human fibroblasts. The antimicrobial potency of increasing concentrations of the tea was tested against S. aureus and M. ulcerans by pre-incubation prior to microscopy and culture to observe morphological changes and viability respectively. Yeasts in the Kombucha tea were identified as *Dekkera bruxellensis, Brettanomyces bruxellensis, Rhodotorula mucilaginosa and Lachancea fermentati* and the major bacteria as Acetobacter sp, Paenibacillus lactis, Bacillus licheniformis and Lactobacillus amylolyticus. Phytochemicals detected in the tea were saponins, flavonoids, alkaloids, and phenols. The antioxidant property and phenolic content of Kombucha was significantly higher compared to unfermented tea with the latter being 2-fold less potent in total phenolic content than Kombucha tea. The fermented tea possessed antimicrobial activity against S. aureus but not against M. ulcerans as viable bacilli of M. ulcerans were observed after Kombucha treatment. Mycolactone treated with Kombucha tea retained its potency against human fibroblast cells suggesting that Kombucha tea had no toxin inactivating capacity.

1755

FIRST REPORTED HUMAN CASE OF *RICKETTSIA FELIS* IN GUATEMALA

Beatriz Lopez-Castellanos[1], Maria R. Lopez[2], Arlyn N. Gleaton[3], Ida H. Chung[3], Cecilia Y. Kato[3], Paige A. Armstrong[3], Manuel Sagastume[4], John P. McCracken[2], Andres Espinosa-Bode[5]

[1]*TEPHINET/Centers for Disease Control and Prevention, Guatemala City, Guatemala,* [2]*Universidad del Valle de Guatemala, Guatemala City, Guatemala,* [3]*Centers for Disease Control and Prevention, Atlanta, GA,*

United States, [4]Ministerio de Salud Publica y Asistencia Social, Guatemala City, Guatemala, [5]Centers for Disease Control and Prevention, Guatemala City, Guatemala

Rickettsia felis, from the spotted fever group *rickettsiae*, is an emerging pathogen that has been reported worldwide. The first human cases were documented in 1994 in the United States and in 2000 in Mexico. Early clinical presentation of *R. felis* infection can resemble that of dengue and malaria, which makes differentiating it from other acute febrile illnesses (AFI) difficult. The real burden of *R. felis* rickettsiosis may be underestimated. To our knowledge, no human cases of *R. felis* infection have been reported in Guatemala. However, *R. felis* has been isolated from fleas from cats and dogs in the country. During 2013-2018, 241 blood samples were collected from participants enrolled in an AFI sentinel surveillance implemented by the Guatemala Ministry of Health, the Centers for Disease Control and Prevention (CDC) and the Universidad del Valle de Guatemala. Five of these samples were positive for *Rickettsia sp.* by PCR assays for the detection of spotted fever group *rickettsia* (SFGR) and typhus group *rickettsia* DNA. The samples were sent for confirmation to the CDC Rickettsial Diagnosis Laboratory and one sample was confirmed to be positive for *R. felis* by DNA sequencing with the SFGR 17kDa target. The confirmed *R. felis* sample was collected from a 3 year-old boy screened in December 2017 in Nueva Santa Rosa, Department of Santa Rosa. The case presented with fever that started 2 days before screening. Other reported symptoms were cough, difficulty breathing, vomiting, abdominal pain and fatigue. No additional information was collected because the case was lost to follow-up after enrollment. This is the first identified human case of R. *felis* detected via AFI surveillance efforts in Guatemala. Its detection provides evidence that it may be an under-appreciated cause of illness in Guatemala and possibly all of Central America. Continued surveillance for *R. felis* and other emerging rickettsiosis is imperative to better understand the magnitude and public health impact of these infections in the region.

1756

INCIDENCE OF MENINGOCOCCAL MENINGITIS SEROGROUP C IN TWO NORTHWESTERN STATES OF NIGERIA

Olaiya Paul Abiodun[1], Zachary Gwa[2], Olumide Ajani[1], Felix Olaniyi Sanni[3], Abiodun Ogunniyi[4], Abiola Abiodun[5]

[1]*Department of National Integrated Specimen Referral Network, AXIOS International, Utako, FCT, Abuja, Nigeria,* [2]*Department of Business Development, AXIOS Foundation, Utako, FCT, Abuja, Nigeria,* [3]*Department of Global Health, Lagos State University Teaching Hospital, Ikeja, Lagos, Nigeria,* [4]*Department of Prevention and Program Coordination, Nigeria Centre for Disease Control Utako, FCT, Abuja, Nigeria,* [5]*General Hospital North Bank, Makurdi, Nigeria*

The localized outbreaks of meningitis caused by a new strain of Neisseria meningitidis serogroup C (NmC) were reported in the northern parts of Nigeria in 2013, 2014 and 2015. From December 2016 to June 2017, an outbreak caused by the same novel NmC strain also occurred in several States over a wider geographical area, similar in characteristics to the 2015 outbreaks. We report the incidence of the outbreak in Sokoto and Zamfara using the case definition for cerebrospinal meningitis (CSM) as designed by Médecins Sans Frontières (2008), UNICEF and WHO. From week 51 2016 to week 19, 2017, data on cerebrospinal meningitis (CSM) cases and deaths were recorded on standardized line-lists from case management sites. Cerebrospinal fluid (CSF) samples collected from suspected cases during the outbreak were tested using rapid Pastorex® latex agglutination to determine causative serogroup. A total of 5,372 suspected cases of MNC were reported in Zamfara and Sokoto states. CSF was collected from 281 (5.2%) suspected cases (190 from Sokoto and 91 from Zamfara), there were 277 deaths in Sokoto and 81 in Zamfara, making a total of 358 deaths, 5,188 probable cases and 184 confirmed cases from both states. Out of 5,372 suspected cases of NmC seen, 57.2% were males and 42.8% were females (M: F = 1.3:1). The most affected age in both states was 6-15 years with 49.3% for Sokoto, 53.9% for Zamfara and overall 49.8%. The peak of meningitis cases was observed at week 7, 2017 in Zamfara while the peak was observed in Sokoto at week 15. Marudun local government recorded the highest incidence (146) in Zamfara while in Sokoto state, Sokoto North and South LGAs accounted for the highest incidence (1016; 21.2%). The outbreak was one of the largest caused by NmC documented in Nigeria. Reactive vaccination in the affected areas may have helped curtail the epidemic. A vaccination campaign against NmC with a long-lasting conjugate vaccine should be considered in the northern parts of Nigeria. Keywords: Meningitis belt, outbreak, cerebrospinal fluid, reactive vaccination, epidemiology

SEROLOGICAL EVIDENCE AUGMENTED BY NEXT-GENERATION SEQUENCING IDENTIFIES *ORIENTIA TSUTSUGAMUSHI* AS A CAUSATIVE AGENT OF SEPSIS IN CAMBODIA

Amitha Fitkariwala[1], Dennis Faix[1], Tin Som[1], Pichit Pin[1], Sokhun Song[1], Daraden Vang[1], Heng Bun[1], John Brooks[1], Te Vantha[2], Logan Voegtly[3], Regina Z. Cer[4], Kimberly A. Bishop-Lilly[3], Casandra Philipson[5], Chien-Chung Chao[6], Kevin L. Schully[7], Danielle V. Clark[8]

[1]*Naval Medical Research Unit-2, Phnom Penh, Cambodia,* [2]*Takeo Provincial Referral Hospital, Takeo, Cambodia,* [3]*Genomics and Bioinformatics Department, Biological Defense Research Directorate, Naval Medical Research Center-Frederick, Fort Detrick, MD, United States,* [4]*Leidos, Reston, VA, United States,* [5]*Defense Threat Reduction Agency, Fort Belvoir, VA, United States,* [6]*Viral and Rickettsial Diseases Department, Naval Medical Research Center-Silver Spring, Silver Spring, MD, United States,* [7]*Austere Environments Consortium for Enhanced Sepsis Outcomes Department, Biological Defense Research Directorate, Naval Medical Research Center-Frederick, Fort Detrick, MD, United States,* [8]*The Henry M Jackson Foundation, Bethesda, MD, United States*

Diagnosis of *Orientia tsutsugamushi*, the agent of scrub typhus, is typically accomplished by serological analysis of acute and convalescent samples using ELISA and IFA. However, in cases where patients succumbed to their infections or failed to follow-up, the absence of a convalescent sample makes serological diagnosis unreliable. Next Generation Sequencing (NGS) offers a comprehensive and complementary method for unbiased profiling of sepsis pathogens, and its integration into clinical and surveillance programs is increasingly more common. As part of an observational trial of sepsis in Takeo Province, Cambodia, we enrolled 200 patients hospitalized under the suspicion of infection. In addition to serum, blood was collected directly into PAXgene RNA stabilization tubes. Using standard serological techniques, we identified serological evidence of *O. tsutsugamushi* infection in 8 patients based on a four-fold increase in antibody titer. However, for patients who succumbed to infection or were lost to follow up, confirmation of seroconversion was impossible due to the lack of convalescent sera. To detect potential etiological agents of sepsis in a broad and unbiased manner, RNAseq was performed on all acute whole blood samples. By targeting RNA, the sequence space was focused transcripts indicative of actively replicating bacteria. Microbes were identified using read-based taxonomy tools embedded in EDGE bioinformatics software. *O. tsutsugamushi* was identified as the predominant microbe in 8 additional samples of which 7 were from patients exhibiting elevated acute IgM titers but nonexistent convalescent samples. This identification was further confirmed by aligning reads that mapped to the *O. tsutsugamushi* genome to the 16S rRNA and 23S rRNA regions of *O. tsutsugamushi*. While standard microbiological techniques are essential to disease surveillance, they are not always effective surveillance tools for unculturable bacteria, viruses, nor novel pathogens. The *in silico* identification of *O. tsutsugamushi*, a bacterium not culturable by standard culture methods, demonstrates the utility of NGS as a biosurveillance tool.

1758

STENOTROPHOMONAS MALTOPHILIA: SELDOM ALONE, NON-INVASIVE

Don W. Kannangara, Priya Patel, Dhyanesh Pandya

St Luke's University Health Network, Phillipsburg, NJ, United States

Stenotrophomonas maltophilia (SM) is known for inherent resistance to multiple antibiotics and bio-film formation.We studied 316 isolates of *S. maltophilia* from wounds, sputum, bronchial secretions, urine, blood and sinus cultures reported by our network lab during the last 3 years. Majority of the isolates were from respiratory (107), wound (71), urine (58), blood (10) and other sites. In every site including blood, the organism was present as part of a polymicrobial infection excluding a small number of cases. Of 316 isolates only 10 were isolated from blood. Only 2 out of 10 Blood cultures were monomicrobial infections. The organism was present only in 1 out of 2 blood cultures drawn in all 10 patients and was always absent in the repeated blood cultures. None of the patients with urinary or wound isolates had positive blood cultures. One patient with advanced sarcoidosis on high dose prednisone had 1positive blood and sputum cultures with SM and *Enterobacter cloacae*. 5 bacteremic patients were narcotic dependent. Two were iv drug users and 3 had chronic pain syndromes. Three were line infections. Majority of isolates from wounds were from the lower extremity. Majority of patients with urine and wound isolates were above the age 50. All isolates were susceptible to Bactrim. All but 2 were susceptible to levofloxacin. About half the isolates were susceptible to ticarcillin/clavulanate or ceftazidime. This study shows a remarkable lack of invasive infections by SM. Detailed statistics will be presented. The present study was limited by absence of burn wound or organ transplant patients.

1759

UTILITY OF NEXT GENERATION SEQUENCING (NGS) BASED METHODS AND THE GENE MEDIATED ANTI-MICROBIAL RESISTANCE (AMR) IN DEFINING MICROBIAL COMMUNITIES IN CHRONIC DIABETIC FOOT ULCERS IN RURAL SRI LANKA

Sandani Yasara Weerasundara, Harshika Sachini Welgama, Hiruni Shermila Weerasingha, Iruni Weerathunga, Kusal Dulanjala Weerakkody, Sudaraka Harindu Wageesha, Suneth Buddhika Agampodi

Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka

Rapidly developing molecular and NGS methods are usually not accessible to healthcare institutions in rural middle and low income country settings. We investigated the utility of these techniques in defining the microbial communities of chronic Diabetic Foot Ulcers (DFUs), the leading cause for non-traumatic lower extremity amputation and an emerging epidemic in even rural Sri Lanka. Using a commercially available sequencing service, we evaluated the microbial communities of tissue samples of patients with DFUs admitted to the Teaching Hospital, Anuradhapura. Conventional culture methods were also used for comparison of NGS based bacterial 16S and fungal ITS rRNA sequencing using Ion Torrent. The presence of AMR genes in common infecting organisms was evaluated by quantitative Polymerase Chain Reaction (qPCR) with previously validated, specific primers for bla_{VIM} and bla_{IMP} genes. Of the 50 patients selected, NGS was available for 20. The majority of the bacteria detected by 16S rRNA sequencing were aerobes and facultative anaerobes (90%) but anaerobic *Bacteroides fragilis*(20.0%) was the commonest species detected, followed by *P. aeruginosa* (15.0%), *Streptococcus spp*. Group B(15.0%), *Arcanobacterium haemolyticum* (15.0%), *Corynebacterium diphtheriae*(15.0%), *Corynebacterium simulans*(15.0%), *Klebsiella pneumoniae*(10.0%), *Enterococcus faecalis*(10.0%). Fungal ITS rRNA sequencing identified a single growth of *Candida albicans.* Of the 50 wound swabs, 47 were culture positive and 35 (70.0%) had mixed growths with a single sample with fungal growth. The most frequent culture isolate was *Pseudomonas spp.*(n=27,54.0%) followed by *Staphylococcus spp.* (n=21,42.0%), *Proteus spp.*(n=10,20.0%), *Streptococcus spp.*(n=6,12.0%), *Escherichia spp.*(n=3,6.0%) and *Klebsiella spp.*(n=1,2.0%). None of the *Pseudomonas* isolates exhibited AMR through bla_{VIM} or bla_{IMP} genes. NGS based methods are complementary to traditional methods and cannot be replaced due to differences in detection. We haven't observed the AMR through the selected genes in this cohort of patients.

1760

A CLUSTER OF MELIOIDOSIS CASES FOLLOWING HEAVY RAINS IN BATTICALOA, SRI LANKA

Aruna D. De Silva[1], Himali S. Jayasinghearachchi[1], Enoka M. Corea[2], Vaithehi R. Francis[3], Shivankari Krishnananthasivam[4], Harindra D. Sathkumara[4]

[1]*General Sir John Kotelawala Defence University, Ratmalana, Sri Lanka,* [2]*Faculty of Medicine, University of Colombo, Colombo, Sri Lanka,* [3]*Faculty of Health-Care Sciences, Eastern University, Batticaloa, Sri Lanka,* [4]*Genetech Research Institute, Colombo, Sri Lanka*

Burkholderia pseudomallei is a Gram-negative environmental bacterium that causes melioidosis, a potentially life-threatening infectious disease. There was a cluster of 10 cases (with 4 deaths) that occurred in Batticaloa in the Eastern Province of Sri Lanka in October/November 2015 following heavy rains. The deaths included three female patients with severe community-acquired bronchopneumonia, suggesting acquisition via inhalation. The *B. pseudomallei* strains isolated from these patients had MLST and whole-genome sequencing carried out to understand the phylogeography, transmission and also help deduce evolutionary relatedness between isolates from this cluster of cases. Eight isolates (BPs110, BPs111, BPs112, BPs114, BPs115, BPs116, BPs122 and BPs 133) of *B. pseudomallei* obtained from these melioidosis patients were confirmed by real-time polymerase chain reaction (PCR) assay, amplifying *lpxO*, Yersinia-like fimbrial (YLF) and *B. thailandensis*-like flagellum and chemotaxis (BTFC) gene clusters of *B. pseudomallei* using a multiplex SYBR green real-time PCR assay. The molecular diversity of strains was assessed using the *B. pseudomallei* multilocus sequence typing (MLST) schema. Seven housekeeping genes (*ace, gltB, gmhD, lipA, narK, lep* and *ndh*) were amplified for MLST and the PCR products were subjected to automated Sanger sequencing. The genomic DNA of each isolate was independently subjected to whole-genome sequencing (WGS) from a paired-end with a ~301-bp insertion size using the Illumina MiSeq 2000 platform at Agiomix, FZ LLC, UAE. SPAdes Version 3.10.1 was used for the assembly with *B. pseudomallei* K96243 as reference. There is a substantial diversity of ST types in the areas where the case cluster of melioidosis was reported following the heavy rains. ST 594 is the predominant ST type and other ST types detected were ST1152, ST1364, ST1442, ST1413, ST1179. This matches with previous reports of case clusters resulting from severe weather events such as cyclones, in which a single infectious disease is caused by strains of diverse molecular types, probably due to widespread aerosolization of multiple strains.

1761

DETERMINATION OF AREAS WITH POTENTIAL RISK OF HUMAN LEPTOSPIROSIS IN THE DEPARTMENT OF CÓRDOBA, COLOMBIA

Virginia C. Rodríguez, Eidy Martinez, Ana M. Castro, Alfonso Calderón, Misael Oviedo

Universidad de Córdoba, Monteria, Colombia

Leptospirosis is an emerging zoonotic bacterial disease, which has become a global public health problem. A descriptive study was designed by means of a convenience sampling, and the registries of patients were selected (and the patients retroactively notified) from the National Surveillance System of Colombia as a case of leptospirosis, from 2012 to 2015. Active surveillance was carried out in the Lending Institutions of Health Services of the department of Córdoba. Patients with clinical symptoms of leptospirosis during the years 2016-2018 were included. After signing the informed consent form and completing the epidemiological record, blood

and urine samples were taken. The cases were confirmed by PCR and Microagglutination Test (MAT). Association between cases of leptospirosis and risk factors through univariate and bivariate analysis of information was established. A multivariable logistic regression analysis was carried out for the elaboration of the predictive model. The distribution of cases of the disease was analyzed by means of the Bernoulli model. Were identified 532 patients as possibly infected, of these 40 were confirmed with leptospirosis. The majority were men, aged 12-26 years old, and no significant differences were found regarding sex and age. Social risk factors were identified such as: living in urban areas, working as a farmer, having contact with domestic and synanthropic animals, lacking inadequate disposal of solid waste and participating in recreational activities or sports in dams. No association was established with the confirmed cases of leptospirosis regarding the environmental risk factors. The results of the predictive model showed that patients with fever, headache, myalgia, jaundice and conjunctival bleeding are more likely to have complications during the disease. Coming into contact with horses represents a risk factor for acquiring the bacteria. The disease is widely distributed in a homogeneous way, not concentrated in the different subregions of the department.

1762

ANTIBACTERIAL EFFECT OF *CORRYOCACTUS BREVISTYLUS* (SANKY) AGAINST *ACINETOBACTER BAUMANII*

Hugo Carrillo-Ng[1], Ronald Aquino-Ortega[2], **Miguel A. Aguilar-Luis**[1], Wilmer Silva-Caso[1], Luz M. Paucar-Menacho[3], Juana M. del Valle[4]

[1]*Investigation Center and Innovation of the Health Sciences Faculty, Universidad Peruana de Ciencias Aplicadas (UPC), Av. San Marcos cdra* [2] *Cedros de Villa, Lima, Peru,* [2]*Instituto de Investigacion Nutricional, Lima, Peru,* [3]*Universidad Nacional del Santa, Av Universitaria, Nuevo Chimbote, Peru,* [4]*Universidad Peruana de Ciencias Aplicadas, Lima, Peru*

Acinetobacter baumanii is an oportunistic nosocomial pathogen with an increasingly rate of antibiotic resistance worldwide. In 2017, the WHO published a group of bacteria for which new research in antibiotics is urgently needed. *Acinetobacter baumanii* was included in first group among the bacteria that require the development of new antibiotics. *Corryocactus brevistylus*, is a peruvian cactacea with traditional medicinal use that grows in the Andes, however, its antibacterial effect agaisnt *Acinetobacter baumanii* has not been studied yet. The aim of this study was to determine the antibacterial effect of the methanol extract of the *Corryocactus brevistylus* fruit (Sanky) against *Acinetobacter baumanii (ATCC 19606).* The fruits of *Corryocactus brevistylus* were pulverized, soaked with methanol (1:2, w/v) and stored for 7 days. The antibacterial effect against *Acinetobacter baumanii* were evaluated using the cup-plate agar diffusion method by preparing wells with the experimental solutions cultivated in aerobic conditions for 24 h at 37 °C . Six independent tests were performed using ampicillin-sulbactam, tigecicline and tetracycline as positive controls. The MIC was determined using the microdilution method as described by the CLSI. Antibacterial effect of the methanol extract was observed with inhibition halos of 25.12 ± 0.52 mm. Meanwhile, ampicillin-sulbactam, tigecicline and tetracycline showed inhibition halos of 21.97 ± 0.18 mm, 22.36 ± 0.45 mm, 21.44 ± 0.28 mm, respectively. The minimum inhibitory concentration of the fruit extract was 101 mg/L. The *Corryocactus brevistylus* methanol extract showed a favorable antibacterial effect against *Acinetobacter baumanii*. These findings contribute to the potential development of new treatment options based on natural products. However, further studies are required to determine the bioactive compound responsible for this effect and the cytotoxicity of the extract.

REPORT OF HIGH PREVALENCE OF *ACINETOBACTER BAUMANNII* INFECTION IN PEDIATRIC PATIENTS IN PERU

Miguel A. Aguilar-Luis[1], Isaac Peña-Tuesta[2], Juana del Valle-Mendoza[1], Victor Zavaleta- Gavidia[3]

[1]*Investigation Center and Innovation of the Health Sciences Faculty, Universidad Peruana de Ciencias Aplicadas (UPC), Lima, Peru,* [2]*Instituto de Investigacion Nutricional, Lima, Peru,* [3]*Dirección Regional de Salud de Cajamarca, Cajamarca, Peru*

Acinetobacter baumanni is an opportunistic nosocomial pathogen that has the ability to develop mechanisms of antibiotic resistance, including resistance to broad-spectrum β-lactamases and carbapenemases. The most common clinical manifestations are acute pneumonia and bacteremia, *A. baumannii* is ranked 1st in the critical priority category in the list of priority pathogens for research published by the World Health Organization (WHO). The objective of this study was to determine the prevalence of A. baumannii in hospitalized children under 1 year of age in Peru. A cross-sectional study was conducted in 286 children under 1 year of age with a clinical diagnosis of whooping cough admitted in 5 hospitals in Peru during January 2010 - July 2012. Samples of nasopharyngeal swab were collected with the help of a calcium alginate swab and samples They were immersed in phosphate buffer solution. The detection of A. baumannii was performed by Real Time PCR using primers specific for the OXA-51 gene. The amplified products were sequenced for confirmation. The presence of A. baumannii was detected in 19.1 % (48/252) of the samples. Children from 29 days to 3 months were the most affected, with a prevalence of 52.1 % (25/131), followed by 25% (12/71) in children whose age is 3 to 5 months. The most frequent symptoms in the positive cases were paroxysmal cough (85.4 %, 41/48), respiratory difficulty (79.2 %, 38/48), redness (68.8 %, 33/48), cyanosis (62.5 %, 30/48) and difficulty in breastfeeding (58.3 %, 28/48). It was found that 56.3 % (27/48) of the positive cases showed coinfection with *Bordetella pertussis*, 4.2 % (2/48) with *Mycoplasma pneumoniae* and respiratory syncytial virus type A and 2.1 % (1/48) with parainfluenza I. In conclusion, a high frequency of A. baumannii was detected in children recently admitted to hospitals in Peru. This result supports the report of the increase in infections of *A. baumannii* worldwide. It is concluded that it is necessary to carry out more studies on the infection of *A. baumannii* acquired in hospitals in order to determine the real prevalence in the Peruvian population.

The increasing incidence of patients with the diagnosis of Diabetes Mellitus type 2 (DM2) has shifted the focus of new research on preventative therapeutic approaches. Recent evidence suggests an important association between the prognosis of patients with DM2 and their gastrointestinal bacterial microbiota linked to modifications that may positively or negatively change the host's metabolism. The study included 26 patients diagnosed with Diabetes Mellitus Type 2 in the Endocrinology service of a tertiary referral hospital, between August 2016 and February 2017. Stool samples were collected from each patient as well as their food consumption frequency record and relevant clinical data. The fecal bacterial microbiota was analyzed by conventional PCR to identify and characterize 13 different genus of gastrointestinal bacteria.

The mean body mass index (BMI) for the uncontrolled diabetic patients' group was 28.8 kg/m^2, considered as obesity for a mean age of 65 years. These patients had the highest incidence of associated comorbidities. We identified at least one genus of bacteria in 71.4 % and 57.9 % of cases in the controlled and uncontrolled group of diabetic patients respectively. In conclusion, the bacterial microbiota of a host is unique to each patient and varies constantly. Some differences were observed according to the state of the disease between the controlled and uncontrolled group.

THE BURDEN OF AND RISK FACTORS FOR TRACHOMA IN SELECTED DISTRICTS OF ZIMBABWE: RESULTS OF 16 POPULATION-BASED PREVALENCE SURVEYS

isaac Phiri[1], Portia Manangazira[1], Nicholas Midzi[2]

[1]*Ministry of Health- Zimbabwe, Harare, Zimbabwe,* [2]*University of Zimbabwe, Harare, Zimbabwe*

Trachoma, a leading cause of blindness, is targeted for global elimination as a public health problem by 2020. In order to contribute to this goal, countries should demonstrate reduction of disease prevalence below specified thresholds, after implementation of the SAFE strategy in areas with defined endemicity. Zimbabwe had not yet generated data on trachoma endemicity and no specific interventions against trachoma have yet been implemented. Two trachoma mapping phases were successively implemented in Zimbabwe, with eight districts included in each phase, in September 2014 and October 2015. The methodology of the Global Trachoma Mapping Project was used. Our teams examined 53,211 people for trachoma in 385 sampled clusters. Of 18,196 children aged 1-9 years examined, 1526 (8.4%) had trachomatous inflammation-follicular (TF). Trichiasis was observed in 299 (1.0%) of 29,519 people aged ≥15 years. Of the 16 districts surveyed, 11 (69%) had TF prevalences ≥10% in 1-9-year-olds, indicative of active trachoma being a significant public health problem, requiring implementation of the A, F and E components of the SAFE strategy for at least 3 years. The total estimated trichiasis backlog across the 16 districts was 5506 people. The highest estimated trichiasis burdens were in Binga district (1211 people) and Gokwe North (854 people). In conclusion, implementation of the SAFE strategy is needed in parts of Zimbabwe. In addition, Zimbabwe needs to conduct more baseline trachoma mapping in districts adjacent to those identified here as having a public health problem from the disease.

1766

QUALITY ASSURANCE THROUGH POSTOPERATIVE FOLLOW-UP OF OPERATED TRACHOMATOUS TRICHIASIS (TT) CASES IN BURKINA FASO AND CAMEROON

Whitney Goldman[1], Assumpta Lucienne Bella[2], Clarisse Bougouma[3], Emilienne Epée[2], Martin Kabore[3], Issouf Bamba[4], Fanny Yago-Weinne[4], Jean-Paul Djiatsa[4], Albert Kiemde[4], Phylippe Bayala[4], Marc Sepama[4], Julie Akame[5], Jules Patrick Evenga[5], Michel Hendji[5], Yannick Nkoumou[5], Carine Fokam Tagne[5], Stephanie Parker[1]

[1]*Helen Keller International, Washington, DC, United States,* [2]*Ministry of Health, Cameroon, Yaounde, Cameroon,* [3]*Ministry of Health, Burkina Faso, Ouagadougou, Burkina Faso,* [4]*Helen Keller International, Burkina Faso, Ouagadougou, Burkina Faso,* [5]*Helen Keller International, Cameroon, Yaounde, Cameroon*

Ensuring high-quality trachomatous trichiasis (TT) surgery is essential for trachoma programs. As one of several quality assurance activities, the U.S. Agency for International Development (USAID)'s Morbidity Management and Disability Prevention Project has collaborated with ministries of health in Burkina Faso and Cameroon since 2016 to implement postoperative follow-up of individuals 3-6 months after they receive TT surgery. In 2017, the project revised its approach of a single 3-6 month follow-up activity targeting a random sample of operated cases to conducting two distinct activities: surgical audit and outcome assessment. Outcome assessments aim to provide clinical follow-up 3-6 months following TT surgery by organizing appointments at a centralized site. Surgical audits assess individual surgeons' performance across a sample of patients who are visited in their homes. In Cameroon, when surgical output did not allow for auditing the minimum recommended number of cases per surgeon, the project implemented a single activity that integrated surgical audit and outcome assessment principles. From 2017 onward, approaches to outcome assessment and surgical audit were iteratively improved through adjustments such as increasing time spent at each outcome assessment site and providing phone credit to increase contact between health staff and operated cases. Overall, the average proportion of operated cases receiving a 3-6 month follow-up exam increased following the shift from the original approach to the revised approach (from 39% to 57% in Burkina Faso and from 38% to 74% in Cameroon). Through the refinement of the approach to outcome assessment in Burkina Faso, specifically, the proportion of cases self-presenting increased from 16% to 53%. These results indicate that the shift to the revised strategy was followed by an improvement in the rates of follow-up within the 3-6 month postoperative window. In addition, iterative adjustments to the revised strategy implemented in Burkina Faso were followed by an increased proportion of operated cases self-presenting for follow-up 3-6 months after surgery.

1767

USING PHOTOS OF OPERATED TRACHOMATOUS TRICHIASIS (TT) CASES AS A TOOL TO FACILITATE SURGEON AND TECHNICAL SUPERVISOR DISCUSSION

Whitney Goldman[1], Assumpta Lucienne Bella[2], Clarisse Bougouma[3], Emilienne Epée[2], Martin Kabore[3], Issouf Bamba[4], Jean-Paul Djiatsa[4], Albert Kiemde[4], Phylippe Bayala[4], Marc Sepama[4], Julie Akame[5], Jules Patrick Evenga[5], Michel Hendji[5], Yannick Nkoumou[5], Carine Fokam Tagne[5], Lauren Johnson[1], Katherine Nerses[1], Stephanie Parker[1], Emily Gower[6]

[1]*Helen Keller International, Washington, DC, United States,* [2]*Ministry of Health, Cameroon, Yaounde, Cameroon,* [3]*Ministry of Health, Burkina Faso, Ouagadougou, Burkina Faso,* [4]*Helen Keller International, Burkina Faso, Ouagadougou, Burkina Faso,* [5]*Helen Keller International, Cameroon, Yaounde, Cameroon,* [6]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Since 2018 the U.S. Agency for International Development (USAID)'s Morbidity Management and Disability Prevention Project has collaborated with ministries of health in Burkina Faso and Cameroon to pilot photographing operated eyelids during trachomatous trichiasis (TT) surgery and during 3-6 month post-operative follow-up exams. Surgeon and technical supervisor feedback during the pilot suggested photos could potentially be useful to facilitate technical supervision and generate feedback to support surgical capacity strengthening. To explore this potential utility, each country held a photo review and feedback session in Nov.-Dec. 2018. Surgeons and supervisors followed a structured facilitator guide (with questionnaires) to conduct a technical review of a sample of photographed eyelids (22 eyelids in Burkina Faso and 41 in Cameroon). Surgeons independently assessed characteristics visible in the photos of eyelids they had previously operated; technical supervisors then independently assessed the same photos and provided feedback to the surgeons on the observed characteristics. Surgeons and supervisors had complete agreement in their assessment of the overall surgical quality for 64% of eyelids (14/22) in Burkina Faso and 56% of eyelids (19/34) in Cameroon. Among the six characteristics assessed, rates of agreement were highest for granuloma (98%) and post-operative TT (82%) and lowest for assessing eyelid margin regularity (65%). Surgeons more frequently failed to identify issues identified by supervisors. All completed questionnaire responses rated the technical review as "Very useful" and surgeons noted "Yes" when asked if they learned something about their surgical capacity. The structured review revealed supervisors and surgeons did not have complete agreement on the overall quality of the surgery. The facilitator guide and questionnaires for photo review provide a framework

for technical supervisors and surgeons to discuss surgical quality and post-operative complications to potentially support surgical capacity strengthening.

TRACHOMA PREVALENCE FOLLOWING DISCONTINUATION OF MASS AZITHROMYCIN DISTRIBUTION

William W. Godwin[1], Paul M. Emerson[2], Pamela J. Hooper[3], Ana Bakhtiari[3], Michael Deiner[1], Travis C. Porco[1], Thomas M. Lietman[1], Catherine E. Oldenburg[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Emory University, Atlanta, GA, United States,* [3]*International Trachoma Initiative, Decatur, GA, United States*

Mass Drug Administration (MDA) regimens of azithromycin have proved to be effective in reducing the prevalence of trachomatous inflammation—follicular (TF) in children age 1-9 years. While there is evidence that the number of rounds of MDA can predict TF decline in locations of continuous MDA, little is known about how TF prevalence behaves in locations of discontinued MDA. Current guidelines suggest regular regimens of MDA in locations above 10% TF until reaching "control" (<5%). However, TF may decline in borderline prevalence areas without additional antibiotic intervention. Here, we evaluate the effect of discontinuation of antibiotic on TF prevalence in formerly endemic areas. We used district-level data from the International Trachoma Initiative database to assess how TF prevalence responds after discontinuation of MDA. Districts were included in the analysis if they had at least one year of MDA, followed by two annual surveys in which there was no MDA between the surveys. A total of 233 districts fit the inclusion criteria. Mean number of years between most recent MDA and initial survey was 1.5 and mean number of years between initial survey and follow-up survey were 3.2. Mean (SD) TF prevalence was 2.4% (2.0) and 2.1% (2.7) for initial and follow-up survey, respectively. Between initial and follow-up survey, TF prevalence decreased by >50% in 37.3% (87/233) of the districts. Of the 19 districts with baseline TF >5%, 15 districts achieved control, while 9.3% (20/219) of districts with TF control at baseline increased to >5% at follow-up. Sixteen of the 20 districts that increased from control status to above control status were in Ethiopia and Niger. In most districts, resurgence of TF in the absence of continued MDA does not appear to occur. However, in some districts, predominantly in Ethiopia and Niger, TF has increased above control status. This may be due to misclassification error or, less likely, true resurgence. Understanding the degree to which TF may display resurgence and factors associated with resurgence will be important to achieving global TF control in a timely, resource-efficient manner.

1769

HOW TO DETERMINE WHERE TO SURVEY FOR TRACHOMA: LESSONS LEARNED FROM THE DEMOCRATIC REPUBLIC OF CONGO

Bonaventure Ngoyi[1], Pitchouna A. Uvon[2], Janvier N. Kilangalanga[3], Felix Makangila[2], Katie Crowley[4], Raymond Stewart[1], Jeremiah M. Ngondi[4]

[1]*RTI International, Kinshasa, Democratic Republic of the Congo,* [2]*Ministry of Health, Kinshasa, Democratic Republic of the Congo,* [3]*Saint Joseph Hospital, Kinshasa, Democratic Republic of the Congo,* [4]*RTI International, Washington, DC, United States*

Until 2014, trachoma was suspected to be endemic in the Democratic Republic of Congo (DRC); however, evidence to support program initiation was limited. Health zones (HZ) were prioritized for surveys in a phased approach. Phase I (2014-2015) identified priority HZ based on a desk review of Global Atlas of Trachoma, local clinical reports on trachoma, results of a questionnaire-based survey of health care workers (HCW) enquiring about known trichiasis cases and a questionnaire-based community key informants' interviews (KII) during transmission assessment surveys (TAS) enquiring about the presence of trichiasis. Phase II (2016-2017) comprised HZs bordering those DRC HZ identified as endemic in the Phase I surveys. Phase III (2017-2018) HZ were selected based on the results of trachoma rapid assessments (TRA) conducted in HZ contiguous to those mapped in Phases I & II. We analyzed the distribution of surveys results by prioritization method. From 2014 to 2018, surveys were conducted in 111 HZ (21% of all DRC HZ) and TRA was conducted in 66 HZ. Survey results indicated that 51 HZ (45.9%) of the 111 surveyed HZ had trachomatous inflammation-follicular (TF) prevalence ≥ 5% and 55 HZ (49.5%) had trachomatous trichiasis (TT) prevalence ≥ 0.2%. By phase the number of HZ mapped were: 31 in phase I; 50 in phase II; and 30 in phase III. TF prevalence varied by prioritization method. The proportion of HZs with TF≥5% was as follows: review of health records and HCW trichiasis survey (100%); HZ bordering endemic district across countries (71.4%); HZs bordering endemic ones after Phase I mapping (44.4%); community trichiasis KII survey during TAS (35.3%); and TRA (33.3%). The results illustrate that a variety of methods can be employed to inform prioritization of investments for mapping in settings like DRC where vast areas are still un-mapped. This DRC case study provides important lessons for countries that have not yet started mapping, no completed mapping, and strategies to be considered in under-resourced settings.

1770

VALIDATING AND COSTING A TRACHOMATOUS TRICHIASIS "SUPER SURVEY"

Rebecca Mann Flueckiger[1], Rachel Stelmach[2], George Kabona[3], Alistidia Simon[3], Upendo Mwingira[3], Jeremiah Ngondi[4]

[1]*RTI International, Atlanta, GA, United States,* [2]*RTI International, Washington, DC, United States,* [3]*Tanzania NTD Control Programme, Dar es Salaam, United Republic of Tanzania,* [4]*RTI International, Dar es Salaam, United Republic of Tanzania*

As trachoma programs move towards elimination, the number of surveys necessary to evaluate the status of trachomatous trichiasis (TT) is growing. Currently, the World Health Organization recommends a district-level population-based prevalence survey for trachoma that involves a two-stage cluster design. Previous work has demonstrated that a random selection of 30 clusters within a district suffices for measuring TT prevalence with precision against the elimination threshold. In an effort to reduce survey costs, we explored the validity of an alternative survey design and the associated cost. There are scenarios where multiple districts are geographically contiguous and homogeneous. We determined homogeneity in terms of TT through grouping districts with consistent climatic, environmental and socioeconomic variables. We evaluated the loss of precision involved in combining these districts into single evaluation units (EUs) and modulating the sample size by running simulations on existing data sets. Preliminary findings from two scenarios in Tanzania show variability in when it is appropriate to implement this alternative survey design. In scenario A, which evaluated Babati DC and Mbulu DC, the mean TT prevalence estimate maintained the same likelihood to be above the elimination threshold (TT prevalence <0.2% in adults >=15 years old) when the districts were combined into a single EU and the sample size was decreased to 80% of the original sample. However, in scenario B, which evaluated Iringa DC, Kilolo DC and Mufindi DC, this was not the case. These preliminary findings stress the importance of determining climate, environmental and socioeconomic characteristics associated with classifying districts as homogeneous in terms of TT. Learnings from this first portion of work will be carried forward for testing in additional settings and the cost saving of this approach will be determined prior to ASTMH.

1771

USING DATA FROM DOOR TO DOOR (*RATISSAGE*) TRACHOMATOUS TRICHIASIS SURGERY CAMPAIGNS TO DEMONSTRATE ACHIEVING ELIMINATION CRITERIA IN MALI

Lamine Traoré[1], Modibo Keita[2], Benoit Dembele[2], Famolo Coulibaly[1], Mamadou Dembele[1], Boubacar Guindo[2], Dramane Traoré[2], Brehima Mariko[1], Seydou Goita[2], Abdoul Karim Sidibé[1], Fama Kondo[2], Mama Niele Doumbia[2], Mohamed Lamine Yattara[2], Yaobi Zhang[3], Steven Reid[4]

[1]*Ministère de la Santé et de l'Hygiène Publique, Bamako, Mali,* [2]*Helen Keller International, Bamako, Mali,* [3]*Helen Keller International, Regional Office for Africa, Dakar, Senegal,* [4]*Helen Keller International, New York, NY, United States*

As Mali nears trachoma elimination, the Malian National Eye Health Program (PNSO) has conducted door-to-door (*ratissage*) outreach in each health district (HD) where the trichiasis (TT) prevalence remains above the WHO elimination threshold of 0.2% according to the latest survey results. Following these surgical outreach campaigns, to demonstrate that the elimination criteria have been attained, an additional survey or TT only survey can be performed. However, surveys provide a point estimate in TT prevalence in a limited number of people and often have wide confidence intervals. In Mali, Kayes region is one of the regions affected most by trachoma with a large backlog of patients who need TT surgery. Following WHO guidelines, trachoma surveillance surveys (TSS) conducted in 2017 in Diéma and Yélimané health districts (HDs) indicated that the prevalence of trachomatous inflammation-follicular (TF) in children aged 1-9 years in was 0.08% and 0.36% respectively. However, the TT prevalence was 0.53% in Diéma and 0.41% in Yélimané. The PNSO estimated the number of patients requiring TT surgery (the backlog) was 450 in Diéma and 241 in Yélimané. The PNSO conducted *ratissage* campaigns in these HDs to screen and find TT patients and offer them surgical services. During the ratissage campaigns, the PNSO screened 131 out of 146 (90%) villages in Diéma and 93 out of 98 (95%) villages in Yélimané. In Diéma 128,747 adults out of an estimated adult population of 131,846 were screened (97.6% coverage) and 248 new TT cases were detected (0.19% TT). In Yélimané 105,945 adults were screened out of an estimated adult population of 121,459 (coverage of 87.2%) and 110 new TT patients discovered (0.1%). These data indicate that, in contrast to the prevalence estimate from the TSS in 2017, where 1,501 and 1,456 adults were surveyed in Diéma and Yélimané respectively, the criteria for TT elimination has been reached. Given the larger number of people screened for TT, these ratissage data are more compelling evidence than a TSS or TT-only survey and therefore could be used in the trachoma elimination dossier as evidence of achieving the elimination criteria.

1772

TRACHOMATOUS TRICHIASIS MANAGEMENT IN TANZANIA: INVESTIGATION OF THE PRODUCTIVITY OF CASE FINDING AND REFERRAL OF PATIENTS TO SURGERY SERVICES

George Kabona[1], Jeremiah Ngondi[2], Alistidia Simon[1], Upendo Mwingira[1], Rebecca Flueckiger[3]

[1]*Tanzania NTD Control Programme, Dar es Salaam, United Republic of Tanzania,* [2]*RTI International, Dar es Salaam, United Republic of Tanzania,* [3]*RTI International, Atlanta, GA, United States*

Prolonged conjunctival infection with Chlamydia trachomatis leads to an inflammatory response, trachomatous inflammation follicular (TF). Overtime, repeat infection can progress to scarring of the conjunctiva causing the eyelid to turn inward, resulting in lashes rubbing against the cornea. This stage of the disease is called trachomatous trichiasis (TT). TT can damage the cornea, leading to vision impairment or blindness. However, TT can be managed through quality surgery. The continuum of care involves: (1) identification of a case by case finder, (2) identified case screened by eye care professional, (3) identified case confirmed by TT surgeon, and (4) identified case receives surgery. To initiate this continuum of care, district-level prevalence is estimated through population-based prevalence surveys (PBPS) and after a period of intervention another PBPS is conducted. The Tanzania NTD Control Programme has found high TT prevalence after intervention in several districts. To understand why targets are not being achieved and provide learnings for informing program adaptations to improve access to services a mixed method study is underway. The study involves a retrospective review and analysis of program data and implementation of key informant interviews (KIIs). The quantitative analysis will provide evidence around which factors influence success in a district. This information will be interpreted and used for identifying recommendations for improving equitable access to services, lessening the gap between linking to services and receiving surgery, and explore better strategies for creating service demand. The KIIs will provide contextual information around the quantitative findings. In addition, they will provide insight into how linkage and receival of surgery could be more equitable and what the current barriers/facilitators are. The KIIs among case finders, surgeons and particularly among district-level health officials will provide much needed insight into how TT case finding, and surgical delivery can be incorporated into existing disease control programs and service delivery platforms.

1773

HOUSE-TO-HOUSE CASE FINDING FOR TRICHIASIS SURGERY IN AMHARA REGIONAL STATE, ETHIOPIA: AN END GAME STRATEGY

Eshetu Sata[1], Yirga Bieza[1], Ayalew Shiferaw[1], Berhanu Melak[1], Sintayehu Aweke[1], Abebe Fissha[1], Mengesha Halefom[1], Mulat Zerihun[1], Temesgen Minas[1], Tedla Desta[1], Getachew Mekonnen[1], Demis Assegie[1], Scott D. Nash[2], Aisha E.P. Stewart[2], Zerihun Tadesse[1], E. Kelly Callahan[2], Melkamu Beyene[3]

[1]*The Carter Center, Addis Ababa, Ethiopia,* [2]*The Carter Center, Atlanta, GA, United States,* [3]*Amhara Regional Health Bureau, Bahir Dar, Ethiopia*

Trachomatous trichiasis (TT) surgery is one of the WHO endorsed SAFE strategies to treat the blinding stage of trachoma. Since 2001, the Amhara Regional Health Bureau, in collaboration with The Carter Center, operated more than 680,000 TT cases throughout the region. As the backlog of TT declines, case finding has become increasingly challenging as cases often live in remote areas. To reach these cases, this study piloted an intensive house-to-house case finding approach and assessment of reasons for refusing surgery in 31 districts. The estimated TT backlog in the 31 districts was 52,387 cases, 32.7% of the regional backlog. In 23 of the districts case finding was done by trained case finders who were selected from the community, and in the remaining districts health extension workers (HEWs) served as case finders. The case finders moved from house-to-house district-wide, targeting 100% coverage of both households and adults 15 years and older. Between October and December 2018, 871,377 households (85% of the household target) were visited and 2,093,860 people above 15 years (82% of the population target) were examined for TT. 85,303 suspected TT cases (4% of the examined people) were registered; 70,222 (82% of suspect cases) were mobilized to surgery sites; and 15,129 (22%) were confirmed to have TT. Of the confirmed TT cases, 10,255 (68%) were operated, 2,779 (18%) refused the service and, for the remaining cases, surgery was postponed. The number of TT cases confirmed was considerably lower than the estimated TT backlog. The house-to-house case finding showed an estimated TT backlog of 18,536 in the 31 districts. The case detection rate by HEWs/health workers and case finders was 50% and 18%, respectively. The majority of the refusals were due to participation in harvesting and household tasks. Findings from the house-to-house case finding suggest the approach is an effective way to reach cases living in remote areas. Future plans include mop-up in areas with low mobilization, addressing refusals and examining the feasibility of applying the house-to-house strategy in other areas.

1774

MASS DRUG ADMINISTRATION OF AZITHROMYCIN FOR TRACHOMA ALONG THE CROSS-BORDER COMMUNITIES OF KENYA AND UGANDA IN MARCH/APRIL 2019

Getrude Nasike Barasa[1], Daniel Esimit Echakan[1], Samson Lokele Akichem[1], Hadley Sultani Matendechero[2], Peter Otinda[3]

[1]*Turkana County Government, Lodwar, Kenya,* [2]*Neglected Tropical Diseases Unit, Nairobi, Kenya,* [3]*Sight Savers Kenya, Nairobi, Kenya*

Trachoma an eye disease caused by infection with the bacterium Chlamydia trachomatis, is a public health problem responsible for irreversible blindness or visual impairment with 158 million people living in endemic areas being at risk (WHO). In Kenya, Turkana is one of 6 prevalent counties, with about 1.25 million people at risk. The multi-sectoral SAFE (Surgery, Antibiotics, Face washing and Environmental cleanliness) strategy is implemented in collaboration with Queen Elizabeth Trust. With six mass drug administration campaigns (MDA) within 2011-2019 and an average coverage of 82.9%, the lowest recorded in two sub counties bordering Uganda in Jan 2019, was attributed to migration of border populations in search for pasture. The objective for the cross-border MDA exercise was to ensure the missed pastoralists are followed into Uganda. This was an eight day ecological case study serving as the baseline for future cross border activities, targeting regions along the border in 6 districts with 3 of these bordering Turkana County. Data was compiled and presented in Ms. Excel. The activity was integrated with immunization and Trachoma trichiasis screening. Across 3 districts, a total of 15,497 (61.9%) people were reached and administered with Azithromycin (tablets or syrup) or Tetracycline ointment. A total of 30 children were immunized, 34 pregnant women given Ante-Natal Care services, 63 treated for other ailments and 2 Trachoma trichiasis cases identified and referred for surgery. This first cross border exercise, reassured good will between two countries for future collaborations. Challenges were: insecurity in some areas, unreachable hard to reach areas, inadequate time for mobilization and implementation, inadequate resources among others. Positively, it facilitated linkage between counterpart facilities along the border for communication and future planning especially integrated outreaches. Need to plan alongside these migratory patterns to ensure there are effective intervention measures that enable continuity of health services among these highly mobile populations was recommended.

1775

TRACHOMA ELIMINATION IN CAMEROON: RESULTS FROM A BASELINE MAPPING OF A REFUGEE CAMP IN MINAWAO

Emillienne Epée[1], Bella Assumpta[1], Georges Nko'Ayissi[1], Mahamat Fane[1], Julie Akame[2], Patrick Mbia[2], Carine Fokam[2], Steven D. Reid[3], Yaobi Zhang[4], Jean Jacques Tougué[5], Ismael Teta[2]

Baseline trachoma surveys conducted prior to 2012 in the Far North and North regions of Cameroon revealed that 21 health districts (HDs) were endemic. The Cameroon ministry of health, with financial support from USAID implemented mass drug administration (MDA) with azithromycin in these HDs where the trachomatous inflammation - follicular (TF) prevalence was >5%. Impact surveys carried out between 2014 and 2017 revealed that all 21 HDs had reached the criteria for stopping MDA (TF<5%). However, as a result of ongoing insecurity in the area, there was an influx of people, mostly from a trachoma-endemic HD of Nigeria, to a refugee camp in Minawao in the Far North region. As Cameroon nears trachoma elimination, trachoma baseline surveys in Minawao, and other refugee camps, were necessary to document any need for intervention. During August 2018, a baseline survey, was conducted, following WHO guidelines, to estimate the prevalence of TF in children 1-9 years and trachomatous trichiasis (TT) in adults ≥15 years in the Minawao camp. The prevalence of TF in 1,167 children aged 1-9 years, examined for trachoma, was 0% while the prevalence of TT among 3,070 adults examined was 0.71%. The survey results of this survey in the Minawao refugee camp in the Far-North region reveal that TF in children was not a public health problem. However, TT prevalence was above the WHO elimination threshold of 0.2%, which suggests that TT surgery intervention was needed. The National Program will plan be required interventions for trichiasis surgery outreach to achieve the goal of eliminating trachoma as a public health problem.

1776

TRACHOMA PREVALENCE IN REFUGEE CAMPS IN THE EAST REGION OF CAMEROON

Assumpta Bella[1], Sidi Coulibaly[2], Georges Nko'Ayissi[1], Bidjang Mathurin[1], Julie Akame[3], Carine Fokam[3], Patrick Mbia[3], Ismael Teta[3], Yaobi Zhang[4], Jean Jacques Tougué[5], Steven D. Reid[6]

[1]*Ministry of Public Health, Yaoundé, Cameroon,* [2]*Independent Consultant, Bamako, Mali,* [3]*Helen Keller International, Yaoundé, Cameroon,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal,* [5]*RTI International, Washington, DC, United States,* [6]*Helen Keller International, New York, NY, United States*

Cameroon aims to eliminate trachoma as a public health problem by 2020 thus, reviewing trachoma epidemiology in areas previously not suspected to be endemic is critical. The National Blindness Control Program (PNLCé) carried out baseline mapping in six HDs from East region to estimate TF and trachomatous trichiasis (TT) prevalence as these HDs border highly endemic HDs (range 6.8%- 32.3%) in the Central African Republic (CAR). These HDs had been declared non-endemic and no baseline survey was carried out during initial mapping. Four of these HDs house five refugee camps which were established in 2014. The refugee camps were grouped as one evaluation unit (EU). Using a 2-stage cluster random survey design, refugee camps were subdivided into clusters, defined as camp blocks. Thirty clusters were randomly selected and 30 households were sampled in each cluster. Household residents aged 1 year and above were examined for signs of trachoma. The data were recorded using the Tropical Data (TD) software and then transferred to the TD platform for analysis. Prevalence estimates were adjusted for age and sex. Among 1,150 children aged 1 to 9 years examined, TF prevalence was 0.49% (95% confidence interval [CI] 0.1-1.0). Among 1365 adults aged ≥15 years examined, prevalence of TT unknown to the health system was 0.19% (95% CI 0.01-0.47). Of the surveyed households: 100% had an improved drinking water source; 95.5% has a water source less than 1km away; and 89.6% had improved sanitation facilities. Although the refugee camps have populations from trachoma endemic HDs of CAR, the lower than expected TF prevalence observed suggest that camps have lower risk of trachoma possibly due to good access to water and sanitation facilities. No trachoma control activities are warranted in these refugee camps.

1777

OUTCOMES WITHIN AN ANEMIA SCREENING AND TREATMENT SERVICE EMBEDDED IN A WELL-BABY CLINIC IN THE DOMINICAN REPUBLIC

John D. McLennan[1], Maria Mosquea[2]

[1]*Children's Hospital of Eastern Ontario - Research Institute, Ottawa, ON, Canada,* [2]*Servicio Nacional de Salud, Santo Domingo, Dominican Republic*

Despite the prevalence and importance of child anemia, there are few published reports on process and outcome indicators from child anemia management in primary care services. A few available reports from US clinics serving low-income communities suggest substantial quality care gaps. The aims of this study were to: (1) examine outcome indicators for child anemia management in a well-baby clinic in the Dominican Republic, and (2) determine whether a set of variables predicted change in hemoglobin (Hb) at follow-up. The study setting was a well-baby clinic in a low-income community in the Dominican Republic which offered free anemia screening and treatment with ferrous sulfate. Data available on children who were screened through a complete blood count (CBC)

between 11-23 months of age were analyzed. Baseline hematological parameters, treatment variables, pre-post changes in hematological parameters, and predictors of Hb change were determined. Of 135 eligible children, 80.7% (n=109) had Hb <11.0g/dl at the screening point. Among this anemic subgroup, 75.2% (n=82) had a follow-up CBC between 16-52 weeks later. Ferrous sulfate was provided to the child caregivers of 98.9% (n=81) of this group with an aim for a 12 week course of treatment. Only a modest mean increase in Hb (0.9g/dl) was found at follow-up for this group and many (72.0%) still had Hb<11.0g/dl. Lower Hb at baseline predicted greater Hb change at follow-up, but other hypothesized predictors were not significant. Although attainment on some key treatment processes were higher than values reported in some previous health services studies (e.g., fraction of anemic children receiving iron and follow-up), the amount of associated change in Hb was smaller than observed in clinical trials of iron treatment for anemia. Further determination of realistic outcomes that can be achieved with a simple anemia screen and iron provision approach is warranted, including consideration of more refined, but still cost-effective, strategies.

MORBIDITY AMONG SPECIAL AIR SERVICE (SAS) PERSONNEL DURING THE MALAY EMERGENCY

David Adams, Valerie Adams

Point University, Midway, GA, United States

Morbidity among Special Air Service (SAS) Personnel during the Malay Emergency The Malay Emergency, a counterinsurgency effort mounted by British and Commonwealth troops between 1948 and 1960, proved to be one of the more anti-communist efforts by Western forces. The anti-colonial struggle, mounted by the Malayan Communist Party's militant Malayan National Liberation Army (MLNA), had begun on 1948 to attack British and Commonwealth-owned rubber plantations and mines. Ironically, the "emergency" was termed such—rather than calling it a "war"—because insurers would have refused to cover the damages had it been deemed anything other than an "emergency". Hence, the label stuck. This presentation, based on archival data, will examine morbidity among the SAS (Special Air Service) in the early 1950s. This case study highlights the extreme difficulty of maintaining combat-readiness among even the most highly trained troops of that time.

Infectious diseases are the most common illnesses plaguing low- to middle-income countries. In this regard, vaccines offer the most reliable and cost-effective method for improving health outcomes. One of the challenges related to vaccine use is the maintenance of cold-chains, which limit reliable storage of vaccines in low resource settings. Freeze-dried vaccines have become attractive, but some antigens are sensitive to this process. Our lab has pioneered VacSIM (patent 9,566,338), a self-assembling matrix which uses the (RADA)4 polypeptide as a non-immunostimulatory adjuvant. VacSIM increases vaccine persistence, enhances immune responses, and eliminates local and systemic reactogenicity caused by molecular adjuvants. Herein, we evaluated maintenance of immunogenicity and efficacy after both lyophilization and long-term storage of protein-based vaccines mixed with VacSIM. Initial trials to study the feasibility of freeze-drying antigens mixed with VacSIM were performed using the model antigen ovalbumin (OVA). We found that we could store lyophilized OVA/VacSIM for up to 36 months at 37C with no loss of immunogenicity. We next evaluated the ability to freeze-dry malaria (*Plasmodium berghei* CelTOS and CSP) and influenza (N/C rHA) in VacSIM. Compared to conventional delivery of these 3 antigens, we found VacSIM enhanced the humoral response three-fold more after prime-boost, and lyophilization did not alter the immune response. To determine if freeze-drying influences vaccine efficacy, we have just initiated our challenge studies. For influenza HA vaccine, BALB/c mice were challenged with 1 x 10^7 pfu of influenza virus from N/C strain and for malaria CelTOS and CSP vaccines, mice were challenged with 1000 *P. berghei* sporozoites. We are currently evaluating vaccine efficacy. Future work includes assessing T-cell responses and determining the effect of long-term storage (1 to 36 months at 4, 20 and 37C) on these vaccines. If effective, these experiments and results will aid our long-term goal of generating functional thermostable subunit human vaccines in a cost-effective manner for global infectious diseases.

1780

INTEGRATING OPT-OUT HEPATITIS C SCREENING WITH EMERGENCY SERVICES FOR HIGH RISK POPULATIONS

Austin T. Jones[1], Lisa Moreno-Walton[2], Kanayo R. Okeke-Eweni[2], Jenna Miller[2], Dylan Soderstrum[2], Patricia Kissinger[1]

[1]*Tulane University, New Orleans, LA, United States,* [2]*Louisiana State University, New Orleans, LA, United States*

Hepatitis C virus (HCV) chronically infects 71 million people worldwide. Updated World Health Organization (WHO) guidelines recommend a "Treat All" approach to eliminate HCV by 2030, calling for 90% of cases to be identified and 80% to be treated. The objective of the study was to evaluate the effectiveness of an emergency department opt-out HCV screening program at identifying HCV+ patients and linking them to health services. A retrospective cohort study was conducted. Patients who tested HCV antibody-reactive in the University Medical Center Emergency Department in New Orleans, LA from March to December 2015 were included. Outcomes measured include retention along the HCV care cascade and time to follow-up. A total of 902 patients screened HCV antibody-reactive. The majority had not been previously tested for HCV (67.5%). Of those antibody-reactive, 855 (94.8%) completed viral load testing. Median follow-up time was less than 1 day (IQR 7). Of those who received RNA testing, 633 (74.0%) were found to be chronically infected, while 222 (26.0%) had spontaneous viral clearance. Of those chronically infected, 294 (46.4%) followed up with radiology for hepatic ultrasound. Median radiology follow-up time was 183 days (IQR 287) post-screening. Primary care was attended by 192 patients (30.3%). Median primary care follow-up time was 136 days (IQR 253) post-screening. Viral hepatitis clinic was attended by 192 patients (30.3%). Median viral hepatitis clinic follow-up time was 173 days (IQR 261) post-screening. Treatment was initiated in 80 patients (12.6%). Median time to begin treatment was 302 days (IQR 403) post-screening. Sustained virologic response (SVR) was achieved in 59 patients (9.3%). Median time to SVR was 419 days (IQR 545) post-screening. Opt-out screening successfully captures previously undiagnosed patients and links them to curative treatment. Integration of HCV screening with emergency services is an effective delivery model, supporting the WHO recommendation to incorporate HCV screening with existing health services. Updated 2018 WHO guidelines for HCV and lessons applicable to resource-limited areas will be discussed.

TRACHOMATOUS TRICHIASIS (TT) CASE FINDERS AND THEIR IMPACT IN PATIENT IDENTIFICATION AND UPTAKE OF SURGICAL SERVICES. CASE STUDY OF DODOMA AND LINDI REGIONS OF TANZANIA

Alistidia Simon[1], Hope Rusibamayila[1], Jeremiah Ngondi[2], Upendo Mwingira[1], Jennifer Harding[3], Harran Mkocha[4], Peter Kivumbi[5], Gosbert Katunzi[6], George Kabona[7], Andreas M. Nshala[8]

[1]*NTD Control Program, Dar Es Salaam, United Republic of Tanzania,* [2]*RTI, Washington, DC, United States,* [3]*HKI, Dar Es Salaam, United Republic*

of Tanzania, [4]Kongwa Trachoma Project, Dodoma, United Republic of Tanzania, [5]Sight Savers, Dar Es Salaam, United Republic of Tanzania, [6]Sightsavers, Dar Es Salaam, United Republic of Tanzania, [7]Iringa Regional Hospital, Iringa, United Republic of Tanzania, [8]Uppsala University, Uppsala, Sweden

The World Health Organization (WHO) targets global elimination of trachoma as a public health problem by the year 2020 through the SAFE (surgery, antibiotics, facial cleanliness, environmental change) strategy. Since inception of SAFE in 1999, Tanzania has implemented trichiasis surgical services based on WHO guidelines with the aim of achieving GET 2020 goals. According to WHO elimination of trachomatous trichiasis (TT) is considered when the prevalence of trichiasis cases un-known to the health system is <0.2% in people aged 15 years and above. In Tanzania TT surgical services are provided mainly through camps. Cases are identified through two different approaches: active Case finders; and Community sensitization. Case finders are trained to search for TT patients in their community and report back the list of patients identified to the nearest health facility. The Case finder searches for patients through house-to-house approach. Community sensitization on the other hand, is usually done through village meetings and road show announcements to invite all people with eye problems to show up during the planned camp at their designated health facility. Cultural leaders are very influential people in calling such village meetings. The Case finder approach has showed promising results with increased patient identification, increased surgical uptake and substantial declines in TT backlog. Since implementation of case finder approach Lindi and Dodoma regions in 2016 a total of 911,132 people have been screened and 9,064 were brought to the camp by case finders and 5,429 surgeries have been done. TT burden estimates suggest the backlog has been reduced from 5,150 cases in 2016 to 2,924 cases in 2018. The case finder approach was effective in identification and referral of TT cases for surgery and will facilitate elimination of trachoma in Tanzania.

INTEGRATING CHAGAS DISEASE CARE INTO PRIMARY CARE: THE STRONG HEARTS/CORAZONES FUERTES/CORAÇÕES FORTES PROJECT IN BOSTON, MASSACHUSETTS

Jillian Davis[1], Jennifer Manne-Goehler[2], Juan Huanuco Perez[1], Ingrid Carmelo[3], Hong Sun Park[4], Katherine M. Collins[4], Natasha S. Hochberg[3], Davidson H. Hamer[3], Elizabeth D. Barnett[3], **Julia R. Köhler**[4]

[1]East Boston Neighborhood Health Center, Boston, MA, United States, [2]Brigham and Women's Hospital, Boston, MA, United States, [3]Boston Medical Center, Boston, MA, United States, [4]Boston Children's Hospital, Boston, MA, United States

In Massachusetts, there are over 3,000 estimated cases of Chagas disease (CD). Treatment in the asymptomatic interval before development of cardiac signs is the best chance for the 20-30% of patients who will otherwise progress to heart disease and death. Asymptomatic *T. cruzi* infection hence must be detected by serologic screening. The Strong Hearts (Corazones Fuertes/Corações Fortes) program intends to establish CD screening as a component of primary care for at-risk patients and to implement, as the standard of care, referral to specialized care including treatment as indicated. The program comprises 1. raising awareness among medical providers, 2. education of at-risk communities, 3. establishment of a robust screening program, and 4. referral for treatment and support of patients. In our local experience, logistical hurdles within the health care system that obstruct appropriate care include need for confirmatory testing of positive screening results at the CDC; need for an affirmative referral process by which each electronic referral receives follow-up; language barriers; and challenges in obtaining benznidazole from the manufacturer. For infants of *T. cruzi*-positive mothers, follow-up protocols had to be established between the tertiary care hospital and the health center. Systematic interdisciplinary efforts among clinician teams to address these hurdles are productive and ongoing, since not all problems have been solved. In the first 23 months of screening in one health center, 42 patients had positive confirmatory *T. cruzi* antibody testing at the CDC, among 4833 completed serologic tests (0.87%). All patients were referred for treatment, though barriers to medical care for persons at risk for CD are high. These barriers include lack of health insurance, lack of transportation, fear of asking the employer for time off work, fear of an unknown hospital and fear of persecution as Latin-American immigrants. Support for patients is crucial, as best possible with available resources. The Strong Hearts program shows that addressing CD can be part of standard care when attention is directed to the health needs of at-risk communities.

1783

ANALYTICAL PERFORMANCE OF THE FILMARRAY® GLOBAL FEVER PANEL

Jared R. Helm, Corike Toxopeus, Pascal Belgique, Lex Border, Olivia Jackson, Alex Kelley, Micah Mortenson, Cynthia Phillips

BioFire Defense, Salt Lake City, UT, United States

A large number of pathogens that include bacteria, viruses, and parasites can cause Acute Febrile Illness (AFI). BioFire Defense is developing the Global Fever (GF) Panel to be used on the FilmArray® System in collaboration with the U.S. Department of Defense[a] and NIAID[b]. The FilmArray is an *in vitro* diagnostic test platform that combines nucleic acid purification and nested multiplex PCR for the simultaneous identification of many infectious agents in under an hour using a closed, sample-to-answer system. The FilmArray GF Panel detects and identifies nucleic acid from chikungunya virus, CCHF virus, dengue virus (serotypes 1-4), Ebolavirus, Lassa virus, Marburgvirus, West Nile virus, Yellow fever virus, Zika virus, *Bacillus anthracis*, *Francisella tularensis*, *Leptospira* spp., *Salmonella enterica* serovar Typhi and Paratyphi A, *Yersinia pestis*, *Leishmania* spp., and *Plasmodium* spp. in venous blood specimens from individuals with signs and/or symptoms of AFI or recent AFI and with known or suspected exposure to target pathogens. The LoD studies demonstrate that the GF Panel is a sensitive system that can accurately detect multiple pathogens, including Category A biothreat pathogens, and is appropriate to use testing samples that may contain multi-analytes. Analytical specificity (exclusivity) testing demonstrates that the GF Panel is highly specific for the pathogens it is designed to detect in blood specimens. Assessment of the analytical reactivity and efficacy (inclusivity) show that the assays possess a high level of reactivity for their intended targets. A multiplex FilmArray panel could aid in rapid and actionable AFI diagnosis.

SEVERE MUCOSAL LEISHMANIASIS: CLINICAL MANIFESTATIONS AND BRONCHOSCOPIC FINDINGS

Alejandro Elmer Llanos[1], Braulio Valencia[1], Cesar Colunche[2], Ana A. Ramos[1], Fiorela Alvarez[1], Oscar Gayoso-Liviac[1], Oscar Gayoso[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Servicio de Neumología y DEITD, Hospital Cayetano Heredia, Lima, Peru

Severe Mucosal Leishmaniasis: Clinical manifestations and bronchoscopic findings. Alejandro Llanos-Cuentas[1,3], Braulio Valencia[1], Cesar Colunche3, Ana Ramos[1], Fiorela Alvarez[1], Oscar Gayoso-Liviac[1] and Oscar Gayoso[2,3] 1 Instituto de Medicina Tropical *Alexander von Humboldt*, Universidad Peruana Cayetano Heredia (UPCH), Lima, Peru. 2 Facultad de Medicina, UPCH. 3 Servicio de Neumología y DEITD, Hospital Cayetano Heredia. Mucosal leishmaniasis (ML) is the most severe form of tegumentary leishmaniasis (TL). Most cases in the New World are caused by *Leishmania (V.) braziliensis* with a prevalence around 4% of total TL yearly cases. ML has no spontaneous cure, patients with severe disease can die due to invasion of the mucous membranes and underlying tissues. The severity of mucosal disease is the main parameter of the therapeutic response. In severe form, patients present compromise of the mucous membranes: nasal, oropharynx, larynx, trachea, and even bronchi. The cure rate of ML is <10% when treated with pentavalent antimonials, because of this

reason the therapy of choice is amphotericin B, either in the liposomal presentation or as deoxycholate. We report the results of 20 patients with clinical diagnosis of severe ML who underwent bronchoscopy prior to the start of therapy with amphotericin B. All patients were male, the mean age was 39 years (range 23-55 years),70% were infected in the department of Madre de Dios. Reported symptoms were hoarseness 90%, productive cough 80%, severe dysphagia 80%, dysphonia 75%, and dyspnea during physical activities 42%. The main clinical findings were wheezing 60%, stridor 45% and clubbing 30%. The bronchoscopy detected compromise of epiglottis and vocal chords 100%, subglottic 70%, upper 2/3 of the trachea 60%, lower third of the trachea 30%, subglottic stenosis 40% and compromise of the bifurcation of the major bronchi 14%. Only 15% ML patients had a normal spirometry. The remaining spirometries had an obstructive 70%, restrictive 5% and mixed 10% pattern. In summary, patients with the severe ML form present extensive and severe upper and lower airway involvement and need different therapeutic approach.

1785

RISK FACTORS AND TRENDS IN NEONATAL MORTALITY IN A SPECIAL CARE NEWBORN UNIT IN A TERTIARY CARE HOSPITAL

Ananya Kumar[1], Kyu Han Lee[1], Abu Faisal Pervez[2], Sanwarul Bari[3], Shams El Arifeen[3], Farzana Islam[3], Emily S. Gurley[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Faridpur Medical College Hospital, Dhaka, Bangladesh,* [3]*International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh*

South Asian countries accounted for 38% of the global burden of neonatal mortality in 2017; within the region, 60% of under-5 deaths were neonatal deaths. Bangladesh's neonatal mortality rate in 2017 was 18.4 deaths per 1000 livebirths - special care newborn units (SCANUs) have been established in multiple hospitals country-wide to improve neonatal survival. We conducted a retrospective cohort study in the SCANU of Faridpur Medical College Hospital, Bangladesh to profile the neonates admitted to the unit in 2018, describe trends in admissions and deaths, and establish risk factors associated with death within 48 hours of admission to the unit. Neonates (0-28 days old) who were admitted alive to the unit between January and November 2018 with admission dates available in the medical records and did not abscond in the first 48 hours from admission were included in the study population. We described demographic and clinical characteristics of the population as well as trends in admissions and deaths each month. Logistic regression models were generated to examine the relationship between death within 48 hours of admission to the unit and potential demographic, diagnostic and clinical risk factors. 646 neonates were included in the study population; 41% (n=263) died in hospital, 26% within 48 hours of admission. Sixty-one percent were admitted on the day of birth, 56% were male, and 82% were born prematurely (before the completion of 37 weeks of pregnancy). No seasonal clustering of admissions or deaths was observed. Each additional day of age was associated with a 5% reduction in the odds of death within 48 hours of admission to the unit (OR: 0.95, 95% CI: 0.9, 0.99); male sex (OR: 1.53, 95% CI: 1.04, 2.23), prematurity (OR: 2.5, 95% CI: 1.3, 4.7) and a perinatal asphyxia diagnosis (OR: 2.2, 95% CI: 1.4, 3.4) were all associated with an increased odds. The high mortality among neonates in this unit warrants further investigation to identify strategies to improve outcomes. Other SCANUs in the country with similar treatment gaps may also require attention and resources in order to improve child survival in these units.

1786

FACTORS ASSOCIATED WITH MORTALITY IN PRETERM NEONATES AND INFANTS WITHIN THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) NETWORK

Navit T. Salzberg[1], Dianna M. Blau[2], Shams El Arifeen[3], Victor Akelo[4], Quique Bassat[5], Richard Chawana[6], Emily Gurley[7], Karen Kotloff[8], Shabir Madhi[6], Inacio Mandomando[9], Dickens Onyango[10], Samba O. Sow[11], Robert F. Breiman[1], for the CHAMPS Network Consotrium[1]

[1]*Emory Global Health Institute, Emory University, Atlanta, GA, United States,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*International Centre for Diarrhoeal Diseases Research, Bangladesh, Dhaka, Bangladesh,* [4]*United States Centers for Disease Control and Prevention-Kenya, Kisumu, Kenya,* [5]*ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain,* [6]*Medical Research Council: Respiratory and Meningeal Pathogens Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,* [7]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [8]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States,* [9]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique,* [10]*Kisumu County Public Health Department, Kisumu, Kenya,* [11]*Center for Vaccine Development, Bamako, Mali*

While it is known that mortality is inversely proportional with gestational age at birth, the specific causes of death that are associated with the increased vulnerability among preterm infants is not well characterized in locations with high mortality. Through the collection of comprehensive cause of death data, including postmortem specimen testing, to determine the sequence of events leading to death, CHAMPS will help define specific causes of under-five mortality in Africa and South Asia. Causes of death among neonates (0-27 days) and infants (28 days to < 12 months), born preterm (n=245) and full term (n=205), from December 2016 –March 2019 were compared. Preterm was defined as a gestational age of less than 37 weeks (when information available) or as determined by a panel of experts using available clinical data. Over half of enrolled deaths were born premature and 27% of those died of complications unique to prematurity. With respect to those complications, the majority died of respiratory distress syndrome (71%), followed by pulmonary hemorrhage (9%), primary atelectasis of the lung (7%) and necrotizing enterocolitis (NEC) (3%). Among neonates and infants born preterm, 62% had a pathogen-associated illness identified in the causal chain of death, compared to 49% of neonates and infants born full term. While causes of death among infants born prematurely were similar to those among infants born full term (i.e. pneumonia, sepsis), the pathogens associated with death had different distributions; preterm infants were less likely to die of pneumococcal, *Haemophilus influenzae*, malaria, and HIV infections, whereas they were more likely to have had gram negative sepsis, many resulting from nosocomial infections acquired during long-term hospitalization needs. No significant differences in pathogen associated illness were found between preterm neonates and preterm infants. CHAMPS data supports and provides granularity to the role of infections in preterm mortality; this detail will help focus efforts on identifying and treating infection through the through the first year of life to increase the chances for survival.

1787

CHILDHOOD GROWTH AND NEUROCOGNITION ARE ASSOCIATED WITH DISTINCT SETS OF METABOLITES

G. Brett Moreau[1], Girija Ramakrishnan[1], Heather Cook[1], Todd Fox[1], Uma Nayak[1], Swapna Kumar[2], Jennie Ma[1], E. Ross Colgate[3], Beth Kirkpatrick[3], Charles Nelson[2], Rashidul Haque[4], William Petri, Jr.[1]

[1]*University of Virginia, Charlottesville, VA, United States,* [2]*Boston Children's Hospital, Boston, MA, United States,* [3]*University of Vermont, Burlington, VT, United States,* [4]*International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh*

Undernutrition is a serious global problem that contributes to increased child morbidity and mortality, impaired neurocognitive development, and decreased educational and economic attainment. Current interventions are only marginally effective, and identification of associated metabolic pathways can offer new strategies for intervention. Plasma samples were collected at 9 and 36 months from an undernourished child cohort in Bangladesh and targeted metabolomics was performed on bile acids, acylcarnitines, amino acids, phosphatidylcholines, and sphingomyelins. Metabolic associations with linear growth and neurocognitive outcomes at four years were evaluated using correlation and penalized-linear regression analysis as well as conditional random forest modeling. Analysis identified that different metabolites were associated with growth and neurocognitive outcomes. Improved growth outcomes were associated with higher concentrations of hydroxy-sphingomyelin and essential amino acids as well as lower levels of acylcarnitines and bile acid conjugation. Neurocognitive scores were largely associated with phosphatidylcholine species and early metabolic indicators of inflammation. All metabolites identified explain ~45% of growth and neurocognitive variation. Growth outcomes were predominantly associated with metabolites measured early in life (9 months), many of which were biomarkers of insufficient diet, environmental enteric dysfunction, and microbiome disruption. Hydroxy-sphingomyelin was a significant predictor of improved growth. Neurocognitive outcome was predominantly associated with 36 month phosphatidylcholines and inflammatory metabolites, which may serve as important biomarkers of optimal neurodevelopment. The distinct sets of metabolites associated with growth and neurocognition suggest that intervention may require targeted approaches towards distinct metabolic pathways. Further work is currently underway to identify the mechanisms underlying these metabolic associations.

CLINEPIDB: THE CLINICAL EPIDEMIOLOGY DATABASE RESOURCE

Danica A. Helb[1], Cristina Aurrecoechea[2], John Brestelli[1], Brian P. Brunk[1], Danielle Callan[1], David Falke[2], Steven Fischer[1], Jay Humphrey[2], John Judkins[1], Jessica C. Kissinger[2], Brianna Lindsay[1], David S. Roos[1], Sheena Shah Tomko[1], Christian J. Stoeckert Jr[1], Jie Zheng[1]

[1]*University of Pennsylvania, Philadelphia, PA, United States,* [2]*University of Georgia, Athens, GA, United States*

Population-based epidemiological studies provide new opportunities for innovation and collaboration among researchers addressing pressing global health concerns, however access to study data pose many challenges. ClinEpiDB (https://clinepidb.org) is an open-access online resource that enables investigators to maximize the utility and reach of their research and to make optimal use of data released by others. Existing infrastructure for EuPathDB (https://eupathdb.org)--a collection of databases covering 170+ eukaryotic pathogens, relevant free-living and non-pathogenic species, and select pathogen hosts--was used to build the ClinEpiDB database, and enables complex interrogations of underlying data with a sophisticated search strategy system. When Integrating studies into the database, a unified semantic web framework is used to describe the data. Over 2400 different variables about participants, their associated anthropometry, demographics, and disease episodes were collected in the clinical and epidemiological studies hosted on ClinEpiDB to date. Query results can be analyzed and graphically visualized via interactive web applications launched directly in the ClinEpiDB browser, providing insight into distributions and exploratory associations with any covariates. ClinEpiDB currently hosts data from the Gates Foundation-supported Malnutrition and Enteric Diseases Network (MAL-ED) and the Global Enteric Multicenter Study (GEMS) projects, which studied the etiology, incidence and impact of childhood enteric disease in low-income countries. ClinEpiDB also hosts data from two NIH-supported International Centers for Excellence in Malaria Research (ICEMR) studies, which used comprehensive longitudinal data to elucidate interactions between malaria parasites, their mosquito vectors, and human hosts. The ClinEpiDB resource will continue to grow with enhanced tool development, significant user outreach and education, and integration of new datasets (such as Pneumonia Etiology Research for Child Health (PERCH) and several additional ICEMR studies, which will be released over the coming year).

GAZELLE, A PROMISING POINT-OF-CARE DIAGNOSTIC FOR HEMOGLOBIN DISORDERS IN INDIA: BRIDGING THE GAP IN CONTROL PROGRAM

S. Rajasubramaniam[1], Rajat Kumar[1], Shweta Shrivas[1], Anil K. Verma[1], Priyaleela Thota[2], Praveen Bharti[1], Anne Rocheleau[2], Tyler Witte[2], R. Uikey[1], Muhammad Noman Hasan[3], Umut A. Gurkan[3], Aparup Das[1]

[1]*National Institute of Research in Tribal Health, Jabalpur, India,* [2]*Hemex Health, Portland, OR, United States,* [3]*Case Western Reserve University, Cleveland, OH, United States*

Sickle Cell Disease (SCD) and thalassaemias are the two prevalent genetic disorders causing anaemia and associated complications. The prevalence of both SCD and carriers varies from 5-35% among ethnic groups and Scheduled caste communities in 5 states namely Madhya Pradesh, Gujarat, Maharashtra, Odisha, Chhattisgarh and Andhra Pradesh in India. Mass screening involves solubility test followed by confirmation by high-performance liquid chromatography (HPLC) or haemoglobin electrophoresis. Absence of public health diagnostic facilities results in high morbidity and mortality among undetected patients. Evaluatory phase I studies on "Gazelle™", a microchip-based cellulose acetate electrophoresis device were conducted in tribal-dominated Madhya Pradesh and Chhattisgarh states of. Gazelle™ is a rapid (<10 minutes) and easy-to-use test that can be carried out using a finger-prick volume of blood. Blood samples were collected from 300 patients enrolled in a pilot study at a high prevalence setting (ICMR-NIRTH, India). Each sample was tested with Gazelle™, and the results were compared to electrophoresis and HPLC. A total of 295 patient samples were included in the analysis (3 samples were excluded due to incomplete runs; sequencing results are pending for 2 samples). Phase II testing with improved Gazelle™ is ongoing and results will be presented at the Conference. Of the 295 tested samples, 4% were HbSS and HbSβ-thal, 21% were sickle cell trait and 74.9% were of normal (HbAA) category. Gazelle™ showed high accuracy (100%), sensitivity and specificity in detecting SCD (HbSS) and β-Thalassemia, sickle cell trait (HbAS) when compared with standard screening tests. Microchip electrophoresis technology is a promising, low-cost ($2 per test), rapid, and accurate method for detecting hemoglobin disorders such as SCD in limited resource settings in India. Gazelle aims to bridge the gap in diagnosis of sickle cell and hemoglobin disorders in healthcare.

SUCCESSFUL MANAGEMENT OF POISONING WITH IVERMECTIN (MECTIZAN®) IN THE OBALA HEALTH DISTRICT (CENTRE REGION, CAMEROON): A CASE REPORT

Hugues Nana Djeunga, Cyrille Donfo Azafack, Floribert Fossuo Thotchum, Joseph Kamgno

Centre for Research on Filariasis and other Tropical Diseases (CRFilMT), Yaoundé, Cameroon

The efficacy, safety and tolerability of ivermectin (IVM) have led to its large scale use for mass treatments, that is without any prior diagnosis. Data reporting the clinical presentation of poisoning to IVM are very scanty, even in experimental studies. We report the case of a 19 years old female patient who deliberately swallow about 400 IVM pills with self-murder intention after a family conflict. Of note, she opened a sealed box of 500 tablets of IVM 3 mg and when she was found in a state of obsession, less than 100 pills were remaining. The patient was admitted to the Obala district hospital the day after drug intake for obnubilations, asthenia and vomiting. Once admitted, a physical checkup was undertaken and revealed an alteration of her general state with asthenia and anorexia, a digestive disorder with nausea and marked sensitivity to of right iliac fossa, visual involvement with reactive bilateral mydriasis and visual acuity without correction of 1/10 for both eyes, heart involvement regular heartbeats, and neurological involvement with rotational vertigo, headache, kinetic ataxia with osteotinous hyperreflexia. Prior the unfortunate event, the patient reported a visual disorder that never required consultation, though a history of visual disorder was reported in her family. She had no known psychiatric pathology and no known allergy to a drug. She declared never received any IVM treatment before the event. The case management consisted in saline-based hyperhydration, antiulcer drug (Omeprazole 40mg daily), and Paracetamol 1g for headache. The clinical evolution was satisfactory from day 2 to day 4 post-poisoning, with a decrease of vertigo, asthenia, ataxia but persistent visual disturbances and asthenia. The patient was discharged at day 4 and totally recovered by one-month post-poisoning. This is the first report of a poisoning with ~100 times higher the recommended dosage. This case report confirms the safety and tolerability of IVM, even at exceptionally high dosage, and is supportive of the suspected mechanism underlying severe adverse events occurring post IVM among individuals heavily infected with *Loa loa*.

1791

IMPACT OF PRENATAL MATERNAL STRESS ON BIRTH ANTHROPOMETRICS AND PREGNANCY OUTCOMES IN RURAL GHANA

Kenneth Ayuurebobi Ae-Ngibise[1], Blair J. Wylie[2], Darby W. Jack[3], Felix B. Oppong[1], Seyram Kaali[1], Oscar Agyei[1], Patrick L. Kinney[4], Rosalind J. Wrigh[5], Kwaku Poku Asante[1], Alison G. Lee[5]

[1]*Kintampo Health Research Centre, Kintampo, Ghana,* [2]*Beth Israel Deaconess Medical Center, Boston, MA, United States,* [3]*Mailman School of Public Health, Columbia University, New York, NY, United States,* [4]*Boston University School of Public Health, Boston, MA, United States,* [5]*Icahn School of Medicine at Mount Sinai, New York, NY, United States*

In developed countries, prenatal maternal stress has been associated with impaired fetal growth, however this has not been evaluated in rural sub-Saharan Africa. We evaluated the effect of prenatal maternal stress on fetal growth and birth outcomes in rural Ghana. Leveraging a prospective, rural Ghanaian birth cohort, we ascertained prenatal maternal negative life events, categorized scores as 0-2 (low stress; referent), 3-5 (moderate), and >5 (high) among 353 pregnant women in the Kintampo North Municipality and Kintampo South District located within the middle belt of Ghana. We employed linear regression to determine associations between prenatal maternal stress and infant birth weight, head circumference, and length measured within 24 hours of birth. We additionally examined associations between prenatal maternal stress and adverse birth outcomes, including low birth weight, small for gestational age, and stillbirth using logistic regression. Models were adjusted for maternal age, weight, height, socioeconomic status, marital status, ethnicity, infant sex, and intervention cluster. . Effect modification by infant sex was examined. Compared with low prenatal maternal stress, high stress was associated with reduced birth length (=-0.91 cm, p=0.04; p-value for trend=0.04) for all infants. Among female infants, moderate and high prenatal maternal stress were both associated with reduced birth weight (=-0.16 kg, p=0.02; =-0.18, p=0.04 respectively; p-value for trend=0.04) and head circumference (=-0.66 cm, p=0.05; =-1.02, p=0.01 respectively; p-value for trend=0.01). In female infants, high prenatal stress increased odds of a composite of adverse birth outcomes (OR 2.41, 95% CI 1.01-5.75; p for interaction=0.04). In conclusion, in this rural Ghanaian cohort, our data suggests that prenatal maternal stress may negatively impact fetal growth and pregnancy outcomes in all infants, especially for female infants. Understanding risk factors for impaired fetal growth may help develop preventative health strategies for future public health interventions

1792

PREVALENCE AND CORRELATES OF STUNTING AMONG CHILDREN 1-59 MONTHS DISCHARGED FROM THREE HOSPITALS IN WESTERN KENYA

Hannah E. Atlas[1], Rebecca L. Brander[1], Kirkby D. Tickell[1], Christine J. McGrath[1], Susan K. Oongo[2], Ingred V. Bitengo[2], Grace C. John-Stewart[1], Barbra A. Richardson[1], Benson O. Singa[2], Judd L. Walson[1], Patricia B. Pavlinac[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Kenya Medical Research Institute, Nairobi, Kenya*

Stunting (length-for-age z-score {LAZ} < -2 SD) is associated with significant morbidity and mortality among children under age 5 in sub-Saharan Africa. We determined correlates of stunting among children 1-59 months upon discharge from 3 hospitals in Western Kenya enrolled in an ongoing clinical trial (Toto Bora Trial, NCT02414399), using log-binomial regression to estimate prevalence ratios (PRs), adjusting for child age and study site. Of the 991 children enrolled to date, the median age was 18 months (interquartile range: 9-32) and 24.2% were stunted. Among stunted children, 7.4% also had moderate acute malnutrition (-3 ≤ weight-for-length z-score [WLZ] -2) and 4.1% were severely acutely malnourished (WLZ < -3). Children whose caregivers had primary school education or less were also more likely to be stunted (aPR: 2.00 [95% CI: 1.54-2.61]), after additional adjustment for caregiver age. Having a flush toilet was associated with a lower prevalence of stunting relative to pit latrine (aPR: 0.47 [95% CI: 0.25-0.89]). Not exclusively breastfeeding in the first 6 months of life was associated with higher stunting prevalence compared to exclusively breastfeeding (aPR_{never}: 3.89 [95% CI: 1.50-10.04]; $aPR_{partial}$: 1.69 [95% CI: 0.80-3.56]). Children who were HIV-infected (1.6%) or HIV-exposed, uninfected (9.5%) were more likely to be stunted than HIV-unexposed children (84.7%) ($aPR_{HIVINFECT}$: 2.49 [95% CI: 1.27-4.88]); aPR_{HEU}: 1.76 [95% CI: 1.18-2.64]). Presence of diarrhea at presentation, discharge diagnosis and previous hospitalization in the last year were not associated with stunting. Among children hospitalized for an infectious condition, several routine sociodemographic factors, as well as HIV exposure, were important contributors to stunting. Hospital discharge may represent an important opportunity for administering targeted interventions to prevent further growth faltering, particularly among HIV-affected children.

1793

IMPACT OF TOXOPLASMOSIS AND CYTOMEGALOVIRUS ON PREGNANT WOMEN AND THEIR NEWBORNS IN LIMA, PERU

Grace Trompeter[1], José Camones Huerta[2], Alexander Cordero Campos[2], Mayra Ochoa Porras[2], Sonia Apaza Chayña[2], Andrea Diestra Calderón[2], Erasmo Huertas Tacchino[3], Mónica Pajuelo Travezaño[2], Maritza Calderón Sanchez[2], Robert Gilman[4]

[1]*Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY, United States,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Instituto Nacional Materno Perinatal, Lima, Peru,* [4]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Toxoplasma gondii, the parasite that causes toxoplasmosis, and cytomegalovirus (CMV) are two pathogens with the ability to cause significant morbidity in the developing fetus, resulting in such problems as hearing or vision loss, brain calcifications, CNS abnormalities, and hepatosplenomegaly. Often times, infants are born with subclinical infection, which remains undetected until they develop sequelae later in childhood. Globally, it is estimated that these infections affect 0.5-2.0% of all births. While the seroprevalences of *T. gondii* and CMV among the general population are known to be higher in developing countries, the rates of vertical transmission in Latin America, and its subsequent effects on fetal development, remains understudied. Therefore, understanding the contribution of both CMV and *T. gondii* congenital infections will be important to help focus public health efforts. The primary goal of the initial phase of the study was to determine the rates of *T. gondii a*nd CMV congenital infection in a sample of newborns in Lima, Peru and to characterize the epidemiological characteristics of those subjects determined to be positive by either serology and/or nucleic acid testing. Women over age 18 who presented to Instituto Nacional Materno Perinatal in Lima, Peru were recruited prior to delivery. A brief questionnaire assessing maternal risk factors for infection was conducted and samples from the mother, newborn, and placenta were collected. ELISA was used to detect IgM antibodies to *T. gondii* in serum from cord blood of newborns. Real time PCR was used to detect CMV DNA in newborn saliva samples. IgG ELISA was used to determine the seroprevalence of CMV and *T. gondii* among participating mothers. This work is important in contributing to the understanding of the relative risks of CMV and *T. gondii* to public health and will allow communities across Peru to better direct public health efforts.

1794

OUR EXPERIENCE WITH HISTOPATHOLOGIC, MICROBIOLOGIC AND GENETIC CHARACTERISTICS OF THE PARASITIC OOMYCETE, *PYTHIUM INSIDIOSUM*

Dennis J. Rocheleau, Rupal M. Mody, Rebecca A. Smiley, Matthew J. Perkins

William Beaumont Army Medical Center, El Paso, TX, United States

Pythiosis, caused by *Pythium insidiosum*, is a very rare infection that mimics mucormycosis. Differentiating between the two infections is important as the efficacy of antifungal agents against P. insidiosum is unclear and there is a therapeutic vaccine for treatment of pythiosis. A case of pythiosis was identified at our institution. A report of this case, focusing on the clinical features, has previously been published. At the time of the patient's admission, histopathology of a lesion showed hyphae with rare septae on Grocott's methenamine silver (GMS) stain concerning for cutaneous zygomycosis. Samples of abnormal tissue were plated directly on to Sabouraud-dextrose agar plates. The organism was subsequently cultured in liquid media. A fine, white, filamentous organism grew on Sabouraud-dextrose agar plates three days after samples were plated. Vegetative growth adhered closely to the agar and was not characteristic of a "lid-lifter" with extensive upward growth as has been described with agents of mucormycosis. The organism was identified as *P. insidiosum* via ribosomal RNA sequencing. Phylogenetic analysis revealed clade-I genotype, the clade most typically identified in the North America. Liquid media culture was performed resulting in induction of motile zoosporogenesis. Histopathologic samples of skin and fascia revealed inflammation with areas of necrosis, abscess formation, granulomas and marked eosinophilic infiltrate. Hyphae stained most clearly with GMS stain but did not stain well on periodic acid-Schiff with hyphal structures 4-6μm in width. Our experience with pythiosis is illustrative of characteristics helpful to differentiate it from mucormycosis. Eosinophilic infiltrate is suggestive of a diagnosis alternative to mucormycosis. Agents of mucormycosis typically having hyphae 6-15μm in diameter and P. insidiosum hyphae ranging from 2-7μm. Induction of zoosporogenesis in liquid culture is diagnostic of *Pythium*. Identification of the organism utilizing PCR is most useful for diagnosis and, if suspected, samples of tissue or organism growing in culture should be sent to a laboratory with this capability.

1795

INCIDENCE OF ACUTE GASTROENTERITIS AND NOROVIRUS IN A COMMUNITY COHORT, CUSCO, PERU, 2015-2018

Giselle M. Soto[1], Candice Romero[1], Yeny Tinoco[1], Wesley Campbell[2], Patricia Galvan[1], Roxana Caceda[1], Laura Calderwood[3], Anita Kambhampati[3], Andrea McCoy[1], Aron Hall[3]

[1]*US Naval Medical Research Unit Six, Callao, Peru,* [2]*Walter Reed National Military Medical Center, Bethesda, MD, United States,* [3]*US Centers for Disease Control and Prevention, Atlanta, GA, United States*

Norovirus is the most common cause of sporadic and outbreak-associated acute gastroenteritis (AGE).The highest incidence of norovirus is reported among children <5 years of age but norovirus can cause disease at any age. Population-based data on norovirus epidemiology from tropical settings are limited and the impact of norovirus in low- and middle-income countries (LMIC) is poorly understood. In April 2015, we implemented active surveillance in 268 households in Cusco, a highland city in Peru, to assess the burden of AGE and norovirus. We defined AGE as either ≥3 loose stools, ≥2 vomiting episodes, or ≥1 vomiting episode and ≥1 loose stool within 24 hours. Stool samples from participants meeting the case definition were tested for norovirus by RT-PCR. Stool samples from household members of AGE cases and members of matched control households were also collected and tested for norovirus. During April 2015 – December 2018, overall incidence of AGE and of norovirus across all ages was 25 cases/100 person-years (PY) (95% confidence interval [CI], 23–27/100 PY) and 5/100 PY (95% CI, 4–6/100 PY), respectively. Children aged ≤2 years had the highest incidence of norovirus with 66/100 PY (95% CI, 51–86/100 PY). Norovirus prevalence was 11.8% among non-AGE household members of index AGE cases and 8.5% among members of healthy control households. Norovirus is an important etiology of AGE in this LMIC community. Further assessment of associated risk factors as well as circulating norovirus genotypes will help to better understand the burden of AGE and norovirus in this community and guide future interventions.

UNBIASED METAGENOMIC SEQUENCING FOR MICROBIAL DETECTION AND IDENTIFICATION USING THE IDSEQ PLATFORM

Vida Ahyong[1], Maira Phelps[1], Michelle Tan[1], Rene Sit[1], Norma Neff[1], Joseph DeRisi[1], Cristina Tato[1], IDseq Engineering team Chan Zuckerberg Initiative[2]

[1]*CZ Biohub, San Francisco, CA, United States,* [2]*Chan Zuckerberg Initiative, Redwood City, CA, United States*

Metagenomic next generation sequencing (mNGS) has enabled the rapid detection and identification of microbes without the need for specialized microbiological tests, culturing, nor *a priori* knowledge of the microbial landscape. In a partnership between the Chan Zuckerberg Biohub and the Chan Zuckerberg Initiative, we have developed a cloud-based, open-access web portal, IDseq, to facilitate the computationally demanding analyses of mNGS data derived from a diversity of biological samples, for the purpose of unbiased interrogation of pathogens. By enabling bench scientists, clinicians, and bioinformaticians alike the ability to analyze these

large datasets, our aim is to bring this technology to bare in lower resource laboratory settings where advanced research or diagnostic tools are limited. In this talk, I will describe our training program which includes best practices for performing a successful metagenomic sequencing experiment from initial study design, sample collection, library preparation, and sequencing on a benchtop sequencer. Finally, I will demo the IDseq portal to demonstrate the ease of use and the strength of the tool to generate new hypotheses and to drive data-based decisions around clinically validated pathogens identified with this method.

1797

THE WEST AFRICAN CENTER OF EXCELLENCE FOR GLOBAL HEALTH BIOINFORMATICS TRAINING PROGRAM IN MALI, A MODEL FOR STRENGTHENING DATA SCIENCE CAPACITY BUILDING IN AFRICA

Mamadou Wele[1], Jian Li[2], Cheickna Cisse[1], Mahamadou Diakité[1], Alia Benkahla[3], Cheick Oumar Tangara[1], Darryl Hurt[4], Christopher Whalen[4], Doulaye Dembele[5], Donald J. Krogstad[2], Frances J. Mather[2], Seydou O. Doumbia[1], **Jeffrey G. Shaffer**[2]

[1]*University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Tulane University, New Orleans, LA, United States,* [3]*Institute Pasteur of Tunis, Tunis, Tunisia,* [4]*National Institutes of Health, Bethseda, MD, United States,* [5]*Institute of Genetics and Molecular and Cell Biology, Strasbourg, France*

Bioinformatics and data science research has boundless potential across Africa due to its high levels of genetic diversity and a disproportionate burden of the world's most devastating infectious diseases, including malaria, tuberculosis, HIV-AIDS, Ebola virus disease, and Lassa fever. The West African Center of Excellence for Global Health Bioinformatics Training program is a joint effort between the University of Sciences, Techniques and Technologies of Bamako, Mali (USTTB), Tulane University, and NIAID providing advanced bioinformatics and data science training to West African students and researchers. This work highlights the program's inaugural bioinformatics symposium and training workshop series funded by NIH/Fogarty International through its Human Health and Heredity in Africa (H3Africa) initiative. We designed a Bioinformatics for Global Health Symposium at USTTB uniting researchers and students from Mali and its neighboring countries. The inaugural symposium was held in March 2019 and included 106 attendees, 19 oral presentations, 8 student poster presentations, and 4 panel discussions. Workshop training was provided on geographic information systems (GIS), bioinformatics, and data science topics. The program participants and moderators included USTTB faculty and students and representatives from The African Society for Bioinformatics Computational Biology, and the National Institutes of Health. Home countries for the program participants included Mali, Tunisia, France, Burkina Faso, Morocco, and the U.S. Among n = 14 workshop participants only 21.4% (3/14) reported prior GIS or bioinformatics training. Enhanced bioinformatics and data science training and publication is vital in Mali as it is the epicenter for some of the world's deadliest diseases. Bioinformatics and data science symposiums provide a platform for nurturing research networks, sharing research ideas, and monitoring progress of training and research efforts. More literature on the topic of symposium development is needed to exhibit its utility and expand such efforts in developing countries.

1798

PREVALENCE OF ANTIMICROBIAL RESISTANCE IN COMMENSAL *E. COLI* FROM CHILDREN DISCHARGED FROM HOSPITAL IN WESTERN KENYA

Stephanie N. Tornberg-Belanger[1], Doreen Rwigi[2], Rebecca L. Brander[1], Kirkby D. Tickell[1], Christine J. McGrath[1], Michael Muraya[2], Lynnete Kitheka[2], Nancy Onamu[2], Derrick Ounga[2], Samuel M. Kariuki[2], Benson O. Singa[2], Judd L. Walson[1], Patricia B. Pavlinac[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Kenya Medical Research Institute, Nairobi, Kenya*

Children who have been discharged from hospital in sub-Saharan Africa are at high risk of death and re-hospitalization. This increased risk may be partially due to carriage of antimicrobial resistant (AMR) bacteria leading to treatment failure during the post-discharge period. The Toto Bora trial (ClinicalTrials.gov # NCT02414399) randomizes children at hospital discharge to a 5-day course of azithromycin or placebo to determine the effect of azithromycin on morbidity and mortality. Utilizing a random selection of commensal *Escherichia coli* (*E. coli*) isolates collected from children enrolled in this RCT prior to receiving the intervention, we determined susceptibility to azithromycin, imipenem, and antibiotics prescribed for common childhood illnesses in sub-Saharan Africa. Interpretations of resistance was based on the 2018 Clinical & Laboratory Standards Institute and intermediate zone sizes were considered as resistant. Resistance prevalence and 95% confidence intervals (CI) assuming a binomial distribution were reported. Among 991 children enrolled in the RCT, 88% had *E. coli* isolated. Of the 191 participants with *E. coli* who had AMR testing performed, the median age was 18 months (interquartile range: 9 - 32 months), the average length of hospitalization was 4 days, and 87% were prescribed at least one antibiotic during their hospital stay. The prevalence of resistance to ampicillin was 92% (95% CI: 87% - 96%), 33% (95% CI: 26% - 40%) to azithromycin, 29% to gentamicin (95% CI: 22% - 36%), 28% (95% CI: 22% - 35%) to ciprofloxacin, and 40% (95% CI: 33% - 47%) to ceftriaxone. Resistance to imipenem, a carbapenem not routinely available in this setting, was 1% (95% CI: 0% - 2%). Additionally, 39% (95% CI: 32% - 46%) of isolates were extended-spectrum beta-lactamase (ESBL) producing. Children discharged from hospitals demonstrate a high prevalence of resistance to commonly prescribed antibiotics and to azithromycin, despite the relatively infrequent use of azithromycin in the area. As children discharged from hospital are particularly vulnerable to death and re-hospitalization, high carriage of AMR may be contributing to poor outcomes.

1799

ANTIBIOTIC PRESCRIPTION IN FEBRILE PATIENTS ATTENDING AN EMERGENCY DEPARTMENT IN RIO DE JANEIRO, BRAZIL

José Moreira, Roxana Mamani, Patricia Brasil, Andre Siqueira

Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil

Fever is a common reason for seeking care in Emergency Departments (ED), and evidence on antibiotic prescription practices in febrile patients attending ED is limited.We aim to determine the proportion of antibiotic prescriptions given to febrile patients visiting an ED in Rio de Janeiro and its risk factors. We did a cross-sectional analysis ofconsecutive patients who presented to the ED over a total of 7-weeks throughout 2019 (14^{th}January - 28^{th}February) and were evaluated for fever. Eligible subjects had either a history of fever before arrival at the ED or axillary temperature ≥ 37.5 °C at arrival at the ED. Information related to antibiotic prescribed and source of infection were collected. Categorical variables were compared with Fisher's test and continuous with Mann-Whitney. Binary logistic regression was used to model the antibiotic prescription. 12.721 patients attended the ED during the study period, and we screened 1106 (8.69%) patients during the working hours. 239 patients presented to the ED with fever, corresponding to a cumulative incidence of 21.6 per 100 triaged patients over the seven weeks. The mean age was 32.7 years (± 14.3), and 147 (61.5%) were females. 94 (69%; 95% CI 61-77%)

patient presentations were prescribed at least one antibiotic. Infections of the upper respiratory tract (42.2%) were the most common indication for prescribing antibiotics, followed by urinary tract (14.8%), and skin infections (13.3%). The antibiotic drug class most prescribed were Beta-lactam (52.7%), followed by quinolone (18.3%), and macrolides (12.9%). Patient who were prescribed antibiotics had a higher proportion of prior antibiotic use (17.9% *vs*. 2.5%, p=0.02), temperature ≥ 37.5 °C at presentation (22.8% *vs*. 13.6%, p=0.11), and distinct source of infection (p<0.005), compared to untreated group, respectively. In the adjusted model, only the presumed source of infection remained statistically associated with antibiotic prescription (urinary infection aOR: 7.58 (1.21-47.5%). Antibiotics are frequently prescribed for febrile patients seeking care at ED and respiratory infection account for the predominantly type of infection.

LEADING CAUSES OF DEATH IN INFANTS AND CHILDREN UNDER 5 FROM THE CHAMPS NETWORK

Claudia M. Moya[1], Dianna M. Blau[2], Shabir Madhi[3], Victor Akelo[4], Quique Bassat[5], Karen L. Kotloff[6], Shams E. Arifeen[7], Richard Chawana[3], Emily S. Gurley[8], Inacio Mandomando[9], Dickens Onyango[10], Samba O. Sow[11], Robert F. Breiman[1], for the CHAMPS Network Consortium[1]

[1]*Emory Global Health Institute, Emory University, Atlanta, GA, United States,* [2]*Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States,* [3]*Medical Research Council: Respiratory and Meningeal Pathogens Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,* [4]*United States Centers for Disease Control and Prevention-Kenya, Nairobi, Kenya,* [5]*Institut de Salut Global de Barcelona (ISGlobal), Universitat de Barcelona, Barcelona, Spain,* [6]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States,* [7]*icddr,b (International Centre for Diarrhoeal Disease Research), Bangladesh, Dhaka, Bangladesh,* [8]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [9]*Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique,* [10]*Kisumu County Public Health Department, Kisumu, Kenya,* [11]*Center for Vaccine Development, Mali, Bamako, Mali*

The Child Health and Mortality Surveillance (CHAMPS) Network aims to better identify and understand specific causes of under-5 mortality in areas of Sub-Saharan Africa and South Asia through postmortem minimally invasive tissue sampling (MITS), laboratory tests, clinical records, and verbal autopsies. From these gathered data, determination of cause of death (DeCoDe) expert panels review each case and assign a cause of death using WHO guidelines. As of April 2019, we analyzed 246 cases of infant and child deaths with cause of death determined from CHAMPS sites in Bangladesh (0.4%), Kenya (30.1%), Mali (6.6%), Mozambique (14.1%), and South Africa (48.8%). Across all five sites, the most common underlying causes of death among infants and children were congenital birth defects (13.7%), malnutrition (11.9%), lower respiratory infections (11.0%), HIV (10.6%), and neonatal preterm birth complications (9.7%). Main immediate causes of death included lower respiratory infections (36.1%), sepsis (28.6%), diarrheal diseases (6.2%), malaria (6.2%), and meningitis (4.0%). For those deaths due to lower respiratory infections, the most frequent etiologic pathogens were *Klebsiella pneumoniae* (8.5%), *Streptococcus pneumoniae* (7.3%), *Haemophilus influenzae* (3.7%), *Staphylococcus aureus* (3.5%), and Cytomegalovirus (3.3%), and for sepsis, the most common etiologies were *Klebsiella pneumoniae* (13.6%), *Acinetobacter baumanii* (5.8%), *Streptococcus pneumoniae* (4.8%), *Staphylococcus aureus* (3.0%) and *Pseudomonas aeruginosa* (2.7%). Of these infant and children deaths, approximately 71% were considered preventable by the panels. Early CHAMPS data show the importance of understanding specific conditions leading to death in infants and children across five sites so that actions can be developed and utilized for reducing under-5 mortality.

UNDERSTANDING AND RELATING THE EFFECTS OF INFECTIOUS PARAMETERS WITH G6PD DEFICIENCY

Tina Marye Slusher[1], Sarayu Patturi[2], Troy Lund[1], Stephanie Lauden[3], Grace Edowohorhu[4], Kolade Ernest[5], Daniel Gbadero[4]

[1]*University of Minnesota, Minneapolis, MN, United States,* [2]*Wayzata High School, Plymouth, MN, United States,* [3]*Nationwide Children's Hospital, Columbus, OH, United States,* [4]*Bowen University Teaching Hospital, Ogbomoso, Nigeria,* [5]*University of Ilorin Teaching Hospital, Ilorin, Nigeria*

Glucose-6-Phosphate Dehydrogenase deficiency (G6PDD) is the most common enzymopathy worldwide, affecting approximately 400 million people and causes hemolytic anemia as well as oxidative stress. The largest prevalence rates are in Africa. A previous study in Cameroon suggested G6PD deficiency might be related to Hepatitis C and syphilis infections. This study was undertaken to Determine the relationship between G6PDD and infectious and demographic parameters while validating the local prevalence of G6PD deficiency. Leftover blood from potential blood donors was collected at a large referral hospital in southwest Nigeria. Demographic information, blood types, and infectious markers [Hepatitis B , Hepatitis C, VDRL (syphilis) all using LabACON™ Rapid Test Strips; and HIV using Allere Determine™ HIV-1/2 test strip] were collected per hospital screening protocol except for addition of syphilis (VDRL) screening which was not routine. Additionally, the prevalence of G6PD deficiency was determined using the Carestart® screening test. G6PDD was found in 21% of 1085 blood donors tested. Mean age, hematocrit, and Rhesus status did not differ between groups. Blood groups did differ with type O being more common in the G6PD sufficient group (56.4% vs 46.8%). The prevalence of Hepatitis B, Hepatitis C viruses and VDRL were not statistically significant with respect to G6PDD (p=0.19, 0.67 and 0.09 respectively). HIV was positivity statistically correlated with G6PDD (p values 0.02). In conclusion, we demonstrate a relationship between G6PDD and HIV with a trend toward a relationship between G6PDD and HIV. This suggests correlation between G6PDD and HIV. VDRL screening should be validated with RPR before correlation can be assumed. Both findings highlight the need for further studies, raise questions about G6PDD representing an underlying immunodeficiency, and suggest possible changes to routine screening practices.

FACTORS ASSOCIATED WITH DELAYS IN DIAGNOSIS AND TREATMENT OF MALARIA IN RETURNED TRAVELERS

Ariella Goldblatt[1], Emily Shaffer[2], Adrienne Showler[3]

[1]*MedStar Georgetown University Hospital Department of Internal Medicine and Pediatrics, Washington, DC, United States,* [2]*Georgetown University School of Medicine, Washington, DC, United States,* [3]*MedStar Georgetown University Hospital Division of Infectious Disease, Washington, DC, United States*

Malaria is the leading cause of infection-related death in returned travelers, who are at risk for severe disease due to lack of pre-existing immunity. In non-endemic areas, significant delays in malaria diagnosis and treatment are common, and contribute to poor outcome. We aimed to identify patient and health care systems factors associated with delayed care in returned travelers. We retrospectively identified all patients with an ICD 9/10 code diagnosis of malaria presenting to two academic tertiary care hospitals in Washington, DC, United States between January 1, 2013 and December 31, 2017. Only patients with microscopically confirmed malaria, or a positive Rapid Diagnostic Test (RDT) were included. We recorded patient demographics, and timing of hospital triage, malaria diagnostics, and anti-malarial administration. Fifty-nine patients had laboratory-confirmed malaria, the majority with *Plasmodium falciparum* acquired in Africa. Median time from triage to malaria diagnosis was 3.9 hours [IQR 2.4-5.9]. Only 16% of patients were diagnosed within 2 hours, and 22% experienced prolonged diagnostic delays of >6 hours. There was no difference in time to diagnosis based on race, insurance status, RDT availability, season, presentation on a night or weekend, % parasitemia,

malaria species, or presence of fever at triage. The median time from malaria diagnosis to treatment with any anti-malarial was 2.4 hours [IQR 1.1-5.3], with severe delays of >6 hours in 12% of patients. Median time from triage to treatment was 6.6 hours [IQR 4.5-8.5]. Patients treated with artemether-lumefantrine received antimalarials twice as quickly as those treated with atovaquone-proguanil (p<0.04). The World Health Organization recommends that results of malaria diagnostics be available within 2 hours, followed by immediate anti-malarial treatment. Only a minority of patients in our study received timely care, with a median time from presentation to treatment of almost 7 hours. Future quality improvement initiatives are needed to enable rapid identification and treatment of malaria in returned travelers.

CLINICAL EVALUATION OF THE FILMARRAY® GLOBAL FEVER PANEL

Brian W. Jones, David Rabiger, Mark A. Gurling, Wendy Smith, Madeline Veloz, Olivia Jackson, Nathan King, Marisssa Burton, Christa Shorter, Cynthia D. Andjelic, Cynthia L. Phillips

BioFire Defense, LLC, Salt Lake City, UT, United States

Acute Febrile Illness (AFI) is caused by a diverse set of pathogens. Standard testing for the causal agent is often difficult, slow, costly, and complicated by the overlapping differential diagnoses for each potential pathogen. Testing for multiple pathogens simultaneously would simplify and accelerate diagnosis. The FilmArray Global Fever (GF) Panel, developed by BioFire Defense in collaboration with the U.S. Department of Defense[a] and NIAID[b], uses an automated, multiplex PCR system to evaluate whole blood samples for 19 pathogens simultaneously in under an hour. Targets of the GF Panel are Chikungunya virus, CCHF virus, dengue virus (serotypes 1-4), Ebolavirus, Lassa virus, Marburgvirus, West Nile virus, Yellow fever virus, Zika virus, *Bacillus anthracis*, *Francisella tularensis*, *Leptospira* spp., *Salmonella enterica* serovar Typhi and Paratyphi A, *Yersinia pestis*, *Leishmania donovani* complex, *Plasmodium* spp., *P. falciparum*, and *P. ovale/vivax*[c]. BioFire Defense is conducting a prospective clinical study to evaluate the sensitivity and specificity of the GF Panel when used to test blood collected from subjects with fever or who have recently had fever. This multi-center study is being conducted at locations around the world. Comparator testing consists of in-house developed PCR assays followed by bidirectional sequencing. Here we report the positive percent agreement and negative percent agreement of the GF Panel versus comparator testing, the rate of positive detections, and the fraction of specimens with more than one detected infection. Our results show that the FilmArray GF Panel could aid in rapid and actionable AFI diagnosis.

1804

HIGH REACTIVITY FOR HEPATITIS B AND OTHER TRANSFUSION-TRANSMISSIBLE INFECTIONS IN THE PREDONATION SCREENING OF BLOOD DONOR BY RAPID TEST IN A PUBLIC HOSPITAL OF THE PERUVIAN AMAZON

Mary Jeanette Rios[1], Andrea Saavedra[1], Jessye Cubas[1], Maher Zapana[1], Stalin Vilcarromero[2], Graciela Meza[1], Amy Morrison[3], Jaime Ramos-Flores[4]

[1]*Universidad Nacional de la Amazonía Peruana (UNAP), Iquitos, Peru,* [2]*Department of Medicine, Division of Infectious Diseases, Stony Brook University, New York, NY, United States,* [3]*Department of Entomology and Nematology, University of California Davis, Davis., California, CA, United States,* [4]*Hospital Regional de Loreto, Iquitos, Peru*

Infectious risk associated with blood transfusion remains a major public health concern in Peru, especially in endemic areas for other blood borne disease. Iquitos, the largest city of the Peruvian Amazon, is endemic for malaria and HIV, but other infectious disease such hepatitis B and Chagas are more prevalent in rural setting. Donations in the Peruvian Amazon of Peru require screening for at least five infectious markers: surface antigen (HBsAg) and the core antibody of hepatitis B virus (HBcAb), antibodies against human immunodeficiency virus (HIV) type 1 and 2 (anti-HIV 1 and/or anti-HIV 2), antibodies against hepatitis C virus (HCV); Treponema pallidum(syphilis); human lymphotropic viruses (anti-HTLV-1/2) and markers for Chagas disease. Usually potential donor gives the total blood sample before it is screened by rapid test (Vircell kit or Chagas and Beijing Wantai Biological Pharmacy Enterprise, Beijing, China for others). During January 2008 and December 2016, Hospital Regional de Loreto, a reference center for blood transfusion, received 43,288 blood units for potential blood donors, from which 4003 (9.25%) units were rejected and discarded due reactivity or indeterminate rapid test result. 3160 (78.94%), 629 (15.7%), 95 (2.38%), 59 (1.47%), 49 (1.2%) and 35 (0.87%) were reactive for HBcAb, Syphilis, HTLV I & II, HBsAg, Chagas and VIH 1&2. Other 161 (4.2%) were undetermined with a 74% for HBcAb. 3441 (86%) were male, 2635 (65.8%) had 17-38 years old, 1330 (33.22%) were single, 3420 (85.43%) live in urban setting. HTLV 1&2 and HBsAg and syphilis shows a marked trend to increase from 2008 to 2016. Other markers show a flat curve suggesting an endemicity. Interestingly, similar to the other markers, for HBcAb, 2641/3130 (84.37%) of rejected blood donators lived in urban setting. In a region with deficits of blood units, and also endemic for several blood-borne pathogens, it is worrisome that almost 10% of donated units are discarded demanding time and high cost. This analyze would be reflecting an epidemiological change (from rural to urban setting) especially for hepatitis B. Recent studies of seroprevalence would be necessary.

1805

INTEGRATING COMMUNITY CASE MANAGEMENT (ICCM) PAST THE BEND IN THE RIVER IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

Kate E. Gilroy[1], Jocelyne Kibungu[2], Elizabeth Hourani[1], Jimmy Anzolo[3], Osée Lieke Likunda[3], Emmanuel Likunde[4], Papy Luntadila[2], Michel Pacque[1]

[1]*MCSP/JSI, Washington, DC, United States,* [2]*MCSP/JSI, Kinshasa, Democratic Republic of the Congo,* [3]*MCSP/JSI, Kisangani, Democratic Republic of the Congo,* [4]*MCSP/JSI, Kinsangani, Democratic Republic of the Congo*

In the DRC, remote and vulnerable communities have benefited from community case management (CCM) of malaria services through vertical programs. Health facilities also benefit from malaria programs, but often do not have other child treatments available. In 2017, with support from USAID's flagship Maternal and Child Survival Program (MCSP), Tshopo and Bas-Uélé provinces introduced a more complete package of integrated CCM services in 119 remote and underserved communities. Community volunteers already providing malaria CCM were trained to manage and treat diarrhea and pneumonia for children under five years of age. With USAID support, MCSP procured oral rehydration solution and zinc for treating diarrhea and dispersible Amoxicillin tablets for treating pneumonia free of charge in the 119 community sites and 106 linked health facilities. Using data from the national health management information system, we assessed if the introduction of a complete package of services in communities increased the number of sick children treated or if it remained the same—indicating that sick children who would have sought care at the facility were now accessing community-based services. In 2016, approximately 60,000 cases of malaria, 7,000 of pneumonia, and 6,400 of diarrhea were treated at 106 facilities and 54 community sites with complete data. In 2018, this rose to over 85,500, 37,800 and 26,800 cases treated for childhood malaria, pneumonia and diarrhea, respectively, at the same facilities and community sites. The number of cases of childhood diarrhea and pneumonia treated increased over four-fold between 2016 and 2018 at the facility level and eight-fold at the community level. Over 20% of new cases of sick children were seen in the community in 2018. Our results suggest that introducing integrated CCM can increase the number of sick children treated for malaria and other illnesses in remote areas. The provision of free drugs through donor support can substantially increase the number of cases of child illnesses treated at all levels, although it raises important challenges in balancing sustainability versus equity and reaching the underserved.

SHARED PATHOGEN-SPECIFIC RESERVOIRS AND TRANSMISSION PATHWAYS ASSOCIATED WITH ENTERIC PATHOGEN CO-INFECTIONS AMONG CHILDREN FROM THE KOLKATA, INDIA SITE OF THE GLOBAL ENTERIC MULTICENTER STUDY

Kurt Z. Long[1], Suman Kanungo[2], Inong Gunanti[3], Johanna Sanchez[4], James P. Nataro[5], Dilruba Nasrin[6], Myron Levine[6], Karen Kotloff[7]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*National Institute of Cholera and Enteric Diseases, Kolkata, India,* [3]*Faculty of Medicine and Biomedical Sciences, University of Queensland, Brisbane, Australia,* [4]*, Faculty of Medicine and Biomedical Sciences, University of Queensland, Brisbane, Australia,* [5]*Department of Pediatrics, University of Virginia School of Medicine, Charlottesville, VA, United States,* [6]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States,* [7]*Department of Pediatrics, University of Maryland School of Medicine, Baltimore, MD, United States*

The implementation of WASH programs and the development of new vaccine concerned with reducing the burden of diarrheal disease among young children have not considered the contribution of co-infections to this burden. Enteric co-infections may lead to poorer clinical outcomes in children compared with single infections. Bayesian path analyses were used to model the effect of household pathogen transmission pathways on the risk of the most prevalence co-infections among children enrolled in the Indian component of the Global Enteric Multicenter Study (GEMS). Models were developed to test whether such potential pathogen reservoirs as water source, storage and treatment as well as sanitation facilities were associated directly with greater risk of enteric co-infections or had indirect effects mediated by hygiene behaviors. Twenty-eight percent of pathogen isolates among children were co-infections of which 20 percent of these were co-infections due to *Giardia* and *Cryptosporidium*. Unimproved sanitation facilities in the household was associated with a greater risk of infections by both pathogens but this risk was reduced when caretakers washed hands before nursing with a greater reduction found for *Cryptosporidium*. A household water source in the yard was negatively associated with infections by both pathogens indirectly among children from households with unimproved sanitation facilities when mediated by handwashing before nursing. Storage of water was directly associated with greater risk of *Giardia* infections but a reduced risk of *Cryptosporidium* infections. An indirect and negative association of water storage with infections by both pathogens was also found in households with unimproved sanitation facilities when mediated by handwashing before nursing. These results suggest that co-infections by *Giardia* and *Cryptosporidium* may result from shared transmission pathways involving water source and water storage in households with unimproved sanitation but that specific handwashing behaviors can block such transmission.

IDENTIFYING POTENTIALLY PREVENTABLE UNDERLYING CIRCUMSTANCES THAT LED TO INFANT DEATH IN LUSAKA, ZAMBIA: AN EXTENDED APPROACH TO THE THREE DELAYS MODEL

Andrew William Enslen[1], Ronke Olowojesiku[1], Anna Larson[2], William Macleod[2], Rotem Lapidot[2], Christopher J. Gill[2]

[1]*Harvard TH Chan School of Public Health, Boston, MA, United States,* [2]*Boston University School of Public Health, Boston, MA, United States*

Infant mortality rates remain disproportionately high in the sub-Saharan African region. Studies suggest that many of these deaths may be preventable and correspond to types of three delays: delay in seeking care, delay in reaching care, and delay in receiving adequate care. The purpose of this study is to identify preventable structural and sociocultural factors contributing to infant death in Zambia by applying an extended approach to the three delays model using narratives from caregivers. We reviewed a community-based collection of 230 verbal autopsies of infants aged 0-6 months who died outside of the hospital in Lusaka, Zambia. The verbal autopsies were collected between August 2017 and October 2018 as part of the ongoing Zambia Pertussis-RSV Infant Mortality Estimation (Z-PRIME) study conducted at the University Teaching Hospital. We performed a retrospective qualitative analysis of free text narratives included in the verbal autopsies. We assigned themes to the narratives and analyzed the results using Nvivo v12. 14 qualitative themes were assigned to the 230 verbal autopsies. 190 deaths were associated with the following delays in care: seeking care (n = 127, 55.2%), reaching care (n = 10, 4.3%), receiving adequate care (n = 53, 23.0%). The most common locations of death were in the home (n = 111, 48.2%) and en-route/upon arrival to clinic (n = 74, 32.2%). Among those who died prior to reaching care, over one-third (65/185) were previously seen by a provider. Four of the most common symptoms associated with a delay in seeking care were weakness (20/25), poor feeding (50/69), fever (75/109), and fast breathing (44/88). Additionally, 32 of the cases were not inconsistent with a diagnosis of sudden unexpected infant death. The majority of infant deaths were associated with household or structural circumstances leading to delays in care. Although more work is needed to further characterize these factors, our study suggests several opportunities for future interventions, such as improving caregiver education of "danger signs" and instituting triage protocols and patient return policies.

HIGHER TREATMENT TO DIAGNOSIS RATIO IN MALARIA CASE MANAGEMENT IN NIGERIA

Wellington A. Oyibo[1], **Wellington Oyibo**[2], Diwe Ekweremadu[3], Genevieve Eke[3], Chukwudi Uche[3], Victoria Erinle[3], Victor Adebayo[3], Temitope Ipinmoye[3]

[1]*College of Medicine of the University of Lagos, Nigeria, Lagos, Nigeria,* [2]*College of Medicine, University of Lagos, Department of Medical Microbiology and Para., Lagos, Nigeria,* [3]*Catholic Relief Services, Abuja, Nigeria*

The policy recommendation that all suspected cases of malaria be confirmed with malaria rapid diagnostic tests (RDT) or microscopy before treatment with artemisinin combination therapies (ACTs) is critical in the implementation of the World Health Organization's test, treat and track recommendation which has also been adopted as the diagnosis and treatment of malaria policy in Nigeria since 2010. Over diagnosis and over-treatment of malaria is a challenge and has been reported in several countries in the literature. However, assessment of tests performed and treatment given in the case management of malaria in public health facilities where malaria RDTs are supplied through the Global Fund Programme is yet to be fully highlighted in a larger scale, especially as it relates to commodity quantification in making procurement decisions. We assessed malaria RDT and ACT use in public health facilities in six Global Fund supported States in Nigeria: Kwara, Osun, kano, Bauchi, Imo and Cross River States. In the six States where Malaria case management was strengthened through on-the-job supervision, the ratio of testing to treatment ranged from 1:2 - 1:4 in Health Facilities while in the states, it was 1:2 - 1:3. Overall diagnosis to treatment ratio was 1:2, indicating that diagnosis was yet to catch up with treatment. This finding has great implications in effective malaria case management with diagnosis, the implementation of the mandatory testing prior to treatment policy, waste of malaria medicines due to overuse of ACTs, increased spending on ACT procurement that ought to be reducing with declining malaria prevalence, and likely pressure on parasites that could trigger resistance to the ACTs. On-the-job supervision of healthcare worker infused with on-site training is recommended for increased RDT utilisation and a more strengthened malaria case management practices.

1809

COMPARISON OF RISKS OF READMISSION AFTER BREAST CANCER RECONSTRUCTION PROCEDURES: AN ANALYSIS OF 2011 TO 2014 NATIONAL READMISSION DATABASE

Oumar Thiero[1], Meghan Garstka[2], Alan Stolier[2], Emad Kandil[2]

[1]*International Center of excellence in research (ICER-MALI), University of Sciences, Techniques and Technology of Bamako (USTTB), Bamako, Mali,* [2]*Tulane University, School of Medicine, New Orleans, LA, United States*

The psychosocial benefits of breast reconstruction are numerous, particularly for women wellbeing. Study of specific risks factors associated with the readmission after breast cancer reconstruction may steer and optimize the reconstruction strategies. From 2011 to 2014, we performed a retrospective analysis of adult patients in the National Readmission Database. Patients undergoing breast reconstruction were grouped as implant/tissue -expender or autologous reconstructions. We used a weighted descriptive, univariate and the survey logistic regression analysis to compare risk factors associated with the two reconstructions procedures. Of 12532, 12503, 12951, and 12789 patients included in this study, 9400(75.01%), 9514(76.09%), 9784(75.55%), and 9337(73.01%) respectively underwent Implant/Expender reconstructions in 2011, 2012, 2013 and 2014 respectively. The two groups experienced similar readmission rates/year (around 10%=implant/expender and 11%=autologous, p's>0.5). However, of 12 commons predictors of the adjusted model/year, 10 were significantly associated with the reconstruction types. Furthermore, the autogenous experienced high rates (up to 6 times) in *All_Patient_Refined DRGs_Severity* loss of function (ref=*minor_loss*), comorbidities(ref=no-comorbidity) etc.., while implant/expender experienced high rates (up to 12 times) in *All_Patient_Refined_DRGs _Mortality* risk (ref=*minor_risk*) and number of chronic conditions(ref=no-chronic). The two groups maintained similar *zip_income* rate/year. In conclusion, autologous and implant/expender breast reconstruction procedures were found to be strongly risk-specifics related, suggesting an appropriate risk-stratification and scrutiny before discharge may reduce the impact of readmission.

1810

LYMPHATIC FILARIASIS ENDGAME: UNDERSTANDING HOTSPOTS IN ELIMINATION PROGRAMS

Sellase A. Pi-Bansa[1], Joseph Harold Osei[1], Kwadwo Kyeremeh Frempong[1], Elisabeth Elhassan[2], David Agyemang[2], Samuel Dadzie[1], Maxwell Alexander Appawu[1], Michael David Wilson[1], Benjamin Guibehi Koudou[3], Dziedzom Komi de Souza[1], Jürg Utzinger[4], Daniel Adjei Boakye[1]

[1]*Noguchi Memorial Institute for Medical Research (N.M.I.M.R), Accra, Ghana,* [2]*SightSavers International, Accra, Ghana,* [3]*Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire,* [4]*Swiss Tropical and Public Health Institute, Basel, Switzerland*

Lymphatic Filariasis (LF) is earmarked for elimination through mass drug administration (MDA). Six years was hypothesized to interrupt LF transmission. There have been at least 16 years of MDA in some districts of Ghana and yet there is ongoing low level transmission. Several factors which may be endemic area specific could be contributing to transmission in these districts termed LF "hotspot districts". These factors need understanding if elimination is to be achieved. The objective of this study was to identify possible factors contributing to persistent LF transmission and their impact on elimination in Ghana. The study was done in two hotspot (Ahanta West, Kassena Nankana West) and control (Mpohor, Bongo) districts in the Western and Upper East regions of Ghana respectively. Community vector collectors (CVCs) were trained in all districts to collect mosquitoes using human landing catches (HLC), pyrethrum spray catches (PSC) and window exit trap (WET). *Anopheles* (*An.*) *gambiae* were dissected from all districts and polymerase chain reaction (PCR) run for *An. gambiae* and *Wuchereria bancrofti* identification respectively. Questionnaires were administered in all districts to assess vector control activities. Mosquitoes collected by CVCs were 31,064 [HLC=27,739 (89.3%), PSC=2687 (8.7%) and WET=638 (2.1%)]. In all districts, *Aedes*, *An.coustani*, *An.gambiae* s.l., *An.pharoensis*, *Culex* and *Mansonia* mosquitoes were found. *An.melas* was found only in Ahanta West district and also infective therefore likely to be sustaining LF transmission (annual transmission potential =7.4). There was no infection in all other districts. Bednet usage was generally higher in control compared to hotspot areas (Mpohor=87.0%, Ahanta West=69.1%; and Bongo=91.1%, Kassena Nankana West=82.4%). It is feasible to use CVCs for xenomonitoring and/or post-MDA surveillance. We observed higher mosquito abundance and specific species may be involved in the ongoing transmission. Due to spatial heterogeneities, there should be unique intervention programs in LF endemic districts. Xenomonitoring should therefore be considered as part of the LF end time surveillance.

1811

MICROFILARIAE CIRCULATING IN DOGS FROM CALI, COLOMBIA

Luisa M. Nieto Ramirez[1], Tania Gaviria[1], Claudia L. Villegas[2], Isabel C. Garcia[2], Leidy L. Diaz[3], Beatriz E. Ferro[3]

[1]*Universidad Santiago de Cali, Cali, Colombia,* [2]*Laboratorio Zoolavet, Cali, Colombia,* [3]*Universidad Icesi, Cali, Colombia*

Different filarial species can be transmitted by vectors and affect mammals, including humans and dogs. In Cali, Southwestern Colombia, microfilariae cases in dogs is not well documented. A local diagnostic laboratory described an observational study that detected 61 microfilariae cases during 1999 to 2003, while 50 cases were detected in one-year period in 2017, suggesting a potential parasitic outbreak. However, the causing species were not identified for most of the cases. To study this potential outbreak and the circulating microfilaria species, we conducted a molecular characterization of positive cases identified from August 2018 to February 2019 in dogs from Cali. Microfilariae cases detected by blood smears stained with Wright were also evaluated by a standard immunoassay. In addition, DNA was extracted from EDTA-blood samples to perform a PCR test to amplify ribosomal DNA spacer sequences for different canine microfilaria species including: *Acanthocheilonema reconditum, Dirofilaria immitis* and *D. repens*. Sanger-sequencing of PCR products was used for the specie confirmation in a subset of samples. Clinical and demographic data were also collected. We detected 34 positive microfilariae cases. All except one were negative for *D. immitis* by the immunoassay. PCR test was positive for all the cases and negative for 15 negative DNA control samples obtained from healthy dogs. Partial sequencing results revealed the presence of *A. reconditum* in 11 cases tested. Mixed-breed (17/34, 50%), followed by poodle (6/34, 17.6%) were the most affected breeds, with a median age of 6 years (interquartile range 3-10 years). Male dogs represented 85.3% (29/34) of the positive cases. All cases ranged from no signs of disease to cutaneous lesions, anorexia, and anemia (50% of cases). The PCR test contributed to the further detection of the causing microfilariae specie in most of the studied cases, revealing a microfilaria specie, *A. reconditum,* that has not been widely identified in Colombia. The clinical significance of this specie in dogs as well as its zoonotic potential remains to be determined with a larger number of cases.

1812

MAPPING THE PRE-CONTROL PREVALENCE OF LYMPHATIC FILARIASIS ACROSS NIGERIA

Obiora A. Eneanya[1], Claudio Fronterre[2], Ifeoma Anagbogu[3], Chukwu Okoronkwo[3], Tini Garske[1], Jorge Cano[2], Christl Donnelly[1]

[1]*Imperial College London, London, United Kingdom,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Federal Ministry of Health, Abuja, Nigeria*

The pre-control endemicity profile of lymphatic filariasis (LF) is a key benchmark for planning control programmes, monitoring their impact on transmission and assessing the feasibility of achieving elimination. Presented in this work is the modelled serological and parasitological

prevalence of LF prior to the scale-up of mass drug administration (MDA) in Nigeria using a machine learning based approach. LF prevalence data generated by the Nigeria Lymphatic Filariasis Control Programme during country-wide mapping surveys conducted between 2000 and 2013 were used to build the models. The dataset comprised of 1,103 community-level surveys based on the detection of filarial antigenaemia using rapid immunochromatographic card tests (ICT) and 184 prevalence surveys testing for the presence of microfilaria (Mf) in blood. Using a suite of climate and environmental continuous gridded variables and compiled site-level prevalence data, a quantile regression forest (QRF) model was fitted for both antigenaemia and microfilaraemia LF prevalence. Model predictions were projected across a continuous 5 × 5km gridded map of Nigeria. The number of individuals potentially infected by LF prior to MDA interventions was subsequently estimated. Maps presented predict a heterogeneous distribution of LF antigenaemia and microfilaraemia in Nigeria. The North-central, North-west, and South-east regions displayed the highest predicted LF seroprevalence, whereas predicted Mf prevalence was highest in the southern regions. Overall, 8.7 million and 3.3 million infections were predicted for ICT and Mf, respectively. QRF is a machine learning-based algorithm capable of handling high-dimensional data and fitting complex relationships between response and predictor variables. Our models provide a benchmark through which the progress of ongoing LF control efforts can be monitored.

DOSING POLE RECOMMENDATIONS FOR MASS DRUG ADMINISTRATION OF IVERMECTIN AND DIETHYLCARBAMAZINE FOR LYMPHATIC FILARIASIS ELIMINATION: A HEIGHT-WEIGHT QUANTILE REGRESSION MODELING APPROACH

Charles W. Goss[1], Katiuscia O'Brian[1], Peter U. Fischer[1], Myra Hardy[2], Purushothaman Jambulingam[3], Christopher L. King[4], Moses Laman[5], Jean Frantz Lemoine[6], Leanne Robinson[7], Josaia Samuela[8], Swaminathan Subramanian[3], Taniawati Supali[9], Gary J. Weil[1], Kenneth B. Schechtman[1]

[1]*Washington University, St Louis, MO, United States,* [2]*Murdoch Children's Research Institute, Melbourne, Australia,* [3]*ICMR-Vector Control Research Centre, Puducherry, India,* [4]*Case Western Reserve University, Cleveland, OH, United States,* [5]*Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea,* [6]*Ministère de la Santé Publique et de la Population (MSPP), Port au Prince, Haiti,* [7]*Burnet Institute, Melbourne, Australia,* [8]*Fiji Ministry of Health and Medical Services, Suva, Fiji,* [9]*Universitas Indonesia, Jakarta, Indonesia*

Lymphatic filariasis (LF) is a debilitating parasitic disease that affects over 70 million people across the world. To eliminate this disease the World Health Organization (WHO) recommends treating entire endemic communities with drug combinations that include ivermectin (IVM) diethylcarbamazine (DEC). Ideally, the amount of drug administered should be determined by weight. However, this is often not feasible in rural, resource limited areas. The alternatives currently recommended by the WHO based on height (a dosing pole for IVM) and age (DEC) have maximal doses below those recommended by weight-based dosing. In this study we used data from a large multi-center LF community-based clinical trial (5 countries, >26,000 individuals) to evaluate current WHO age- and height-based dosing recommendations, and to develop and evaluate new height-based dosing (dosing poles) recommendations based on these data. Our analysis involved a 3-step modeling approach to develop and evaluate new dosing pole cutoffs for both IVM and DEC. We first analyzed data collected from the LF clinical trial using quantile regression to predict weight from height. Weight predictions from our models were then used to develop new dosing pole cutoffs. Finally, we compared our model-based dosing poles to recommended weight-based dosing to determine whether our models improved upon the current height and age-based dosing recommended by the WHO. Our results showed that the WHO methods would have resulted in 32% and 27% of individuals in the clinical trial dataset receiving below the recommended weight-based dosage of DEC and IVM, respectively. Underdosing would have been especially common in adult males (54% for DEC and 39% for IVM), who tend to have the highest LF prevalence in many endemic areas. Results from our statistical analyses showed that a model-based dosing pole would markedly reduce underdosing with 2% and 6% receiving below the recommended dosage for DEC and IVM, respectively. The dosing pole we propose has the potential to dramatically improve dosing and facilitate the elimination of lymphatic filariasis globally.

The low sensitivity of microscopy in the diagnosis of skin microfilariae of *Onchocerca volvulus* is a shortcoming for effective monitoring and evaluation of control programmes of onchocerciasis based on micro- or macrofilaricides. We compared the microscopy technique to two nucleic acid-based techniques in the detection of skin microfilariae of *O. volvulus* following ivermectin treatment at 1, 3 and 6 months. Identified microfilaridermic individuals in Bafia and Melong were treated with ivermectin and re-examined after 1, 3, and 6 months. Infection prevalence was compared for the three techniques. Microscopy was used as an imperfect gold standard to determine performance characteristics of real-time PCR and LAMP assay. The performances of the tests were evaluated using Bayesian Latent Class Models (LCM). From the 51 patients monitored, microscopy detected 21.6%, 23.5% and 45.8% prevalence of *O. volvulus* skin infection at 1, 3 and 6 months of screening, respectively. However, real-time PCR detected prevalence of 23.5%, 31.4% and 54.2%, whereas LAMP technique detected prevalence of 29.4%, 37.3% and 64.6%, respectively. There was a statistically significant difference in the prevalence of infection at the different time points using the three diagnostic methods ($P \leq 0.014$). The overall prevalence for the 150 samples collected during the six-month period was 30%, 36.3% and 43.7% for microscopy, real-time PCR and LAMP assay respectively and the difference between them was statistically significant ($P < 0.05$). LAMP assay had the best sensitivity (99.4%) compared to real-time PCR (98.1%) and microscopy (80.7%). This study has demonstrated that LAMP technique has superior sensitivity over microscopy and real-time PCR in detecting skin microfilariae of *O. volvulus* within six months following ivermectin treatment. The LAMP assay could be useful in monitoring *O. volvulus* microfilariae following treatment with filaricides.

ACCOUNTING FOR PREFERENTIAL SAMPLING IN SPATIOTEMPORAL MODELS OF LYMPHATIC FILARIASIS PREVALENCE

Chris Schmidt, Kevin Kwong, Katie Donkers, Elex Hill, David Pigott, Shreya Shirude, Simon Hay, Elizabeth Cromwell

University of Washington, Seattle, WA, United States

Lymphatic filariasis (LF), a leading cause of long-term disability, has been targeted for global elimination as a public health problem. Programmatic decision-making for the initiation or cessation of mass drug administration

(MDA), the primary intervention for LF elimination, relies on estimates of infection prevalence obtained through a multi-year strategy of baseline mapping, longitudinal sampling in sentinel sites, transmission assessment surveys (TAS), and post-MDA surveillance. High-resolution geospatial models can leverage existing sources of LF prevalence data to predict prevalence in data-poor regions and identify priority locales for additional data collection. While LF monitoring programs may emphasize sampling in areas expected to have particularly high or low prevalence, depending on programmatic stage, standard geospatial models assume that data are collected non-preferentially, i.e., that survey sites are sampled independently of their expected prevalence. Failing to account for this preferential sampling may bias model inferences. In order to improve global estimates of LF prevalence, we test for evidence of preferential sampling in Bayesian spatiotemporal models of global LF prevalence. We compare inferences from three models: (1) a standard model assuming non-preferential sampling; (2) the addition of simple fixed effects for programmatic stage (e.g., mapping, sentinel site, or TAS); and (3) an explicit preferential sampling model employing Poisson point processes for spatial sampling probabilities. We compare model predictions in both heavily sampled and undersampled regions and discuss implications for LF elimination programs and for other neglected tropical diseases with similarly complex data generation.

1816

IMPACT OF REPEATED ANNUAL MASS DRUG ADMINISTRATION WITH IVERMECTIN THROUGH COMMUNITY DIRECTED TREATMENT ON THE ENTOMOLOGICAL INDICATORS OF *LOA LOA* TRANSMISSION IN CAMEROON

Patrick W. Ndongmo, Glory Ngongeh, Fanny Fri Fombad, Abdel Jelil Njouendou, Bertrand Ndzeschang, Mathias Eyong Esum, Peter Enyong, Samuel Wanji

University of Buea, Buea, Cameroon

Loiasis is a filarial infection endemic in the rainforest zone of west and central Africa. Repeated treatments with ivermectin have been delivered using the annual community directed treatment with ivermectin (CDTI) approach for several years to control onchocerciasis in some *Loa loa*-*Onchocerca volvulus* co-endemic areas. The impact of CDTI on *L. loa* transmission in those areas is not known. We, therefore, designed this cross-sectional study to assess the impact of several rounds of CDTI on entomological indicators of loiasis. The study was conducted in 3 CDTI projects of Cameroon. Two communities per CDTI project were selected. *Chrysops* were collected with sweep net and dissected using microscopy. A total of 7029 female *Chrysops* were collected from the 6 communities under study. *Chrysops* biting densities and parous rates were reduced significantly in the northwest and southwest sites post CDTI while in the east, biting densities were similar in CDTI and nonCDTI sites with higher parous rates in the nonCDTI area. Infection and infective rates in the East nonCDTI site were 4.4% and 1.8% respectively but 3.3% and 1.3% in the CDTI district with 8 ivermectin treatment rounds. In the Northwest site, significant reductions of *Chrysops* infection and infective rates from 10.2% and 4.2% respectively to 3.5% and 1.2 (after 9 ivermectin rounds) were registered post CDTI while in the southwest, infection rates significantly increased from 1.74% to 2.8% and infective rates remained statistically unchanged after 14 rounds of CDTI (0.45% - 0.40%). Similar trends in Mean Head L3 were observed in all but the east CDTI site. Globally, a negative relationship was observed between the number of CDTI rounds and *Chrysops* infection and infective rates. Monthly transmission potentials significantly decreased after CDTI only in the northwest sites. This study has for the first time demonstrated that in areas where onchocerciasis and loiasis are co-endemic, CDTI has reduced the number of *Chrysops* carrying infective larvae with concomitant decrease in *L. loa* monthly transmission potentials; but has not interrupted transmission of loaisis.

1817

INDIVIDUAL RISK OF POST-IVERMECTIN SEVERE ADVERSE EVENTS IN INDIVIDUALS INFECTED WITH *LOA LOA*

Cédric B. Chesnais[1], Sebastien D. Pion[1], Jacques Gardon[1], Nathalie Gardon-Wendel[2], Joel Fokom-Domgue[3], Joseph Kamgno[4], Michel Boussinesq[1]

[1]*Institut de recherche pour le Développement, Montpellier, France,* [2]*Antenne ORSTOM auprès du Centre Pasteur, Yaoundé, Cameroon,* [3]*The University of Texas MD Anderson Cancer Center, Houston, TX, United States,* [4]*Centre for Research on Filariasis and other Tropical Diseases, Yaoundé, Cameroon*

Implementation of onchocerciasis and lymphatic filariasis elimination programs has been delayed in Central Africa because of the risk of post-ivermectin severe adverse events (SAEs) in people with high *Loa loa* microfilarial densities (MFD). The incidence rate of SAEs (i.e. with a functional impairment requiring for at least one week full-time assistance) has been assessed in some settings and the relative risk, compared to subjects without *Loa* microfilariae (mf), of developing a SAE or a marked reaction (with functional impairment for several days) for increasing *Loa* MFD has been evaluated. However, the individual predicted risk of SAE for a given *Loa* MFD is unknown. To estimate this individual risk, as well as the MFD for which the predicted risk of SAE is 1/1,000 and 1/100, we used information from two trials conducted in Cameroon: one in 1997 in the Lekie division (Central region), and the other in 2005 in the Lom-et-Djerem division (East region). We performed mixed multivariable logistic models using fractional polynomials for age and pre-treatment *L. loa*, and *Mansonella perstans* MFD and category for sex. The models included a random effect on the village of residence. All possible interactions were tested. Among the 10,506 trial subjects treated with ivermectin (males: 48.9%, mean age: 35.4 years), 38 developed an SAE, including two cases of coma. A total of 2,792 (28.3%) subjects were microfilaremic for *L. loa*. The results showed a higher risk of SAE in males and in subjects with high *L. loa* MFD and no significant association with age and *M. perstans* MFD. This statistical modeling allows for predicting individual risk of SAE for a given *L. loa* MFD: subjects with 10,000 mf/ml and 27,000 mf/ml have a risk of 1/1,000 and 1/100, respectively, to develop a SAE following ivermectin treatment. These results can help to better predict the risk of post-ivermectin SAE in communities where the distribution of *L. loa* MFD has been assessed, for example during mapping activities.

Increasing evidence suggests that loiasis (caused by the filarial nematode *Loa loa*) poses a significant public health threat to the estimated 10 million infected individuals across Central Africa. Treatment of the disease is complex: although the anti-parasitic drugs diethylcarbamazine and ivermectin are highly efficacious at clearing the infection, they cannot be administered to individuals with heavy microfilarial loads, due to the

risk of fatal encephalopathy associated with treatment. A 3-week course of daily albendazole was reported to safely and progressively decrease *L. loa* microfilaraemia, but shorter regimens would be more practically applicable. Previous trials on the effect of short-term regimens have shown mixed results, including significant inter-individual variability of their effect on *L. loa* microfilaremia: further clarification of their effect is crucial given that albendazole remains one of the few anthelmintics routinely administered to individuals with the highest microfilarial densities. We undertook a systematic review and meta-analysis of trials (n = 5, containing data for 226 patients) using various albendazole regimens (ranging from 1-21 days) and dosages (400-800mg daily) to better understand their effect on loiasis. We constructed a set of pharmacokinetic/pharmacodynamic models of treatment dynamics to integrate the available longitudinal individual-level data detailing microfilarial densities following treatment, and assessed the effect of the drug, dosage and treatment regimen on microfilaremia. Our results reveal substantial variation both between studies (in which dose and regimen have varied considerably) and between individuals (despite identical dosing and treatment regimen), and better resolves the extent of the effect of albendazole treatment on *L. loa*. This work highlights potential drivers of the pronounced heterogeneity observed in response to albendazole treatment, as well as possible strategies to optimise the use of albendazole in loiasis infected individuals moving forward.

1819

THE CURRENT EVIDENCE BASE FOR LYMPHATIC FILARIASIS ELIMINATION THRESHOLDS: IDENTIFYING THE KEY UNKNOWNS

Emma L. Davis[1], Lisa J. Reimer[2], Lorenzo Pellis[3], T Deirdre Hollingsworth[4]

[1]*University of Warwick, Coventry, United Kingdom,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*University of Manchester, Manchester, United Kingdom,* [4]*Big Data Institute, University of Oxford, Oxford, United Kingdom*

In the global drive for elimination of lymphatic filariasis, 15 countries have brought prevalence below the WHO-specified thresholds for halting mass treatment and achieved validation of elimination as a public health problem (EPHP). There is a strong mathematical and biological basis for the existence of a break-point for lymphatic filariasis: a threshold below which transmission cannot be sustained. The current thresholds for stopping MDA were set as practical targets with the expectation that they would lead to a high probability of transmission fading away in most settings (this is called elimination of transmission, or EOT). However, this assumption has been undermined by recent evidence of ongoing transmission in some regions. Here we show that the probability of EOT explicitly depends on key biological parameters, many of which have a poor evidence base. We calculated the probability of lymphatic filariasis transmission elimination, given a particular prevalence (e.g. 1%), by considering the probability a chain of transmission will die out to show that stochastic extinction is possible before the true break-point is reached. However, our results demonstrate that the existing experimental evidence does not support a high probability of elimination for the current WHO targets, partially due to uncertainties in parameters. We also demonstrate the importance of the annual biting rate in determining suitable threshold levels for targeting EOT. As more countries progress through MDA programs and begin to cease interventions it is vital that we ensure this process is well-informed, as prematurely halting control programs could pose a serious threat to global progress. Our findings demonstrate that we cannot be comfortably assured of EOT following validation of EPHP, according to the current thresholds for passing TAS, and that refining experimental estimates of key unknowns could be a vital step to greater understanding of the conditions that make elimination possible.

ASSESSMENT OF LYMPHATIC FILARIASIS (LF) PREVALENCE TRENDS ALONG THE COASTAL REGIONS OF TANZANIA

Upendo John Mwingira[1], Denis Kailembo[2], Andreas Nshala[3], Veronica Kabona[4], Cecilia Uisso[1], Mwelecele Malecela[5]

[1]*National Institute for Medical Research, Dar Es Salaam, United Republic of Tanzania,* [2]*NTD Control Program, Dar Es Salaam, United Republic of Tanzania,* [3]*Uppsala University, Uppsala, Sweden,* [4]*IMA World Health, Dar Es Salaam, United Republic of Tanzania,* [5]*World Health Organization, Geneva, Switzerland*

Tanzania is endemic for all preventive chemotherapy Neglected Tropical Diseases NTDs and adopted the World Health Organization (WHO) resolutions for elimination and control of NTDs including elimination of Lymphatic Filariasis (LF). Mapping for LF reported 65% (120 out 185) of the districts in Tanzania to have >2% Circulating Filarial Antigen (CFA) levels thus necessitating MDA to be initiated. By 2019, over 80% of the endemic districts (96 out of 120) have met criteria for stopping MDA. However, the remain 20% (24 out of the 120 endemic councils) still require MDA. We assessed the transmission dynamics of *Wuchereria bancrofti* in the human population along the Pwani, Lindi and Mtwara regions. We gather evidence from mapping, baseline assessment, sentinel and spot-check sites to gauge impact of mass drug administration in the absence of the complete transmission assessment survey (TAS). Mapping in the 24 coastal districts had average CFA levels of 46% (0.0% to 72.0%). Following MDA CFA level have steadily declined to <1% in 62.5% (i.e. 15 of 24 districts), thus meeting the criteria to stop MDA. These coastal districts bear most of the burden of LF as 37.5% still require MDA compared the national average of 20%. Over 51 sentinel and spotcheck sites were assessed and individual aged 5 years and above tested for CFA- resulting in decrine over the years from 46% to an average of 4.8%. In stopping MDA, CFA levels and MDA coverage for 5 rounds are important for interruption of transmission, however, only 4% of the districts treated for five (5) rounds as recommended by WHO achieved criteria for stopping MDA. There is clear trend of persistent infection transmission in this coastal belt, with 46% of districts going up to nine (9) rounds of MDA before stopping MDA. Coverage monitoring is important. All districts had average epidemiological coverage ranging from 65% to 78% over the implementation period. In conclusion, a significant reduction of CFA prevalence is noted however, 37% of districts have persisted infections as CFSA is still <2% despite more than five annual rounds of MDA.

1821

THE ENVIRONMENTAL SUITABILITY OF ONCHOCERCIASIS IN AFRICA

Elizabeth Cromwell, Joshua Osborne, Kimberely Johnson, Elex Hill, Shreya Shirude, Katie Donkers, David Pigott, Simon I. Hay

University of Washington (IHME), Seattle, WA, United States

Recent evidence from the Americas, Sudan and Uganda suggest that onchocerciasis elimination may be feasible after 10-15 years of mass drug administration with ivermectin. A shift from control to elimination of onchocerciasis will require national programs in Africa to conduct new baseline data collection in implementation units (IUs) where prevalence of infection is unknown. Using Boosted Regression Trees with optimized hyperparameter selection, we implemented an environmental suitability analysis using available data on the presence of onchocerciasis in Africa to predict to what extent any of the approximately 2,400 IUs identified by WHO ESPEN as uncertain endemicity status were likely to be suitable for transmission. Covariates included elevation, enhanced vegetation index, tasseled cap brightness, tasseled cap wetness, minimum distance from rivers of 25m in width or larger, elevation grade, aridity, cumulative annual precipitation, land surface temperature, and urbanicity. Mean environmental suitability estimates were concordant with areas currently defined as endemic with 96% of IUs with at least one pixel >75% suitability. The majority of IUs with high environmental suitability are located in Angola (76 IUs), Ethiopia (82 IUs), DRC (167 IUs), Kenya (81

IUs) and Nigeria (72 IUs). Of the IUs considered for baseline surveys not currently under MDA for LF, model results suggest approximately 45% are highly suitable. We observed maximum pixel and minimum pixel values per IU ranging as high as .95, suggesting a high degree of variation within each IU at the fine spatial scale. Among IUs for which onchocerciasis endemicity status is unknown but are currently under MDA with ivermectin for the purpose of LF elimination, 57% were predicted to have environmental suitability exceeding 75%. The scale of baseline data collection required to complete mapping of onchocerciasis endemicity across the entire African continent presents an opportunity to use spatial data to facilitate survey planning. IUs most likely to sustain transmission of onchocerciasis could be prioritized for data collection, enabling earlier initiation of MDA programs.

1822

COVERAGE ASSESSMENT FOLLOWING MASS DRUG ADMINISTRATION OF THE NEW WHO-RECOMMENDED THREE-DRUG REGIMEN FOR LYMPHATIC FILARIASIS ELIMINATION IN AMERICAN SAMOA

Tara A. Brant[1], Rebecca J. Chancey[1], Lynette Suiaunoa-Scanlan[2], Tamara Buhagiar[2], Ryan E. Wiegand[1], Emily A. Dodd[1], Kimberly Y. Won[1], Emi Chutaro[3], Fara Utu[4], Motusa Tuileama Nua[4]

[1]*US Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Pacific Island Health Officers' Association, Pago Pago, American Samoa,* [3]*Pacific Island Health Officers' Association, Honolulu, HI, United States,* [4]*American Samoa Department of Health, Pago Pago, American Samoa*

In 2017, the World Health Organization (WHO) introduced a three-drug regimen of ivermectin, diethylcarbamazine, and albendazole (IDA) for lymphatic filariasis (LF) mass drug administration (MDA). Models suggest that in most settings ≥75% coverage of IDA MDA is needed for two rounds to reach elimination targets. Despite efforts to eliminate LF from American Samoa (AS) from 2000-2015, results from a 2016 survey indicated widespread transmission. In 2018, AS became the second site globally to implement IDA MDA at program scale. The reported drug coverage based on the 2010 census data was approximately 55%. However, coverage in Manu'a District was >90% based on a community census conducted during MDA, bringing into question the accuracy of the 2010 census data. We conducted a coverage survey in February 2019 to assess program reach and validate reported drug coverage. We used systematic random sampling to identify 30 clusters in 24 of the 74 villages and interviewed all members of selected households about their participation in the MDA. Program reach and coverage were calculated based on the number of participants who were offered and who swallowed the drugs. Results indicated that among the 715 participants sampled, 88.7% (95% Confidence Interval (CI), 84.7%-78.0%) stated they were offered drugs during MDA. Coverage was 72.7% (95%CI, 66.5%-78.0%) and coverage estimates by village ranged from 48.6% to 100.0%. Of the 68 who were offered but did not take the drugs, 27.9% were ineligible and 22.0% were too busy. Based on coverage assessed by the survey, we estimate that 30,314 people were treated during the MDA and that 41,697 people were actually residing in AS during the MDA, approximately 25% fewer than recorded in 2010. Based on the program report of coverage, AS did not meet the current WHO threshold of ≥65%; however, surveyed coverage was close to the ≥75% threshold needed for effective IDA MDA. As monitoring and evaluation guidelines for IDA MDA are being refined, coverage will likely be an important indicator of impact of the new regimen. These data highlight the importance of coverage surveys, especially in the absence of accurate population estimates.

1823

DETECTION OF RESIDUAL *FOCI* OF LYMPHATIC FILARIASIS TRANSMISSION TWO YEARS AFTER STOPPING MASS DRUG ADMINISTRATION: CASE OF DANO HEALTH DISTRICT IN BURKINA FASO

Roland Bougma[1], Mamadou Serme[1], Christophe Nassa[1], Micheline Ouedraogo[2], Appolinaire Kima[1], Clarisse Bougouma[1], Dieudonné Nare[2], Jean-Paul Djiatsa[2], Fanny Yago-Wienne[2], Amy Veinoglou[3], Yaobi Zhang[4]

[1]*NTD Control Program, Ministry of Health, Ouagadougou, Burkina Faso,* [2]*Helen Keller International, Ouagadougou, Burkina Faso,* [3]*Helen Keller International, New York, NY, United States,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Burkina Faso has made great progress toward the elimination of lymphatic filariasis (LF) as a public health problem, with 61 of 70 originally endemic health districts (HDs) having stopped mass drug administration (MDA). Dano HD was mapped in 2000 and recorded a high prevalence (ICT: 72%). After more than 15 years of MDA, Dano was the only HD in the South West region to meet the criteria for stopping MDA during the transmission assessment survey (TAS1) using the Filariasis Test Strip (FTS) in 2016: 8 positive cases were detected (critical cut-off of 18). Two years after stopping MDA, TAS2 was conducted in December 2018 using FTS. A total of 1818 children of 6-7 years were surveyed with zero positives detected (critical cut-off of 18). A descriptive cross-sectional study was integrated with TAS2 to follow-up the positive cases originally detected during TAS1 in 2016. The objective was to detect possible LF transmission *foci* around the old positives. All individuals two years and older residing in the same compound as the 8 TAS1 positive cases were surveyed. The variables studied were sex, age, the FTS result, and the status of ivermectin and albendazole treatment. Each child was tested with at least two FTS tests. 81 people were surveyed around the 8 index cases in 68 households. The age ranged from 2 to 78 years (average 22.2 years) and 50.6% were female. 79.0% of the respondents had received treatment at least once. Four people were tested positive (4.9%). Among them, 3 index cases remained positive in 2018 and a new positive case was detected who was the grandmother of one of the 3 remaining positive index children sharing the same room. The positives and all persons within the compound were treated. The results of the TAS2 confirmed the sustained interruption of LF transmission. Five of the old 8 positives turned negative. It suggests that the risk of recrudescence of transmission around index cases is minimal. This study provided an example of following up positive cases combining with other surveys that would allow for the detection and selective treatment of positives and their families.

1824

EPIDEMIOLOGY OF LYMPHATIC FILARIASIS DURING MASS DRUG ADMINISTRATION IN DREIKIKIR, PAPUA NEW GUINEA

Daniel J. Tisch[1], Brooke Mancuso[2], Nelly Sanuku[3], Philip Lus[3], Estee Cramer[1], Willie Pomat[4], Christopher L. King[1], Peter A. Zimmerman[1], James W. Kazura[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Tulane University, New Orleans, OH, United States,* [3]*Papua New Guinea Institute for Medical Research, Maprik, Papua New Guinea,* [4]*Papua New Guinea Institute for Medical Research, Goroka, Papua New Guinea*

Lymphatic filariasis infection and transmission has been monitored in 14 communities of Dreikikir, Papua New Guinea since the 1990's during mass drug administration (MDA) and bednet interventions. This study characterizes serological markers of infection during current and prior interventions. In the past year, these communities have completed 4 rounds of annual mass drug administration (MDA) with DEC and Albendazole. Night-time finger prick blood samples were collected during repeated cross sectional surveys in 3,000 individuals before and after annual MDA from 2015 to 2018 (immediately before the 1st and 4th MDA, respectively). Samples were processed for microscopy to detect circulating microfilaria (MF) and serological markers of infection. The results are

analyzed according to geography, age, and estimates of entomological transmission. MF prevalence decreased from 18.0% to 1.1% a year after 3 MDAs in western communities and from 1.4% to 0% in eastern communities. Among individuals with longitudinal observations, no negative individuals acquired MF positivity during three annual MDAs. However, antigen prevalence detected by Filarial Test Strips (FTS) remained high across the study site (8.4% to 30.6%). Among 78 antigen positive individuals followed longitudinally, 76% did not clear antigen and 5% of individuals FTS negative at baseline became FTS positive after 3 rounds of MDA. These results suggest that elimination targets may have been met in communities geographically located in the eastern communities, but that the adjacent western communities may have ongoing transmission, despite uniformly high coverage of MDA and long lasting insecticide treated bednets (LLIN). Additional serological biomarkers provide additional context to understand the impact of these results on LF elimination efforts. The fact that MF prevalence remains above 1% in some communities located <5km away from communities with no detectable MF highlights the focal distribution of infection post-MDA in this region. The distribution of infection also highlights the potential reservoir of adults for MF in these communities.

1825

ILLUMINA SEQUENCING TO MONITOR *WUCHERERIA BANCROFTI* INFECTION DURING AND AFTER MASS DRUG ADMINISTRATION

Daniel J. Tisch[1], E. Ricky Chan[1], Krufinta Bun[1], Scott T. Small[2], James W. Kazura[1], Peter A. Zimmerman[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*University of Notre Dame, Notre Dame, IN, United States*

Lymphatic filariasis infection and transmission has been monitored in 14 communities of Dreikikir, Papua New Guinea since the 1990's across mass drug administration (MDA; DEC and Albendazole) and bednet interventions. During this time, these interventions have been associated with significant decreases in infection and transmission across numerous age groups. However, antigen prevalence detected by Filarial Test Strips (FTS) still remains high across the study site (8.4% to 30.6%), even after recently renewed MDA, suggesting that elimination targets have not been met. Furthermore, some communities likely to serve as an reservoir for transmission due to persistent microfilaria (MF) prevalence >1%. In order to understand how parasite population genetics may be used to monitor *Wuchereria bancrofti* (Wb) elimination, we studied "paired" historical samples from five individuals (ages 6 to 40 years) with MF density of 33 to 26,468 MF/ml. One ml night-time blood samples (10pm-2am) were collected during the initial MDA intervention in these communities (1996) and 10 years after the cessation of the intervention (2008); Wb diagnostics were performed by microscopy and serological assays. Here we performed targeted Illumina sequencing of the Wb mitochondrial gene, cytochrome oxidase 1 (CO1) to assess the complexity of infection during and after MDA. Overall coverage of Wb CO1 ranged from 4,777 to 46,825 (median=30,756). Analyses provide evidence of complex infections characterized by 55 haplotypes. By comparing specific haplotype proportions across these sampling time points we observed significant differences in the overall population complexity in all five infected individuals. We also observed a significant shift in haplotype distribution in individuals between 1996 to 2008 suggesting a change in population structure within infected individuals following MDA. Results provide a unique approach for assessing Wb infection complexity, provide perspective for monitoring the impact of new treatment strategies, identifying resilient parasite strains and assessing elimination of lymphatic filariasis.

1826

PROGRESS TOWARD ELIMINATION OF LYMPHATIC FILARIASIS (LF) AFTER IMPACT SURVEYS IN 11 HEALTH DISTRICTS (HDS) OF 3 REGIONS IN CAMEROON

Biholong Benajmin[1], Ebene Clarisse[1], Georges NKO'Ayissi[2], Julie Akame[3], Patrick Mbia[3], Carine Fokam[3], Michel Hendji[3], Yaobi Zhang[4], Steven D. Reid[5], Ismael Teta[3]

[1]*Ministry of Public Health, PNLO, Yaoundé, Cameroon,* [2]*Ministry of Public Health, NTD Coordination Unit, Yaoundé, Cameroon,* [3]*Helen Keller International, Yaoundé, Cameroon,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal,* [5]*Helen Keller International, New York, NY, United States*

Cameroon is endemic for lymphatic filariasis (LF). The country aims to eliminate LF by 2020 and one of the steps towards elimination is that the health districts (HDs) must meet criteria for stopping mass drug administration (MDA). According to WHO recommendations, this is done through a transmission assessment survey (TAS) in HDs having completed at least 5 rounds of MDA with epidemiological coverage >65% and passed pre-TAS. In 2017, 11 out of 12 HDs from three regions successfully passed a pre-TAS, and were thus eligible for TAS1. One HD was not reached due to insecurity in the South West region. In 2018, this TAS1, conducted under the USAID-ENVISION project led by RTI International, in 11 HDs from Adamawa, Center and Eastern regions. The HDs were grouped into 8 evaluation units (EUs) according to their epidemiological profile and geographical location. The Survey Sample Builder (SSB) was used to calculate sample size and select the clusters. The sampled population consisted of children aged 6-7 years. The survey was conducted in schools in Center and East regions and in communities in Adamawa region where the school enrolment rate was <75%. The Filariasis Test Strip (FTS) was used to detect LF antigen. Data were captured on smartphones using ODK technology, stored on an ONA platform and processed through an electronic template with control measures. The teams performed day-time calibrated blood smears (CBS) in *Loa Loa* co-endemic areas. Children testing positive were all confirmed by a second FTS test. 11,548 children in 276 clusters were tested and the initial FTS was positive in 6 children. All of them were re-tested and only 1 child was positive with the second, confirmatory FTS in only one EU, well below the critical cut-off value. This TAS1 results showed recrudescence is unlikely to occur in these 11 HDs bringing the number of HDs having met the criteria to stop MDA to 136 (out of 137 endemic HDs). These results suggest that the National NTD Program should start preparing the LF surveillance phase across the country.

1827

SEROPREVALENCE AND DETERMINANTS OF TRANSFUSION TRANSMISSIBLE INFECTIONS AMONG VOLUNTARY BLOOD DONORS IN HOMABAY KISUMU AND SIAYA COUNTIES IN WESTERN KENYA

George Calleb Onyango[1], Lilian Ogonda[2]

[1]*Kenya Medical Training College, Kisumu, Kenya,* [2]*Maseno University, Kisumu, Kenya*

Since the implementation of a series of blood donation safety improvements in Kenya, information about seroprevalence and determinants of transfusion transmissible infections among voluntary blood donors especially in high HIV burden regions of Homabay, Kisumu and Siaya counties remain scanty. A cross-sectional study examining HIV, syphilis, hepatitis B and C virus sero-markers and associated determinants was conducted among voluntary blood donors. Their demographic characteristics and previous risk exposure were recorded in a pre-donation questionnaire, while blood samples collected were screened for hepatitis B, hepatitis C, human immunodeficiency viruses by ELISA and RPR (syphilis), then confirmed using CMIA. Overall TTIs seroprevalence was 114 (9.4%), distributed among HIV, HBV, HCV and syphilis at 14 (1.15%), 42 (3.46%), 39 (3.21%) and 19 (1.56%), respectively, with co-infections of 3 (0.25%). There were no significant differences in proportions distributions among

demographic variables. However, high risk sex was significantly associated with higher odds of HBV infections [> 1 partner vs. 0-1 partner; odd ratio (OR) 2.60; 95% confidence interval (CI) 1.098-6.86; p = 0.046]. In conclusion, a substantial percentage of blood donors still harbor transfusion transmissible infections despite recent safety improvements with greater majority cases caused by HBV infections arising from previous exposure to high risk sex.

1828

AWARENESS, ACCEPTABILITY AND WILLINGNESS TO USE A PROSPECTIVE HIV VACCINE AMONG HEALTHCARE WORKERS IN SOUTHEAST NIGERIA

Ikechukwu N. Dozie, Chiamaka C. Eluwa-Okonkwo, Chikere I. Ebirim, Uchechukwu M. Chukwuocha

Federal University of Technology, Owerri, Imo state, Nigeria

This study was undertaken to investigate the awareness, acceptability and willingness to use a prospective HIV vaccine by healthcare workers in Imo State, South east, Nigeria. Information was elicited using structured pretested questionnaire administered to 297 respondents drawn from the Federal Medical Centre (FMC) Owerri, Imo State, Nigeria. Data analysis was using Chi-square on Statistical Package for Social Sciences (SPSS) version 21. Majority of the respondents (81.3%) were aware of a prospective HIV vaccine, with the 50+ age group (95.8%) and Consultants (100.0%) being the most aware. Their main source of information was journal articles (24.5%), followed by conferences/workshops (22.1%) while the least source was radio (3.9%). About 260 (87.5%) of the respondents agreed that HIV vaccine can prevent spread of virus and the best time suggested for vaccination was at birth (60.8%) as against attaining puberty before first sexual activity (7.4%). Also 290 (97.6%) respondents showed willingness to accept vaccination and would encourage their patients to accept vaccination too. Very few respondents (13.5%) did not agree that vaccination should be free and the adduced reasons included misuse (45.0%), taken for granted (47.5%) and encouragement of unsafe sex practices (7.5%). Nonetheless, 92.3% of respondents would pay for vaccination which should cost between USD 30 and USD 50 per vaccine. Socio-demographic variables were not found to be statistically significant predictors of awareness while only gender(P=0.025) was statistically associated with acceptability. The study showed that awareness and acceptability of HIV vaccine is high amongst healthcare workers in Imo State, South east Nigeria. This underscores the probability of high uptake of a prospective vaccine in the area as a preventive measure against HIV infection.

1829

A CASE OF SEVERE CRYPTOCOCCAL IMMUNE RECONSTITUTION INFLAMMATORY SYNDROME PRESENTING WITH BRAIN AND INTRADURAL ABSCESSES IN AN HIV PATIENT

Thomas Michael Kalinoski[1], Arthur Jeng[1], Jason Malenfant[2], Catherine Yim[1], Wenchang Guo[3]

[1]*Olive View - University of California Los Angeles Medical Center, Sylmar, CA, United States,* [2]*University of California Los Angeles, Los Angeles, CA, United States,* [3]*LAC+USC Medical Center, Los Angeles, CA, United States*

Clinical worsening or new manifestation of cryptococcal disease following initiation of anti-retroviral therapy (ART) in an HIV-infected individual is a hallmark of cryptococcal immune reconstitution inflammatory syndrome (C-IRIS). However, it can be difficult to distinguish IRIS from worsening infection or new pathogen, especially in the setting of severe disease and ART initiation following an adequate window period. Here, we present a case of severe C-IRIS, involving development of multiple cerebellar abscesses, spinal intradural abscesses, and spinal arachnoiditis seven months after ART initiation in an AIDS patient who had uncertain ART compliance before that time. He had a complicated history of multiple prior episodes of cryptococcal meningitis necessitating placement of a ventriculoperitoneal shunt (VPS), and had been on suppressive fluconazole when he developed worsening and new brain manifestations. The patient received empiric re-induction of anti-cryptococcal therapy without any improvement and was subsequently treated for tuberculous meningitis as well as possible VPS infection. During this presentation, all CSF cultures remained sterile, with negative *Cryptococcus* PCR testing, and his condition continued to worsen prior to corticosteroid initiation. Ultimately, C-IRIS was diagnosed by brain biopsy. This case documents both an extreme in severity of C-IRIS and in the timeline of presentation after ART initiation.

1830

HIGH FREQUENCIES OF TUMOR-INFILTRATING AND CIRCULATING ΓΔ T CELLS IN ENDEMIC BURKITT LYMPHOMA PATIENTS

Cecilia Smith-Togobo[1], Maria del Pilar Quintana[2], Michael F. Ofori[1], **Lars Hviid**[2]

[1]*University of Ghana, Accra, Ghana,* [2]*University of Copenhagen, Copenhagen N, Denmark*

Endemic Burkitt lymphoma (eBL) is a highly aggressive B-cell cancer that is only seen in children exposed to massive, early Epstein-Barr virus infection, and who are living in areas with stable and intense transmission of the malaria parasite *Plasmodium falciparum*. In such areas, eBL can be the most common pediatric cancer, which has a very poor prognosis in the absence of effective chemotherapy that is often not available. High frequencies (>5% of all circulating T cells) of Vδ1$^+$ γδ T cells have been reported in various infectious and neoplastic diseases, but also among healthy individuals from areas with stable transmission of *P. falciparum* malaria. The function of the Vδ1$^+$ T-cell subset is largely unknown, but it appears to be "adaptive-like" and quite distinct from that of the "innate-like" and largely complementary Vγ9Vδ2$^+$ γδ T-cell subset, which universally responds to non-peptide prenyl pyrophosphate metabolites (so-called phospho-antigens) produced by a variety of stressed cells and pathogens. We have previously proposed that the still quite enigmatic Vδ1$^+$ T-cell subset serves an adaptive auto-regulatory function in conditions characterized by massive and/or chronic B-cell activation. On the above basis, we set out to test the hypothesis that the Vδ1$^+$ T-cell subset subset is expanded in patients with endemic Burkitt lymphoma (eBL). We recruited a series of Ghanaian children with eBL, and compared the frequencies and phenotypes of Vδ1$^+$ T cell in fine-needle tumor aspirates and in the peripheral blood of the patients. Our preliminary evidence documents high frequencies of Vδ1$^+$ γδ T cells in both cell compartments. We will present results of our detailed multi-parameter phenotypic analysis of these cells, which will be the first detailed report of its kind in patients with this important tropical cancer.

1831

FIVE-YEAR VIH INCIDENCE, PREVALENCE AND MORTALITY IN CANADA, MEXICO AND USA: OBSERVATIONAL DESCRIPTIVE STUDY

Nina Mendez-Dominguez[1], Sabrina Fajardo-Ruiz[1], Peter Gulick[2], Andrea Cámara[1], Martin Inurreta[1]

[1]*Universidad Marista de Merida, Merida, Mexico,* [2]*Michigan State University, Michigan, MI, United States*

At the end of 2017, 940,000 people died due to HIV worldwide. In the absence of an etiologic cure for HIV, antiretroviral therapy (ART) can provide a better quality of life and survival and provide infected people a chance to live a healthy and productive live. Even when Mexico, USA and Canada share environmental and biological common aspects, differential access to preventive medicine services might might not be equal. The objective of the present study is to describe the epidemiologic profile of HIV and its relationship with mortality patterns in the three North American countries between 2012 to 2016. *Methods.* In this observational retrospective study, the VIH epidemiologic surveillance open access datasets from Canada, Mexico, and United States for years 2012-2016 is described. Data was analyzed by country considering gender, age

and region and presented in tables and figures. Chi squared tests and mean comparison tests followed by post hoc analyses were developed when comparing between groups. *Results.* In the USA, the yearly estimated incidence in population infected by HIV from the years 2012 to 2016 was 15.06, in Mexico for the same years it was 4.74 and in Canada 5.94 per 10,000 inhabitants. The highest rates of new HIV cases occurred in young adult men. Incidence increased in Mexico among women living in rural areas. The modal age group in Mexico is 25-34, in the USA the 45-54 group have the highest seroprevalence and in Canada, subjects aged 30-39 have the highest seroprevalence. The average age at death caused by HIV in Mexico is 39 years old, which could represent a shorter life expectancy among infected Mexicans when compared to Americans and Canadians. The HIV epidemiology vary between these three North American countries, while USA has a higher incidence of HIV, the average age of mortality in México is at a younger age. Epidemiology of HIV in Mexico might reflect that HIV diagnosis could be improved to implement ART treatment and achieve a longer survival.

1832

FACTORS ASSOCIATED WITH DIARRHEAL ILLNESS AMONG HIV PATIENTS IN AN OUTPATIENT CLINIC IN JAMAICA

Obinna Nnaemeka Nnedu[1], Rasheedah Godfrey[1], Clara Engmann[2], Alaa Mohammed[1], Tamara Thompson[3]

[1]*Ochsner Clinic Foundation, New Orleans, LA, United States,* [2]*Tulane University School of Medicine, New Orleans, LA, United States,* [3]*University of West Indies Mona, Mona, Kingston, Jamaica*

HIV infected individuals are at increased risk for developing diarrhea from both infectious and non-infectious causes. A previous study in Jamaica showed that 26.3% of HIV infected adults sought medical care in the prior 12 months for gastrointestinal complaints. We undertook a case-controlled study to determine the factors associated with diarrheal illness among HIV infected patients seeking care at an outpatient HIV clinic in Jamaica. The study period was January 1, 2011 to December 31, 2015. A total of 514 individuals met our inclusion criteria for the study. Basic demographic and clinical information were obtained via chart review. We performed univariate analysis to determine what factors to fit in a multivariate logistic regression model. In univariate analysis, patients on HIV medications were less likely to have diarrhea OR=0.27 (95% CI: 0.17-0.42) compared to those not on therapy. Looking at specific HIV medications, univariate analysis showed that any protease inhibitor use and use of ritonavir-lopinavir specifically may be associated with increased risk of diarrhea; OR=1.68 (95% CI: 1.05-2.68) and OR=2.58 (95% CI: 1.56-4.03) respectively. Use of efavirenz decreased the risk of diarrheal illness in univariate analysis; OR=0.41 (95% CI: 0.24-0.69). In multivariate logistic regression analysis, we found that use of ritonavir-lopinavir was associated with an increased risk of diarrhea, OR=1.9 (95% CI: 1.18-3.06) while use of efavirenz was associated with decreased risk of diarrhea, OR=0.5 (95% CI: 0.29-0.86). Our findings suggest that with increased access to HIV medications in developing countries, ritonavir-lopinavir use may become an important risk factor for diarrheal illness. It will be important to have additional treatment options for patients who are not able to tolerate ritonavir-lopinavir.

1833

DIAGNOSIS OF NEUROLOGICAL TOXOPLASMOSIS IN URINE IN PERSONS LIVING WITH HIV

Hannah Steinberg[1], Andrea Diestra[2], Cusi Ferradas[2], Maritza Calderón[2], Catherine Apaza[2], Marilly Donayre Urquizo[3], Melanie Ayachi López[4], Viviana Pinedo Cancino[3], Lastenia Ruiz[3], Cesar Ramal[4], Paul Russo[5], Natalie Bowman[6], Lance Liotta[5], Alessandra Luchini[5], Robert H. Gilman[7]

[1]*University of Illinois Chicago, Chicago, IL, United States,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Universidad Nacional de la Amazonía Peruana, Iquitos, Peru,* [4]*Hospital Regional de Loreto, Iquitos, Peru,* [5]*George Mason University, Manassas, VA, United States,* [6]*University of North Carolina Chapel Hill, Chapel Hill, NC, United States,* [7]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Secondary neurological infections in persons with HIV are challenging to diagnose. CT and MRIs with a clinical suspicion can guide treatment, but definitive diagnosis remains elusive for many patients. One causative pathogen is *Toxoplasma gondii (T. gondii).* Though difficult to diagnosis, it has up to 90% clinical response rate to treatment. A point of care, non-invasive diagnostic would allow for the expeditious ruling in or out of neurological toxoplasmosis. Our team has developed a diagnostic western blot with a hydrogel nanoparticle concentration step in urine for *T. gondii* antigen. To complete the assay, urine is incubated with reactive blue 221 dyed hydrogel nanoparticles. The reactive blue 221 dye semi-specifically binds to the *T.* gondii antigens in the patients' urine. The nanoparticles are then collected by centrifugation and eluted in sample buffer for gel electrophoresis and transferred to PVDF membrane. PVDF membrane is blotted using standard western blot technique for anti-GRA1 and anti-SAG1. The nanoparticle concentration step allows for the detection of as little as 7.8pg/ml of antigen. The detection of antigen in patient urine is consistent with toxoplasmosis symptoms and CT findings. The detection of antigen is most sensitive and specific in patients prior to the initiation of treatment; however it is possible to detect antigen in urine up to a week after the initiation of treatment for toxoplasmosis. Additionally, testing of urine in asymptomatic toxoplasmosis seropositive persons does not yield a positive result. It is our hope to continue this research to transition our western blot to a lateral flow assay to improve the accessibility of this diagnostic approach.

1834

HUMAN IMMUNODEFICIENCY VIRUS ASSOCIATED MULTICENTRIC CASTLEMAN'S DISEASE (MCD) WITH COEXISTING KAPOSI SARCOMA TRIGGERING POTENTIALLY FATAL HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS

Vijai Bhola[1], Steven Hatch[2], Nicole Theodoropoulos[2], Salwa Khedr[2]

[1]*University of Massachusetts Medical School, Shrewsbury, MA, United States,* [2]*University of Massachusetts Medical School, Worcester, MA, United States*

A 47 year old HIV positive male from the Central African Republic presented to a US hospital with persistent fevers, hypotension and lymphadenopathy. HIV Viral load of 123 copies/mL and CD4 count of 346, on long term HAART. He was started on broad-spectrum antibiotics. Routine radiographs and cultures were unrevealing, but fevers persisted. CT scan revealed diffuse abdominal lymphadenopathy, and splenomegaly. His ferritin level was markedly elevated at 2147 ng/mL; soluble Interleukin 2 receptor alpha (s-IL2R) level was 14,770 pg/ml (normal less than 1033 pg/ml); and an HHV8 PCR was positive at 3,300,000 copies/mL. A left inguinal lymph node biopsy revealed coexistent MCD and KS. He was diagnosed with HLH in the setting of HHV8/KS-associated MCD. He was started on etoposide, rituximab, valganciclovir, and dexamethasone; fever and hypotension resolved, with rapid clinical improvement. MCD is a rare lymphoproliferative disease characterized by hyperactive immune cells secreting multiple cytokines leading to fevers, lymphadenopathy, and organ dysfunction. It is classically seen in HIV patients who are HHV8-positive. HLH is a hyper-inflammatory syndrome characterized by uncontrolled T cell activation with subsequent cytokine storm and potentially lethal multi-organ failure. Diagnosis of HLH requires meeting at least five of eight criteria: fever; splenomegaly; cytopenias; elevated ferritin; elevated IL2R; hypertriglyceridemia; low or absent NK cell activity; and visual evidence of hemophagocytosis on biopsy (our patient met the first five criteria; a bone marrow biopsy was not performed once he met criteria). HLH triggered by HIV-MCD is quite rare. In one HIV-associated MCD cohort in Europe, only nine percent of patients developed HLH. Treatment regimens include etoposide, which halts T-cell expansion, and anti-inflammatory agents such as dexamethasone. Our case highlights the rare condition of MCD in an HIV-positive patient, the role of HHV8 in

tumorigenesis, and the possibility of simultaneous MCD and KS. We also highlight that HLH is a rare, but potentially lethal, complication of MCD, and can easily be misdiagnosed for sepsis.

1835

COUMARIN ANTIFUNGAL LEAD COMPOUNDS FROM *MILLETTIA THONNINGII* AND THEIR PREDICTED MECHANISM OF ACTION

Sylvester Kaminta[1], Daniel M. Ayine-Tora[2], Abdul-Salim Musah[3], Felix C. Mills-Robertson[4]

[1]*Monash University, Clayton, Melbourne, Austria,* [2]*University of Auckland, Auckland, New Zealand,* [3]*St. Theresa's Hospital, Nandom, Upper-west region, Ghana,* [4]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*

Fungal infections including candidiasis remains a public health threat of high morbidity and mortality, affecting immunosuppressive patients such as HIV/AIDS victims despite several attempts to control its invasion. The etiological agent of candidiasis is *Candida albicans*. Currently, effective antifungal drugs that were used to treat infections due to *C. albicans* are challenged with drugs resistance. Thus, the search for new antifungal drugs that are safe and effective to replace them is warranted. Plants have shown to be a valuable source of antifungal agents. Here, we demonstrated the antifungal activity of isolated compounds from seeds of *M. thonningii*, robustic acid, thonningine-C, alpinumisoflavone and O'O-methylalpinumisoflavone against the wild *C. albicans* strain and a reference strain (ATCC18804). The agar well diffusion method was used to evaluate zones of inhibition. Thermochemical calculations were performed using Gausian 09 software suite. The predicted mechanism and bioassay results revealed that the tested fungal strains were sensitive to robustic acid, thonningine-C. Two coumarins, robustic acid and thonningine-C isolated from *M. thonningii*, show promising activity against the fungus, *C. albicans* with minimum fungicidal concentration of 1.0 and 0.5 mg/ml, respectively. Molecular modelling against the putative bio-molecular target, lanosterol 14α-demethylase (CYP51), revealed a possible binding mode for the active compounds, in which the hydroxyl group binds with a methionine backbone carboxylic group blocking access to the iron catalytic site. This binding disrupts the synthesis of several essential sterols for the survival of fungi. The findings provided useful data on the antifungal potential of *M. thonningii* compounds that can be used in drug developing for the treatment of candida infections.

1836

HISTOPLASMOSIS AND TUBERCULOSIS CONFECTION IN PEOPLE LIVING WITH HIV: A RETROSPECTIVE CASE-SERIES

Audrey Valdes, Pierre Couppie, Roxane Schaub, Romain Blaizot, Felix Djossou, Loic Epelboin, Mathieu Nacher, Denis Blanchet, Magalie Demar, Antoine Adenis

Centre Hospitalier de Cayenne, Cayenne, French Guiana

Tuberculosis and histoplasmosis coinfection is rarely suspected though case series report over 10% coinfections in people living with HIV (PLWHIV) being diagnosed for histoplasmosis. Coinfections represent a diagnostic and therapeutic challenge for clinicians with no evidence-based guidance available in PLWHIV guidelines. Thus, the objective of the study was to describe tuberculosis and histoplasmosis coinfections in PLWHIV in French Guiana. Cases of concomitant (within 3 months) culture-proven histoplasmosis and tuberculosis occurring in adult PLWHIV were identified in a retrospective cohort of PLWHIV diagnosed in Cayenne General Hospital between 01/01/1997 and 12/31/2017. Care and treatment findings were collected on a standardized form. All patients gave informed consent. Among the 14 coinfection cases identified, 8 (57%) were diagnosed simultaneously and 6 within 3 months (range:11-90 days). Lymph node (5/8) and liver (2/8) samples yielded most simultaneous diagnoses. The mean age was 40.9 ± 9.2 years. The H:F gender ratio was 2.5. Nine out of 12 patients (75.0%) declared drug addictions, half of them being crack cocaine users. Fever was reported in all cases. Cough (9/14), diffuse abdominal pain (6/14) and lymph node enlargement (6/14) were mainly reported. The median CD4 count level was 50/mm³ (Interquartile range 25%-75%: 25-79) [Range:6-253]. Hepatic cytolysis was found in 2/14 cases, hepatic cholestasis in 7/14 and an increase in LDH in 8/9 patients. An interstitial syndrome was reported in 5/10 chest X-ray performed. Within 3 months after treatment initiation no deaths and one case of lost to follow-up were observed. Similarly to previous reports, histoplasmosis and tuberculosis coinfections described herein reported a disseminated pattern in PLWHIV at the advanced stage of HIV disease. But, in comparison to other reports, prognosis was good using first line treatment for the two diseases. Clinical or biological features alone may not give clinicians relevant clues in the diagnosis of coinfections. It relies on a high index of clinical suspicion and the access to relevant diagnostic facilities for the two diseases.

1837

FREQUENCY OF NON-AIDS DEFINING EVENTS IN PATIENTS INFECTED WITH HIV IN AN OUTPATIENT CLINIC IN SANTO DOMINGO, DOMINICAN REPUBLIC

Guillermo Alexander Asmar Vargas, Mylene Gisela Asmar-Rios, Leandro Tapia, Robert Paulino-Ramirez

Institute for Tropical Medicine and Global Health, Universidad Iberoamericana, Santo Domingo, Dominican Republic

With new advances in combined antiretroviral therapy, the frequency of AIDS defining events have decreased, however, an increase in the frequency of non-AIDS defining events has been observed. The objective of this study was to establish the frequency of non-AIDS defining events in patients infected with HIV in an outpatient clinic in Santo Domingo, Dominican Republic. Patients enrolled in care in a community- based clinic were evaluated for clinical indicators of non-AIDS defining events. Socio-demographic determinants and serological data were collected from clinical files, and statistical analyses were used to assess their distribution in different key populations. A total of 500 patients were analyzed, 66 of the had described non-AIDS defining events. Cardiovascular Disease and Chronic Liver Disease accounted for 26.3% of the presented non-AIDS defining events. Hypercholesterolemia accounted for 20%, Dyslipidemia 17.5%, Chronic Kidney Disease 6.3% and Anal Dysplasia 3.8% of the cases. Male patients were the most commonly affected gender representing 55.4% cases, followed by female patients with 35.4% cases. The most affected vulnerable population were MSM with 18.5% cases, sexual workers accounted for 15.4% of cases. 91% were adherent to HAART. 82% cases had a cd4+/cd8+ proportion <1. Although most of the patients that were studied remained adherent to the antiretroviral therapy non-AIDS defining events were still observed and the proportion of CD4 + / CD8 + lymphocytes remained <1 in the majority of the cases, reflecting the immunosenescence that can be observed in the vast majority of HIV-infected patients, possibly increasing their risk of suffering a defining or non-defining event of AIDS. The vulnerable populations of MSM and sexual workers affected with higher frequency.

1838

RAPID DIAGNOSIS OF CO-INFECTION WITH INVASIVE ASPERGILLOSIS AND ACTIVE HEPATITIS B INFECTION IN A HIV INFECTED PATIENT

Rone-Chun Lin, Joseph Y. Kim

University of Illinois, COM at Peoria, Peoria, IL, United States

A 54 year-old Hispanic MSM with a history of HIV/AIDS initially diagnosed in 1995 and nadir CD4 count of 12 presented with persistent cough for one month, progressive shortness of breath, and intermittent chills for two weeks. Four months prior to his presentation, he stopped taking his antiretroviral therapy due to nausea, but has restarted them two months later. Prior to the onset of his presenting symptoms, he was given prednisone for 14 days by his primary care physician due to generalized weakness. He was later diagnosed with influenza A, and received Bactrim and later Levofloxacin for presumed bacterial bronchitis. He subsequently

spiked a fever of 102F, and was admitted for further evaluation and treatment. He was found to have a CD4 of 76 (prior CD4 was 379 four months earlier) with an undetectable HIV viral load. Chest X ray showed bilateral infiltrates, and laboratory testing showed mild transaminase level elevation. Next-generation sequencing (NGS) of cell-free DNA was performed. Within 72 hours, the result came back with detection of Aspergillus fumigatus, Hepatitis B and CMV. Sputum cultures eventually grew Aspergillus fumigatus, and subsequent confirmatory testing revealed elevated serum aspergillus antigen and beta-D-glucan levels. Hepatitis B DNA of >100 million IU/ml and CMV of 256 IU/ml were also detected. Despite previous Hepatitis B vaccination with negative Hepatitis B surface antigen and positive surface antibody titers one year earlier, he was found to have lost his Hepatitis B immunity, and demonstrated positive Hepatitis B surface antigen, core antibody and E antigen. CT scan of the chest revealed multilobar pneumonia with a four-centimeter cavitary lesion of left lower lobe. MRI of brain revealed multiple ring-enhancing lesions likely representing abscesses from Aspergillosis. LP was unremarkable. He subsequently improved with voriconazole and micafungin treatment, and was discharged home. This case illustrated the potential utility of using NGS of cell-free DNA to rapidly diagnose multiple co-infections in severely immunocompromised HIV infected patients without the need for invasive diagnostic procedures.

1839

A SYSTEMATIC REVIEW OF VIRULENCE FACTORS IN THE *LEISHMANIA* GENUS

Osaru Omoruna[1], Avinash N. Mukkala[1], Ruwandi Kariyawasam[2], Eric Shao[1], Priyanka Challa[1], Michael A. Klowak[1], Shareese Clarke[1], Jamie Sookhoo[1], Dylan Kain[1], Tianna Chong-Kit[1], Olamide Egbewumi[1], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Parasite-determined factors play a complementary role in the pathogenesis of leishmaniasis, a disease caused by protozoans of the genus *Leishmania* with diverse and species-specific clinical manifestations. Virulence factors (VFs), or pathogen moieties facilitating disease, can potentiate host cell damage by Leishmania species via increased expression, host cell invasion, stress tolerance, and modulation of the host immune system. Due to large eukaryotic genomes in Leishmania species, there is a wide array of VFs which contribute to different aspects of pathogenesis. Here we conduct a comprehensive, systematized review of the literature around VFs in *Leishmania* spp. and construct a complete picture of parasite-determined contributors to the pathogenesis of various clinical forms of leishmaniasis. PubMed (NCBI), MEDLINE (OVID), EMBASE (OVID), Web of Science, and LILACS (VHL) were searched from inception to July 2018 using combinations of the search terms "virulence factor*", "*Leishmania*", and "Leishmaniasis*", while accounting for unique database syntax. Iterative inclusion and exclusion of search terms was employed to maximize relevant article extraction. For the systematic review, we will include primarily molecular and mechanistic pathogenesis studies in various model systems, observational studies, review studies, cohort studies, as well as clinical trials. Of 2620 articles remaining after title and abstract screening, some major VFs identified in the Leishmania genus are: heat shock proteins (HSP23, HSP70), cysteine peptidases (CPB), mannose phosphate isomerases (MPI), metalloproteases (GP63), and elongation factors (EF1-alpha), among many others. Data will be grouped and summarized by species, geographic region of endemicity, and VFs. This systematic compilation of mechanistic VF data will add to the large body of work in molecular pathogenesis of kinetoplastids and enhance our understanding of species and regional variations in Leishmania pathogenesis.

1840

NEW *LEISHMANIA* SPECIES AND ITS POTENTIAL NEW VECTOR, RESPONSIBLE FOR CUTANEOUS LEISHMANIASIS IN SOUTHEASTERN GHANA

Godwin Kwakye-Nuako[1], Mba-Tihssommah Mosore[2], Priscilla Ankamaa Opare[1], Michelle Bates[3], Rod James Dillon[3], Mary E. Wilson[4], Paul A. Bates[5]

[1]*University of Cape Coast, Department of Biomedical Sciences, School of Allied Health Sciences, College of Health and Allied Sciences, Cape Coast, Ghana,* [2]*Department of Parasitology, Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana,* [3]*Division of Biomedical and Life Sciences, Faculty of Health and Medicine, Lancaster University, Lancaster, United Kingdom,* [4]*University of Iowa, Departments of Internal Medicine, Microbiology and Immunology, and the Veterans' Affairs Medical Center, Iowa City, IA, United States,* [5]*Division of Biomedical and Life Sciences, Faculty of Health and Medicine, Lancaster University, Lnacaster, United Kingdom*

An outbreak of human cutaneous leishmaniasis (CL) was observed in Ho District in the Volta Region of South-eastern Ghana in 1999, which was we proved to be leishmaniasis and isolated the causative protozoan from patients with skin ulcers. The study aimed at identifying the *Leishmania* species responsible for CL and their potential vectors. Aspirates from patients with cutaneous ulcers were cultured *in vitro* in *Leishmania* growth medium (Sloppy Evan's and M199). Isolates of the "yet-to-be-named" *Leishmania* species were amplified, and genomic DNA was extracted. Sequence analysis of RPL23, ITS1, RNAPolII genes were performed with reference genomes. The Ghanaian *Leishmania* isolate clade closely with the pathogens *L. orientalis*, *L. martiniguensis*, *L. marcopodum*, belong to *Leishmania (Mundinia) enriettii* complex on the evolutionary tree. The phylogenetic analysis of Ghanaian isolates and other available sequences revealed it's a newly species. To incriminate the vector transmitting the Ghanaian isolates, two potential vectors, *Lutzomyia longipalpis* (sand fly) and *Culicoides sonorensis* (biting midge) were infected with Ghana *Leishmania* isolate and maintained for more than 10 days. Representative vectors were dissected daily to check infectivity. Heavy infections were characterised in both vectors at the blood meal stage, until the blood meals were digested. Infections in *Lu. longipalpis* decreased to 0, 3 days post-bloodmeal. Infections in the *C. soronensis* were retained beyond 10 days to ≈80%, colonising the midgut and stomodeal valve. A newly identified human pathogenic *Leishmania* species responsible for CL in Ghana was able to heavily infected *C. sonorensis*, colonizing the midgut and stomodeal valve up to 10 days and beyond. Although most *Leishmania* spp. causing human disease are transmitted by a sand fly vector, this result leads us to hypothesize that midges could be vectors of this new *Leishmania* species in Ghana. Further proof is required to demonstrate successful transmission of the parasite by *C. sonorensis* to mammalian host.

1841

ACCURACY OF DIAGNOSTICS IN TEGUMENTARY LEISHMANIASIS: A SYSTEMATIC REVIEW

Sonia Igboanugo[1], Melissa S. Phuong[1], Rachel Lau[2], Robert Chris[1], Eric Shao[1], Ruwandi Kariyawasam[3], Hira Raheel[1], Sharmistha Mishra[4], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario, Toronto, ON, Canada,* [3]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [4]*Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada*

Tegumentary leishmaniasis (TL) is characterized by cutaneous and mucocutaneous ulcerative skin lesions, caused by Leishmania parasites, that can potentially disfigure the midface. The clinical presentation of TL is similar to that of epidemiologically overlapping fungal and mycobacterial infections, thereby necessitating confirmatory diagnostics to inform appropriate treatment. Laboratory diagnostic techniques for TL include

the leishmanin skin test; microscopic identification of amastigotes from skin aspirates, biopsies and scrapings; culture; and molecular assays. We aim to determine optimal methods to accurately and efficiently diagnose TL to improve diagnostic stewardship. We searched five databases from inception to July 16, 2018 including Ovid MEDLINE, Embase, LILACS, Cochrane Library and Scopus with the following search terms: ("cut* leish*" OR "muc* leish*" OR "teg* leish*") AND (diagnosis OR diagnostic accuracy OR sensitivity OR specificity OR stard OR test*) AND NOT (viscer*). All systematic reviews, diagnostic trials and observational studies were included. Titles, abstracts and full-texts are systematically doubled screened by two reviewers with a tertiary arbitrator. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and Quality Assessment of Diagnostic Accuracy Studies (QUADAS) will be employed. 6745 papers were identified from the five databases and 1278 papers remained for abstract evaluation (3391 removed) after title screening, where non-human, non-TL, non-diagnostic and case report articles were excluded. Abstract and full-text screening will be conducted. Data will be extracted from full-texts and assessed using QUADAS for selection and information bias. Heterogeneity of the studies will be determined and meta-analysis performed as appropriate. TL cannot be distinguished from competing infectious etiologies clinically, thus necessitating confirmatory diagnostics. A knowledge synthesis of accurate diagnostic assays can provide insight into the optimal approach for TL confirmation and subsequently guide therapy.

ETHNOPHARMACEUTICALS FOR THE TREATMENT OF OLD WORLD CUTANEOUS LEISHMANIASIS: A SYSTEMATIC REVIEW OF TOPICAL APPLICATION OF TUMERIC

Priyanka Challa[1], Michael A. Klowak[1], Ruwandi Kariyawasam[2], Emma Hagopian[1], Eric Shao[1], Jason Kwan[1], Hira Raheel[1], Tianna Chong - Kit[1], Swana Kopalakrishnan[1], Anjola Ogunsina[1], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Toxicity, expense, and accessibility limit treatment success in Old World Cutaneous Leishmaniasis (OWCL), a neglected parasitic disease caused by members of the genus *Leishmania*found in the Middle East, Mediterranean basin, Arabian Peninsula, Africa as well as the Indian Subcontinent. Better drugs are urgently needed, however, drug discovery is hindered by limited funding given geographic restriction of highly endemic OWCL to LMICs. Plant-based compounds with potential anti-leishmanial effects found in and around local endemic communities present an opportunity to overcome the aforementioned therapeutic challenges, and many such interventions are supported by anecdotal evidence of efficacy. We aim to synthesize existing evidence around available ethnopharmaceuticals to promote drug discovery for the prevention and treatment of OWCL. PubMed (NCBI), Medline (OVID), Embase (OVID), Web of Science (BioSIS) and LILACS (VHL) were searched for from inception to July 26, 2018 using combinations of the search terms "cutaneous leishmaniasis" and "ethnopharmaceuticals". Iterative inclusion and exclusion of search terms was employed to maximize relevant article extraction. The GRADE approach will be used to assess quality of studies reporting therapeutic interventions. 3057 PubMed, 2818 Medline, 4200 Embase, 3183 Web of Science and 490 LILACS articles were retrieved for title and abstract screening; after duplicate removal, 5492 remained. 550 abstracts met inclusion criteria for full-text review, of which, 241 (43.80%) abstracts pertained to Old World species, and 113 (21%) were specific to *L. donovani*. Curcuma spp. "Turmeric" was identified in 4 articles (0.7%) to date. Synthesizing the current evidence surrounding ethnopharmaceuticals for the treatment of OWCL may contribute to drug discovery pipelines and potentially lead to novel therapeutics in a field that has not seen any new drug development for over half a century, especially in the context of turmeric.

ETHNOPHARMACEUTICALS FOR THE TREATMENT OF NEW WORLD CUTANEOUS LEISHMANIASIS: A SYSTEMATIC REVIEW OF TOPICAL APPLICATION OF PEPPER AND ALLIUM

Anjola Ogunsina[1], Ruwandi Kariyawasam[2], Olamide Egbewumi[1], Sonia Igboanugo[1], Shveta Bhasker[1], Shareese Clarke[1], Paul Dunn[1], Avinash N. Mukkala[1], David Harris[1], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada*

New World Cutaneous Leishmaniasis (NWCL) is a neglected parasitic disease caused by members of the genus *Leishmania* primarily identified in Central and South America. Better drugs are urgently needed given the toxicity, expense and accessibility limits of first-line treatment options. Plant-based compounds with potential anti-leishmanial effects found in and around local endemic communities, particularly in and around the Amazon basin, present an opportunity to overcome the aforementioned therapeutic challenges, and many such interventions are supported by anecdotal evidence of efficacy. We aim to synthesize existing evidence around available ethnopharmaceuticals to promote drug discovery for the prevention and treatment of NWCL. PubMed (NCBI), Medline (OVID), Embase (OVID), Web of Science (BioSIS) and LILACS (VHL) were searched for from inception to July 26, 2018 using combinations of the search terms "cutaneous leishmaniasis" and "ethnopharmaceuticals". Iterative inclusion and exclusion of search terms was employed to maximize relevant article extraction. For the systematic review, we included molecular, mechanistic, and observational studies, case reports, case series, cohort studies, as well as clinical trials reporting therapeutic outcomes, if possible using the GRADE approach. A total of 13667 abstracts were retrieved, after which 7566 duplicates were removed. Of the remaining abstracts, 550 abstracts were included in the full text review, of which 176 (32%) abstracts highlighted New World species; 116 (66.0%), 33 (18.7%), and 27 (15.3%) abstracts pertained to *L. amazonensis*, members of *Viannia* subgenus, and other New World species, respectively. Of all the abstracts included in the full text review, 25 (4.5%) and 6 (1.1%) were identified for *Piper* spp. "Pepper" and *Allium spp.* "Garlic", respectively. Synthesizing the current evidence surrounding ethnopharmaceuticals for the treatment of NWCL may contribute to drug discovery pipelines and potentially lead to novel therapeutics, particularly those targeting the *Viannia* complex, where patients often develop more severe clinical manifestations.

1844

AN UPDATE ON THE ROLE OF WOUND CARE IN THE MANAGEMENT OF OLD WORLD CUTANEOUS LEISHMANIASIS

David Harris[1], Ruwandi Kariyawasam[2], Avinash N. Mukkala[1], Christian Lecce[1], Evan Belsky[1], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Old world cutaneous leishmaniasis (OWCL) typically presents as one or several chronic, infiltrative lesions on exposed parts of the body, and is treated pharmacologically to accelerate cure, reduce scarring, and to prevent parasite dissemination or relapse. Limited data support the role of local wound care for the management of OWCL, though the scope of such benefit and to which patient populations wound care should be applied remains undetermined due to the absence of synthesized data on the subject. We aim to synthesize the literature around the role of wound care in the management of OWCL to inform treatment guidelines and evidence-based therapeutic strategies. Medline (Ovid), Embase (Ovid), and PubMed (NCBI) were searched from inception to February 2019 without language restriction using combinations of the search terms "leishmania*" and "wound care". The GRADE approach will be used to assess quality of studies reporting specific wound care interventions. 626 articles were identified with the initial search. After screening titles and

abstracts, 226 articles were selected for final review. 50 publications were specific for OWCL, 5 publications discussed wound care in both OWCL, and New World Cutaneous Leishmaniasis, and 58 publications were review articles. Study characteristics including number of participants, wound care strategy/ intervention (debridement and removal of crusts, occlusive dressings, cream/ointment containing silver, washing, topical antimicrobials), outcomes (cure, time to reepithelilization, induration reduction, scar formation-quality and cosmesis, safety/tolereability, costs, feasibility/accessibility), study location, and species identification, will be extracted from all eligible studies and analyzed. We will systematically map the literature and synthesize the current state of knowledge and topical wound-oriented management practices in OWCL in order to inform optimal adjunctive clinical approaches and guidelines. We will also identify knowledge gaps and potential prospective research questions to fill them.

1845

A SYSTEMATIC REVIEW OF WOUND CARE IN THE MANAGEMENT OF NEW WORLD CUTANEOUS LEISHMANIASIS

Ruwandi Kariyawasam[1], David Harris[2], Christian Lecce[2], Avinash N. Mukkala[2], Evan Belsky[2], Andrea K. Boggild[2]

Despite the recent advances in drug research, finding a safe, effective, and easy to use chemotherapy for Human African Trypanosomiasis (HAT) remains a challenging task. This condition underlines the urgent necessity for the development of new drugs for the treatment of HAT. We previously identified the anti-trypanosome activities of three novel tetracyclic iridoids; ML-2-3, Molucidin and ML-F52, isolated from *Morinda lucida* with IC_{50} values of 3.75μM, 1.27μM and 0.43μM, respectively. Immunohistochemistry (IHC) study showed that the compounds significantly suppressed the expression of PFR-2, which proceeded to the events of cell cycle alteration and apoptosis induction. Scanning Electron Microscopy revealed the severe phenotype of the flagella detached from the body of the parasite. Here we present a phenotypic characterization of ML-F52 treated trypanosomes in detail with analyzing the expression levels of Flagellum Attachment Zone (FAZ) filament proteins, Coiled-coil 2-domain containing protein (CC2D) and Flagella Attachment Zone protein 1 (FAZ-1) by IHC and Western blot assays. Immunohistochemistry study showed that ML-F52 significantly suppressed the expression of CC2D after 12 hours of post treatment whilst FAZ-1 did not show any significant suppression. After 24 hours of post treatment, cell length and FAZ length decreased with the emergence of cell containing detached flagella as compared to the control. Also, ML-F52 caused multinucleated phenotype and an increase in number of cells with only one or no visible kinetoplast. Western blot assay showed that CC2D expression was reduced more than approximately 60% by 12 hours post treatment and approximately 80% by 24 hours post treatment. Our findings suggested that ML-F52 might significantly inhibit the development and function of the flagellum.

1847

VISCERAL LEISHMANIASIS ELISA TESTING: EVALUATION OF SERIAL SERUM SAMPLES REVEALS AN UNANTICIPATED FINDING

Naomi E. Aronson[1], Nancy Koles[1], Saule Nurmukhambetova[1], Rupal Mody[2], Edgie Mark Co[3], Dutchabong Shaw[1], Robert DeFraites[1], Ines Lakhal-Naouar[1]

[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*William Beaumont Army Medical Center, El Paso, TX, United States,* [3]*Walter Reed National Military Medical Center, Bethesda, MD, United States*

Serologic testing for visceral leishmaniasis (VL) includes ELISA and immunochromatographic testing (ICT) methods. Generally antibody responses are reported to wane with time. 200 Iraq-deployed, healthy US servicemembers were enrolled in an asymptomatic VL surveillance study 2015-17 and ELISA testing of current, pre and post deployment sera was conducted. Their prior banked samples were requested from the Department of Defense Serum Repository; timepoints included entry to military service (accession), before deployment and upon return from Iraq. Serologic testing included a soluble *Leishmania* antigen-based ELISA using 1:400 sera dilution with positive ELISA results confirmed using a *Leishmania* Western Blot (WB, LDBios, France). Additionally, post Iraq and enrollment sera were tested with rk39 ICT (Kalazar Detect, Inbios WA). Enrollment sera from seven subjects tested positive on ELISA (3.5%) with one WB confirmed; there were no reactive rK39 serologies. Post-deployment sera tested ELISA positive in 55 subjects (27.5%), 48%

confirmed by positive WB. One subject post-deployment had a positive rK39 serology. Accession sera tested 147/200 ELISA positive (73.5%) and 63/200 (31.5%) pre-deployment sera were positive. An exploratory study of 10 persons who never traveled to Iraq or Afghanistan but had received influenza vaccination within past 3 months found 30% were seropositive on *Leishmania* ELISA testing. As expected, post-deployment serologic anti-*Leishmania* responses were identified in more subjects than currently. However, 73.5% and 31.5% ELISA positive results at accession and prior to Iraq deployment respectively were unexpected. Both groups received influenza vaccination proximate to blood draw and this may have impacted our serologic results.

1848

IN VITRO ANTI-LEISHMANIAL ACTIVITY OF UNRIPE LIME OIL AGAINST *LEISHMANIA MAJOR*

Elvis Suatey Lomotey[1], Godwin Kwakye-Nuako[2], Christian Kweku Adokoh[2], Joan Amoanab[2]

[1]*Noguchi Memorial Institute for Medical Research, Legon-Accra, Ghana,* [2]*University of Cape Coast, Cape Coast, Ghana*

The paradigm shift from chemotherapy to natural products to treat various diseases caused by bacteria, fungi, and protozoa, such as Leishmaniasis has led to the exploration of potential products from plant species, extracts and their main active compounds. This study sought to determine the anti-*Leishmania* activity of unripe lime oil extract on the promastigotes of *L. major*. Employing cell viability assay and trypan blue exclusion method, this research has analyzed and evaluated the *in vitro* inhibitory activity of unripe essential lime oil extract from *Citrus aurantifolia* of the Rutaceae family and its major active constituents, germacrene, against the growth and viability of *L. major.* The unripe lime oil extract showed significant activity against promastigote form of *L. major*, with IC_{50} of 2.76 μg/ml compared to amphotericin B with IC_{50} of 2.45 μg/ml after 72 hours. However, after 6 hours, the IC_{50} of the essential oil was 0.05 μg/ml indicating a substantial activity of the essential oil. Significant morphological alterations and disrupted membrane were observed in the promastigotes. The activity against promastigotes of *L. major* hints unripe lime oil extract as a potential new therapeutic agent against cutaneous leishmaniasis.

1849

USE OF IMAGE PROCESSING FOR A MHEALTH BASED APPROACH TO SCREEN CUTANEOUS LEISHMANIASIS LESIONS IN REMOTE AREAS

Hermali Silva[1], Shahirah Shaik[2], Kalaivani Chellappan[2], **Nadira D. Karunaweera**[1]

[1]*Faculty of Medicine, University of Colombo, Colombo* [8]*, Sri Lanka,* [2]*Faculty of Engineering and Built Environment, Universiti Kebangsaan Malaysia, Bangi, Selangor, Malaysia*

mHealth infrastructure excites the healthcare industry in establishing remote screening and monitoring that is expected to meet the demands and needs of public health sector in developing countries. Leishmaniasis is an epidemic challenge affecting mostly the poor populations living in remote areas of over 80 countries across Asia, East Africa, South America, and the Mediterranean region. Among different clinical types of leishmaniasis, cutaneous leishmaniasis has higher potential to be successfully treated if patients can be identified by effective screening and monitoring. Clinical observation of skin lesions is a commonly used approach in cutaneous leishmaniasis diagnosis where facilities and expertise for confirmatory testing is not available. In the past, images captured from mobile cameras have been used for further processing in establishing the ulcer grading but the results are yet to meet the clinical decision making requirements. The researchers are in a desperate need to establish a more prominent remote image capturing approach due to the mobility limitation and medical practitioners availability in most of the prevalent areas. Establishing a prominent remote imaging solution in producing clinical applicable images will assist in more a more reliable decision making. In this study image processing technique was adapted to process the mobile captured JPEG images. The images were resized to 256x256 pixel resolution and grayscale conversion was done to standardize the variation of images. The standardized images were enhanced by using contrast stretching algorithm to identify the boundary of the lesion to be cropped. The cropped images were further processed to cluster between poor respondents and positive respondents to treatment with intralesional sodium stiboguconate injections through thresholding and contour analysis. Both the techniques resulted in a 50% accuracy in differentiating between poor respondents and respondents. In conclusion the mhealth approach assisted by imaging techniques may provide an added advantage to the remote leishmaniasis screening and treatment process.

MONITORING EFFICACY OF NIFURTIMOX IN CHILDREN WITH CHAGAS DISEASE: RESULTS OF ELISA F-29 OBTAINED IN A PHASE 3 TRIAL (CHICO)

Ulrike Grossman[1], Luis Castro[2], Juan Dib[3], Jimy Pinto Rocha[4], Teresa Ramirez[5], Guillermo Moscatelli[6], Erya Huang[7], Olivia Ding[8], Jaime Altcheh[6], on behalf of the CHICO Study Group

[1]*Bayer AG, Berlin, Germany,* [2]*Centro de Atencion e Investigacion Medica S.A, Yopal, Colombia,* [3]*Centro de Investigacion – Fundacion Hospital Universidad del Norte, Soledad – Baranquilla, Colombia,* [4]*Fundación CEADES – Plataforma de Chagas, Cochabamba, Plurinational State of Bolivia,* [5]*Centro de Enfermedad de Chagas y Patologias Regionale, Santiago del Estero, Argentina,* [6]*Hospital de Ninos Ricardo Gutierrez, Buenos Aires, Argentina,* [7]*Bayer US LLC, Whippany, NJ, United States,* [8]*Bayer Healthcare Co. Ltd, Beijing, China* [9]

A challenge in the treatment of Chagas disease, which is caused by the parasite *Trypanosoma cruzi*, is the establishment of feasible cure criteria. Currently, immunological and parasitological methods have been reported with applicability for post-treatment cure assessment. For conventional serology methods, one of the most relevant limitations is the long time required for conversion of serological responses to negative. In previous studies, *T. cruzi* flagellar calcium-binding protein F-29 was proposed as an early marker of cure in Chagas disease. In a multicenter, multinational, randomized, double-blind phase 3 clinical trial using a historical control, F-29 was analyzed to evaluate the treatment response to nifurtimox in pediatric patients with Chagas disease after 1 year post-treatment follow-up. A total of 330 children aged 0 days to 17 years were assigned at a 2:1 ratio to 60-day (n=219) or 30-day (n=111) treatment with nifurtimox. Serum samples collected before (baseline) and at 7, 30, 60, 240, and 420 days after the start of nifurtimox treatment were analyzed for F-29 in a central laboratory using an enzyme-linked immunosorbent assay (ELISA). At baseline, 214 children (64.85%) tested positive for F-29, whereas in 116 children (35.15%) no F-29 was detected. However, all children showed positive test results measured by conventional ELISA serology or direct observation of *T. cruzi* by concentration test at baseline. The proportion of children with negative F-29 at baseline was similar in both treatment groups, and the majority remained negative at subsequent evaluation time points. In children who tested positive for F-29 at baseline, 66 (30.84%) showed negative responses at 1 year after the end of nifurtimox treatment. Correlations between F-29 and other serological (conventional ELISA) or molecular (quantitative polymerase chain reaction) test results were also evaluated, taking into account the different geographical regions. The response to nifurtimox treatment as evaluated by F-29 is comparable to previous reports for benznidazole in pediatric patients with Chagas disease.

1851

DISEASE AWARENESS, CLINICAL FEATURES AND TREATMENT OUTCOME ASSOCIATED WITH CUTANEOUS LEISHMANIASIS IN ANURADHAPURA, SRI LANKA

Hasna F. Riyal[1], Nilakshi T. Samaranayake[1], Deepani Munidasa[2], Nadira D. Karunaweera[1]

[1]*Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka,* [2]*Teaching Hospital, Anuradhapura, Anuradhapura, Sri Lanka*

Cutaneous Leishmaniasis (CL) is endemic in Sri Lanka with a high incidence in North-Central Province. Efforts were made to study the patients' awareness on the disease & their compliance for treatment given at a tertiary care hospital. 116 clinically-suspect CL patients were included in the study & their clinical data collected. Disease awareness was evaluated, Patients were followed up over an year to record their status of treatment progress & outcome. 102 patients(87.93%) were parasitologically-confirmed for CL with 73 males(71.56%). 42(41.18%) were between 25-40 years & 31(30.39%) were between 41-55 years. Upper limb was the commonest(59.80%) site of lesion, while lower limbs were affected in 23(22.55%). Fifty(49.02%) of them had nodules, 37(36.27%) had ulcers among which 10 had secondary infections. 66(64.70%) of the lesions were smaller than 1.5cm. A notable number of patients(n=43 ;42.16%) tended to seek medical care after lengthy delay i.e. about 3 months after appearance of lesion.Only a small number(n=16 ; 15.69%) of patients had adequate knowledge on CL while the majority of 59(57.84%) patients were totally unaware of the disease. These patients had no idea about sandfly, the prevention methods to get rid from the bites or how important it is to get the lesion cured. Majority(n=61; 59.80%) of the patients successfully completed their course of treatment while 29(28.43%) had discontinued therapy on their own and the rest of the patients continued with the prescribed treatment. Difficulty in attending weekly clinics with lengthy waiting periods were the common complaints the patients had. Patients feeling better as per their own perception after a few doses of medications was another reason for pre-mature termination of treatment. Delay in seeking treatment after the lesion onset & the lack of disease awareness among CL patients are causes for concern. Premature discontinuation of treatment, points towards the need for better patient education and more-patient friendly therapy. A national framework is required to educate the community on the importance of early detection and continuation of treatment for better containment of CL.

1852

NEW PEDIATRIC FORMULATION ALLOWS INDIVIDUALIZED DOSING OF ORAL NIFURTIMOX FOR TREATMENT OF CHILDREN WITH CHAGAS DISEASE

Heino H. Stass[1], Ethel C. Feleder[2], Gustavo Yerino[2], Facundo Garcia-Bournisen[3], Boris Weimann[4], Jaime Altcheh[3]

[1]*Bayer AG, Wuppertal, Germany,* [2]*Pharmacokinetic Unit FP Clinical Pharma SRL, Buenos Aires, Argentina,* [3]*Servicio Parasitologia – Chagas, Hospital de Niños R. Gutierrez, Buenos Aires, Argentina,* [4]*Chrestos Concept GmbH & Co. KG, Essen, Germany*

Nifurtimox (NFX) is one of only two approved treatments for Chagas disease (CD). Pediatric use of NFX requires body weight-adjusted dosing. However, the only NFX formulation currently available (i.e. 120 mg) hinders accurate pediatric dosing, particularly for small children. We performed biopharmaceutical investigations based on pharmacokinetic (PK) evaluations in 3 groups of adult CD patients using the available 120 mg tablet and a new formulation (i.e. 30 mg): 1) adults (n=24) were fed a high-fat, high-calorie meal 30 minutes before receiving a single 120 mg tablet or 4×30 mg tablets; 2) fed adults (n=12) were administered 4×30 mg NFX either as tablets or as an aqueous slurry; 3) adults (n=35) received 4×30 mg tablets in fed or fasting (≥10 hours) states. Washout between treatments was of ≥5 days in each crossover cohort. Blood was sampled over 24 hours post-dose for PK analysis in all studies. In all cohorts, most patients were female (66.7%, 100%, 89%, respectively), and mean age was 32.8, 32.4, and 33.9 years, respectively. Bioavailability was unaffected by formulation: area under the curve from baseline to last measurable NFX concentration ($AUC_{0\text{-tlast}}$) ratio: single 120 mg tablet vs 4×30 mg tablets, 1.05 (90% CI 0.99-1.11); 4×30 mg slurry vs tablets, 0.93 (0.84-1.03). Maximum plasma concentrations (C_{max}) were similar for the two tablets (ratio 1.02 [0.89-1.16]), but slightly lower for the slurry vs tablets (0.76 [0.69-0.85]). Food increased NFX exposure by about 70%: fed vs fasting $AUC_{0\text{-tlast}}$ ratio 1.72 (1.54-1.92); C_{max} ratio 1.68 (1.50-1.87). Only mild-to-moderate NFX adverse events (headache, nausea, abdominal pain, vomiting) were observed, in a minority of patients. Together, these findings help define clear dosing instructions for NFX treatment of young patients with CD in the outpatient setting. The ability to dose in increments from 15 mg to 120 mg, with a slurry option, facilitates reliable, personalized, body weight-based dosing of NFX. Efficacy of the pediatric formulation is under evaluation in an ongoing randomized phase 3 trial in pediatric CD patients (NCT02625974). Interim data from this trial will be presented at the meeting.

1853

EVALUATING NEW REGIMENS FOR THE TREATMENT OF CHRONIC CHAGAS DISEASE: THE BENDITA TRIAL

Fabiana Barreira da Silva Rocha, Bethania Blum, Sergio Estani

Drugs for Neglected Diseases initiative, Rio de Janeiro, Brazil

The current treatment for Chagas disease (CD) has a long duration, and safety and tolerability concerns. Benznidazole (BZN), a nitro-heterocyclic drug, is administered twice daily at a dose of 5 mg/kg/day, for 60 days in adults. Data from recently trials suggest the potential for new therapeutic approaches to improve response, tolerability and reduce resistance. Bendita, a double-blind, randomized, placebo-controlled, phase 2 trial, conducted in Bolivia from 2016 to 2018, assessed efficacy and safety of different regimens of BZN as monotherapy, or in combination with E1224, a broad-spectrum antifungal triazole, in reducing and clearing parasitaemia in adults with chronic indeterminate CD. Primary efficacy endpoint was parasitological response by serial qualitative PCR at end of treatment and sustained until 6 months. 210 participants were randomized to seven groups: BZN 300mg daily for a) 8 weeks, b) 4 weeks or c) 2 weeks); d) BZN 150mg daily for 4 weeks; e) BZN 150mg daily for 4 weeks in combination with E1224 300mg weekly; f) BZN 300mg weekly for 8 weeks in combination with E1224 300mg weekly; g) matching placebos. 202 patients completed the study. Primary efficacy analysis (intention-to-treat population) showed 89.3% of sustained clearance in parasitaemia at 6 months in BZN 300mg 8 weeks and 4 weeks; 82.8% in BZN 300mg 2 weeks; 83.3% in BZN 150mg 4 weeks; 85.2% in BZN 150mg 4 weeks in combination with E1224 and, 82.8% in BZN 300mg weekly in combination with E1224, in comparison to 3.3% in the placebo. Six patients (20%) interrupted treatment in BZN 300mg 8 weeks; 1 (3.3%) in 4 weeks; none in 2 weeks; 1 (3.3%) in BZN 150mg 4 weeks; 3 (10%) in BZN 150mg 4 weeks in combination with E1224 and 4 (13.3%) in BZN 300mg weekly in combination with E1224. Most adverse events were mild to moderate, 6 patients presented serious events (SAE): 2 (6.7%) in the BZN 300mg 8 weeks; 1 (3.3%) in both 300mg 4 weeks and in BZN 150mg 4 weeks in combination with E1224; 2 (6.7%) in BZN 300mg weekly in combination with E1224. Shorter treatment with BZN sustained parasitological response, was well tolerated and may have potential as new treatment for CD.

1854

DEVELOPING TOOLS FOR THE COLLECTION AND EVALUATION OF COSTS OF HUMAN AFRICA TRYPANOSOMIASIS INTERVENTION PROGRAMS

Xia Wang-Steverding[1], Marina Antillon[2], Alex P. Shaw[3], Ron Crump[1], Ching-I Huang[1], Fabrizio Tediosi[2], Jason Madan[1], Paul Bessell[4], Kat S. Rock[1]

Gambiense human African trypanosomiasis (gHAT) is an infectious, vector-borne, parasitic disease of humans. HAT is a neglected tropical disease, and whilst targeted for elimination of transmission, there are limited data and analyses on costs of complete intervention programmes. Consequently there are relatively few economic evaluations assessing the cost-effectiveness of strategies for controlling gHAT. In order to determine and measure the costs of gHAT elimination strategies in endemic countries, the HAT Modelling and Economic Predictions for Policy (HAT MEPP) team developed the Cost Collection Tool (CCT) to collect economic data, which could be used to inform decision-making around strategies for gHAT elimination. Based on a literature review and expert knowledge the CCT was designed to collect country- and focus-specific information on unit and total costs associated with gHAT control programmes. Cost data collected include costs of diagnosis, treatment, and vector control. Additionally, the costs of running the programme itself and sensitisation activities were considered. The CCT is then completed by national gHAT control programmes before analysis of the data by the health economic team. Consequently, the CCT can contribute to the tailored allocation of scarce health resources for specific HAT *foci* to support attainment of local elimination targets and consequently the global elimination goals set by WHO.

EFFORTS AGAINST GAMBIENSE HUMAN AFRICAN TRYPANOSOMIASIS IN CHAD: A MATHEMATICAL AND ECONOMIC MODELING STUDY OF END-GAME INTERVENTIONS

Marina Antillon[1], Xia Wang-Steverding[2], Ron E. Crump[2], Ching-I Huang[2], Rian Snijders[3], Mallaye Peka[4], Severine Mbainda[4], Kat S. Rock[2], Fabrizio Tediosi[1]

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland, [2]Warwick University, Warwick, United Kingdom, [3]Institute of Tropical Medicine, Antwerp, Belgium, [4]Ministry of Health, N'Djaména, Chad*

The incidence of human African trypanosomiasis caused by the gambiense strain of *Trypanosoma brucei* (gHAT) has been on the decline since the 1990's, and it is now a disease identified for elimination of transmission by 2030. gHAT is transmitted by the tsetse fly and the disease is typically fatal if untreated. Among the locations where gHAT remains a concern is Mandoul, Chad. This is an insightful focus for the present case-study on the cost-effectiveness of interventions as the transmission dynamics have been well-characterized and elimination is within reach. No vaccine against gHAT exists and the side-effect profile of treatments precludes mass drug administration strategies, therefore prevention activities rely on identifying and treating infected individuals and complementary vector control. The approval of a novel, multiple-dose oral treatment – fexinidazole –provides an improvement over drugs that require parenteral in-hospital administration, and represents a potential game-changer for gHAT elimination. In our analysis we use a transmission dynamic model fit to epidemiological data from Mandoul to evaluate the cost-effectiveness of combinations of active screening, "enhanced" passive surveillance (expanding the number of health posts capable of screening for gHAT), and vector control activities employing tsetse targets. Our primary outcome is disability-adjusted life-years (DALYs) and costs are denominated in 2018 US$. Although the novel drug fexinidazole will cut inpatient and drug costs, interventions that include vector control provide good value-for-money (at less than $1000/DALY averted) and increase the probability of reaching the elimination target. Active screening activities present the largest cost drivers, so interventions that include vector control would allow safe scale-back of these activities, thus minimizing costs once low prevalence yields few identified cases during surveillance activities.

1856

ANTI-LEISHMANIAL ACTIVITIES OF COMPUTER-DESIGNED PROTEIN DISULFIDE ISOMERASE INHIBITORS

Susie Pham[1], Peter Sedillo[1], Noureddine Ben Khalaf[2], Valeria Pittala[3], Ivy Hurwitz[1]

[1]*University of New Mexico, Albuquerque, NM, United States, [2]Arabian Gulf University, Manama, Bahrain, [3]Univerity of Catania, Catania, Italy*

Leishmaniasis is a neglected tropical disease that affects 12 million people across 98 countries worldwide, with an annual incidence rate between 700,000 to 1.2 million. No vaccines are available, and current standards of treatment are inconvenient and toxic. Furthermore, there is evidence of drug resistant strains of *Leishmania spp*. Therefore, there is a demand for new treatment options. Protein disulfide isomerase plays a central role in the folding of newly synthesized proteins with further molecular chaperone and anti-chaperone activities. *Leishmania major* PDI (*Lm*PDI) is expressed and secreted by both promastigote and amastigote stages of *L. majo*r. In previous studies, deletion of *lmpdi* genes render resulting parasites non-virulent in animal models, suggesting a putative role for *Lm*PDI in parasite pathogenicity. These results further led to the hypothesis that *Lm*PDI may be a suitable target for anti-leishmania chemotherapy. A series of *Lm*PDI inhibitors, VP13, was designed utilizing a computer-aided approach. Fragment-based virtual screening allowed for better understanding of the inhibitors' modes of action on *Lm*PDI. In this work, the anti-leishmanial activities of the VP13 series of PDI inhibitors were investigated. In these assays, the cytotoxicities of the VP13 compounds were tested against *L. major* promastigotes and monocyte-derived macrophages (MDM). Specifically, VP13/74, VP13/83, VP13/98, and VP13/103 at 40uM effectively inhibited growth of *L. major* without significant MDM cytotoxicity. In preliminary experiments, the abilities of the four compounds to clear infection were tested by exposing 40uM of each compound to *L. major*-infected MDM. Following 48-hrs of treatment, there were significant decreases in the numbers of parasites per cell when compared to controls. The ability of the four VP13 compounds to clear *L. major* infections in a dose dependent manner are being investigated. Further, the ability of this class of *Lm*PDI inhibitors to minimize metacyclic *L. major* infection of MDM are in progress.

1857

DETERMINATION OF A MURINE MODEL TO EVALUATE NEW THERAPIES IN THE CHRONIC PHASE OF *TRYPANOSOMA CRUZI* H1 INFECTION ACCORDING TO ITS CARDIAC ELECTRICAL FUNCTION

Bárbara Carolina Arias Argáez[1], Xenia López Blanco[1], Landy Pech Pisté[1], Paulina Haro[2], Eric Dumonteil[3], Miguel Rosado Vallado[1]

[1]*Laboratorio de Parasitología, Centro de Investigaciones Regionales Dr. Hideyo Noguchi, Universidad Autónoma de Yucatán, Mérida, Mexico, [2]CONACYT-Centro de Investigaciones Regionales Dr. Hideyo Noguchi, Universidad Autónoma de Yucatán, Mérida, Mexico, [3]Department of Tropical Medicine, School of Public Health and Tropical Medicine, and Vector-Borne and Infectious Disease Research Center, Tulane University, New Orleans, LA, United States*

Chagas disease (CD), presents two clinical phases. In the acute phase, patients present a high parasitemia with nonspecific febrile illness. The disease progresses to a long-lasting indeterminate chronic phase that is characterized by low parasitemia and lack of any clinical, radiographic, or electrocardiographic abnormalities. Then, about 30% of patients progress to a heart pathology, which is the most serious consequence of CD. To evaluate effective therapies for CD, there is a need for an animal model that can display symptoms of cardiac pathology analogous to those found in humans. Thus, we aimed to define the murine model that better characterize the chronic phase of infection. Since during the course of CD, electrocardiographic alterations are usually the first clinical evidence of disease progression, we evaluated the development of cardiomyopathy through electrocardiographic studies in order to define the early and late chronic phase of infection. Thirteen BALB/c mice and thirteen ICR

mice were infected with 500 blood form trypomastigotes of *T. cruzi* H1. Electrocardiographic studies were performed every 35 days until 210 days post-infection (dpi) using a non-invasive equipment for conscious mice (ECGenie electrocardiograph). A total of 20-25 signals were recorded and analyzed using e-MOUSE software. ICR mice presented electrical alterations before the end of the acute phase (50 dpi); therefore, it was not possible to identify the early chronic phase. On the other hand, BALB/c mice had not only high survival (100%) in comparison with ICR mice (54.5%), but also had electrocardiographic abnormalities only at chronic phase. Cardiac abnormalities found include decreased heart rate and longer RR, QTc, QRS, ST, PR and PQ intervals. We conclude that at 70 dpi BALB/c mice were in the early chronic phase, since no parasites and electrical abnormalities were registered. While the onset of the late chronic phase starting at 105 dpi, as the first electrical abnormalities were recorded. Thus, the BALB/c strain is an appropriate murine model to evaluate therapeutic strategies in the different stages of the chronic phase of *T. cruzi* H1 infection.

1858

BURDEN OF *ANGIOSTRONGYLUS CANTONENSIS* LARVAE IN JUVENILE *PARMARION MARTENSI*

William L. Gosnell, Randi Rollins, Kenton Kramer, Jourdan Posner, Robert Cowie

University of Hawaíi at Manoa, Honolulu, HI, United States

Angiostrongylus cantonensis, the rat lungworm, is a parasitic nematode that is transmitted between rats and mollusks (slugs or snails). Humans and other animals such as dogs may become infected by ingestion of *A. cantonensis* infected slugs or snails. Human angiostrongyliasis presents as an eosinophilic meningitis/meningoencephalitis and has been reported globally. Documented cases of human angiostrongyliasis in Hawaíi and other Pacific islands have been reported since the early 1960's but over the past 10 years there appears to have been an increase in cases for Hawaíi as a whole but particularly for the Big Island of Hawaíi and Maui County. Epidemiological studies have shown that human angiostrongyliasis is commonly acquired via individual and cultural food practices of purposefully consuming raw or partially cooked snails. However, for the majority of recent cases in Hawaíi the route of infection with *A. cantonensis* has remained unknown, although assumed to have been the result of inadvertent ingestion of *A. cantonensis* infected slugs or snails. Among the different species of mollusks in Hawaíi that participate in this parasite's lifecycle one recent invasive species, *Parmarion martensi*, sometimes referred to as a semi-slug, has been reported to have a particularly high prevalence of natural infection with *A. cantonesis*. These findings are important, since Hawaíi and other regions of the world are experiencing conditions that are portentous for the rapid dispersal of this zoonosis and the likely spread and increased abundance of the invasive *P. martensi* and other well-known intermediate molluscan hosts of *A. cantonensis*. Therefore, because of the importance attributed to gastropods in the transmission of *A. cantonensis*, studies of the parasite-host interaction have been conducted as part of a strategy to develop measures to control snails and slugs and consequently lessen the risk of human angiostrongyliasis in Hawaíi.

1859

IDENTIFYING THE ROLE OF THE DIFFERENT RESERVOIR HOSTS OF ZOONOTIC SCHISTOSOMIASIS IN WEST AFRICA

Elsa Leger[1], Stefano Catalano[1], Anna M. Borlase[1], Cheikh B. Fall[2], Samba D. Diop[3], Bonnie L. Webster[4], David Rollinson[4], Nicolas D. Diouf[5], Khalilou Bâ[6], Mariama Sene[5], Joanne P. Webster[1]

Schistosomiasis is a neglected tropical disease caused by *Schistosoma* parasitic worms, which inflicts a significant burden on human and animal populations, particularly across sub-Saharan Africa. Anthropogenic land-use changes affect the distribution and availability of suitable definitive and intermediate hosts, increasing opportunities for hybridization between human and animal schistosomes with subsequent zoonotic transmission. This can have a substantial impact on the dynamics and distribution of schistosomiasis, with further challenges and constraints for effective control. Our aim was to elucidate the role of different definitive hosts as reservoirs of zoonotic *Schistosoma* single species and hybrids in a region of northern Senegal subject to important anthropogenic change. Extensive and systematic parasite sampling from human, livestock, and rodent definitive hosts, combined with snail intermediate hosts, were performed over three years across key transmission sites in northern Senegal. Multi-locus molecular analyses of all *Schistosoma* isolates, followed by Maximum Likelihood (ML) and Bayesian Inference (BI), were used to infer phylogenetic and transmission dynamics between the circulating zoonotic *Schistosoma* species/hybrids and their hosts. Molecular analyses confirmed the presence of widespread viable hybridization within and between *Schistosoma* species of humans and animals. Phylogenetic analyses indicated shared transmission of zoonotic *Schistosoma* species and hybrids between humans and animals (both wild and domestic), providing unique insights into the role of different host species in maintaining transmission. Our study emphasizes the need for a One Health multi-host framework for schistosomiasis control in both people and animals living in high zoonotic transmission zones of sub-Saharan Africa.

1860

LOW RISK PERCEPTION AROUND HANDLING OF LIVING AND DEAD ANIMALS POSES BARRIERS TO ZOONOTIC DISEASE PREVENTION AND PREPAREDNESS IN COTE D'IVOIRE

Danielle Naugle[1], Natalie Tibbels[1], Abdul Dosso[2], William Benié[2], Walter Kra[3], Corinne Fordham[1], Mieko McKay[2], Valère Konan[4], Jeanne Brou[5], Jocelyne Nebre[5], Adaman Kouadio[4], Zandra Andre[6], Diarra Kamara[2], Stella Babalola[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Johns Hopkins University, Abidjan, Côte D'Ivoire,* [3]*Alassane Ouattara University, Bouaké, Côte D'Ivoire,* [4]*Department of Veterinarian Services Ministry of Animal Resources and Fisheries, Abidjan, Côte D'Ivoire,* [5]*National Institute of Public Hygiene, Abidjan, Côte D'Ivoire,* [6]*U.S. Agency for International Development, Abidjan, Côte D'Ivoire*

Partner-supported government preparedness efforts during the 2014 Ebola outbreak helped prevent the incursion of the epidemic into Cote d'Ivoire (CdI); however, gaps remain in knowledge of transmission and appropriate prevention measures to limit the spread of zoonotic diseases. Public health actors in CdI have identified five priority zoonotic disease groups - rabies, mycobacteria, bacterial and parasitic diseases, viral hemorrhagic fevers, and respiratory zoonoses - to target for risk communication and social and behavior change (SBC) interventions. We conducted a qualitative study to understand the determinants of risk and prevention behaviors related to the five priority zoonoses across four sites in CdI through 32 focus groups, 32 individual interviews, 20 observations and 20 community maps with members of the general population and handlers of livestock and poultry. The interviews were recorded, transcribed, coded and analyzed. The data suggest that low knowledge of zoonoses and low perceived risk influence the limited adoption of hygienic or other protective measures by the Ivorian population. There is a general lack of understanding of animal to human disease transmission due to generations of co-habitation with animals, feelings of fondness towards animals, and a lack of first-hand experience with the transmission of zoonoses. Animal handlers and the general public perceive little risk in handling animals and potentially contaminated meat. This results in many risky behaviors, including direct human contact with sick or dead animals, the handling of animal and by-

products without protection, failure to sterilize hands, utensils or surfaces, and the consumption of sick animals. In addition, risk perception, as in the case of Ebola, appears short-lived; once the crisis passed, so did the perception of risk and the practice of related prevention behaviors like hand-washing. SBC programs must raise awareness of zoonotic risks to promote more favorable prevention practices. A key challenge will be creating awareness of the potential for risk and the need for sustained prevention in times where there is no ongoing crisis.

1861

CONCEPTUALIZING CHICKFLOWS IN MAPUTO, MOZAMBIQUE: HIGH-RISK BEHAVIORS AND PATHWAYS FOR CHILDHOOD EXPOSURE TO CHICKEN FECES

Frederica Lamar, Matthew C. Freeman, Karen Levy

Emory University, Atlanta, GA, United States

The risk of exposure to animal feces is unquantified yet likely contributes largely to the global burden of diarrheal disease in children. Studies assessing the impact of water, sanitation, and hygiene (WASH)- related exposures have focused predominantly on infrastructure and associated behaviors along the traditional F-diagram, with less emphasis on exposure to animal sourced pathogens. Poultry is a major reservoir for *Campylobacter* and non-typhoidal *Salmonella* (NTS), two of the top four global causes of the global burden of diarrhea. Poultry production in sub-Saharan Africa is encouraged for economic gain and nutrition, yet the risks associated with zoonotic pathogens may offset the benefits. To understand opportunities for childhood exposure from production to market to consumption in Maputo, Mozambique, we performed formative research to understand and map the chicken value chain - the ChickFlows approach. We conducted key informant interviews to identify potential high- risk behaviors and pathways that expose children to chicken feces. Our preliminary assessment included direct and indirect interactions between children and chickens/chicken products, WASH indicators, biosecurity measures, and waste management. We identified three high-risk settings: 1) live, informal markets, 2) small- scale, backyard farms, and 3) households. Children may also be exposed to chicken feces via the application of chicken litter to produce as fertilizer. Biosecurity measures were minimal to nonexistent across all settings. Adherence to disinfection periods between broiler flocks, antibiotic schedules, and microbial standards was variable and not regulated or enforced. Improved understanding of this complex network of high-risk behaviors and pathways can provide guidance on which locations within and upstream of the household should be prioritized to mitigate exposures. Collaboration with the agriculture sector and assessing risks within the formal and informal food systems may suggest innovative WASH interventions that could limit exposure to zoonotic infection.

1862

PATTERNS AND RISK FACTORS FOR ANTIBIOTIC RESISTANCE AMONG COAGULASE-POSITIVE *STAPHYLOCOCCUS* (CPS) ISOLATED FROM DOGS AND CATS THAT RESIDE WITH A PATIENT RECENTLY DIAGNOSED WITH METHICILLIN-RESISTANT *STAPHYLOCOCCUS AUREUS* SKIN OR SOFT-TISSUE INFECTION

Cusi Ferradas[1], Caitlin Cotter[2], Jonathan Shahbazian[2], Sally Ann Iverson[2], Patrick Baron[2], Ana Misic[3], Amy M. Brazil[2], Irving Nachamkin[3], Jacqueline M. Ferguson[2], Ebbing Lautenbach[3], Daniel O. Morris[4], Andrés G. Lescano[1], Meghan F. Davis[2]

[1]*School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States,* [3]*School of Medicine, University of Pennsylvania, Philadelphia, PA, United States,* [4]*School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA, United States*

Companion animals may be important in the maintenance of methicillin-resistant (MR) and multidrug resistant (MDR) staphylococci in the household. Although risk factors for carriage of staphylococci in veterinary hospital settings have been evaluated, community-acquired staphylococci have not received the same attention. This study is part of a nested sub-study to a randomized controlled trial on methicillin-resistant *S. aureus* (MRSA) decolonization treatment. The objective of this study was to examine the patterns of and risk factors for antibiotic resistance among *S. aureus* (*n*=30), *S. pseudintermedius (n*=24) and other species of coagulase-positive *Staphylococcus* (CPS) *(n*=56) isolated from dogs and cats whose owners were recently diagnosed with MRSA skin or soft-tissue infection. A single isolate per pet was selected based on most likely MRSA phenotype and tested for antibiotic susceptibility against 11 drugs using Kirby Bauer disk diffusion. We used binomial logistic regression to identify risk factors for antibiotic resistance and evaluated the potential for bacterial species to modify associations between putative risk factors and antibiotic resistance outcomes. More than 50% of the *S. pseudintermedius* and more than 20% of other CPS isolates were sensitive to all classes of antibiotics tested, while only 4% of *S. aureus* isolates were susceptible to all classes of antibiotics tested. In addition, more than 8% of. *S. aureus* and more than 10% of CPS isolates were resistant to five or more classes of antibiotics. In a bivariate analysis, the association between a number of factors including: neuter status, use of topical antibiotics, use of clindamycin by the owner or the pet, contact with animals outside the house, and evidence of unwanted pests in the household and antibiotic resistance was modified by bacterial species. In conclusion, *S. aureus* isolates were more likely to be MDR compared to *S. pseudintermedius*. Furthermore, the results suggest that drivers of antibiotic resistance in household staphylococci may vary by bacterial species, which could have implications for intervention strategies.

1863

CHICKEN OWNERSHIP IS NOT ASSOCIATED WITH *CAMPYLOBACTER* INFECTION OR ANEMIA AMONG CHILDREN 6 TO 59 MONTHS OLD IN THE GREATER ACCRA REGION, GHANA

Nathalie J. Lambrecht[1], Dave Bridges[1], Bright Adu[2], Mark L. Wilson[1], Andrew D. Jones[1]

[1]*University of Michigan, Ann Arbor, MI, United States,* [2]*Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Ghana*

Household chicken ownership in low-income countries may increase exposure of young children to enteric pathogens such as *Campylobacter*. In these settings, anemia may develop from such enteric infections through inflammatory mechanisms. In this study, we aimed to determine the association between household chicken ownership and anemia among young children in Ghana and evaluate the potential role of inflammation due to bacterial infection in mediating this association. We randomly sampled 484 children aged 6 to 59 months from 18 communities in the Greater Accra Region. Surveys assessed household ownership of livestock species and household sociodemographic characteristics. Blood samples were analyzed for hemoglobin, serum ferritin (SF), serum transferrin receptor (sTfR), α-1-acid glycoprotein (AGP), and C-reactive protein (CRP). Among a subsample of 264 children, DNA extracted from stool samples was analyzed for *Campylobacter* spp. using the cadF gene by quantitative polymerase chain reaction. Among this subsample, 45.8% of children were anemic (Hb<11.0g/dL) and 17.1% were positive for *Campylobacter* infection (cadF>10^3 copies/gram of stool). In multiple regression models adjusting for child age and sex, household sociodemographic characteristics, and village cluster, household chicken ownership was associated neither with *Campylobacter* infection (OR (95% CI): 1.2 (0.6, 2.6)) nor anemia (0.8 (0.5, 1.3)) in children. In adjusted models, *Campylobacter* infection was marginally associated (p<0.1) with iron deficiency (high sTfR: 1.9 (0.9, 3.8); low SF: 1.9 (0.9, 3.9)) but was not associated with anemia (1.1 (0.6, 1.9). Elevated AGP (AGP>1g/L), indicative of chronic inflammation, was higher among children with *Campylobacter* infection (51.2% vs. 35.2%, p<0.05). In conclusion, we did not find evidence to suggest that *Campylobacter* infection in children

is associated with household chicken ownership. Although *Campylobacter* infection was not associated with child anemia, infection may contribute to iron deficiency among children due to inflammation.

1864

CHARACTERIZING ANTIBIOTIC RESISTOMES IN HUMANS AND DOMESTIC ANIMALS FROM RURAL AND URBAN BANGLADESH

Jenna Swarthout[1], Erica R. Fuhrmeister[2], Angela R. Harris[3], Emily S. Gurley[4], Syed M. Satter[5], Alexandria B. Boehm[6], Amy J. Pickering[1]

[1]*Tufts University, Medford, MA, United States,* [2]*University of California Berkeley, Berkeley, CA, United States,* [3]*North Carolina State University, Raleigh, NC, United States,* [4]*Johns Hopkins University, Baltimore, MD, United States,* [5]*International Centre for Diarrhoeal Disease Research, Dhaka, Bangladesh,* [6]*Stanford University, Stanford, CA, United States*

Antibiotic resistance is a global public health concern, and animals are known reservoirs of resistant bacteria. Antibiotic use as prophylaxis and growth promotion is common in animal husbandry, and resistance development in animal gut microbiomes and exchange with humans has been shown in high-income countries and intensive farming environments. Data on community-acquired drug-resistant infections in low- and middle-income countries, however, are sparse. Widespread antibiotic misuse and insufficient water treatment, sanitation and hygiene practices exacerbate the risk of environmental contamination with resistant bacteria, particularly in urban areas where humans often cohabitate with domestic animals. Our primary objective is to assess whether humans and animals share resistance profiles in Bangladesh and whether there is a stronger correlation between resistomes in urban compared to rural settings. We collected human, goat and chicken fecal samples from one rural and one urban community in Bangladesh to create four fecal composites (pooling five individual fecal samples) for each species within each community. We completed long-read sequencing of all composites with the Oxford Nanopore MinION. Sequence data from composites of each sample type, defined by species and community, were pooled for further analysis. Minimap2 was used to align reads to antibiotic resistance gene (ARG) sequences in the ResFinder database, and Centrifuge was used to assign taxonomic classifications, referencing NCBI's RefSeq database. The sequencing yielded, on average, 9.9 million reads per sample type, with an average length of 1734 bp. Preliminary results show relative ARG abundance (normalized by Gbp) is greater in urban compared to rural samples, across all fecal hosts. Findings will be presented on ARGs circulating among humans and animals in Bangladesh, and long reads will enable identification of pathogenic bacteria carrying particular ARGs. Our findings will contribute to understanding the potential for zoonotic exchange of ARGs, which is necessary to inform antibiotic stewardship strategies in medical and veterinary practices.

1865

DETERMINING THE PRESENCE OF AN ANIMAL RESERVOIR FOR GAMBIAN HAT VIA MATHEMATICAL MODELLING

Ron E. Crump[1], Ching-I Huang[1], Erick M. Miaka[2], Matt J. Keeling[1], Kat S. Rock[1]

[1]*The University of Warwick, Coventry, United Kingdom,* [2]*Programme National de Lutte contre la Trypanosomiase Humaine Africaine, Kinshasa, Democratic Republic of the Congo*

Gambiense human African trypanosomiasis (gHAT) is a disease of humans caused by the parasite *Trypanosoma brucei gambiense* which is transmitted via tsetse. Unlike the closely-related zoonotic disease Rhodesiense HAT, which has a transmission cycle including humans and animals, gHAT is often considered to be anthroponotic despite evidence that animals can be infected. The existence, and importance of an animal reservoir for gHAT is unclear. In this study we explore the transmission dynamics of gHAT in humans, using models with and without an animal reservoir. The models are fitted to human case incidence data recorded at the health zone level across the Democratic Republic of Congo (DRC). Although the data are only on human cases of gHAT, the observed patterns over time may be better explained if an animal reservoir exists. In addition, the animal-specific reproduction numbers for gHAT at the health zone level are calculated and these allow us to postulate about the ability of any animal reservoir to sustain transmission independently of human hosts. Additionally, the impact of presence or absence of such reservoir on future infection dynamics is examined. A number of intervention strategies are considered, with future projections being made for both models. The use of vector control, via tiny targets, will be particularly valuable where an animal reservoir exists as this intervention impacts upon transmission in both human and animal populations.

1866

LAND USE AND HUMAN BEHAVIORAL RISK FACTORS FOR ZOONOTIC DISEASE EXPOSURE IN LAIKIPIA COUNTY, KENYA

Elizabeth Ashby[1], Joseph Kamau[2], James Hassell[3], Dawn Zimmerman[3], Jennifer Yu[3], Lindsey Shields[4], Suzan Murray[3]

[1]*George Mason University, Fairfax, VA, United States,* [2]*Institute of Primate Research, Nairobi, Kenya,* [3]*Smithsonian Institution, Global Health Program, Washington, DC, United States,* [4]*PATH, Washington, DC, United States*

A majority of emerging infectious diseases (EIDs) are zoonotic, highlighting human-animal interactions as a driver of spillover. Laikipia County, Kenya was selected as an area of focus in PREDICT, a global disease surveillance project, due to its human-wildlife-livestock interface. Questionnaires that assessed high-risk behaviors (animal interactions, food safety) were distributed to 327 participants among five communities in Laikipia. Behavioral trends were assessed in R via chi square analysis and LASSO regression. Communities were classified by land use as: Pastoralist (collectively owned group ranches), Commercial Ranching (CR; privately owned land), or Wildlife Conservancy (WC; herding within a private wildlife conservancy). Pastoralist communities expressed the most frequent human-animal interactions and high-risk food and water practices; a majority reported eating sick animals (98%, 55%) and sharing drinking water sources with animals (90%, 100%). The CR community was less likely to report collecting dead animals and sharing a water source when compared to pastoralists ($p < 0.01$). The two WC communities were least likely to report food-safety risk, such as eating sick animals (2%, 0%), but water sharing with animals varied (43%, 11%). LASSO regression revealed that proper management of human waste was a protective factor (OR 0.84) and ill household members were a risk factor (OR 16.68) to participant reports of illness, indicating risk for pastoral communities. Risk is most influenced by human behavior among pastoralists, and higher wildlife densities in WC communities. Livestock-wildlife land sharing is unavoidable as resource availability decreases in a changing climate, and protective human behaviors may reduce spillover. This study addresses an information gap in land use and behavioral EID risk. Effective community intervention should emphasize training for local health workers, who are liaisons between researchers and at-risk communities. Further studies should include qualitative research to develop tailored intervention strategies and assess reasons for behavior variation in land use systems. .

1867

ONE HEALTH SURVEILLANCE FOR BAT-BORNE VIRUSES AT CAVE TOURISM DESTINATIONS IN SOUTHEAST ASIA

Heather S. Davies[1], Alexis C. Garretson[2], Kathryn Hogan[1], A. Alonso Aguirre[1], Michael von Fricken[1]

[1]*George Mason University, Fairfax, VA, United States,* [2]*Brigham Young University, Provo, UT, United States*

Recreational cave tourism may pose risk of zoonotic disease transmission. Tourists to the Python Cave in Uganda contracted Marburg Haemorrhagic Fever; bats subsequently tested positive for high-identity viruses. Cave tourism is popular across Southeast Asia, a promoted activity for the 100+ million visitors to the region where, also, cave-roosting bats are deemed to be reservoirs for coronaviruses that may have been the indirect

source of SARS. While most human-bat contact events do not result in emerging infectious disease spillover, characterizing risk factors at caves with intensive human activity can inform conservation management approaches. This research proposes a cave surveillance network for monitoring bat health and virus shedding. Bat-virus-location associations were abstracted from publications (1997-2019). Spatial range data for cave-roosting bats present in the Philippines, Malaysia, Indonesia, Thailand, Cambodia, Laos, and Vietnam were used to identify areas of high diversity of potential host species. Representative show caves were selected from these areas for possible inclusion in a sentinel monitoring network, with coverage across the region. Disease emergence risk factors were compiled for sentinel caves, including visitation data, roosting ecology, population size, and proximity of bat-virus detection among present species. Surveillance planning considerations were identified, including target virus species by location, use of screening detection methods for longitudinal sampling programs, data sharing and validation measures. Viruses have been detected in nearly 200 chiropteran species in 40 genera across Southeast Asia. Location-specific risk profiles, along with longitudinal monitoring, can support One Health management to protect bat and human health, as well as sustainable cave tourism.

1868

LEPROSY CHEMOPROPHYLAXIS OF HOUSEHOLD CONTACTS: A SURVEY OF CANADIAN INFECTIOUS DISEASE AND TROPICAL MEDICINE SPECIALISTS

Carl Boodman[1], Jay Keystone[2]

[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*University of Toronto, Toronto, ON, Canada*

Leprosy is uncommon in Canada. However, immigration from leprosy endemic areas, notably India, Vietnam and the Philippines, has introduced leprosy to a Canadian context where health care practitioners have little to no knowledge of the disease. While post-exposure chemoprophylaxis (PEP) has been shown to decrease leprosy transmission, no Canadian guidelines exist to advise clinical decision-making about leprosy PEP. We characterized the practice patterns of Canadian infectious disease and tropical medicine specialists regarding the use of PEP for household contacts via an online anonymous survey. Descriptive statistics and Exact Multinomial Tests were performed. Survey response rate was 47% (20 of 43). 35% responded that PEP is needed for household contacts. 45% responded that PEP is not needed for household contacts. 25% did not know whether PEP is needed (multinomial test $P = 0.785$). 25% responded that PEP should be given to all household contacts. 62.5% responded that PEP should only be given to contacts of multibacillary cases and 25% responded that PEP should only be given to contacts that are genetically-related to the index case. For specialists who prescribe PEP, 57.14% use rifampicin, ofloxacin (levofloxacin), minocycline, 14.29% prescribe Single Dose Rifampicin, 28.57% prescribe multiple doses of rifampicin, 14.29% prescribe another unknown regimen (multinomial test $P = 0.106$). 68.42% recommend yearly screening of household contacts, while 31.58% do not (multinomial test $P = 0.167$). A striking lack of consensus defines the practices patterns of Canadian infectious disease and tropical medicine specialists regarding PEP of leprosy household contacts.

1869

MODELING THE IMPACT OF THE USE OF INFLUENZA VACCINE IN CHILDREN UNDER FIVE YEARS OF AGE ON THE CUMULATIVE CASE COUNT OF INFLUENZA IN MALI

Nancy Ortiz[1], Adama Mamby Keita[2], Flanon Coulibaly[2], Uma Onwuchekwa[2], Samba O. Sow[2], Arthur L. Reingold[1], Milagritos Tapia[3]

[1]*University of California Berkeley, Berkeley, CA, United States,* [2]*Centre pour le Développement des Vaccins-Mali, Bamako, Mali,* [3]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States*

Children under five years of age are at high risk of influenza, experiencing a disproportionate burden of influenza illness and are also at risk for severe influenza-related complications. In Mali, one of the poorest countries in the world, half of the population is under fifteen years of age. Rates of respiratory illness among children are highest in Africa, while influenza vaccination in most of Africa is rare. Understanding influenza seasonality is important for the timing of vaccination. In Mali, influenza transmission occurs in September/October and February annually. We used an SEIR compartmental model and developed ordinary differential equations to model the seasonal peaks of influenza activity in Mali to model the impact of introducing influenza vaccination in children on cumulative case count of influenza among children residing with other vulnerable populations at risk for severe influenza-related outcomes (i.e. pregnant, postpartum women and infants). We found that even nominal influenza vaccine coverage (10%) reduced the total epidemic size considerably, to nearly three-fourths of the number of cases observed in the same population without vaccination. Our analyses also demonstrated that the timing of vaccination efforts played an important role in the final epidemic size, with implementation of vaccination after the first case of influenza had appeared resulting in larger projected epidemic sizes than if vaccination had been implemented four weeks before influenza activity began. Vaccinating in late August and third week of December led to the largest projected reductions in total case counts. Our modeling analysis demonstrated that even with minimal vaccination of children, influenza vaccination cut the number of cases dramatically and that projected cumulative case counts increased with each week of delay of vaccination.

1870

SYNTHESIS AND ANTIMYCOBACTERIAL EVALUATION OF D-CYCLOSERINE ANALOGUES

Shoneeze Simone Renga, Vinayak Singh, Kelly Chibale

University of Cape Town, Cape Town, South Africa

Tuberculosis (TB) continues to be the leading cause of death from a single infectious agent worldwide and the rapid emergence of multidrug-resistant and extremely drug-resistant underpin the urgent need for novel, safe and efficacious drugs. D-Cycloserine (DCS) is an oral bacteriostatic anti-tubercular drug used for the treatment of drug-resistant TB. The antimycobacterial mechanism of action of DCS is two-fold. DCS interferes with bacterial cell-wall synthesis by competitively inhibiting the L-alanine racemase and D-alanine:D-alanine ligase enzymes. Additionally, it also inhibits other pyridoxal-phosphate dependent enzymes. Despite attractive properties, DCS displays significant toxicity at effective dosages. However, a synthetic analogue of DCS, terizidone, has been shown to have improved safety margins. The present study utilizes DCS and terizidone as a starting point for the development of a small library of antimycobacterial compounds. The structure-activity relationship is investigated in order to identify new antitubercular agents potentially able to circumvent antitubercular drug-resistance using a pro-drug approach. Herein we report the synthesis of a series of 15 monomers of DCS-based analogues of terizidone, and two hybrid analogues of DCS. These were evaluated for their antimycobacterial activity against the *Mtb* H37Rv strain. Further work is in progress to establish the mechanism of resistance/action of DCS analogues.

The availability and use of multiplexed diagnostic devices now allows for a much more comprehensive understanding of pathogens associated with disease. This devices, particularly those that detect bacterial and viral agents, are of high importance to guide treatment and prevent improper use of antibiotics. The objective of this study was to characterize the infectious causes of acute respiratory disease using a multiplex PCR system. Subjects invited to participate in the study were those who visited health care centers in Bolivia, Colombia, Honduras, Paraguay, and Peru. The inclusion criteria for participants was reporting illness for ≤5 days, fever (≥ 38°C oral, tympanic, or rectal; ≥ 37.5°C axillary) or history of fever within 24 hours of arrival to the clinic and either one or more of the following symptoms: sore throat, cough, or runny nose. Upon obtaining an informed consent, clinical and epidemiological data and a nasopharyngeal swab sample were collected. All samples were processed using the Biofire® FilmArray® respiratory panel (17 viruses, 3 bacteria) using FilmArray 2.0® equipment (BiofireDX, USA). Between July 2016 and March 2019 a total of 2,562 participants were enrolled. An infectious respiratory agent was detected in 68.9% of the samples (1766/2562), and 15.3% out of these presented with co-detection of agents (270/1766). Viruses were more frequently detected (1748/1766) than bacteria (35/1766). The top five agents identified and the average age ± SD, were: 26.6% human rhinovirus/enterovirus (HRV/ENT; 682/2060, 15.0 ± 17.2), 11% influenza A (H1N1)pdm09 (228/2060, 20.7 ± 19.4), 10% influenza B (212/2060), 8% respiratory syncytial virus (174/2060, 5.7 ± 12.8) and 7% human metapneumovirus (142/2060, 14.0 ± 21.7). Importantly, the most frequently detected pathogen (HRV/ENT) causes a self-limiting disease where treatment focuses on mitigating symptoms and bacterial infections were rare. Continued use of multiplexed diagnostic devices are warranted to better guide therapeutic treatment and for broader surveillance efforts.

1872

STREPTOCOCCUS PNEUMONIAE COLONIZATION OF THE NASOPHARYNX IN MOTHER-INFANT PAIRS: A CROSS-SECTIONAL STUDY

Dennis Gyasi Konadu[1], Kaali Seyram[1], Darby Jack[2], Abena Konadu Yawson[1], Louisa F. Iddrisu[1], Zuwera Yidana[1], Farrid Boadu[1], Felix Boakye Oppong[1], Dennis Adu-Gyasi[1], Steven Chillrud[3], David K. Dosoo[1], Patrick Kinney[4], Kwaku Poku Asante[1]

[1]*Kintampo Health Research Centre, Kintampo, Ghana,* [2]*Columbia University Mailman School of Public Health, New York, NY, United States,* [3]*Lamont-Doherty Earth Observatory at Columbia University, Palisades, NY, United States,* [4]*Boston University School of Public Health, Boston, MA, United States*

Bacterial pathogens including *Streptococcus pneumoniae* frequently colonize the nasopharynx and anterior nasal cavity in adults and children and such colonizations increase the risk of Acute Lower Respiratory Infections in children. We set up this study to determine the prevalence of *S. pneumonia*e carriage and antibiotic susceptibility using oxacillin to predict susceptibility to β-lactams in the nasopharynx of mother-infant pairs in the middle-belt of Ghana. We adopted a cross-sectional study design nested into the Ghana Randomized Air Pollution and Household Survey (GRAPHS) in the Kintampo North Municipality and Kintampo South District. The GRAPHS study sort to evaluate the effect of improved cook stove on pregnancy outcome and infant health. Demographic data of mother and infants (>2years) were collected. Nasopharyngeal swabs were obtained from 123 mother-infants pairs and cultured on blood agar plate containing gentamicin to suppress growth of other commensals. Pneumococcal isolates were identified and analyzed for antimicrobial susceptibility testing using the Kirby Bauer disc diffusion method. Prevalence of pneumococcal carriage was 23.6% (29/123) and 70.7% (87/123) among mothers and infants respectively. Maternal pneumococcal carriage was significantly associated with that of infant using chi square test (*P*-value= 0.036). Forty-two (37.2%) out of 113 *Streptococcus pneumoniae* isolates were resistant to oxacillin (Oxacillin zone ≥20 mm). Prevalence of pneumococcal carriage was high among infants in the municipality compared to their mothers. The high level of oxacillin resistance should be of concern and monitored carefully since this predict resistance to β-lactams. Further studies in molecular techniques need to be carried out to elucidate the association of maternal carriage to that of infants.

1873

ETIOLOGY OF ACUTE RESPIRATORY INFECTIONS IN CHILDREN UNDER FIVE YEARS OLD. RESULTS FROM AN ACTIVE COMMUNITY SURVEILLANCE AND PASSIVE HOSPITAL SURVEILLANCE IN LIMA, PERU

Yeny O. Tinoco[1], Candice Romero[1], Felices Vidal[1], Giselle Soto[1], Maria Silva[1], Danielle Iuliano[2], Andrea J. McCoy[1]

[1]*Naval Medical Research Unit-6, Callao, Peru,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Acute respiratory infections (ARI) constitutes a major cause of morbidity and mortality in children. Different pathogens were described to cause ARI however their contribution and role as etiological agents are not well understood. We aimed to describe the etiology of ARI among children < 5 years in two settings: (1) Severe acute respiratory illness (SARI) in a hospital setting and (2) influenza-like illness (ILI) from a community active surveillance, both in a similar geographic area and time period. To perform the testing we used Taqman® Array Cards, which detect 30 respiratory pathogens. From February 2014—March 2015, we sampled 258 nasopharyngeal & oropharyngeal (OP) swabs from SARI children. SARI was defined as fever ≥38 C with cough & disease onset in last 10 days prior to hospitalization. Simultaneously, we collected 150 OP swabs from children with ILI in community cohort; ILI was defined as sudden onset of fever ≥38 C, with cough and/or rhinorrhea and/ or nasal congestion. Of the SARI-patients, 95% (244) had at least one agent detected. Respiratory Syncytial Virus was the most common (33%, 13) followed by *Streptococcus pneumonia* ([STPN], 15%, 6) and Human metapneumovirus (13%, 5). Among ILI patients, 91% (136) had at least one agent detected. Among those with a detected, pathogen, 31% (12) were *Moraxella catarrhalis* (MOCA) and 13% (5) for each Influenza A&B, *Haemophilus influenza* (Hib) and STPN. Identification of only one pathogen was not common among SARI patients (16%, 39) or ILI patients (29%, 39); however, there were statistically significantly more single detections among ILI patients compared with SARI patients (p= 0.003). Hib, MOCA and STPN were the most common co-detections (46% -62%) found among ILI and SARI children. Importantly, we found that *Legionella* species, Human coronavirus NL63 and 229E, *Bordetella pertussis*, *Pseudomonas aeruginosa*, Influenza C, Group A streptococcus and *Pneumocystis jiroveci* were present only in SARI hospitalized children. Our results demonstrate that more than 90% of pathogens could be identified in OP swabs and pathogens detected were different between community and hospitalized settings.

1874

EVALUATING COMMUNITY KNOWLEDGE OF TUBERCULOSIS AND ISONIAZID PREVENTATIVE THERAPY IN RURAL SOUTH AFRICA

Carlo Foppiano Palacios[1], Tejaswi Kompala[2], Anthony Moll[3], Laurie Andrews[4], Sheela Shenoi[4]

[1]*University of Maryland Medical Center, Baltimore, MD, United States,* [2]*University of California San Francisco, San Francisco, CA, United States,* [3]*Church of Scotland Hospital, Tugela Ferry, South Africa,* [4]*Yale University School of Medicine, New Haven, CT, United States*

Isoniazid preventive therapy (IPT) is an efficacious strategy to reduce TB incidence among HIV infected patients, though implementation has been suboptimal. The World Health Organization (WHO) recently expanded the categories of individuals who would benefit from IPT. We sought to understand community members' knowledge of TB, HIV, and IPT to inform future implementation efforts. In rural South Africa, individuals were interviewed anonymously at community events as part of a larger HIV and TB screening project. Four different domains of TB knowledge were evaluated: causes, transmission, treatment and prevention of TB, and IPT. An overall TB knowledge assessment was composed of the sum of the TB causes, transmission, and treatment and prevention scores. Among 104 respondents, the mean age was 35±9.3 years, 65% were female, and 26% completed secondary school. Overall, respondents had poor knowledge about the causes (mean 61±27%) and transmission (mean 46±21%), and good knowledge of the treatment and prevention (mean 88±18%) of TB. Respondents scored lowest on TB transmission, significantly lower than TB causes ($p=0.003$) and treatment and prevention ($p<0.0001$). Years of formal education was significantly associated with total TB knowledge ($p<0.0001$). Specifically, increased education was associated with improved knowledge of TB causes ($p<0.0001$) and transmission ($p<0.0001$), but not with knowledge of treatment and prevention of TB ($p=0.19$) or of IPT ($p=0.82$). Greater knowledge of IPT was associated with higher scores of total knowledge of TB ($p=0.01$) and specifically TB treatment and prevention ($p<0.0001$), with wanting to take care of family ($p<0.0001$), and wanting to keep their family healthy from TB ($p<0.0001$). Community members in rural South Africa had poor TB knowledge, particularly about transmission of TB. Formal education was associated with knowledge of TB. Knowledge of IPT was associated with the motivation to care for family. To implement the new WHO TB prevention guidelines, resource limited settings will require improved public health and individual-level education about tuberculosis.

1875

IMPROVED LATENT TUBERCULOSIS THERAPY COMPLETION RATES IN REFUGEE PATIENTS THROUGH USE OF A CLINICAL PHARMACIST

Kimberly L. Carter[1], Joseph Garland[2]

[1]*University of Pennsylvania, Philadelphia, PA, United States,* [2]*Alpert Medical School, Brown University, RI, United States*

On average 700 refugees resettle in Philadelphia annually and approximately 30% have LTBI upon arrival. In 2012, a pharmacist-run LTBI clinic was established at Penn Center for Primary Care (PCPC) in attempts to improve LTBI completion rates among newly arriving refugees. Prior to 2012, LTBI completion rates at PCPC were less than 20%. A structured model was developed to efficiently track patients and ensure successful completion occurred. All patients diagnosed with LTBI during the study period were referred to the clinical pharmacist for treatment initiation and follow-up. At a minimum, the pharmacist met with each patient at treatment initiation, 5-week follow-up, and treatment completion. Monthly follow-up was arranged for patients with adherence issues. The pharmacist provided extensive counseling and monitored adherence through pill counts and refill dates. Interventions made by the pharmacist were recorded. Patients who successfully completed their treatment according to CDC standards were provided with a Completion of Therapy Certificate. Completion reports were forwarded to the Philadelphia Department of Health for tracking and statistical purposes. Between 2012 and 2017, 150 (21.8%) of 687 refugee patients screened were diagnosed with LTBI and 132 patients were referred to the pharmacist-run LTBI clinic to initiate treatment. Of those referred, 94% successfully completed LTBI treatment within the designated period and 40% required an intervention from the pharmacist to remain adherent. Interestingly, refugees from Africa tended to need more interventions compared to refugees from other countries. LTBI completion rates more than tripled after implementation of a pharmacist-run LTBI clinic. This successful model indicates that incorporating clinical pharmacists into interdisciplinary healthcare teams can enhance medication adherence and completion rates within refugee populations, leading to improved public health outcomes.

1876

INFLUENZA AND OTHER RESPIRATORY PATHOGENS AMONG HOSPITALIZED CHILDREN IN PUBLIC HOSPITALS IN PERU

Candice Romero[1], Giselle Soto[1], Isabel Bazan[2], Wilma Casanova[3], Hugo Rodriguez[3], Roger Hernandez[4], Yeny Tinoco[1], Andrea Mc Coy[1]

[1]*U.S. Naval Medical Research Unit - 6, Lima, Peru,* [2]*U.S. Naval Medical Research Unit - 6, Iquitos - Loreto, Peru,* [3]*Universidad Nacional de la Amazonia Peruana, Iquitos- Loreto, Peru,* [4]*Hospital Nacional Cayetano Heredia, Lima, Peru*

Acute Lower Respiratory Infections (ALRI) are a major cause of morbidity and mortality in young children. Influenza is an important etiology (from 9% to 17%) of Severe Acute Respiratory Infection (SARI) among hospitalized children while respiratory syncytial virus (RSV) is also responsible for substantial global morbidity and mortality. Estimates of the burden of respiratory virus associated hospitalization from low-middle income country are limited and most SARI cases in public hospitals are diagnosed syndromically. From August 2017 to July 2018 we conducted a passive surveillance of SARI among children under 5 years in 3 public hospitals in Peru. SARI case definition followed that of WHO. A nasopharyngeal swab was collected and tested by FilmArray Respiratory Panel, which detects 20 pathogens (17 virus and 3 bacteria). We enrolled 489 SARI hospitalized children and detected at least one pathogen in 84% (411/489) of the sample tested. We identified RSV in 34% (165/489), Human Rhinovirus/Enterovirus in 28% (135/489), Human Metapneumovirus in 13% (65/489), Influenza in 8% (37/489), Parainfluenza virus in 7% (33/489), Coronavirus in 6% (28/489), *Bordetella pertusis* in 2% (8/489) and Adenovirus in 1% (4/489). From April to June 2018, we observed an increase detection of RSV with an average of 72% of positivity. These results provide a description of the etiology of SARI among children less than 5 years. Collectively, the data generated from continued analysis may help to guide clinical judgment of physician in public hospitals and plan mitigation strategies and vaccination policies.

1877

TOWARD A NANOTECHNOLOGY-BASED RAPID DIAGNOSTIC TEST FOR TUBERCULOSIS SCREENING IN LOW-RESOURCE SETTINGS

Ruben Magni, Marissa Howard, Sara Sharif, Sameen Yusuf, Lance Liotta, Alessandra Luchini

George Mason University, Manassas, VA, United States

While Tuberculosis (TB) affects more than 10 million people worldwide, nearly 40% of the patients are never diagnosed or treated. TB drug resistance is also a severe world-wide issue negatively affecting treatment success rate and increasing the spread of the disease. We propose a novel nanotechnology-based integrated urine collection and rapid test platform for TB screening, which can offer high sensitivity and specificity and can be used directly in the field. We employ hydrogel nanoparticles which can selectively sequester and preserve target protein analytes from bio-fluids and enhance assay sensitivity > 100-fold. The individual donating urine for the test simply urinates in a nanoparticle-loaded collapsible collection cup, then dumps out the urine. TB derived molecules, immediately

sequestered by the nanoparticles, can be visualized by plugging a one-step self-working disposable lateral-flow immunoassay in the collection device. Alternatively, the collection device can be collapsed, sealed, stored at room temperature indefinitely or mailed to a laboratory facility for further investigation of TB markers via mass spectrometry. Detection of low-abundance TB antigens was evaluated on a set of 150 urine culture and PCR positive after nanoparticle processing and mass spectrometry analysis. Among the >100 identified proteins, we found markers of active disease as well as potential drug targets (LppX_LprAFG lipoprotein, Alanine racemase, thymidylate synthase, PadR-like family transcriptional regulator, leucyl aminopeptidase, integral membrane indolylacetylinositol arabinosyltransferase EmbB) and proteins associated with drug resistance mechanism (ABS transporter ATP-binding protein, Taurine ABC transporter permease protein, TetR family transcriptional regulator). Further sample testing and validation of the TB molecules identified will be performed in order to identify the panel of most promising markers. This information will be used to develop multiplexed lateral flow assays that can be conducted in the field, in underdeveloped global regions, for tuberculosis screening and patient management.

1878

EVALUATING THE RELATIONSHIP BETWEEN INTRODUCTION OF ACELLULAR PERTUSSIS VACCINE AND WHOOPING COUGH REEMERGENCE IN THE UNITED STATES

Jeegan U. Parikh, Miguel Reina, Ricardo Izurieta

College of Public Health, University of South Florida, Tampa, FL, United States

The incidence of *Bordetella Pertussis,* a highly contagious organism, has increased since 1996 in the United States with cyclical outbreaks in 2010, 2012 and 2014. This increased incidence coincides with the switch from the whole-cell pertussis vaccine (DTwP) to acellular pertussis vaccine (DTaP), which was partially implemented in 1992 and completely implemented in 1997. In addition, the epidemiological profile of cases has also changed in recent years, with increased incidence being observed in adolescents and vaccinated children. Pertussis cases from 1922 to 2016 was obtained from "*Nationally Notifiable Disease Surveillance System*", surveillance reports, CDC & from the WHO vaccination coverage data. A trend analysis was conducted to assess whether correlation between reported incidence and changes in vaccine policy and their implementation. There has been an increase in the number of cases due to *B. Pertussis* with changing epidemiological pattern of the disease. The number of Pertussis cases increased from 4,083 in 1992 to 17,972 in 2016 with cyclical outbreaks of 27,550 cases in 2010, 48,277 cases in 2012, 28,639 cases in 2013 and 32,971 cases in 2014.The incidence in age group of 7-10 and 11-19 increased from 1.95 and 1.99 per 100,000 cases to 14.84 and 16.31 per 100,000 cases. It is impossible to establish causation due to study limitations; however there seems to exist a temporal association between incidence and policy change/implementation. Waning immunity, which is more pronounced in DTaP (0.018 yr^{-1}) as compare to DTwP (3 x 10^{-5} yr^{-1}) and would induce susceptibility to pertussis among adolescents, selective pressure of non-vaccine bacterial strains or a combination of both factors, could explain the observed results. Further research is needed to study the immunological responses of those affected to explain disease re-emergence. Implications of pertussis vaccine policy should be considered.

1879

DEVELOPMENT OF SUSTAINABLE WATER INFRASTRUCTURE FOR SCHISTOSOMIASIS CONTROL IN ETHIOPIA

Meseret Desalegn[1], Feleke Zewge[1], Muluwork Maru[1], Laura Braun[2], Michael R. Templeton[2]

[1]*Addis Ababa University, Addis Ababa, Ethiopia,* [2]*Imperial College London, London, United Kingdom*

Schistosomiasis is a neglected tropical parasitic disease caused by several species of the genus *Schistosoma* worms affecting over 200 million people in 78 countries worldwide, with 90% of the burden currently concentrated in Africa. Many people in developing countries, including Ethiopia, do not have access to piped water and are forced to rely on untreated surface water sources for drinking, washing, and recreational activities. The repeated contact with water infested with cercariae, the human infective stage, hence increases the risk of contamination. As an additional intervention to the commonly practiced preventive and deworming chemotherapy using the drug praziquantel, provision of treated water for schistosomiasis control is considered under this study. Slow sand filtration is a sustainable option for rural water treatment because it is relatively low cost and simple to operate. This study aims to establish specific design and operational parameters for the use of slow sand filters to eliminate cerecariae from water. The filter setup consists of PVC pipes (diameter of 15.4 cm) with an endcap, plastic hose with diameter of 6 mm for water outlet, plastic diffuser and locally available river sand. The parameters chosen for optimization are grain size and depth of sand. Hence, three filters were filled with a drainage layer (15cm of gravel size 2-11.2 mm), and then a 60 cm sand layer of mixed grain size sand: 0.15-0.85 mm (filter 1), 0.425-0.6 mm sand (filter 2) and 0.15-0.425 mm sand (filter 3). Finally, a diffuser was placed 5 cm above the sand layer. Infected snails were collected from nearby endemic areas (Lake Ziway, Ethiopia) and kept in the lab under suitable condition to produce enough cercariae. Results obtained show that filters with sand depth of 60 cm reduce the number of cercariae more than 95 %. As filter depth increases, the efficiency of cercaria removal also increases. Therefore, we conclude that providing treated water with slow sand filters for various uses for rural communities can be a feasible option to control schistosomiasis.

1880

EFFECTIVITY OF WASH/MALARIA EDUCATIONAL COMMUNITY-BASED INTERVENTION IN REDUCING ANEMIA AMONG PRESCHOOL CHILDREN FROM BENGO, ANGOLA

Claudia Fançony, Ania Soares, **Miguel Brito**

CISA - Health Research Centre in Angola, Caxito, Angola

Exclusive therapeutic approaches promptly clear infections, however, in heavy contaminated environments high reinfections and incidence rates may occur limiting the sustainability of these approaches. Integrating therapeutic and preventive WASH/malaria educational strategies can simultaneously treat infections and reduce disease transmission, resulting in reduced anemia. This study, nested into a major research project investigating the efficacy of educational approaches in reducing anemia, was conducted in 2015 /2016 in CISA´s study area, located Bengo - Angola, and included 312 children randomized to the WASH/Malaria arm. Demographic, socio-economic, Water, Sanitation, Hygiene and Malaria parental practices, and parasitological and biochemical data were collected at baseline and at 12-month follow up. These moments were intercalated with 3 monthly domiciliary educational visits aiming at increasing the health literacy of caretakers and collect indicators of changed/improved behavior. T-student, McNemar Test and Chi-2 tests were used to determine variations on the primary and secondary outcomes. 202 children have completed the study. Despite that the mean hemoglobin increased levels and total anemia prevalence reduction were not statistically significant (from 11.2g/dL to 11.4g/dL, p=0.21 and from 38.6 to 33.2%, p= 0.21 respectively), a 8.4% reduction in the Iron Deficiency Anemia prevalence was observed (p=0.01). A significant increase in the prevalence of infections was observed, mainly *P. falciparum* (1.5 to 6.4%), *G.lamblia* (9.2 to 20.6%) and *A. lumbricoides* (6.1 to 26.7%). 50.5% of children's hands and 43.4% of the household's observations scored 5-6 points for the cleaning state of the nails and for the cleaning state of latrines, respectively. 81.2% of the households scored 0-1 point regarding having water in the latrine to wash hands, 53.3%, 60.1% and 78.5% were observed to have garbage, loose domestic animals or puddles in the home surroundings. Neither the reduction of IDA or the increased infection prevalence were found to be statistically associated with the educational process indicators collected here.

1881

IMPACT OF WATER, SANITATION AND HYGIENE ON COMMUNITY-LEVEL INTESTINAL PARASITES IN ETHIOPIA: THE GESHIYARO PROJECT

Anna E. Phillips[1], Kalkidan Mekete[2], Alison Ower[1], Ebba Abate[2], Julia Dunn[1], Heven Sime[2], Gemechu Tadesse[2], Roy Malcolm Anderson[1]

[1]*Imperial College, London, United Kingdom,* [2]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia*

Improving water, sanitation, and hygiene (WaSH) is increasingly seen as a key component of a sustainable soil-transmitted helminth (STH) and schistosomiasis control strategy due to their lifecycles. Current STH and schistosomiasis control strategies rely primarily on preventive chemotherapy, which is effective at killing adult worms in the human body but does not prevent re-infection after treatment. Few large-scale studies have provided WaSH facilities and quantified the relationship between WaSH, treatment and the subsequent impact on transmission of these intestinal parasites. The Geshiyaro project will test the feasibility of interrupting transmission of STH and schistosomiasis in the Wolayita zone of south-western Ethiopia. The monitoring model is quasi-experimental with three arms of interventions (i) expanded community-wide MDA plus WaSH and behaviour change communication (ii) expanded community-wide MDA only and (iii) annual school-based MDA (National STH/SCH control program). In October and November 2018, a population census was conducted collecting household and community WaSH data where individuals and households were registered using biometric fingerprint and barcoded identification cards. Scores were then constructed reflecting exposure to both STH and schistosomiasis, according to adequacy of water access, sanitation facilities and hygiene. Under the assumption that WaSH will reduce parasite transmission, the impact of WaSH was evaluated through epidemiological assessments to assess whether people with better access to WaSH were less likely to be infected. Baseline parasitological mapping was conducted in December 2018 across all age groups (pre-school-aged children (SAC), SAC, adolescents, and adults) and individual results correlated with WaSH data using the biometric and ID cards. Overall, WaSH and parasitology data were available for 11,086 individuals across 32 communities. Our findings demonstrated that improving WaSH may reduce transmission of these parasites. However, different elements of WaSH interventions appear to have different effects on specific parasites.

1882

CHLORINE TABLETS FOR EMERGENCY HOUSEHOLD WATER TREATMENT: QUALITATIVE ASSESSMENT AND DEVELOPMENT OF TABLET SELECTION GUIDELINES

Marlene Wolfe, Brittany Mitro, Mateo Galeano, Mustafa Sikder, Karin Gallandat, Daniele Lantagne

Tufts University, Medford, MA, United States

Chlorine tablets are commonly distributed in emergencies. However, confirmed use ranges widely (from 7-87%), raising concerns about effectiveness. Currently, there is no process for selecting a technically and socially acceptable tablet. We conducted a study in two phases: 1) a qualitative assessment of barriers and facilitators of tablet distribution, and 2) development and field trialing of guidelines to select tablets for distribution. In phase 1, we completed key informant interviews (KIIs) on tablet distribution in emergencies and chlorine taste and odor acceptance and rejection, and a literature review on taste and odor. In phase 2, we convened a working group to develop a process for selecting a context-appropriate chlorine tablet(s) which was then field tested in Cox's Bazar, Bangladesh. In phase 1, we found: 1) chlorine tablets are regarded as an effective and appropriate intervention in emergencies, 2) dosing confusion and taste and odor rejection are perceived as the main problems limiting effectiveness, and 3) the primary solutions suggested were social and behavioral. In phase 2, a guidance document was developed including sections on: 1) gathering key information, and 2) undertaking tablet selection. Tools are provided for assessing: water quality parameters, chlorine demand, and taste and odor acceptance. After information is gathered, tablets that maintain appropriate FCR throughout storage are pre-selected; a final choice is made after consideration of qualitative parameters such as taste and odor preferences. In a field trial in Cox's Bazar, respondents identified needing to chlorinate 10 L of water for 12 hours, and taste and odor rejection was high after 1.0 mg/L FCR. A 17 mg tablet was selected, resulting in a measured FCR of 0.6-0.8 mg/L for 24 hrs. We recommend that social and behavioral scientists are integrated into tablet programming, more research is conducted on taste and odor rejection, and improved guidance is used to select and promote tablets. Our trial suggests that a structured process to select a context-appropriate tablet can alleviate confusion and direct the use of tablets that are context-appropriate.

1883

SMALL INTESTINE BACTERIAL OVERGROWTH IS ASSOCIATED WITH LINEAR GROWTH DELAY IN A LONGITUDINAL ANALYSIS OF BANGLADESHI CHILDREN

Jeffrey Donowitz[1], Zhen Pu[2], Ye Lin[2], Masud Alam[3], Mamun Kabir[3], Tahsin Ferdous[3], Ayesha Zerin[3], Uma Nayak[2], Jennie Z. Ma[2], Rashidul Haque[3], William A. Petri[2]

[1]*Virginia Commonwealth University, Richmond, VA, United States,* [2]*University of Virginia, Charlottesville, VA, United States,* [3]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh*

Introduction: Small intestine bacterial overgrowth (SIBO) is present in up to 30% of children living in low-income countries and has been associated with lower socioeconomic status, poor sanitation, enteric inflammation, and linear growth delays in cross-sectional studies. Methods: We conducted a birth cohort study to assess the effect of SIBO on growth and neurodevelopment. Healthy children were enrolled within the first 7 days of life and followed for two years. SIBO was measured via glucose-hydrogen breath test at 18, 52, 78, and 104 weeks. Socioeconomic and maternal data were collected at enrollment. Early life biomarkers previously associated with growth or neurodevelopmental delays were collected in the serum or stool at 18 weeks. Neurodevelopment was assessed at two years using a culturally adapted version of the Bayley Scales of Infant and Toddler Development, Third Edition (Bayley-III). Area under the hydrogen curve (AUC) was calculated and standardized for time for each glucose-hydrogen breath test and averaged for the four tests. Linear regressions with stepwise selection were performed for length-for-age Z score (LAZ) at two years, and the components of the Bayley-III (cognitive, language, and motor) as outcomes. Co-variates included average SIBO AUC, LAZ at enrollment, sex, mother's weight, maternal education, income, water treatment, improved septic, IL-4 at 18 weeks, fecal myeloperoxidase at 18 weeks, and fecal Reg 1B at 18 weeks. Results: 11.1% of children had a positive breath test (an increase in breath hydrogen > 12 ppm over their baseline) at 18 weeks. 36.4% were positive at 52 weeks, 44.3% at 78 weeks, and 34.5% at 104 weeks. SIBO AUC ranged from 3.0 to 50.0 ppm/min. A one unit increase in average SIBO AUC was associated a 0.1 SD decrease in LAZ at 2 years of age after adjusting for LAZ at enrollment, mother's weight, and maternal education. SIBO was not significantly associated with the three Bayley-III components. Conclusions: SIBO in the first two years of life is associated with linear growth delay but not neurodevelopmental outcomes in young Bangladeshi children.

EVALUATING FETCHING TIME, WATER USAGE AND DIARRHEA PREVALENCE IN RURAL PIPED WATER SYSTEMS IN SOUTHERN ZAMBIA

James Winter[1], Jennifer Davis[2]

[1]*Stanford University, Palo Alto, CA, United States,* [2]*Stanford University, Stanford, CA, United States*

Evaluating fetching time and water usage in rural piped water systems in southern Zambia NGO-led efforts to install piped water systems in rural villages is accelerating in Zambia. This project measures the benefits of

piped water systems on two villages in southern Zambia and two matched control villages in the same district. The piped water systems consist of taps located in shared or private yards of households. We conducted surveys of 150 total households and measured the concentration of fecal indicator bacteria in source and stored water and the hands of respondents. We observed the size and composition of respondents' gardens as a measure of economic utilization of water and, for a subset of respondents, we used GPS tracking devices to measure their location and walking speed every 5 seconds for 16-20 hours. We have collected two rounds of data in May and September of 2018. I will collect endline data in May and June of 2019. To date, we have measured significant decreases in time spent fetching water for men, women and girls in the household and significant increases in total water use per capita. We hypothesize that extended exposure to the piped water will significantly improve garden utilization and crop diversity. We anticipate presenting information on results from GPS tracking data to estimate path-based walk time to water sources, walking v*elocit*y, and time spent in and outside the home.

SANITATION, PATHOGEN EXPOSURE AND CHILD OUTCOMES IN ADDIS ABABA, ETHIOPIA

Leon Espira[1], Brook Gesesse[2], Kaleab Baye[2], Andrew Jones[1], Nancy G. Love[1], Joseph N. Eisenberg[1]

[1]*University of Michigan, Ann Arbor, MI, United States,* [2]*Addis Ababa University, Addis Ababa, Ethiopia*

The provision of clean water and access to sanitation is central to the outcomes set in 2015 by the Sustainable Development Goals (SDGs). The reason for the prominence of water and sanitation in the SDGs is that 2.4 billion people still lack access to basic water and sanitation facilities, placing them at higher risk of diarrheal diseases. Diarrheal diseases remain one of the leading causes of death for children under five years of age. However, current approaches to prevent diarrheal disease and chronic sequele focus primarily on increasing access to sanitation facilities and less on minimizing transmission of enteric or waterborne pathogens. Given that enteric pathogens have multiple and often interdependent transmission pathways, accurate measurement of pathogen loads and types is critical to fully understand the impact of sanitation access. We conducted a study in Addis Ababa, Ethiopia in which 712 households were surveyed across 12 informal settlements with infants aged 6-23 months. Along with data on demographic, socioeconomic, and sanitation variables, we collected 136 stool samples. Using droplet digital PCR (ddPCR) we screened the stool for 16 pathogens and conducted a genomic analysis of the stool samples to determine microbiome composition. The results of this study will enable us to quantify the direct and indirect effects of sanitation by identifying thresholds at which diarrheal risk and stool pathogen profiles change. This will provide a mechanistic understanding of how sanitation interventions work, enabling the delivery of more effective solutions.

1886

ANALYSIS OF ENVIRONMENTAL PATTERNS AND LEPROSY IN MINAS GERAIS, BRAZIL USING SPATIAL AND TEMPORAL STATISTICS

Shaiana Oliveira-Streiff[1], Uriel Kitron[2], José A. Ferreira[3], Maria A. de Faria Grossi[3], Adauto C. Pugedo[4], Maria do Carmo R. de Miranda[4], Jessica K. Fairley[5]

[1]*Emory Rollins School of Public Health, Atlanta, GA, United States,* [2]*Emory University, Atlanta, GA, United States,* [3]*Faculdade da Saude e Ecologia Humana, Vespasiano, Brazil,* [4]*Secretaria de Estado da Saúde de Minas Gerais, Belo Horizonte, Brazil,* [5]*Emory University School of Medicine, Atlanta, GA, United States*

Brazil has the second highest number of new leprosy cases reported annually with the state of Minas Gerais (MG) having pockets of highly endemic leprosy. Transmission remains only partially understood, and in addition to a respiratory route, transmission may also be related to environmental conditions. Potentially viable *Mycobacterium leprae* has been found in water, soil, and armadillos. To investigate the role of the environment on transmission of leprosy, we identified spatial clusters of cases and likely associations between leprosy incidence and environmental predictors, specifically, (1) elevation, (2) normalized difference vegetation index (NDVI), (3) temperature, and (4) precipitation through a cross-sectional study using the Brazilian Notifiable Disease Surveillance System (SINAN) data from 853 municipalities in MG from 2009 to 2013. Multivariable Poisson regression models were used to estimate the rate ratio (or incidence density ratio (IDR)) to compare incidence across municipalities. We then used spatial statistics (global autocorrelation, local indicator of spatial autocorrelation [LISA], Getis Ord Gi(d)*) to analyze clustering of leprosy cases and incidence. Overall incidence decreased from 8.76 per 100,000 in 2009 to 5.04/100,000 in 2013 with the average municipality leprosy incidence at 7.11 per 100,000 annually. The local autocorrelation analysis identified 51 high-high clusters of leprosy incidence in the northeast and west of Minas Gerais. Temperature was positively correlated with leprosy incidence (IDR=1.41, [CI: 1.37, 1.46)], p= <0.0001), while precipitation (IDR=0.96, [CI: 0.94, 0.99], p= <0.0033), NDVI (IDR= 0.94, [CI:0.92, 0.96], p= <0.0001), and elevation (IDR=0.53, [CI:0.52, 0.55], p= <0.0001) were negatively associated with leprosy incidence. The associations between leprosy and environmental predictors, especially higher temperatures, indicate that the role of the environment and geographical conditions need to be considered in the context of disease transmission and viability of *M. leprae* in the environment, especially in the era of global warming and climate change.

1887

BEHAVIORAL AND ENVIRONMENTAL RISK FACTORS ASSOCIATED WITH NEONATAL SEPSIS IN UGANDAN HEALTHCARE FACILITIES

Habib Yakubu[1], Richard Mugambe[2], Constance Bwire[2], Joanne McGriff[1], Christine Moe[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Makerere University, Kampala, Uganda*

Neonate exposure to pathogens in the healthcare facility (HCF) environment can cause healthcare associated infections including sepsis. Sepsis is responsible for 15%-20% of neonatal deaths globally and about 30%-40% occur at the time of birth. Low resource settings are disproportionally affected by the burden of neonatal deaths. In Uganda, newborn deaths constitute 38% of all infant mortality, and an estimated 31% of newborn deaths are attributed to sepsis. However, little evidence exists on behavioral and environmental risk factors for sepsis. The objective of this study is to assess environmental and behavioral risk factors associated with neonatal sepsis in labor & delivery (LD) and post-natal (PN) wards. Two public HCFs in Kampala, Uganda with contrasting water, sanitation and hygiene (WASH) conditions and infrastructure were purposively selected and classified as "good WASH" and "poor WASH" HCF. Structured and unstructured observations were conducted to understand what surfaces and equipment neonates come into contact with and the frequency of contact to inform environmental sampling and identify potential pathogen transmission pathways. An observation checklist was developed based on literature and unstructured observations within each HCF. Structured observations were subsequently conducted using the checklist for 3 hours each in the morning, afternoon and evening for 2 weeks by trained enumerators. In the PN wards, bedsheets (26%) and walls (21%) were the most frequently touched surfaces in the good WASH HCF. In the poor WASH HCF, the most frequently touched surfaces were mobile phones (10%) and delivery kits (9%). In the LD wards, fetal scopes (16%) and bedrails (13%) were the most frequently touched in the good WASH HCF whilst sink faucets (7%) and bed linings (6%) were the most frequently touched in the poor WASH HCF. This information was used to target environmental sampling to determine the pathways of exposure that may pose the greatest risk to neonates. Analysis of the sampling results in conjunction with the behaviors observed will be useful in planning evidence-based interventions in HCFs to reduce pathogen transmission.

1888

INVESTIGATING EXPOSURE TO HEAVY METALS AS A POTENTIAL ETIOLOGY OF MESOAMERICAN NEPHROPATHY, AN UNEXPLAINED EPIDEMIC KIDNEY DISEASE IN LATIN AMERICA

Rebecca S. Fischer[1], Wayne Sanderson[2], Max Costa[3], Kristy O. Murray[4]

[1]*Texas A&M University Health Science Center, College Station, TX, United States,* [2]*University of Kentucky, Lexington, KY, United States,* [3]*New York University, Environmental Medicine, Biochemistry and Molecular Pharmacology, Tuxedo, NY, United States,* [4]*Baylor College of Medicine, Tropical Medicine and Human Immunobiology, Houston, TX, United States*

Mesoamerican Nephropathy (MeN) is a medical mystery affecting working-age adults in rural agricultural communities throughout the Pacific lowlands of Central America. Premature renal mortality there tops 50,000. MeN presents as an aggressive interstitial nephritis, sometimes initiated by acute kidney injury with systemic inflammation and anemia. Clinical and pathologic evidence suggests a toxic, inflammatory etiology, Several heavy metals are nephrotoxic, causing interstitial nephritis as well as disrupted immune and inflammatory processes. To measure exposure to metals and consider metal toxicity in the genesis of MeN, toenail samples were collected from 18 agriculture workers with acute MeN (median age 26.9 yrs), detected through surveillance for AKI and CKD in Nicaragua, and 36 healthy controls (median age 29.5 yrs) without history of renal impairment, recruited at health screenings from the same population. Clinical data was recorded, and nails were aseptically collected 3-6 months later. Zinc, Aluminum, Iron, Copper, Manganese. Selenium, Nickel, Cobalt, Mercury, Vanadium, Chromium, Arsenic, Lead, Cadmium, and Uranium were measured by ICPMS. Nickel (Ni) was the only exposure common to all cases but only 58% of controls ($p=0.001$), and levels were higher in cases (1.55mg/kg, 0.17-42.65; $p=0.003$). Higher levels of Ni correlated ($p<0.05$) positively with serum creatinine, leukocytosis, and neutrophilia, and inversely with hemoglobin/hematocrit and glomerular filtration rate. Clinically, Ni-exposed individuals mirrored what is observed in MeN. Clinical events in Ni toxicity can mirror what is observed during acute MeN: Ni accumulates in kidneys, causing interstitial nephritis with focal inflammatory damage at the corticomedullary junction, and leukocytosis, and anemia are common. Little is known about geogenic or anthropogenic sources of nickel and other metals posing hazards to human and animal health in this and other tropical regions. Human exposure and environmental sources should be thoroughly explored to assess its role in MeN, whether through low-level chronic exposure or acute exposure to toxic levels.

ENVIRONMENTAL CONTAMINATION WITH INTESTINAL PARASITES IN THE SOUTHERN USA

Christine C. Blackburn[1], Macey Lively[1], Catherine Flowers[2], Nicholas L. Herrera[3], Maria Jose Villar Mondragon[3], Rojelio Mejia[3]

[1]*Texas A and M, College Station, TX, United States,* [2]*Center for Rural Enterprise and Environmental Justice, Montgomery, AL, United States,* [3]*Baylor College of Medicine, Houston, TX, United States*

A growing body of evidence shows that intestinal parasites are present in the United States. Communities within the United States that lack proper infrastructure, sanitation, and health access are at risk for parasite infection. The goals of this study were to determine the prevalence of environmental contamination of intestinal parasites in the United States. Soil samples were collected from Louisiana, Mississippi, Alabama, South Carolina, and Texas. Communities were selected based on median household income, rural status, population size, the percentage of residents living in poverty, and having poor sanitation. One hundred environmental samples were collected from each study location for a total of 500 samples. Each sample contained approximately 50 grams of soil or 2 liters of wastewater, which were collected from private residences (60%) and public parks (40%). Both soil and wastewater were processed by a novel concentration and DNA extraction methods using bead beating. Multi-parallel quantitative real-time PCR (qPCR) was performed for *Ascaris lumbricoides, Ancylostoma duodenale, Necator americanus, Strongyloides stercoralis, Taenia solium, Toxocara canis/cati, Trichuris trichiura, Blastocystis* species*, Cryptosporidium* species*, Entamoeba histolytica,* and *Giardia lamblia*. Preliminary results of all five states were 25% soil/water samples were positive for *Blastocystis* species, *Entamoeba histolytica* (2.9%), *Giardia lamblia* (2.9%), and *Toxocara canis* or *cati* (7.4%). In Mississippi, there were 30% positive for *Blastocystis* species*, Toxocara cati* (20%), and *Giardia lamblia* (20%). In Alabama, there were 36.8% positive for *Blastocystis* species*, Toxocara cati* and *canis* (2.6% and 5.2%, total 7.9%), and *Entamoeba histolytica* (5.3%). These environmental studies align with previous human serology and stool findings and provide additional evidence that parasites contaminate environmental samples throughout the Southern United States. Future work will include mapping and modeling the qPCR data to location and environmental conditions to provide remote sensing analysis of predicted parasite exposure in the USA.

1890

USEFULNESS OF LATERAL FLOW ASSAYS FOR RAPID ON-SITE TESTING FOR DETECTION OF BACTERIAL, VIRAL AND TOXIN AGENTS IN ENVIRONMENTAL SAMPLES

Kodumudi S. Venkateswaran, Thomas O'Brien, Neeraja Venkateswaran

Tetracore Inc., Rockville, MD, United States

Environmental samples suspected to have biological agents with potential of harming human, animal and plant health need to be detected quickly to take timely countermeasures to reduce the deleterious effects. Such biohazardous agents can be bacteria, virus or toxins. Various methods using specific immunoreagents are used for detection of harmful biothreat agents or their components directly from the suspected environmental samples. Molecular methods for testing for nucleic acids specific to the agents are also being used for very sensitive detection of various bacterial and viral biothreat agents. Lateral flow immunoassay (LFA) using the principle of immunochromatography is a simple, low cost and rapid method for onsite testing of biothreat agents. Singleplex LFA developed for detection *Bacillus anthracis*, *Yersinia pestis*, *Francisella tularensis*, *Burkholderia mallei*, *Burkholderia pseudomallei*, ricin, abrin, staphylococcal enterotoxin B, botulinum neurotoxins and orthopox virus. These LFAs were evaluated to measure detection limit, cross reactivity and interference by environmental sample matrices. Multiplex assays for either four bacterial agents or four toxin agents were also tested and evaluated for their performance. Multiplex assay needs only fraction of sample needed compared to the volume needed for singleplex assays. LFA results can be seen visually without the need for any instruments. However, an optional field portable LFA reader has also been developed for objective visualization of the LFA result and to digitize data for easy storage and effective sharing of the results. Data will be presented summarizing all the testing done. Performance evaluation of the singleplex and multiplex assays were done using well defined inclusivity, exclusivity, near neighbor, informational and environmental organism panels for each biological agent. Assessment of LFAs were performed by statistical analysis and calculation of sensitivity, specificity and accuracy of visual results and reader results. Our study showed LFA tests as reliable tool for rapid, field portable detection of various biothreat agents.

Multi-drug resistance (MDR) threatens malaria control in Southeast Asia, underscoring the need for identification of more effective drug combinations for *Plasmodium falciparum (P.f)*. The APACT trial was launched in October 2018 in response to the growing threat that malaria may become untreatable by available drug combinations. The main objective is to assess the therapeutic efficacy of the latest approved artemisinin combination therapy, artesunate-pyronaridine (ASPY), and novel multi-drug combinations, atovaquone-proguanil+ASPY (AP+ASPY) and atovaquone-proguanil+artesunate-mefloquine (AP+ASMQ) for *P.f* malaria. The study is being conducted at 2 sites in Cambodia, where study drugs are administered by directly observed therapy, with active follow-up for up to 8 weeks, after a minimum of 3 days inpatient treatment. Volunteers are randomized, open-label, to one of three treatment arms, ASPY, AP+ASPY, and AP+ASMQ. The target sample size is 252. Among the first 24 volunteers who completed 6-8 weeks follow up to date, we have observed 100% adequate clinical parasitological response rate against *P.f* malaria among all 3 treatment arms. Four volunteers (17%) had *Plasmodium vivax* recurrence consistent with the high rate of suspected liver stage *P.vivax* co-infections in this area. Observed transient mild liver enzyme elevations are consistent with prior reports for the study drugs and none of the volunteers met Hy's Law criteria for liver toxicity. No serious adverse events were reported for the drug combinations thus far. Tolerability was high with 100% volunteers reporting that combination treatments were simple to take. Most volunteers (86%) reported that taking multiple tablets was acceptable and 76% were comfortable with taking the same drug regimen the next time they have malaria, while 19% preferred a shorter treatment course. Information on the efficacy, safety and tolerability, and community perceptions about the new drug combinations tested in this trial will be forthcoming, in our effort to respond to the growing threat in Southeast Asia of multidrug resistant malaria that may become untreatable with standard drug regimens.

1892

PYRONARIDINE-ARTESUNATE (PYRAMAX®) FOR THE TREATMENT OF *PLASMODIUM VIVAX* AND DIHYDROARTEMISININ-PIPERAQUINE RESISTANT FALCIPARUM MALARIA IN DAK NONG PROVINCE IN THE HIGHLANDS OF VIETNAM

Nguyen D. Manh[1], Marina Chavchich[2], Nguyen N. San[3], Huynh H. Quang[4], Nguyen V. Thanh[1], Nguyen T. Van[1], Geoffrey W. Birrell[2], Kimberly A. Edgel[5], Nicholas W. Martin[5], Michael D. Edstein[2]

Dihydroartemisinin-piperaquine (DHA-PPQ), Vietnam's first-line treatment drug for uncomplicated *Plasmodium falciparum,* is failing in Binh Phuoc province at an alarming rate of >50%. To contain the spread of DHA-PPQ resistance from south into central Vietnam, there is an urgent need to assess the efficacy of other artemisinin combination therapies. In the present study, we evaluated the therapeutic efficacy of pyronaridine-artesunate (Pyramax®) in treating uncomplicated *P. falciparum* and *P. vivax* malaria in Cu Jut and Dak Mil districts of Dak Nong province. In this open label study, a total of 93 patients have been recruited so far. Of these, 36 participants (39%) were infected with *P. falciparum,* 56 (60%) with *P. vivax* and 1 (1%) had a mixed *P. falciparum/P. vivax* infection. All patients received a 3-day course of Pyramax® with a 42-day follow-up period. Patients with vivax malaria or a mixed infection were treated with primaquine (0.25 mg/kg daily for 14 days). The study is ongoing with a sample size target of 50 evaluable cases for both falciparum and vivax malaria. Pyramax® rapidly cleared vivax malaria within 24 hours of starting treatment in 93% (52/56) of participants, with only 2% (1 in 48 evaluable patients) having a recurrence of malaria. However, of the 35 patients with *P. falciparum,* who completed Pyramax® treatment, 40% (14/35) had parasites present on day 3. Recrudescent parasites were detected in 2 participants on days 31 and 39 after starting treatment. Notably, 94% (33/35) of clinical isolates carried C580Y mutation in the *Kelch 13* gene, implicated in artemisinin resistance. Furthermore, 63% (22/35) of the isolates had multiple copies of plasmepsins 2-3 and 86% (30/35) of parasites had mutation E415G in the *Exo415* gene, both are molecular markers for PPQ resistance. *In vitro* evaluation of *P. falciparum* isolates revealed reduced susceptibility to DHA and PPQ by ring stage survival and PPQ survival assays in 3 out of 5 isolates tested so far, including that from a participant who experienced a recrudescence. The role of Pyramax® for treatment of vivax and artemisinin-piperaquine resistant falciparum malaria in Vietnam will be discussed.

The rapid and aggressive spread of artemisinin-resistant *Plasmodium falciparum* carrying the *kelch13* C580Y mutation is a growing threat to malaria elimination in Southeast Asia, but there is no evidence of their spread to other regions. We conducted cross-sectional surveys in 2016 and 2017 at two clinics in Wewak, Papua New Guinea (PNG) where, among 239 genotyped clinical samples, we identified three infections caused by C580Y mutants. Ring-stage survival assays (RSA) for artemisinin showed that these mutants exhibited the highest survival rate (6.8%) among the parasites surveyed. Analyses of *kelch13* flanking regions by microsatellite markers did not suggest a common origin of mutants in PNG and Cambodia. Comparative analyses based on deep sequencing data from 389 clinical samples from PNG, Papua Indonesia and Western Cambodia supported an independent origin of the Wewak C580Y mutation, showing that the mutants possess several distinctive genetic features. Identity by descent (IBD) showed that multiple portions of the mutants' genomes share a common origin with parasites found in Papua Indonesia. Within these shared haplotypes, a number of alleles differentiate Wewak C580Y mutants from other PNG samples, including several within genes previously associated with drug resistance, such as *mdr1*, *ferredoxin*, *atg18* and *pnp*. These findings suggest that *P. falciparum* lineages are spreading across New Guinea, gradually acquiring a complex ensemble of variants, including *kelch13* C580Y, which may affect their drug sensitivity. This worrying development reinforces the need for increased genetic surveillance of the evolving parasite populations on the island, to contain the spread of resistance.

1894

A LONG-LASTING PROTECTION OF CHEMOPROPHYLAXIS IMPLANT AGAINST MALARIAL INFECTION

Hongxing Wang[1], Shuanghong Liang[1], Yinzhou Fan[1], Zhenping Huang[2], Xiaoyi Huang[1], Siting Zhao[3], Li Qin[2], Xiaoping Chen[3]

[1]*Bluelight Pharmatech. Co. LTD, Guangzhou, China,* [2]*CAS Lamvac Biotech Co., Guangzhou, China,* [3]*Guangzhou GIBH CAS, Guangzhou, China*

Liver stage *Plasmodium* control is essential to decrease new malaria infection and to prevent relapsing malaria. One of the approaches is to parenterally administer an implant to provide a slow and long-acting release of antimalarial agent for causal prophylaxis. In the recent study, we have created a series of formulations for intramuscular or subcutaneous depot of decoquinate (DQ) by using hot melt extrusion (HME) or co-solvency methods. Compared to classic co-solvency method using synthetic polymers typical for controlled drug release, the implants prepared by the HME technique at doses of DQ 50-200 mg/kg provide much better efficacy in preventing *Plasmodium* infection in mice. A single intramuscular injection of an optimized, HME made, cholesterol-based composition, provides a DQ release at a slow rate and maintains a sufficient level of the desired drug active in mice for preventing *Plasmodium* infection for up to 4 months with a single inoculation of *Plasmodium* parasite sporozoites (50,000) by tail vein. To reflect real-world endemic exposure, repeated inoculations of the same number of parasites (sporozoites) were given each time at an interval of each month to mice with initial one time intramuscular injection of the implant. Surprisingly in this case, the mice remained free of the disease for as long as 7 months. The implants made by HME also demonstrated far better protection for the same period of time than the simple physical mixing of the same formulation components, indicating that the mechanic process and the validated parameters for the HME play an important role in making desired implants. Our innovative, safe and controlled-released intramuscular implants utilize naturally available materials that are easily metabolized or degraded or excreted by animals or humans. The implant in the aqueous suspension (saline) for intramuscular placement results in limited pain or distress and the surgical removal rarely is needed. Furthermore, the HME process is environmentally clean, and the product quality and the massive production can also be quarantined. More studies using primates will be needed to further evaluate the implants.

1895

TRIPLE ARTEMISININ COMBINATION THERAPIES: A NEW PARADIGM FOR THE TREATMENT OF MALARIA?

Chanaki Amaratunga[1], Mehul Dhorda[1], Rob van der Pluijm[1], Joel Tarning[1], Ricardo Aguas[1], Maciej F. Boni[2], Phaik Yeong Cheah[1], Paulina Tindana[3], Freek de Haan[4], Wouter Boon[4], Ellen H. Moors[4], Katherine Plewes[1], Rupam Tripura[1], Nick P. Day[1], Nick J. White[1], Arjen M. Dondorp[1]

Artemisinin Combination Therapies (ACT) are first-line treatments for malaria. The Tracking Resistance to Artemisinin Collaboration (TRAC) mapped the spread of artemisinin resistance in 10 countries in Asia (7) and Africa (3) and described artemisinin resistance in Southeast Asia (SEA). In Cambodia, Thailand, and Vietnam, artemisinin resistance is compounded by partner drug resistance resulting in dihydroartemisinin-piperaquine (DHA-PPQ) treatment failure rates of >60%. The TRACII study conducted in 8 countries in Asia (7) and Africa (1) explored the concept of combining an ACT with a third antimalarial drug and assessed efficacy, safety and tolerability of two Triple ACT (TACT): DHA-PPQ+mefloquine (DHA-PPQ+MQ) and artemether-lumefantrine+amodiaquine (AL+AQ). Both TACT were safe, well tolerated and highly efficacious against ACT-resistant parasites in SEA. TACT could become standard treatment for malaria worldwide as part of strategies to prevent or delay emergence of drug resistant malaria in regions outside of SEA. A new project titled Development of Triple Artemisinin Combination Therapies (DeTACT) will take a multifaceted approach to assess potential benefits and disadvantages of deploying TACT as first-line antimalarial treatments. In a randomized, controlled, non-inferiority trial, we will compare safety, tolerability and efficacy of dose-optimised artesunate-PPQ+MQ and AL+AQ TACT in blistered co-packages versus ACT+placebo in 13 countries in Asia (5) and Africa (8). The potential of TACT to delay emergence and spread of antimalarial resistance and cost-effectiveness of deploying TACT will be assessed through mathematical modelling. We will address ethical issues such as balancing individual and community disadvantages versus public benefits of introducing TACT in regions where ACT are still efficacious. Market and demand related issues involved in development, implementation and deployment of TACT will be studied to guide future introduction in the global marketplace and communicated to stakeholders via a strategic engagement plan. Development of the project and progress to date will be presented.

1896

EFFECT OF ARTEMISININ ON THE SEXUAL CONVERSION OF *PLASMODIUM FALCIPARUM*

Harvie P. Portugaliza[1], Anna Rosanas-Urgell[2], Alfred Cortés[1]

[1]*ISGlobal - University of Barcelona, Barcelona, Spain,* [2]*Institute of Tropical Medicine, Antwerp, Belgium*

Artemisinin-based combination therapies (ACTs) remain the frontline treatment for malaria. However, ACTs show limited efficacy against the transmissible sexual forms of the parasite, termed gametocytes, and some reports suggest that drug treatment increases sexual conversion rates. Here we combined *in vitro* and field-based approaches to determine whether artemisinin affects the production of *Plasmodium falciparum* sexual stages. We collected serial blood samples from 32 Vietnamese patients with uncomplicated falciparum malaria enrolled in an artemisinin clinical

trial, and quantified by RT-qPCR the relative transcript levels of the sexual commitment marker *pfap2-g* and other early gametocyte markers every 12h from day 0 to 3. We observed activation of *pfap2-g* (>2 fold) after the first dose in almost 50% of the patients, which was associated with subsequent bloodstream release of mature gametocytes (*pfs25* transcripts peak) on day 7 or 14 (p=0.026). Additionally, fast-clearing infections were associated with *pfap2-g* induction (OR 8.9; 95%CI 1.3-63; p=0.029). We also tested the effect of artemisinin on *pfap2-g* transcript levels and gametocyte production in culture-adapted parasites. For a robust and accurate measurement of sexual conversion, we first generated reporter lines using the CRISPR/Cas9 system and optimized the determination of sexual conversion rates by flow cytometry and immunofluorescence assays. We found that exposure to sublethal concentrations of artemisinin at the trophozoite stage induces sexual conversion and enhances gametocytemia. This was observed under basal conditions, but not under metabolic conditions that stimulate sexual conversion (choline depletion). Altogether, our results show that artemisinin can stimulate gametocyte production. The *in vitro* observation that this can occur at sublethal concentrations implies that substandard drugs, underdosing, and noncompliance with the ACT regimen pose risks to malaria control efforts. We also show that *pfap2-g* can serve as an early marker to test the immediate effect of drugs on gametocyte production both *in vitro* and in epidemiological studies.

1897

TRANSMISSION-BLOCKING EFFECTS OF PRIMAQUINE AND METHYLENE BLUE SUGGEST *PLASMODIUM FALCIPARUM* GAMETOCYTE STERILIZATION RATHER THAN EFFECTS ON SEX RATIO

John Bradley[1], Harouna Soumare[2], Michelle Roh[3], Michael Delves[1], Chris Drakeley[1], Thomas S. Churcher[4], Alassane Dicko[2], Roly Gosling[3], Teun Bousema[5]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*University of Science, Techniques and Technologies, Bamako, Mali,* [3]*University of California, San Francisco, CA, United States,* [4]*Imperial College, London, United Kingdom,* [5]*Radboud University, Nijmegen, Netherlands*

Artemisinins clear asexual parasites but have limited efficacy against gametocytes and do not fully prevent transmission. Primaquine (PQ) and methylene blue (MB) are potent gametocytocidal drugs which reduce transmission. Their effects on transmission may occur before reducing gametocyte density, but it is not clear why. Preferential clearance of male or female gametocytes, resulting in a non-viable sex ratio, is a possible explanation; an alternative is a gametocyte sterilizing effect. We examine these hypotheses using a mathematical model of transmission and data from a clinical trial. The trial in Mali compared sulfadoxine-pyrimethamine plus amodiaquine (SP/AQ) and dihydroartemisinin-piperaquine (DP) as non-gametocytocidal drugs with SP/AQ plus a single dose of 0·25 mg/kg PQ (SP/AQ-PQ), and DP plus 15 mg/kg MB per day for 3 days (DP-MB) in asymptomatic microscopy positive gametocyte carriers. Infectivity was assessed by membrane feeding assay on days 2 and 7. Density of male and female gametocytes was determined by quantitative reverse transcription polymerase chain reaction. On day 2, male and female densities were similar in those on PQ or MB compared to those who took only non-gametocidal drugs. However, despite considerable overlap of gametocyte densities, infectivity after DP-MB (0%) and SP/AQ-PQ (5%) was lower than those on non-gametocytocidal drugs (61%). A model showed strong evidence of lower infectivity at a given male and female density for those on PQ or MB (p<0.001). On day 7, infectivity after DP-MB (0%) and SP/AQ-PQ (0%) was again lower than for those on non-gametocytocidal drugs (53%). Although gametocyte densities were lower, a model suggested that infectivity on PQ or MB was lower than for those on non-gametocital drugs, controlling for density (p=0.044). We have confirmed that PQ and MB reduce infectivity before reducing gametocyte density. Our results show this is due to a sterilizing effect on gametocytes, rather than an effect on sex ratio. The major implication is that studies examining transmission blocking effects of drugs and potentially vaccines require mosquito feeding assays to measure infectivity.

1898

THE ROLE OF IP-10 AND CXCR3 SIGNALING IN ZIKA VIRUS PROSTATE CELL INFECTION

Jennifer L.S. Clinton, Linda L. Tran, Megan B. Vogt, David R. Rowley, Jason T. Kimata, Rebecca R. Rico-Hesse

Baylor College of Medicine, Houston, TX, United States

Zika virus (ZIKV) is a *Flavivirus* recently classified as a sexually-transmitted infection. Infectious ZIKV has been detected in semen up to 69 days after infection, suggesting ZIKV may persist in the male urogenital tract. Flaviviruses can develop persistent infections by inducing specific cytokines and hijacking the interferon (IFN) pathway. However, little is known about which persistence mechanisms mediate long-term sexual transmission. Previously, we demonstrated that ZIKV infects prostate stromal mesenchymal stem cells (MSCs) and immortalized prostate epithelial cells, and that ZIKV preferentially replicates in MSCs. To understand the mechanisms of this differential replication, we measured induction of 41 cytokines during ZIKV infection in three prostate cell types by multiplex immunoassay. To determine which cytokines might augment replication, we treated prostate cells with individual upregulated cytokines before or after infection and measured their effects by qRT-PCR. Our results show that three ZIKV isolates elicit distinct cytokine profiles in infected MSCs and epithelial cells, with an increase in IFNs and IFN-related proteins (IP-10). We focused on the effects of IP-10 due to its association with severe infection with other sexually transmitted viruses. IP-10 treatment of prostate epithelial cells three hours before or 24 hours after ZIKV infection significantly reduced levels of viral RNA compared to untreated infected cells, without altering viability. While IP-10 inhibits replication in epithelial cells, it only slows viral replication kinetics in MSCs. We see similar effects on viral replication when prostate cells are pretreated with an agonist for the IP-10 receptor, CXCR3. This suggests that ZIKV preferentially replicates in prostate stem cells, where it may evade the suppressive effects of IP-10/CXCR3 signaling. IP-10 has been associated with promoting (HIV, Herpes) or protecting (Coronavirus, EBV) against viral infection in different cell types, but the mechanism of action of CXCR3 has not been elucidated. This could lead to treatment options for ZIKV infection, to block sexual transmission.

1899

A POINT MUTATION BETWEEN ASIAN AND AFRICAN LINEAGE ZIKA VIRUSES AUGMENTS MOSQUITO INFECTIVITY

Emily Gallichotte[1], Reyes Murrieta[1], Eric Bellis[1], Thomas Friedrich[2], Matthew Aliota[3], Gregory Ebel[1]

[1]*Colorado State University, Fort Collins, CO, United States,* [2]*University of Wisconsin, Madison, WI, United States,* [3]*University of Minnesota, St Paul, MN, United States*

Zika virus (ZIKV) was isolated in 1947 where it caused only rare infections in humans. After it was introduced to Brazil in 2015, it caused a massive outbreak with over one million infections. It is unclear if changes to the virus lead to the increased incidence of infection. Phylogenetic analyses found that ZIKV contains two lineages, African and Asian. Within Asian-lineage ZIKVs, a serine-to-asparagine substitution emerged at residue 139 of the viral polyprotein. This substitution sits within the pr domain of the prM protein, which covers the fusion-loop of the virion and prevents fusion upon viral egress. Cellular furin cleaves pr from other structural proteins, and upon virus release, cleaved pr dissociates from M. Using a Puerto Rican Asian-lineage ZIKV infectious clone, we generated a reversion mutant (N139S) to test the role of both lineage amino acids at this position. We found that the N139S mutation does not alter furin cleavage or virus maturity. The mutant virus has similar thermostabilities as the parental Asian-lineage virus at multiple temperatures, and replicates similarly in mammalian cells. In the *Aedes aegypti* cell line Aag2, we found that the mutant virus replicates to higher titers than the wild-type virus. Additionally, the N139S mutant is more infectious in *Ae. aegypti* mosquitoes, with higher infection and dissemination rates, and higher viral RNA levels, compared to the wild-type virus. These results are consistent

with multiple studies showing African-lineage ZIKVs are more infectious in mosquitoes compared with Asian-lineage viruses. These results suggest the recent emergence and maintenance of asparagine at position 139 in Asian-lineage ZIKVs was not a result of selection for improved fitness in mosquitoes. Therefore, the substitution may result in a fitness advantage within the mammalian host, or alter the virus-vector interaction through another mechanism that results in enhanced fitness. Additional experimentation in mosquito cells and directly in mosquitoes will test differences in virus binding, entry, interactions with host-receptors, and kinetics of infection to more fully elucidate the role of N139S.

1900

STRUCTURAL PROTEINS (PRME) DICTATE SEXUAL TRANSMISSION POTENTIAL OF ZIKV AND SPONV IN AN *IN VITRO* EPIDIDYMAL EPITHELIAL CELL MODEL

Erin M. McDonald, Aaron C. Brault

Centers for Disease Control and Prevention, Fort Collins, CO, United States

The Spondweni serogroup of flaviviruses (*Flaviviridae*, *Flavivirus*) is comprised of Spondweni virus (SPONV) and Zika virus (ZIKV), which are mosquito-borne viruses capable of eliciting human disease. Following the emergence of ZIKV in the Americas, sexual transmission in humans has been documented. Furthermore, ZIKV can be transmitted *in utero*, leading to ZIKV congenital syndrome. While SPONV is not known to elicit similar congenital pathogenic effects or to be transmitted sexually and has been limited to an African geographic distribution, it was recently identified in mosquitoes in Haiti. In C57bl/6 mice treated with monoclonal antibody to Ifnar1, SPONV can infect the placenta and fetal tissues, including the fetal head, but it does not cause fetal resorption or microcephaly. In interferon α/β and –γ receptor knockout (AG129) mice, ZIKV replication in epididymal epithelial cells in the male reproductive tract (MRT) has been correlated with ZIKV sexual transmission potential. Although SPONV infects the AG129 MRT, including epididymal epithelial cells, it is not found in high frequency in ejaculates from these mice. To determine if viral structural elements mediate sexual transmission potential differences observed between ZIKV and SPONV, the prME genes from Spondweni SAAr94 were cloned into a cDNA clone of ZIKV. In a murine epididymal epithelial cell line, neither SPONV nor the SPONVprME/ZIKV chimeric virus demonstrated viral growth. In contrast, ZIKV was able to infect and replicate in these cells. The sexual transmission potential and *in utero* transmission potential of SPONV prME chimeric virus will be further assessed in a sensitive immunodeficient (AG129) murine model.

Did Zika virus (ZIKV) recently acquire the ability to cause congenital Zika syndrome (CZS)? Data from vertical transmission studies in mice suggest that ZIKVs of both African and Asian lineages have the capacity to cause placental damage and fetal harm. We used an established macaque model of ZIKV, which more closely mimics the reproductive physiology of humans, to further evaluate the pathogenic potential of African-lineage Zika viruses. Three pregnant Indian rhesus macaques were subcutaneously inoculated with 10^4 PFU of ZIKV DAK AR 41524, a low-passage ZIKV isolate from Senegal, during mid-first trimester (approximately gestation day 45; full term is 165±10 days). ZIKV infection was monitored via plasma viremia and fetal growth by weekly ultrasounds. The first pregnancy progressed to term without adverse events and no gross fetal abnormalities were noted at delivery at gestation day 155. A comprehensive set of ~50 maternal and fetal tissue samples were collected at delivery. Sensitive QRT-PCR detected no ZIKV RNA in fetal tissues, but vRNA was detected in a variety of maternal-fetal interface tissues, with particularly high levels found in fetal membranes and the chorionic plate. Histopathological analysis showed acute inflammation in both maternal and fetal tissues, consistent with viral infection—in 7 of 16 placental cotyledons there were microscopic acute, non-hemorrhagic, placental infarctions with neutrophils and histiocytes. Data collected thus far support the hypothesis that ZIKV of both African and Asian lineage pose a threat to women and their fetuses. The other two pregnancies are in progress and we expect a full data set later this summer.

1902

IMPACT OF ZIKA VIRUS EVOLUTION ON MOSQUITO TRANSMISSION DURING THE EPIDEMIC IN THE AMERICAS

Chantal B. Vogels[1], Glenn Oliveira[2], Sharada Saraf[2], Carlos Ontiveros[2], Rimjhim Agarwal[2], Raphaëlle Klitting[2], Joseph R. Fauver[1], Anderson F. Brito[1], Emma Allen[1], James Weger-Lucarelli[3], Gregory D. Ebel[4], Kristian G. Andersen[2], Nathan D. Grubaugh[1]

The rapid and often unpredictable emergence of mosquito-borne viruses such as Zika, chikungunya, and dengue presents serious challenges for public health. Mosquito-borne RNA viruses lack proofreading ability, replicate rapidly, and form large within-host populations, resulting in high evolutionary rates during transmission. Consequently, these viruses have an incredible adaptive potential which allows for continuous emergence into new territories. Previous studies have (1) shown that virus evolutionary rates increase during rapidly expanding epidemics and (2) linked adaptive potential of viruses to few specific mutations; yet, functional evolution of viruses has not been comprehensively studied during an epidemic. Here we present the first thorough investigation of how Zika virus evolved during the rapid spreading epidemic in the Americas. From our preliminary data, we demonstrate that Zika viruses isolated from Cambodia (pre-epidemic), Brazil, Panama, Honduras, and Puerto Rico exhibit different levels of competitive fitness *in vitro*, leading us to hypothesize that Zika virus evolution during its spread within the Americas may alter transmission fitness in mosquitoes (*in vivo*). To test this hypothesis, we constructed a phylogenetic tree using our previously sequenced and available Zika virus genomes and identified 13 clade-defining amino acid changes that appeared during the epidemic. Next, we engineered these mutations in a Zika virus cDNA clone derived from a 2015 Brazilian isolate, and will use these viruses to infect *Aedes aegypti* mosquitoes and evaluate the impact on transmission. We will use outcomes from *in vivo* assays to inform vectorial capacity models which allows us to assess the impact of specific mutations on Zika virus transmission potential. Our study system provides a framework for evaluating functional evolution of viruses during rapidly evolving outbreaks and to investigate if emergence was facilitated by recent virus evolution.

1903

CHARACTERIZING THE IMMUNE RESPONSE TO ZIKA VIRUS USING EPITOPE MAPPING: REPORTER VIRUS PARTICLES AND ANTI-ZIKV ANTIBODIES

Edgar Davidson[1], Chuck Whitbeck[1], Anu Thomas[1], Aubrey L. Bryan[1], Tabb Sullivan[1], Lewis J. Stafford[1], Ross Chambers[1], Michael G. Rossmann[2], James E. Crowe Jr.[3], Benjamin J. Doranz[1]

[1]*Integral Molecular, Inc., Philadelphia, PA, United States,* [2]*Department of Biological Sciences, Purdue University, West Lafayette, IN, United States,* [3]*Departments of Pathology, Microbiology and Immunology, Vanderbilt University, Nashville, TN, United States*

We have characterized the immune response to ZIKV infection and vaccines by epitope mapping over 70 anti-ZIKV MAbs at amino acid-resolution, using a comprehensive ZIKV prM/E library of 672 single alanine mutants expressed in human cells. Published studies described epitopes of MAbs isolated from a Brazilian patient, including a highly neutralizing MAb protective in animal models of ZIKV fetal disease. The epitope locations suggested that the some MAbs act by binding across adjacent protein E dimers, preventing the rearrangements necessary for ZIKV infectivity. The epitope maps obtained also reveal which epitopes are specific for ZIKV or are common to DENV, information that can be used to create better vaccines and therapeutics. We have also identified mutations that increased ZIKV RVP budding, and which may be applicable to the design and production of anti-ZIKV vaccines, by screening each individual ZIKV library prM/E variant for ZIKV particle budding and infectivity. To provide critical reagents, we have isolated anti-ZIKV MAbs for ZIKV-specific immunodetection, diagnostic applications, and ZIKV neutralization studies. MAbs were isolated after immunization with DNA and sub-viral particles, and phage library panning with ZIKV reporter virus particles (RVPs) that we have developed. RVPs are capable of one round of infectivity, with luminescent or fluorescent readout. We isolated 48 conformational MAbs specific to prM/E from ZIKV, but not DENV, including a MAb that potently neutralized ZIKV RVPs (IC_{50} 45 ng/ml) and for which mapping identified a quaternary epitope spanning adjacent E proteins. We have also used ZIKV RVPs to identify new cellular receptors and attachment factors that enable ZIKV entry. ZIKV RVPs were tested on our Membrane Proteome Array (MPA), comprising 5,300 unique human membrane proteins individually expressed in live human cells. Known receptors and attachment factors were identified (validating the approach), as well as a number of membrane proteins not previously known to enable ZIKV entry. These newly identified proteins help explain viral tropism and pathogenesis, and may be useful as therapeutic targets.

1904

CD8+ LYMPHOCYTES MODULATE ZIKA VIRUS DYNAMICS AND TISSUE DISSEMINATION AND ORCHESTRATE ANTIVIRAL IMMUNITY

Blake Schouest[1], Marissa Fahlberg[1], Elizabeth A. Scheef[1], Matthew J. Ward[2], Kyra Headrick[2], Dawn M. Szeltner[1], Robert V. Blair[1], Margaret H. Gilbert[1], Lara A. Doyle-Meyers[1], Victoria W. Danner[1], Dawn M. Wesson[2], Antonito T. Panganiban[1], Nicholas J. Maness[1]

[1]*Tulane National Primate Research Center, Covington, LA, United States,* [2]*Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States*

CD8+ lymphocytes are critically important in the protection and control of viral infections, but their roles in acute Zika virus (ZIKV) infection remain incompletely explored. Nonhuman primate models of ZIKV have been valuable in understanding immune mechanisms of ZIKV control due to similarities in immune function to humans and due to their susceptibility to infection with primary human isolates of the virus. Here, we use CD8+ lymphocyte depletion to dissect immune responses and viral dynamics in adult male rhesus and cynomolgus macaques infected with ZIKV. CD8 depletion delayed serum viremia and dysregulated patterns of innate immune responses in the blood, demonstrated by a complete lack of neutrophil recruitment and a striking absence of monocyte-driven transcriptional changes in type-I interferon and other key immune genes. Depletion also modulated patterns of monocyte expansion and activation. CD8-depleted macaques showed evidence of compensatory adaptive immune responses, with elevated Th1 activity and persistence of neutralizing antibodies beyond the clearance of serum viremia. The absence of CD8+ lymphocytes increased viral burdens in lymphatic tissues, semen, and cerebrospinal fluid, and neural lesions were also evident in both CD8-depleted rhesus macaques. Together, these data support a role for CD8+ lymphocytes in the control of ZIKV dissemination and in maintaining immune regulation during acute infection of nonhuman primates.

1905

A LOCALIZED SANITARY SURVEY AS A PROXY FOR FECAL CONTAMINATION IN LOW-INCOME URBAN MAPUTO, MOZAMBIQUE

Drew Capone[1], David Berendes[2], David Holcomb[3], Jackie Knee[1], Joe Brown[1]

[1]*Georgia Institute of Technology, Atlanta, GA, United States,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Sanitary surveys are increasingly used in low- and middle-income countries to assess water, sanitation, and hygiene conditions, but few data exist comparing such surveys with direct measures of environmental fecal contamination. We conducted a cross-sectional survey of sanitary conditions in low-income neighborhoods of Maputo, Mozambique to assess the association between compound level (household clusters) sanitary conditions and *E. coli* counts in soils and on surfaces. We adapted the World Bank's Urban Sanitation Status Index to implement a sanitary survey tool specifically for compounds: a Localized Sanitation Status Index (LSSI) ranging from 0 (poor sanitary conditions) to 1 (better sanitary conditions) calculated from 20 variables that characterized local sanitary conditions. We measured the variation in the LSSI with environmental *E. coli* counts in soil (nine locations per compound) and surface swabs (seven locations per compound) in 80 compounds to assess reliability. We detected *E. coli* in 74% of soil samples at an average concentration of 4.10 $\log_{10}$ CFU *E. coli* per gram of dry soil and detected *E. coli* at 5.4% of swab locations. The presence of chickens, soil moisture, sun exposure, intra-compound location, and the compound's wealth index were all significantly associated with *E. coli* counts in soil. No covariates were significantly associated with the detection of *E. coli* on compound surfaces in univariable or multivariable Poisson regression. Multivariable linear regression indicated that a ten-percentage point increase in LSSI (e.g. 0.55 to 0.65) was associated with 0.05 (95% CI: 0.00, 0.10) $\log_{10}$ fewer *E. coli* per dry gram in compound soil and a 2% decrease (95% CI: 0%, 4%) in the risk of detection of any *E. coli* from compound soil. Findings suggest the LSSI can be a useful proxy for environmental fecal contamination as measured by *E. coli* counts in this low-income urban setting. However, the expected reduction in *E. coli* counts from substantial improvements in the LSSI may not reflect a meaningful difference in compound level exposure risk to feces-associated enteric pathogens.

1906

EXPLORING THE POTENTIAL RELATIONSHIP BETWEEN FECAL EXPOSURE PATHWAYS AND SYMPTOMATIC AND ASYMPTOMATIC ENTERIC INFECTIONS IN CHILDREN IN AN URBAN ENVIRONMENT IN VELLORE, INDIA

Yuke Wang[1], Sydney Hubbard[1], Gagandeep Kang[2], Suraja Raj[1], Habib Yakubu[1], Arun Karthikeyan[2], Senthil Kumar[2], Venkata R. Mohan[2], Christine Moe[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Christian Medical College of Vellore, India, Vellore, India*

Rapid urbanization has led to a sanitation crisis in many low- and middle-income countries (LMIC). In March 2014, SaniPath in collaboration with

the Christian Medical College (CMC) of Vellore, India conducted an exposure assessment in Old Town, a dense, urban unplanned settlement in Vellore. A total of 191 samples were collected from open drains, drinking water, public latrines, soil, raw produce, bathing water, child handrinse, and toy feeding spoon rinse and analyzed for *E. coli*. From March 2010 - February 2012, the MAL-ED study, a multi-site project examining enteric and growth outcomes enrolled a birth cohort of 190 children in Old Town. Multiple stool samples were collected from each child over two years of follow up and tested for bacterial and viral pathogens. Symptomatic illness was recorded. Each child in the MAL-ED study was linked with the closest environmental samples from the SaniPath study. Spatial variables, like the distance to the closest open defecation site, were generated. Generalized linear models were used with the bacterial infection rate, viral infection rate, and symptomatic illness rate as outcomes and environmental fecal contamination from different pathways and spatial variables as covariates. *E. coli* concentration from the closest public latrine and the distance to the closest open defecation site were significant predictors of bacterial infection rate in children. The sum of the open drain lengths within a 100-meter radius of the child, as well as the sum of street lengths within a 100-meter radius of the child, were significant predictors of viral infections in children. The *E. coli* concentration of the closest piped water was the only significant predictor of symptomatic illness in children. These results highlight the need for safe excreta management in dense, urban settings to prevent bacterial infections, while contaminated drinking water seems to be a major driver of symptomatic illness in this population. Human congestion, as proxied by summative surrounding street lengths and open drains, is a key risk factor for viral infection.

1907

TRACKING TRANSMISSION SOURCES OF DIARRHEA: AN INVESTIGATION ON DIARRHEAGENIC *ESCHERICHIA COLI* IN URBAN HOUSEHOLDS OF BANGLADESH

Zenat Zebin Hossain[1], Rokaia Sultana[1], Anowara Begum[1], Peter Kjær Jensen[2]

[1]*University of Dhaka, Dhaka, Bangladesh,* [2]*University of Copenhagen, Copenhagen, Denmark*

It is already recognized that poor hygiene practices may trigger the rapid distribution of pathogens, particularly waterborne diarrheagenic bacteria, in overpopulated urban settings. Prevalence of pathogenic *E. coli* contamination in diarrhea case household environments of low-income urban area in Bangladesh has not been explained before. This study collected diarrhea patients' rectal swabs and in-house environmental samples from case households in Arichpur, Dhaka city, Bangladesh for four months period to reveal in-house environmental hotspots for diarrheagenic *E. coli* transmission and their involvement in diarrhea. The environmental samples include: swabs from four frequently touched surfaces (water vessel used for drinking water, cutting knife or "Boti"- a floor based knife, latrine doorknob, and food plate), drinking water and food which were collected from a total of 34 low-income households with reporting diarrhea patients. Total 245 DNA samples were examined for virulence genes characteristic of five major diarrheagenic *E. coli* pathotypes (ETEC, EHEC, EIEC, EPEC, EAEC) by PCR. The isolated *E. coli* strains were analyzed for virulence typing.Results showed that genomic presence of diarrheagenic *E. coli* was detected in 36% (89 of 245) of all samples. The frequency rate of virulent genes of *E. coli* from the rectal swab, household swabs, food, water samples were 28% (10/36), 44% (63/144), 12% (4/34), 10% (3/31) respectively in PCR analysis. Six out of 36 rectal swab samples and associated household swabs, water, and food samples showed the presence of similar *E. coli* pathotypic genes, and among the different sample types, drinking vessel surface contamination was highest. One EAEC strain was commonly found in both clinical and latrine door knob swab. Kitchen tools and utensils appeared to play a role in the circulation of diarrheagenic *E. coli* within the household. This study data suggests the existence of high-risk hotspots, particularly surfaces directly related to the human food chain for diarrheagenic *E. coli* contamination within low-income case household environment in Bangladesh.

1908

WATER, SANITATION, AND ANIMAL-SPECIFIC RISK FACTORS FOR MODERATE-TO-SEVERE DIARRHEA IN YOUNG CHILDREN IN THE VACCINE IMPACT ON DIARRHEA IN AFRICA (VIDA) STUDY—THE GAMBIA, KENYA, AND MALI, 2015-2018

Environmental exposure to contaminated water, unsafe sanitation, and animals contributes to child diarrhea. We examined associations between these risk factors and moderate-to-severe diarrhea (MSD) in children &lt5 years old in the Vaccine Impact on Diarrhea in Africa (VIDA) case-control study in The Gambia, Kenya, and Mali. We enrolled cases seeking care for MSD at health facilities; age-, gender-, time- and community-matched controls were enrolled at home. Site-specific conditional logistic regression models, adjusted *a priori* for mother's education, evaluated associations between household drinking water source, sanitation type, animal ownership, and MSD. Preliminary risk factor proportions in cases and controls and matched Odds Ratios with 95% confidence intervals are reported. From 2015-2018, sites enrolled 4,841 cases and 6,214 matched controls. Compared to controls, cases had higher odds of using an unimproved main drinking water source recently in all sites (Gambia: 19% v. 14%, OR: 1.76 [1.39-2.23]; Mali: 10% v. 8%, OR: 1.38 [1.09-1.75]; Kenya: 29% v. 25%, OR: 1.22 [1.03-1.46]). Associations between levels of the Joint Monitoring Program sanitation ladder and MSD varied by site. Compared to at least basic sanitation, cases had lower odds of using an unimproved facility in The Gambia (54% v. 67%, OR: 0.56 [0.48-0.65]). In Kenya, cases had higher odds of using a shared sanitation facility (33% v. 29%, OR: 1.42 [1.13-1.77]) but lower odds of using no facility (3.6% v. 7.9%, OR: 0.48 [0.33-0.70]). In The Gambia, cases were more likely to own ruminants (87% v. 85%, OR: 1.26 [1.01-1.56]) and fowl (84% v. 81%, OR: 1.32 [1.10-1.59]). In Kenya, the reverse association was noted (ruminants: 73% v. 80%, OR: 0.66 [0.56-0.78]); fowl: 90% v. 94%, OR: 0.57 [0.44-0.74]). No associations between sanitation or animal ownership and MSD were observed in Mali. Results suggest that use of unimproved water was a consistent risk factor for MSD, but contributions of other environmental exposure pathways were site-specific. Further analyses will explore variation in etiologic agents associated with MSD with the coverage and types of waste containment by site.

1909

AN INDIVIDUAL PARTICIPANT DATA META-ANALYSIS ON THE ASSOCIATION BETWEEN ENVIRONMENTAL FECAL CONTAMINATION AND CHILD HEALTH

Frederick G. Goddard[1], Amy J. Pickering[2], Ayse Ercumen[3], Joe Brown[4], Howard H. Chang[1], Thomas F. Clasen[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Tufts University, Boston, MA, United States,* [3]*North Carolina State University, Raleigh, NC, United States,* [4]*Georgia Institute of Technology, Atlanta, GA, United States*

Water, sanitation and hygiene (WaSH) interventions have historically sought to improve child health by interrupting fecal-oral transmission of enteric pathogens. However, recently published evaluations of large WaSH trials have shown mixed results on diarrhea and growth, raising questions about the extent to which WaSH interventions reduce fecal contamination

in the environment. To design more effective interventions, there is a need to better understand the associations between fecal contamination and child health and how those differ along various transmission pathways. We systematically identified studies that quantified household-level fecal indicator bacteria concentrations in environmental samples or fly densities, and individual-level reported diarrhea or growth for children <5 years in low- and middle-income settings. We pooled raw individual participant data from eligible studies and used multilevel generalized mixed effects models to estimate the odds ratio for diarrhea and the change in height-for-age Z (HAZ) scores associated with a 1-log increase in fecal contamination along individual transmission pathways. We obtained data from 16 eligible studies, totaling over 42,000 data points on reported diarrhea and over 20,000 growth measures, linked to four transmission pathways: drinking water, child hands, fly density and fomites (sentinel toys). We found significant increases in odds of diarrhea with an increase in fecal contamination in drinking water and on hands, but not on fomites or kitchen fly densities. Children exposed to higher levels of fecal contamination in water had reduced HAZ scores, but we did not find this effect for other pathways. Our findings indicate that fecal contamination in the domestic environment is associated with child diarrhea and growth. Interventions that failed to yield health benefits may not have sufficiently interrupted fecal-oral transmission. Our mixed findings by pathway suggest that fecal contamination along proximal pathways (water and hands) is more strongly associated with child health than contamination along distal pathways in the broader domestic environment.

ENVIRONMENTAL PATHOGEN SURVEILLANCE OF WASTEWATER: TIME-VARYING VIRAL SHEDDING INTENSITY IN THE 2013 SILENT POLIO OUTBREAK IN ISRAEL

Andrew F. Brouwer, Joseph N. Eisenberg, James S. Koopman, Lester M. Shulman, Marisa C. Eisenberg

University of Michigan, Ann Arbor, MI, United States

The power of environmental pathogen surveillance was apparent in the 2013 polio outbreak in Israel when scientists used it to detect circulation despite the absence of any cases of human paralysis. Polio researchers have promoted the use of environmental surveillance to enhance traditional epidemiologic disease surveillance; it is now an important tool used in the global effort to eradicated polio. Beyond its use in detection, quantitative, longitudinal environmental surveillance has the potential to describe the epidemiology of waterborne outbreaks for a wide variety of pathogens. To do this, we need to characterize the dynamics of pathogen shedding, including both the fraction of people likely to be shedding as function of time since exposure and varying pathogen shedding intensity over that time period. Here, we analyzed data from 665 quantitative environmental surveillance samples for 3 strains of polio from 7 sentinel sites in southern Israel during the 2013 silent epidemic using a transmission modeling framework we developed to incorporate environmental surveillance data. We found that the data are consistent with a shedding duration (29 days (95% CI 27-31 days)) closer to what experts have predicted for fully susceptible individuals than to what might be expected for individuals who have had multiple doses of inactivated polio vaccine, as was believed to be the case for this population. We characterized our modeled infection stages as having high or low shedding rates and found that the outbreak dynamics were consistent with person-to-person pathogen transmission occurring only during high shedding periods. Our work highlights the need for realistic models of time-varying pathogen shedding to understand how to convert the observed environmental surveillance signals into public health metrics. With this understanding, environmental surveillance has the potential to transform our analysis of waterborne pathogen epidemiology and, in turn, help inform control strategies.

1911

ASSOCIATION BETWEEN GASTROINTESTINAL DISEASE IN CHILDREN AND WASTEWATER AGRICULTURAL IRRIGATION IN VALLE DEL MEZQUITAL, MÉXICO

Eunice Elizabeth Félix-Arellano[1], Sandra Leticia Rodriguez-Dozal[1], Jesse Contreras[2], Rafael Meza[2], Joseph N.S. Eisenberg[2], Horacio Riojas-Rodriguez[1]

[1]*National Institute of Public Health, Cuernavaca, Mexico,* [2]*University of Michigan, Ann Arbor, MI, United States*

Wastewater reuse for agriculture has intensified over the years partly due to increases in urbanization. In the Valle del Mezquital, Hidalgo, wastewater from Mexico City is used for agricultural irrigation. Human and animal pathogens are continuously high in wastewater, potentially putting farmers and their families at risk. The Atotonilco Wastewater Treatment Plant began partially treating wastewater in May 2017, providing treated water to some irrigation districts of the Mezquital. We compared the risk of gastrointestinal diseases in children under five living in three areas of the Mezquital: zone A where crops are irrigated with treated wastewater after the treatment plant began operation, zone B where crops are irrigated with untreated wastewater, and zone C where crops are irrigated with well water. We conducted a longitudinal study following 880 children under five with three household visits: recruitment (November 2016-April 2017), first follow-up (May-July 2017), and second follow-up (August-November 2017). We administered questionnaires to the primary caregiver about diarrheal disease in children under five, use of water in the household, hygiene practices, and participation in agriculture. We estimated the odds of presenting with diarrhea using multivariate logistic regression models with fixed and random effects. Children under five living in zones that irrigated crops with wastewater (zones A and B) had 2.0 times the odds of diarrheal disease compared to zone C (CI 95% 1.27 - 3.1). Compared to Zone C, Zone B had 2.3 times the odds of diarrheal disease (95% CI 1.41 - 3.84), followed by zone A (OR = 1.72 times, 95% CI 1.04 - 2.86), after adjusting for age, sex, presence of chickens, and access to sewerage. The odds of diarrhea in children under five increased in the presence of chickens (OR = 1.74, 95% CI 1.18 - 2.57) and decreased with access to sewerage (OR = 0.50, 95% CI 0.27 - 0.93). Our results suggest that exposure to wastewater used for irrigation, with or without treatment, contributes to the presence of diarrheal disease in children under five years of Valle del Mezquital.

1912

EXPLORING THE EFFECTS OF NEXT-GENERATION NETS ON HIGHLY PYRETHROID-RESISTANT *ANOPHELES COLUZZII* MOSQUITOES USING BENCHTOP BEHAVIOR ASSAYS

Natalie Lissenden, Jeff Jones, Hilary Ranson, Philip J. McCall

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

In Burkina Faso, malaria is increasing despite high coverage of WHO recommended vector control tools - a phenomenon that could be partly due to surging pyrethroid-resistance in the vector population. Insecticide-resistant populations can be controlled using insecticide synergists, such as piperonyl butoxide (PBO). We used novel benchtop video assays to investigate the physiological and behavioural impacts of exposure to pyrethroid-PBO nets of a highly pyrethroid-resistant *An. coluzzii* population in South-West Burkina Faso. Adult females reared from larvae were exposed to test netting (baited with a human host) in filmed assays for 3 (Video Cone Tests) or 20 (Baited Box Test) minutes, and immediate and delayed mortality was recorded. Composite video analysis and scan sampling were used to examine mosquito responses. During exposure to PermaNet 3.0 roof (i.e. pyrethroid-PBO net) in the Baited Box Test, flight activity declined rapidly until knockdown began at 180 seconds. In Video Cone Tests, flight declined after 60 seconds accompanied by an increase in resting. In both assays 24hr mortality was 100% following exposure to PermaNet 3.0 roof. Following exposure to PermaNet 3.0 sides (i.e. pyrethroid-only net) 24hr mortality was 0% in Baited Box and 2.13% in Video Cone tests - this increased to 9.68% and 6.38% after 7 days,

respectively. Mosquito flight behaviour on exposure to PermaNet 3.0 sides was comparable to untreated controls. Composite video analysis revealed that contact with the pyrethroid-PBO net was greatly reduced in comparison with untreated controls, but this brief exposure is enough to rapidly knock down and kill highly pyrethroid-resistant vectors. The implications of these results for the design of next-generation bed nets for targeting insecticide resistant mosquitoes are considered.

1913

PYRIPROXYFEN REDUCES FECUNDITY IN *ANOPHELES ARABIENSIS*: A NEW POTENTIAL TOOL FOR MALARIA CONTROL IN ETHIOPIA

Solomon Kibret[1], Delenasaw Yewhalaw[2], Guofa Zhou[1], Guiyun Yan[1]

[1]*University of California Irvine, Irvine, CA, United States,* [2]*Tropical and Infectious Diseases Research Center, Jimma University, Jimma, Ethiopia*

Insecticide resistance poses a major threat to current malaria control campaigns. Insecticides with novel modes of action are therefore needed to improve malaria control. Pyriproxyfen (PPF), a conventional juvenile mosquitocide, has a unique mode of action that also sterilizes adult mosquitoes upon direct contact. However, the application of PPF on larval vs adult mosquitoes has not been well studied. This study investigated the rate of fecundity of *Anopheles arabiensis* after PPF exposure to determine the potential of PPF-induced sterilization in malaria mosquitoes control. Larvae of *An. arabiensis* were collected from field and two treatment regimens were tested. First, we placed 60 larvae each in 12 washbasins (used as larval breeding habitat) half-filled with water treated with 0.0001% of PPF in the malariasphere and evaluated the rate of larval development and mortality. Second, we released adult *An. arabiensis* into the malariasphere with a wall dusted with PPF and evaluated autodissemination of the PPF by mosquitoes from the wall to breeding habitats in the malariasphere. Fecundity was measured as the number of viable eggs laid by the mosquitoes after blood feeding. The results showed that 92% *An. arabiensis* larvae placed in breeding habitats treated with PPF died either at their larval or pupal stage compared to only 15% of the larvae that died in the control breeding habitats (with no PPF treatment). The average number of eggs laid by *An. arabiensis* resting on PPF dusted walls was 32.4 eggs/batch compared to 189.6 eggs/batch in controls without the PPF. None of the eggs laid by mosquitoes subjected to PPF dusted walls were developed to larvae when placed in breeding habitats while 102 eggs/batch in the control developed to larvae and 72% of them pupated. Our study found out that PPF autodessemination is effective in controlling *An. arabiensis* mosquitoes, the major malaria vector in Ethiopia.

1914

ENTOMOLOGICAL EVALUATION OF INDOOR RESIDUAL SPRAYING (PYRIMIPHOS-METHYL) ON MALARIA TRANSMISSION IN DIEBOUGOU DISTRICT, SOUTHWEST BURKINA FASO

Dieudonne Diloma Soma[1], Jacques Edou Gnambani[1], Georges Anicet Ouedraogo[2], Alphonsine Koffi[3], Cedric Pennetier[4], Roch K. Dabire[1], Nicolas Moiroux[4]

[1]*Institut de Recherche en Sciences de la Sante, Bobo-Dioulasso, Burkina Faso,* [2]*Université Nazi Boni, Bobo-Dioulasso, Burkina Faso,* [3]*Institut Pierre Richet, Bouake, Côte D'Ivoire,* [4]*MIVEGEC, IRD, CNRS, University Montpellier, Montpellier, France*

The rapid spread of insecticide resistance in malaria vectors and the possible recent increase in malaria cases in Africa require to develop and evaluate new vector strategies able to manage resistance. The combination of two insecticides targeting different time of the life cycle of the *Anopheles* vector is one possibility. A randomized controlled trial was performed with the objective to evaluate in communities, the effect of indoor residual spraying (IRS) with pyrimiphos-methyl (PM) in combination with Long-Lasting Insecticidal Nets (LLINs) on malaria transmission and the vectors diversity, resistance and behaviour. The study took place in 13 villages (5 sprayed and 8 control) between November 2017 to June 2018. We performed 4 surveys of hourly mosquito collection following the implementation of IRS using the human-landing collection technique from 17:00 to 09:00 in each village. Malaria vectors species, *Plasmodium* infection, blood-meal source, *kdr-west*, *kdr-east* and *ace1* target-site mutations were searched by molecular technique. Residual activity of PM was monitored with susceptible *"Kisumu"* and wild strains using the WHO cone wall bioassay technique. The residual efficacy of the PM ranged 88-100% for 7 months on mud and cement walls against both susceptible and wild strains of *Anopheles gambiae s.l.* Average densities of *Anopheles* sp were 0.69 bites per human per night in the sprayed villages, significantly lower than in the control villages (3.2 $b.h^{-1}.n^{-1}$; RR= 0.38 ; 95%CI[0.15-0.94]). The majority of biting activities of *Anopheles* occurred between 02:00 to 3:00h and 06:00 to 7:00h in the control villages and sprayed villages respectively. Overall, entomological inoculation rate was lower in the sprayed villages (0.14 infective bites per human per night) compared to the control villages (0.84 $ib.h^{-1}.n^{-1}$). PM insecticide IRS allowed to drastically reduce malaria transmission in our trial. PM should be considered as a potential good complementary tool to LLINs in high transmission areas of Burkina Faso but in association with surveillance of malaria vector behaviour.

1915

FEEDING AND RESTING BEHAVIOR OF *ANOPHELES GAMBIAE* S.L. IN AREAS GETTING INDOOR RESIDUAL SPRAYING FOR MALARIA VECTOR CONTROL AND AREAS NOT SPRAYED IN NORTHERN GHANA

Sylvester Coleman[1], Samuel K. Dadzie[2], Yemane Yihdego[1], Frank Gyamfi[1], Lena Kolyada[1], Dereje Dengela[3], Aklilu Seyoum[3], Jon Eric Tongren[4], Sixte Zigirumugabe[5], Dominic Dery[5], Kristen George[6], Jennifer Armistead[6], Maxwell Appawu[2], Kingsley Badu[7], Kwasi Obiri-Danso[7], Daniel Boakye[2], Daniel Szumlas[8]

[1]*U.S. President's Malaria Initiative Vectorlink Project, Accra, Ghana,* [2]*Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana,* [3]*U.S. President's Malaria Initiative Vectorlink Project, Abt Associates Inc., Bethesda, MD, United States,* [4]*U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Accra, Ghana,* [5]*U.S. President's Malaria Initiative, U.S. Agency for International Development, Accra, Ghana,* [6]*U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States,* [7]*Department of Theoretical and Applied Biology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [8]*Armed Forces Pest Management Board, Silver Spring, MD, United States*

Since 2008, Ghana has implemented indoor residual spraying (IRS) in the Northern region, where a 48% decrease in parasite prevalence was observed from 2011 to 2016 along with significant reductions in entomological indices of malaria transmission. However, preference of *Anopheles gambiae* s.l. for outdoor biting has also been observed. To better understand how mosquito outdoor behavior relates to the dynamics of malaria transmission, we investigated the feeding and resting activity of *An. gambiae* s.l. in selected sprayed and unsprayed rural areas of Northern Ghana, during the rainy and dry seasons of 2017 and 2018. We collected mosquitoes monthly using prokopack aspiration and used enzyme-linked immunosorbent assay to measure human blood index (HBI). *An. gambiae* s.l. (93%) was the predominant species, primarily collected from places outside of sleeping rooms in both sprayed (94.9%) and unsprayed (82.7%) areas (P<0.001). Of those mosquitoes collected outside sleeping rooms, most were caught in animal shelters; 89% in sprayed and 77% in unsprayed areas (P<0.001). The indoor resting density was 0.17 and 0.95 mosquitoes per room per day for sprayed and unsprayed houses respectively (p<0.05). *An. gambiae* s.l. was further identified by polymerase chain reaction (PCR) as *An. gambiae* (81%), *An. coluzzii* (18 %) and *An. arabiensis* (1%). The HBI was lower in the sprayed areas (82%) compared to the unsprayed areas (94%) (p=0.001). Mortality of mosquitoes collected alive from non-sleeping shelters and held for 24hrs was 55% and 13% in IRS and unsprayed areas, respectively (p<0.05); indicating that even some of the mosquitoes resting outdoors have been

exposed to the insecticides on sprayed surfaces or nets indoors. Lower HBI of *An. gambiae* s.l. in sprayed compared to unsprayed areas may indicate a slight shift towards zoophagy or higher mortality of human blood fed mosquitoes in sprayed areas, possibly due to IRS. *An. gambiae* s.l. is still predominantly anthropophilic. These findings suggest that further interventions, in addition to IRS, may be required to target outdoor resting mosquitoes and achieve further reductions in malaria transmission.

1916

THE IMPORTANCE OF COPY NUMBER VARIATION IN METABOLIC INSECTICIDE RESISTANCE IN *ANOPHELES GAMBIAE*

Lizzie Bridget Tchongwe[1], Eric Lucas[2], Martin Donnelly[2]

[1]*Malawi Liverpool Wellcome Trust, Blantyre, Malawi,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Insecticide based interventions have significantly contributed to the reduction of malaria, one of the leading causes of death in sub-Saharan Africa. However, insecticide resistance is a threat to this success due to intensified use of the available insecticides. Target site and metabolic resistance are the key mechanism that mosquitoes use to evade the insecticide. Genetic variations in the *Anopheles gambiae* genome are important in increased resistance as evidenced in target site mutations. However, genetic variations such as copy number variations (CNVs) have been poorly studied and their role poorly understood in metabolic resistance. The aim of this study was to identify metabolic resistance genes that exhibit copy number variation and their significance in metabolic resistance. Pyrethroid phenotyped samples from Malawi (59) and Kenya (354) were screened for the presence of a specific *Cyp6aa1* duplication known to exist in East Africa (*Cyp6aa1*-Dup1) with conventional PCR and *Cyp6aa1* duplications general with qPCR. CNV discovery was done using the *Anopheles gambiae* 1000 genomes phase 3 data from Uganda and Tanzania, focusing on known metabolic resistance genes; *Cyp6aa1*, *Gstes* and *Cyp9k1*. A high frequency of *Cyp6aa1*-Dup1 was found in both dead and alive phenotypes. A total of 177 (43 %) individuals had the duplication, 137 (33 %) did not have a duplication and 99 (24 %) were dropouts. The *Cyp6aa1*-Dup1 duplication was significantly associated with the resistance phenotypes. The CNV discovery using the *Anopheles gambiae* 1000 genomes phase 3 data found high CNV frequencies in the candidate genes screened. *Cyp6aa1*-Dup1, so far only known to exist as a duplication, was found to exist as a triplication in the Tanzania data, and a new duplication was found on *Gste2* in two individuals from Uganda. These results have shown an importance of gene duplication in pyrethroid resistance, as well as high frequency of CNVs in the three metabolic resistance genes. More work should be done to functionally validate *Cyp6aa1* in *Anopheles gambiae* and understand its role in insecticide resistance and as a diagnostic marker in metabolic insecticide resistance.

1917

USE OF GRAVID OVIPOSITION STICKY (GOS) TRAP AND DENGUE NON-STRUCTURAL 1 (NS1) ANTIGEN TEST FOR EARLY SURVEILLANCE OF DENGUE AMONG *AEDES* MOSQUITOES TO REDUCE DENGUE OUTBREAK

Jonathan Wee Kent Liew, Sivaneswari Selvarajoo, Wing Tan, Indra Vythilingam

University of Malaya, Kuala Lumpur, Malaysia

Dengue is a global disease, transmitted by *Aedes* mosquitoes. The current dengue vector surveillance/control in many nations, including Malaysia are riddled with flaws, being delayed, reactive and non-relevant. These are likely reasons for the struggle in controlling dengue epidemics. Although novel control techniques (eg *Wolbachia* to control *Aedes* populations) have great potential, these are still under trial. Urgent and effective strategies for vector surveillance/control are required pending their results. Previous studies showed that gravid oviposition sticky (GOS) traps with use of the dengue NS1 test is able to detect dengue in trapped adult *Aedes*. Subsequently, dengue cases were found to occur 1 week after detection of infected mosquitoes, with a peak lag of 2 – 3 weeks. Evidently, this method is a cheap (less than USD 0.60 per trap) and effective way for early dengue surveillance. The next phase is to determine if this early and pro-active method of surveillance is able to reduce dengue cases. Thus, a cluster, randomized controlled trial of 18 months has been initiated since October 2018 in Selangor, Malaysia. Eight apartments were randomly assigned into intervention (3686 residential units) and control (4203 residential units) arms. The primary outcome concerns the reduction of dengue cases and dengue outbreak period in the intervention arm. GOS traps were set at the intervention apartments to collect *Aedes* weekly, following which dengue NS1 antigen were detected in these mosquitoes. When a positive mosquito was detected, the communities were alerted and advised to execute vector search-and-destroy and protective measures. As of March 2019, 9 dengue NS1-positive *Aedes* pools have been found in separate weeks in the intervention arm. The trial is ongoing, and the number of dengue cases will be obtained from the District Health Office, for further analysis to achieve the primary outcome with preliminary results available in September 2019. We foresee this intervention to reduce dengue cases in the study arm and be feasibly implemented as part of the dengue control program.

1918

APPLICATION OF SPATIAL ANALYSIS METHODS TO IDENTIFY AND EXPLAIN INSECTICIDE RESISTANT CLUSTERS OF *AEDES AEGYPTI* MOSQUITOES IN FLORIDA

Stephanie J. Mundis

University of Florida, Gainesville, FL, United States

Insecticide resistance can lead to vector control failure, disease resurgence, and wasted time and resources spent applying ineffective treatments. While insecticides are widely used in Florida, monitoring resistance status can be costly and challenging, meaning resistance may go undetected. This study examined the resistance status of *Aedes aegypti*, using genetic data from the V1016I and F1534C *loci* from populations sampled at 59 sites across 18 counties in Florida. The objectives of this study were to identify statistically significant clusters of resistant and susceptible genotypes and test for associations between landscape factors and resistance frequencies. We employed a SaTScan analysis and a linear regression model selection framework. We found urban areas along the western coast of the state had high frequencies of the resistant genotype, though locations with higher than expected frequencies of susceptible genotypes were also identified along both coasts. The clusters of susceptible mosquito populations likely represent "refuges," which could be important in re-establishing susceptible populations. The linear regression models indicated that landscape characteristics including distance from agricultural land cover and the enhanced vegetation index had statistically significant associations with the outcome of insecticide resistance. These results indicate that spatial factors could be used to predict and potentially manage insecticide resistance in the field.

1919

WIDESPREAD ANTIBIOTIC USE AMONG SUSPECTED ENTERIC FEVER CASES IN NEPAL, BANGLADESH AND PAKISTAN

Krista Vaidya[1], Kristen Aiemjoy[2], Farah N. Qamar[3], Samir K. Saha[4], Caitlin Barkume[5], Denise Garrett[5], Stephan P. Luby[6], Jason R. Andrews[6]

[1]*Dhulikhel Hospital, Kathmandu University Hospital, Dhulikhel, Nepal,* [2]*Stanford University, San Francisco, CA, United States,* [3]*Aga Khan University, Karachi, Pakistan,* [4]*Dhaka Shishu (Children) Hospital, Dhaka, Bangladesh,* [5]*Sabin Vaccine Institute, Washington, DC, United States,* [6]*Stanford University, Stanford, CA, United States*

Enteric fever, caused by *Salmonella Typhi* and *Paratyphi*, is a major cause of morbidity globally. Antibiotic use prior to seeking care can reduce the sensitivity of blood culture for enteric fever, with implications for both clinical care and surveillance. Moreover, easy access and indiscriminate use of antibiotics prior to formal care is likely a major contributor

to the emerging threat of antimicrobial resistance. Antibiotic use is typically measured via self or caregiver report and may be vulnerable to measurement error. The Surveillance of Enteric Fever in Asia Project is a prospective study of enteric fever incidence in Nepal, Bangladesh and Pakistan. Among a subset of SEAP participants, we measured *in vitro* inhibition of growth of pan-susceptible bacteria (*Kocuria rhizophila*) as an assay for antibiotic presence in urine and inquired about antibiotic use prior to seeking care at a study hospital. All participants received a blood culture. We calculated the sensitivity and specificity of reported antibiotic use against a reference standard of antibiotics detected in the urine using binomial logit models. We enrolled 2,916 patients with suspected enteric fever over two years, from 2016 to 2018. Antibiotics were detected in 256/1000 (26.5%) of urine samples collected in Nepal, 337/910 (37.0%) of samples in Bangladesh, and 468/882 (53.1%) of samples in Pakistan. The sensitivity and specificity of reported antibiotic use, compared with the urine assay, were 79% and 80% in Bangladesh and Nepal; and 58% and 67% in Pakistan. Individuals who were culture positive for enteric fever were more likely to have antibiotics detected in the urine (RR 1.3; 95%CI 1.17, 1.48), likely because antibiotic use is an indicator of disease severity. The widespread pre-hospital antibiotic use documented in this study has implications for clinical care, enteric fever surveillance and public health. Relying on patient or caregiver-reported antibiotic use may not be sufficiently valid. High levels of pre-hospital antibiotic use may reduce the sensitivity of blood culture and thus underestimate the true burden of enteric fever.

1920

INTEGRATING TRADITIONAL MICROBIOLOGY WITH CUTTING-EDGE METAGENOMICS TO ADVANCE PATHOGEN DETECTION AND ELUCIDATE MICROBIOME SIGNATURES OF *E. COLI* INFECTION

Karen Levy[1], Angela Pena-Gonzalez[2], Maria J. Soto-Girón[2], Shanon Smith[1], Jeticia Sistrunk[1], Lorena Montero[3], Maritza Paez[3], Estefanía Ortega[3], Janet K. Hatt[4], William Cevallos[5], Gabriel Trueba[3], Konstantinos T. Konstantinidis[4]

[1]*Rollins School of Public Health, Emory University, Atlanta, GA, United States,* [2]*School of Biological Sciences, Georgia Institute of Technology, Atlanta, GA, United States,* [3]*Instituto de Microbiologia, Universidad San Francisco de Quito, Quito, Ecuador,* [4]*School of Civil and Environmental Engineering, Georgia Institute of Technology, Atlanta, GA, United States,* [5]*Centro de Biomedicina, Universidad Central del Ecuador, Quito, Ecuador*

Escherichia coli infectious diarrhea is an important contributor to child mortality worldwide. While important advances have been made in characterizing the virulence mechanisms of pathogenic *E. coli*, understanding of the compositional and functional alterations in the intestinal microbiome during active infections is still limited. For example, it remains unknown how alterations in the gut microbiome vary by pathotypes with different virulence mechanisms, and whether these metagenomic signatures can be used for diagnostic purposes. Here, we present an integrative methodology that combined culture and PCR techniques with metagenomics and epidemiology to identify cases of diarrhea where *E. coli* was most likely the causative disease agent and to evaluate specific signatures in the disease-state gut microbiome that distinguish between DAEC, ETEC and EPEC pathotypes. Application of this methodology to Ecuadorian children with diarrhea showed that ~50% of the cases where an *E. coli* pathotype was detected through culture/PCR were likely not caused by *E. coli*, based on low relative abundance, level of clonality and/or virulence gene content within the metagenome. Those diarrhea samples where *E. coli* was most likely the causative agent had higher abundance of the pathogenic isolate compared to controls or commensal *E. coli*, high prevalence of virulence factors and/or enterotoxins, including the metagenomic detection of the pathotype-specific marker gene, and a reduced *E. coli* intra-population diversity compared with control samples. Our results also revealed at least four species that discriminated DAEC from ETEC infections. At the functional level, no major differences were detected. DAEC infections were accompanied by co-elution of high amounts of human DNA and conferred significant shifts in the composition of the gut microbiome relative to controls without diarrhea or ETEC infections. Our results demonstrate that metagenomic approaches can provide a high resolution approach for the detection of the etiologic agent of diarrhea and a better understanding of the disturbance of the gut microbiome caused by enteric infections.

1921

HOST GENOME-WIDE ASSOCIATION STUDY OF *SHIGELLA*-ASSOCIATED DIARRHEA IN A BIRTH COHORT OF BANGLADESHI INFANTS

Dylan Duchen[1], Rashidul Haque[2], Genevieve Wojcik[3], Laura Chen[1], Poonum Korpe[1], Beth Kirkpatrick[4], William A. Petri[5], Priya Duggal[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*Stanford University, Stanford, CA, United States,* [4]*University of Vermont, Burlington, VT, United States,* [5]*University of Virgina, Charlottesville, VA, United States*

Shigella is a leading cause of moderate-to-severe diarrhea in African and South Asian children and the causative agent of shigellosis and dysentery. Associated with 80 - 165 million cases of diarrhea and up to 600,000 deaths annually, exposure to shigella is ubiquitous in many regions while colonization or infection is heterogenous. To characterize the host-genetic susceptibility to shigella-associated diarrhea, we performed two independent genome-wide association studies (GWAS) including 589 Bangladeshi infants, 429 from the PROVIDE birth cohort and 160 infants from a Cryptosporidium-focused study birth cohort in Dhaka, Bangladesh. We classified children as ever having shigella associated diarrhea or not in the first 13 months of life. A qPCR Ct distribution of the ipaH gene, carried by all four shigella species and enteroinvasive E. coli, identified a total of 143 infants with a shigella-associated diarrheal event and 446 infants with no evidence of shigella-associated diarrhea within their first 13 months of life. Host GWAS's were performed using the Illumina Infinium 5 Multiethnic Global Array and analyzed under an additive genetic model. A joint analysis (imputed variants n=6,547,362) identified *loci* of interest on chromosomes 11 (rs582240, within the *KRT18P59* pseudogene, average MAF=29.4%, $p=8.37x10^{-8}$) and 8 (rs12550437, within the lincRNA *RP11-115J16.1*, average MAF=38.1%, $p=1.69x10^{-7}$). This study suggests host genetic factors may influence the response to shigella colonization and pathogen-associated diarrhea. Additional replication and further research on the function of these genes and their association with shigellosis and other pathogen-associated diarrheal diseases is warranted.

1922

EPIDEMIOLOGY OF *SHIGELLA* INFECTIONS AND DIARRHEA IN THE FIRST TWO YEARS OF LIFE USING CULTURE-INDEPENDENT DIAGNOSTICS IN THE MAL-ED STUDY

Najeeha Iqbal[1], Elizabeth T. Rogawski McQuade[2], Arjumand Rizvi[1], Fariha Shaheen[1], Furqan Kabir[1], James A. The use of culture-independent diagnostics has revealed a larger burden of *Shigella* diarrhea and *Shigella*-associated linear growth decrements among children in low-resource settings than previously recognized. We further characterized the epidemiology, risk factors, and seasonality of *Shigella* in the first two years of life in the multisite longitudinal birth cohort, MAL-ED. We tested 41,405 diarrheal and monthly non-diarrheal stools for *Shigella* by quantitative PCR and culture. To identify risk factors, model seasonality, and assess culture positivity, we used mixed effects log-binomial regression with a random effect for individuals. The prevalence of *Shigella* varied from 4.9%-17.8% in non-diarrheal stools across the 8 sites, and the incidence of *Shigella*-attributable diarrhea was 22.9 cases (95% CI: 21.3, 24.6) per 100 child-years (range 2.2-68.4 across sites). Among approximately half of *Shigella*-attributable diarrheal stools that could be typed to *S. flexneri* or *S. sonnei*, 60.6% were *S. flexneri* and 44.7% were *S. sonnei*. The sensitivity and specificity of culture compared to qPCR were 6.6% and 99.8%, respectively. Sensitivity increased to 17.1% in the subset of *Shigella*-attributable diarrheal stools and to 27.8% in *Shigella*-attributable dysentery. PCR-positive stools from younger children were less likely to be culture positive. Older age (RR: 1.73, 95% CI: 1.68, 1.78 per 6-month increase in age), unimproved sanitation (RR: 1.19, 95% CI: 1.06, 1.35), low maternal education (<10 years, RR: 1.18, 95% CI: 1.07, 1.30), less than 3 months of exclusive breastfeeding (RR: 1.12, 95% CI: 1.02, 1.22), and malnutrition (RR: 0.92, 95% CI: 0.89, 0.96 per unit increase in weight-for-age z-score) were risk factors for *Shigella* infection. *Shigella* was highly seasonal in some sites, such as a peak in December/January in Tanzania and a peak in March/April in the South Asian sites. The burden of *Shigella* varied widely across sites, but uniformly increased through the second year of life. Culture missed most clinically relevant cases of severe diarrhea and dysentery, signaling the critical inadequacy of culture and necessity of molecular methods.

1923

IDENTIFICATION OF HOUSEHOLD RESERVOIRS AND TRANSMISSION PATHWAYS ASSOCIATED WITH *SHIGELLA FLEXNERI* DIARRHEA AMONG CHILDREN FROM THE MIRZAPUR, BANGLADESH SITE OF THE GLOBAL ENTERIC MULTICENTER STUDY

Kurt Z. Long[1], AGS Faruque[2], Inong R. Gunanti[3], Johanna Sanchez[3], James P. Nataro[4], Dilruba Nasrin[5], Myron Levine[6], Karen Kotloff[7]

Rural communities in Bangladesh have some of the highest rates of shigellosis reported among young children. Identification of environmental reservoirs and transmission pathways for *Shigella flexneri* in these communities can aid in the development of more effective intervention strategies to reduce this burden. Bayesian path analyses were used to model the effect of household pathogen transmission pathways on the risk of *Shigella* infections among children enrolled in the Bangladeshi component of the Global Enteric Multicenter Study (GEMS). Models were developed to test whether such potential pathogen reservoirs as water source and treatment, sanitation facilities and dirt flooring were associated directly with greater *Shigella* infections or had indirect effects mediated by hygiene behaviors. There were 430 isolates of *S. flexneri* identified in stools collected from the 3,859 children enrolled in Mirzapur, Bangladesh. The disposal of a child's feces in a latrine or toilet was significantly associated with a higher risk of *Shigella* diarrhea compared to disposal in the bush while having a concrete or tile floor was associated with a reduced risk. A further positive association of feces disposal in a latrine was indirectly associated with a higher risk when the latrine was unimproved. Children from households with unimproved sanitation facilities had a significantly lower risk of diarrhea when their caretakers washed hands before cooking while no effect of handwashing was found in households with improved sanitation. Deep tube wells were positively associated with *Shigella* diarrhea directly and indirectly through unimproved sanitation but this indirect association was reduced when handwashing before cooking was reported. Water treatment also had an indirect positive association through unimproved sanitation but this indirect association was again reduced with reported handwashing before cooking. These results suggest that handling and disposal of feces can lead to greater transmission of *Shigella* directly and indirectly through water sources but that specific handwashing behaviors can block such transmission.

1924

DEVELOPMENT OF A MULTIPLEXED *SHIGELLA*-SPECIFIC BACTERICIDAL ASSAY

Hailey Petersen Weerts, Akamol E. Suvarnapunya, Robert W. Kaminski

Walter Reed Army Institute of Research, Silver Spring, MD, United States

Shigella is a leading cause of diarrhea-associated global morbidity and mortality in children under the age of 5. Developing a *Shigella* vaccine has been complicated because there are multiple serotypes of *Shigella,* and previous infection provides protection from subsequent infection only in a serotype-specific manner. Current epidemiological data suggest that a quadrivalent vaccine will be required to protect against 80% of global disease caused by *Shigella*. A multivalent vaccine will require assessment of immune responses directed to multiple *Shigella* serotypes and, as the target population for vaccination is children under 5, sample volume will be a limiting factor. Multiplexed assays will therefore play an essential role in assessment of immune responses in vaccine field trials. A multiplexed *Shigella*-specific bactericidal assay (SBA) is under development to allow for high-throughput analysis of functional antibody responses while also conserving sample volumes. To develop this multiplexed SBA, *S. flexneri* 2a, *S. flexneri* 3a, and *S. sonnei* strains were transformed with plasmids containing GFPuv, iRFP670, or mRuby2, and frozen bacterial stocks prepared. Bactericidal assays were conducted with modifications to previously published protocols by incubating all three transformed *Shigella* strains, monoclonal or polyclonal antibodies, and exogenous baby rabbit complement in 96 well plates. Plates were subsequently incubated at 37°C for two hours, transferred onto PVDF filter bottom 96 well plates and incubated overnight to allow for bacterial growth. Fluorescent colonies were detected and enumerated using a CTL Immunospot S6 Analyzer. Monoclonal antibodies were used to develop appropriate parameters, controls, and bacterial growth conditions. This multiplexed SBA allows for the simultaneous measurement of bactericidal activity against three *Shigella* serotypes, ultimately conserving time, reagents, and sample. As the field moves towards evaluating multivalent *Shigella* vaccines in target populations, multiplexed assays will become increasingly necessary to evaluate immune responses induced after immunization.

1925

SIGNIFICANCE OF DIARRHEAL DISEASES TO UNDER-FIVE MORTALITY AND DIAGNOSTIC VALUE OF RECTAL SWABS IN CHILDREN WITH FATAL DIARRHEAL DISEASES IN SUB-SAHARAN AFRICA

Portia Mutevedzi, Richard Chawana, Shabir Madhi

RMPRU, Johannesburg, South Africa

Diarrheal disease is the second leading under-five mortality cause worldwide. To achieve the World Health Organisation (WHO) sustainable development goal for child mortality of at most 25 deaths per 1000 live births by 2030, it is imperative to implement targeted and contextually

effective morbidity and mortality prevention strategies as well as ensure early disease specific diagnosis. Our study aimed to quantify under-five mortality attributable to diarrheal disease and assess the diagnostic value of rectal swabs collected as part of the Child Health and Mortality Prevention Surveillance (CHAMPS). CHAMPS network procedures involved minimally invasive tissue sampling (MITS) within 24-36 hours of death in children aged 1-59 months, between 18 January 2017 and 1 June 2018 in Soweto, South Africa (one of the 7 CHAMPS sites). Microbiological culture and/or molecular tests were performed on lung, blood, cerebrospinal fluid, nasopharyngeal swab and stool samples. The causes of death (CoD) were determined for each case by a multi-disciplinary panel of 12-15 specialists. A total of 365 deaths in children aged 1-59 months were evaluated; 221 (60.5%) were males, majority 248 (67.9%) were neonates whilst 44 (12.1%) were aged 1-5 years. Diarrheal related deaths accounted for 13% of child deaths; 14 (29.1%) classified as immediate, 14 (29.1%) morbid and 20 (41.6%) underlying respectively. Twenty-two (6%) of the total deaths presented with diarrhea for a median of 4 days (IQR: 2-7days); 2 of whom had persistent diarrhea as underlying CoD. Of the 248 neonatal deaths, 4 (1.6%) had listeriosis in the causal chain. E.coli was detected in stool samples from 5 (10.4%) children whose immediate or underlying CoD was classified as acute gastroenteritis whilst in one death classified as dysentery both E.coli and Shigella were isolated. Rotavirus A was detected in 3 children whose underlying CoD was considered to be diarrheal related. Our study highlights significant under-five preventable mortality attributable to diarrheal disease which may be successfully diagnosed through rectal swabs.

WUCHERERIA BANCROFTI CIRCULATING FILARIAL ANTIGEN EXHIBITS DIFFERENT LECTIN-BINDING SPECIFICITY AND GREATER PROTEASE RESISTANCE COMPARED TO OTHER FILARIAL GLYCOPROTEINS

Marla Hertz[1], Amy Rush[2], Philip Budge[2]

[1]*Washington University in St. Louis, St. Louis, MO, United States,* [2]*Washington University in St. Louis, St Louis, MO, United States*

The Global Program for the Elimination of Lymphatic Filaraiasis relies on rapid diagnostic tests (RDTs) for LF that detect a ~200-250 kDa circulating *W. bancrofti* antigen via a carbohydrate epitope that is recognized by the monoclonal antibody AD12. This epitope is present on many glycoproteins of other filarial nematodes, but little is known about its structure and function. Nor is it clear why the *W. bancrofti* circulating filarial antigen (Wb-CFA) is persistently present in infected individuals, while antigens containing this epitope are not detected in individuals with brugian filariasis and are only detected in a subset of patients with loiasis. We sought to improve our understanding of this epitope and the differences between Wb-CFA and other filarial antigens decorated with it. Binding to a lectin array showed that AD12 epitope-containing proteins from *B. malayi* are captured by many lectins, while the Wb-CFA was not well captured, suggesting that a variety of other glycans are present on epitope-containing *Brugia* glycoproteins, but not on the Wb-CFA. Mass spectrometry analysis of *B. malayi* AD12-epitope containing proteins identified many of the same antigens present in cross-reactive loiasis sera. We found that the AD12 epitope is not removed from Wb-CFA or other filarial antigens by PNGase F digestion, nor by several other commercially available glycosidases. Wb-CFA was also more resistant to several proteases than AD12 glycoproteins of *B. malayi*, including trypsin, pronase, lys-C and O-sialoglycoprotein endopeptidase. Preliminary observations indicate that treatment of bancroftian filariasis releases additional AD12 glycoproteins of lower molecular weight that Wb-CFA; these transiently released *Wuchereria* antigens are also more susceptible to protease digestion that the high molecular weight Wb-CFA. The inherent stability of the Wb CFA may explain how it is consistently detected in sera while other AD12-eptiope containing proteins are more readily lost.

1927

POTENTIAL OF CYTOSOLIC AND ENDOSOMAL PRR-AGONISTS IN IMPROVING VACCINATION EFFICACY AGAINST THE FILARIAL NEMATODE *LITOMOSOIDES SIGMODONTIS*

Johanna F. Scheunemann, Frederic Risch, Julia J. Reichwald, Alexandra Ehrens, Marianne Koschel, Achim Hoerauf, Christoph Coch, Beatrix Schumak, Marc P. Hübner

University Hospital Bonn, Bonn, Germany

Current efforts to eliminate human filarial infections are hampered by the lack of protective vaccination approaches. Here we investigated the potential of cytosolic vs. endosomal PRR-ligands to boost the efficacy of anti-filarial vaccination. *In vitro* studies with human peripheral blood mononuclear cells revealed that RNA and DNA of the rodent filarial nematode *Litomosoides sigmodontis* but not human RNA or DNA trigger the release of pro-inflammatory cytokines. Cytosolic RNA delivery in human PBMC induced a strong IFNα release, while endosomal delivery led to TNF and IL-1β secretion. This correlated with monocyte activation as indicated by significantly increased expression of MHC class II and CD80. In order to test *in vivo* whether different nucleic acid receptor agonists improve vaccination efficacy using irradiated *L. sigmodontis* L3 larvae, BALB/c mice received 3 subcutaneous injections in 2-week intervals with irradiated L3 larvae in combination with different agonists prior to a challenge infection via the natural mite vector. The vaccination approach using irradiated L3 larvae alone reduces the adult worm burden by 80%. First results indicate that subcutaneous injection of 3pRNA (RIG-I agonist), naked poly (I:C) (TLR3 ligand) or 2'3'cGAMP (STING agonist) within 4h induced the recruitment of immune cells, in particular neutrophils, which were previously shown to mediate protection against invading L3 larvae. Further, 2'3'cGAMP triggered upregulation of co-stimulatory molecule CD86 on myeloid cells. For all agonists this was accompanied by elevated local CXCL-10 mRNA levels (skin), but minor changes in systemic CXCL-10 levels. Ongoing experiments address the impact of a combined vaccination with irradiated L3 larvae with different cytosolic and endosomal PRR ligands on the adult worm recovery, microfilariae release, generation of *L. sigmodontis*-specific antibodies, systemic cytokine and chemokine levels and immune cell activation. We hypothesize that an activation of nucleic acid receptors boosts the elicited immune response and triggers protective immune responses against invading L3 larvae.

1928

LYMPHATIC FILARIASIS ELIMINATION IN SAMOA: EVALUATING THE USE OF MOLECULAR XENOMONITORING AS A SURVEILLANCE TOOL

Brady McPherson[1], Sarah Sheridan[2], Kei Owada[3], Take Naseri[4], Robert Thomsen[4], Tautala Mauala[5], Helen Mayfield[1], Lisa Rigby[6], Silvia Ciocchetta[3], Julia Maguire[1], Nils Pilotte[7], Andrew M. Gonzalez[7], Steven A. Williams[7], Katherine Gass[8], Patricia M. Graves[9], Colleen L. Lau[1]

[1]*Australian National University, Canberra, Australia,* [2]*University of New South Wales, Sydney, Australia,* [3]*University of Queensland, Brisbane, Australia,* [4]*Samoa Ministry of Health, Apia, Samoa,* [5]*Samoa Red Cross, Apia, Samoa,* [6]*Queensland Institute of Medical Research, Brisbane, Australia,* [7]*Smith College, Northampton, MA, United States,* [8]*Task Force for Global Health, Atlanta, GA, United States,* [9]*James Cook University, Cairns, Australia*

The World Health Organization recently recommended triple drug mass drug administration (ivermectin, diethylcarbamazine, albendazole: IDA) in areas with slow progress towards lymphatic filariasis (LF) elimination. The 2018 'Surveillance and Monitoring to Eliminate Lymphatic Filariasis and Scabies from Samoa' project consisted of human and mosquito surveys to identify the best indicators for determining when LF transmission has been interrupted by IDA. To assess the value of molecular xenomonitoring (MX) as a surveillance tool, we investigated village-level associations between the presence of PCR-positive mosquitoes for *Wuchereria bancrofti* DNA (PCR+) and circulating filarial antigen (Ag) in humans. Mosquitoes were

collected from 28 randomly selected villages using BG Sentinel traps, and sorted into 4 categories: *Aedes polynesiensis* (the reported main vector in Samoa), *Ae. (Finlaya) spp*, other *Aedes spp*, and *Culex spp*. Pools of ≤25 mosquitoes of each category were tested using PCR. Analyses were conducted for each category and for 'all species combined'. Of 475 pools tested (29% *Ae. polynesiensis*, 7% *Ae. (Finlaya) spp,* 22% other *Aedes spp,* 42% *Culex spp*; total 8506 mosquitoes), 18.1% were PCR+. Pools with the highest positivity rate were other *Aedes spp* (29.5%) and *Ae. polynesiensis* (24.3%). Infection prevalence (maximum likelihood estimate using Poolscreen 2) was 1.1% (95% CI 0.9-1.4%) for 'all species', 2.0% for other *Aedes spp,* and 1.5% for *Ae. polynesiensis*. The 'all species' category proved most sensitive for detecting villages with Ag-positive humans, with PCR+ pools identified in 81.8% (18/22) of these villages, compared to 50.0% sensitivity with *Ae. polynesiensis*. Presence of PCR+ *Ae. polynesiensis* pools provided the best predictor of villages with Ag-positive people with a positive predictive value (PPV) of 78.6% (11/14) followed by the 'all species' category with a PPV of 78.3% (18/23). Our study provides promising evidence to support the value of MX in post-MDA surveillance, even if there is no entomological capacity to sort mosquitoes by species. Further work in 2019 will explore the use of MX to assess the impact of IDA.

1929

DIAGNOSTIC PERFORMANCE OF ELISA, RAPID DIAGNOSTIC TESTS AND MULTIPLEX BEAD ASSAY TO DETECT ONCHOCERCIASIS OV-16 IGG4 ANTIBODY REACTIVITY USING SAMPLES FROM A FORMERLY ENDEMIC AREA

Marisa Hast[1], Oscar de Leon[2], Circe McDonald[1], Renata Mendizabal de Cabrera[2], Alison Golden[3], Paul Cantey[1], Vitaliano Cama[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Universidad del Valle de Guatemala, Guatemala City, Guatemala,* [3]*PATH, Seattle, WA, United States*

The World Health Organization has published guidelines for endemic countries to verify the elimination of onchocerciasis transmission. The optimal strategy for post-elimination surveillance remains unclear, but an accurate serologic assay will be needed. We compared the relative performance of diagnostic assays to detect onchocerciasis OV-16 IgG4 antibodies in a formerly endemic area: a multiplex bead assay (MBA), an SD BIOLINE rapid diagnostic test (RDT), and an alkaline phosphatase (AP) enzyme-linked immunosorbent assay (ELISA) developed in Guatemala. Using sera and dried blood spots (DBS) collected in 2014 from 209 participants in a post-endemic focus in Guatemala, we compared overall and positive agreement for five OV-16 detection methods: AP ELISA, RDT on performed on stored sera and read at 20 minutes (wet), RDT read the next day (dry), and an MBA on both sera and DBS. We calculated MBA cutoffs using receiver operating characteristic (ROC) analyses on a panel of 86 known positive and 454 negative samples. To calculate positive agreement, sera MBA and the wet RDT were the references where applicable. The MBA was positive in 60.3% of sera samples and 43.8% of DBS samples, with 79.4% overall agreement and 68.3% positive agreement. The wet and dry RDTs were positive in 24.6% and 25.9% of samples, respectively, with 96.9% overall and 95.7% positive agreement. The AP ELISA was positive in only 7.2% of samples. Overall and positive agreement between the sera MBA and dry RDT were 63.3% and 40.7%, respectively, and were 46.6% and 11.4% between the sera MBA and AP ELISA. Of five methods for measuring OV-16 IgG4 serology for onchocerciasis, MBA using sera had the highest positivity, followed by MBA using DBS, dry RDT, wet RDT and AP ELISA. These results suggest that MBA assays may be the most sensitive diagnostic tool for post-elimination surveillance. The potential to incorporate MBA OV-16 detection into integrated disease serosurveillance efforts should be evaluated further. Additional research is needed to investigate the causes of disparities between OV-16 detection methods and to further understand the performance of the MBA assay.

1930

ENTOMOLOGICAL SURVEILLANCE GUIDED PARASITOLOGICAL SURVEILLANCE, AN EFFECTIVE POST-ELIMINATION STRATEGY TO CLEAR LAST FEW LYMPHATIC FILARIASIS CASES IN SRI LANKA

Indeewarie Eranga Gunaratna[1], Dammika de Mel[1], Manjula W. Punchihewa[2], Isuri C. Wijethunga[3], Tharanga D. Dassanayake[1], Lakmini K. Liyanage[1], Wimal J. Migelhewa[2], Sameera R. Meegahapalage[1], Devika Mendis[1]

[1]*Anti Filariasis Campaign, Colombo* [05]*, Sri Lanka,* [2]*Regional Anti-Filariasis Unit, Galle, Sri Lanka,* [3]*Office of Medical Officer of Health, Balapitiya, Sri Lanka*

Microfilaria rate in Sri Lanka was less than 0.5% since 1981. This was further reduced to 0.05% with five rounds of Mass Drug Administration (MDA) in all eight endemic districts during 2002-2006 and three rounds in the highest risk Galle district during 2014-2016. Sri Lanka was certified as a country eliminated filariasis as a public health problem in 2016. Anti Filariasis Campaign (AFC) introduced a new post-elimination strategy aiming to reach total elimination of filariasis by 2021; entomological surveillance guided parasitological surveillance with house to house night blood film (NBF) screening in 2016 to detect reservoir infection who contribute to continuous transmission. To assess the effectiveness of the new strategy, it was piloted in two high risk health administrative areas; Balapitiya and Habaraduwa in Galle district in 2018. High risk localities within selected areas to carryout NBF were identified by positivity of gravid traps. Total of 672 pools (25 mosquitoes per pool) were obtained from 336 traps were subjected to Real Time Polymerase Chain Reaction. Maximum likelihood filarial DNA rate was 0.64%, CI 0.46-0.85 (trap positivity rate 22.2%, pool positivity rate 33.3%). All trap locations were mapped and areas to be screened around positive trap sites were marked for human survey. NBF screening programme was organized along with community mobilization (advocacy, house to house messaging, school programmes, community awareness through media) within 200m radius of positive trap sites. Thick blood smears were prepared for microfilaria detection by microscopy. Total of 51 patients were identified from 31,370 people screened (44% males) from all households within selected areas. Microfilaria rate was 0.16%. Majority (88%) of patients were males (microfilaria rate is 0.32%) and 78% were >50 years of age (microfilaria rates 0.29%). Results suggest that screening should focus on males and older people. This strategy can be used as an end game strategy with higher coverage to plan out focused high risk screening to detect hidden cases and effective treatment and recommend for countries in post-elimination phase to stop transmission.

1931

TESTING A METHOD OF SAMPLING FOR ENTOMOLOGICAL DETERMINATION OF TRANSMISSION OF *WUCHERIA BANCROFTI* TO INFORM LYMPHATIC FILIARIASIS (LF) TREATMENT STRATEGY IN URBAN SETTINGS.

Rogers Nditanchou[1], Ruth Dixon[2], Benjamin Koudou[3], Dung Pam[4], Sunday Isiyaku[5], Christian Nwosu[5], Safiya Sanda[5], Elena Schmidt[2], David Molyneux[6]

[1]*Sightsavers, Yaounde, Cameroon,* [2]*Sightsavers, Haywards Heath, United Kingdom,* [3]*Centre Swisse de Recherches Scientifiques en Cote d'Ivoire, Abidjan, Côte D'Ivoire,* [4]*Department of Zoology, University of Jos, Jos, Nigeria,* [5]*Sightsavers, Kaduna, Nigeria,* [6]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

There is an on-going debate about scale-up of LF treatment to include urban areas. Determining transmission is more complex in these settings; entomological methodologies with no clear approach. Within Kaduna and Minna cities in Nigeria, we selected 3 communities with pre-disposing risk factors and LGA level TAS data indicating transmission. After mapping local breeding sites we selected 41 households in proximity to the risk factors for 5 gravid traps (GT), 15 exit traps (ET) and 21 pyrethrum spray catch sites (PSC). We collected mosquitos over 5 months corresponding

to high transmission season using a combination of entomologists and community based researchers. Mosquitos were counted, speciated and abdominal state determined on the day of collection. We targeted 10,000 mosquitos per city inclusive of 1500 *Anopheles* in order for transmission to be determined based on presence of the L3 infective stage of *Wuchereria bancrofti.* In 5 427 trapping events, we collected 36,880 mosquitos (2818 *Anopheles)*. 92% were *Culex* species. PSC were the most likely to yield *Anopheles* with a mean of 1 per trapping event compared to 0.5 for ET and 0.1 for GT. 77% of *Anopheles* came from ETs with successful *Anopheles* catches occurring later in the season. Community researchers were influential in ensuring collections were acceptable and were able to conduct collections independently. 14.5% of trapping events were impacted by householder actions, weather conditions or trap malfunction. ETs were the most cost effective way to catch *Anopheles* (6.4$ per trapping event and 12.8$ per *Anopheles* caught). Community acceptability of the methods of collection was high. Sample size for mosquitos was met though *Anopheles* catch was insufficient in one city. Findings of transmission are hard to apply as cities themselves are not implementation units and collection coverage was not city-wide. Methods need adapting to maximise *Anopheles* catch: we propose planning 250 GT and 3724 ET events in similar settings and weighting trapping events later in the rainy season. Evaluation units should be analogous with implementation units/ the units at which treatment decisions are made.

1932

DEVELOPMENT AND EVALUATION OF SCFV (SINGLE-CHAIN VARIABLE FRAGMENT) ANTIBODIES AGAINST RWB-SXP1 AND ITS IMPLICATION IN THE DIAGNOSIS OF FILARIAL SXP-1

Kaliraj Perumal, Kamatchi R, Mahalakshmi N, Prince R. Prabhu, Meenakshisundaram S

Anna University, Chennai, India

Lymphatic filariasis is one among the globally challenging neglected tropical disease. In the wake of MDA efforts to block transmission of infection in endemic areas, there is a growing need for more efficacious diagnostic tools. Hence, we have already developed various antigen/ antibody based immunodiagnostic methods using a parasite-mf-surface protein *Wb*SXP-1 identified from *Wuchereria bancrofti*. A rapid field applicable immunoassay kit for diagnosis/surveillance is currently available for screening. To augment this effort, we have also developed a functional single-chain fragment variable (scFv) antibody specific for Wb-SXP-1 antigen as an alternative to the production of complete antibodies using hybridomas. The variable heavy chain (VH) and the variable light chain (kappa) (Vκ) genes were amplified from the mouse hybridoma cell line and were linked together with a flexible linker by overlap extension PCR. The ScFv construct (Vκ-Linker-VH) was expressed and purified by IMAC. Immunoblotting and sandwich ELISA were used to analyze the antigen binding affinity of purified scFv, which also recognized recombinant and native Wb-SXP-1 antigen in microfilariae-positive patient sera. To further enhance the efficiency of the scFv against rWb-SXP1, a procedure was developed to create diverse libraries of scFv based on a single DNA framework with all the requisites for an *in vitro* protein synthesis and ribosomal display technique. Sandwich ELISA technique was devised to detect the Kd value between WbSXP1 and native scFv (His tagged). Screening by ribosome display, shows Kd value for WbSXP1 to be 10 fold lesser than the Kd value of native scFv. Reactivity with clinical samples showed significant augment ($p<0.0001$) in reactivity to MF samples with evolved scFv in comparison to wild-type scFv. This evolutionary method coupled with ribosome display has facilitated us to improve the reactivity of the scFv without diminishing the specificity.

1933

THE GLOBAL PREVALENCE OF *CYP2D6* HAPLOTYPE VARIATION AND PREDICTIONS FOR PRIMAQUINE EFFECTIVENESS IN MADAGASCAR

Estee Y. Cramer[1], Rajeev Mehlotra[1], Ernest Chan[1], Jacquelaine Bartlett[1], Rosalind Howes[2], Daniel Tisch[1], Andrea Gaedigk[3], Arsene Ratsimbasoa[4], Scott Williams[1], Peter Zimmerman[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Big Data Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [3]*University of Missouri, Kansas City, MO, United States,* [4]*National Malaria Control Programme of Madagascar, Ministry of Health, Antananarivo, Madagascar*

Plasmodium vivax is treated with primaquine (PQ) to prevent relapsing malaria. PQ must be activated during phase 1 metabolism by CYP2D6 in order to be effective. CYP2D6 has four phenotypic classifications of metabolic activity. Poor (PM) and intermediate (IM) metabolizers appear to exhibit compromised PQ-bioactivating capacity, rendering the medication not or less effective. There are currently no guidelines regarding PQ administration for patients with PM or IM status. The study population includes 2504 samples from the 1000 Genomes Project and 66 samples from Madagascar. Genome-wide haplotype data was generated by whole genome sequence (1000G) or the Illumina MEGAv1.0 SNP array (Madagascar) to perform a principle component analysis (PCA). In addition, *CYP2D6* genomic data (5kb upstream and downstream, 36 SNPs) was also analyzed for PCA. Because the haplotypes are phased in this dataset, nonfunctional (e.g. *CYP2D6*4*) and decreased function haplotypes (e.g. **9, *10, *29, *41*) can be determined. Results from the genome-wide PCA demonstrate that the genetic variation in the Malagasy population draws from both African and East-Asian population origins, consistent with migration patterns into Madagascar. The frequency of the *CYP2D6*4* allele (13.25%) is higher in the Malagasy population than in the East-Asian population (0.4%) and the African population (12%). Frequencies of *CYP2D6*9* (0%), **10* (61%), *29* (6.3%), and **41* (4.8%) alleles in the Malagasy population are in between those seen in African (0.15%, 22%, 21%, 3.6%) and East-Asian (0%, 84%, 0%, 7.5%) populations. Our results highlight the prevalence of nonfunctional and decreased activity alleles in Madagascar, which puts the population at risk of less effective or ineffective PQ treatment. Additionally, our PCA results are consistent with the migration patterns of African and East-Asian populations into Madagascar. To reach *Plasmodium vivax* elimination goals, additional guidelines regarding PQ administration should include *CYP2D6* haplotype information.

1934

FUNCTIONAL IMPLICATIONS OF *PLASMODIUM*-CONSERVED ESSENTIAL GENES IN *P. VIVAX* MALARIA TRANSMISSION BIOLOGY

Jenna Oberstaller, Justin Nicholas, John H. Adams

University of South Florida, Tampa, FL, United States

Genome-wide screens of the most-deadly malaria parasite *Plasmodium falciparum* and the primary rodent-malaria model *Plasmodium berghei* have identified genes essential for parasite survival during asexual blood-stage development. These breakthrough studies provide revelatory insights into prioritizing parasite pathways and processes for new therapeutic interventions. Since most essential genes are conserved among all *Plasmodium spp*., the new functional annotations can be applied to *Plasmodium vivax*, which is much more difficult to study due to lack of continuous culture systems. Though *P. vivax* and *P. falciparum* are both human-infective malaria parasites, they are as far-removed evolutionarily from each other as they are from the rodent-infective *P. berghei*, and it may be the 'dispensable' and 'essential' roles for these genes that are more likely to vary among these species than the gene conservation. While some of the unique *P. vivax* clinical characteristics make it a major hurdle to elimination efforts and will be important metabolic functions to target, we expect that most high-value core metabolic functions will be conserved as

~80% of *P. vivax* genes have an ortholog in *P. falciparum* and *P. berghei*. In this study, we use data from the essentiality screens, coupled with recent transcriptome analyses of *P. vivax* sporozoites and *in vivo* transcriptomic data from longitudinal infection studies in macaques of the vivax-like *P. cynomolgi*, to explore the relationship between blood-stage essentiality and multi-stage function in *P. vivax*. Furthermore, we explore the potential functional implications of *Plasmodium*-conserved essential genes in *P. vivax* sporozoite activation and hepatocyte infectivity to evaluate multi-stage essential genes. Streamlined parasite genomes suggest that every gene is essential in some condition or developmental stage; here we apply an integrated approach to predict multi-stage essential genes to prioritize as targets for intervention.

1935

EXAMINING QUININE MECHANISM OF ACTION AND RESISTANCE USING A NOVEL *PLASMODIUM FALCIPARUM* GENETIC CROSS IN HUMANIZED MICE

Mariko Kanai[1], Leila S. Ross[1], Tomas Yeo[1], Melanie J. Shears[2], Abhai Tripathi[2], Sachel Mok[1], Photini Sinnis[2], David A. Fidock[1]

[1]*Columbia University Irving Medical Center, New York, NY, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Quinine (QN) is used for the treatment of severe *Plasmodium falciparum* malaria; however, it has a complex mechanism of action (MOA) and resistance that remains unresolved. Previous studies suggest a multifactorial mechanism, as polymorphisms in *P. falciparum* chloroquine resistance transporter (*pfcrt*) and *P. falciparum* multidrug resistance-1 (*pfmdr1*) and possibly *pfut* (HECT E3 ubiquitin-protein ligase) partially associate with cytostatic (growth inhibitory) QN resistance (QN^R), as defined by 72-hour drug susceptibility assays (IC_{50}). None of these genes have been validated as the primary QN^R driver and at least one other unidentified mediator is thought to exist. To interrogate the QN mechanism, we have used FRG-NOD human liver-chimeric mice to perform a genetic cross between Cam3.II (QN^R; $pfcrt^{Dd2}$ $pfmdr1^{184F}$) and NF54 (QN-sensitive (QN^S); $pfcrt^{WT}$ $pfmdr1^{WT}$). Microsatellite genotyping with 12 markers showed that of the 163 cloned progeny, at least 64 were genetically distinct recombinants. Preliminary IC_{50} studies with 20 progeny tested at lower QN concentrations indicate that the primary driver of resistance to cytostatic QN activity is neither *pfcrt* nor *pfmdr1*, as two $pfcrt^{Dd2}$ $pfmdr1^{184F}$ progeny had QN sensitivity similar to the QN^S NF54. Similarly, in a QN lethal dose (LD_{50}) assay (N=10) where parasites were exposed to high QN concentrations for 48 hours, washed, and analyzed 24 hours later, variations in LD_{50} values within the $pfcrt^{WT}$ $pfmdr1^{WT}$ genotype also indicate that *pfcrt* and *pfmdr1* do not fully explain resistance to cytocidal (cell killing) QN action at clinically relevant concentrations. Different sensitivities were also observed at the cytocidal vs. cytostatic QN level, suggesting that distinct mechanisms may be involved. We have obtained whole-genome sequences of the independent recombinant progeny and parents, and are proceeding with quantitative trait locus analysis to identify QN resistance mediators. This study will help identify novel surveillance markers and inform new targets for drug development.

1936

WHOLE-GENOME ANALYSIS OF *PLASMODIUM FALCIPARUM* TO UNDERSTAND CLINICAL IMMUNITY TO MALARIA

Zalak Shah[1], Alexis Boleda[2], Kara Moser[1], Matthew Adams[1], Andrea Buchwald[3], Karl Seydel[4], Don Mathanga[5], David Serre[1], Miriam K. Laufer[1], Michael Cummings[2], Joana C. Silva[1], Shannon Takala-Harrison[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*University of Maryland College Park, College Park, MD, United States,* [3]*University of Colorado School of Public Health, Aurora, CO, United States,* [4]*Michigan State University, East Lansing, MI, United States,* [5]*University of Malawi College of Medicine, Blantyre, Malawi*

After repeated *Plasmodium falciparum* infections, individuals in high-transmission areas acquire clinical immunity to malaria. However, the mechanisms important in determining clinical immunity are not entirely known. Here we take a whole-genome approach to identify genes that may be involved in acquisition of clinical immunity to malaria by sequencing and analyzing parasite genomes collected from infected individuals followed over time as part of a longitudinal study in Malawi. We compared parasite genomes from individuals with varying levels of clinical immunity, defined using an individual's age and number of symptomatic infections per year. We also examined pairs of parasites collected at different time points from the same individuals, hypothesizing that these parasites will be more different from each other than expected by chance, at *loci* important for clinical immunity. Using F_{ST} as a measure of genetic differentiation, we identified several SNPs, including SNPs in vaccine candidate antigens such as AMA1, LSAP2 and RESA, that are significantly genetically differentiated between individuals with varying levels of clinical immunity. Analysis of infections from the same individuals showed that there is lower identity-by-descent between parasites from the same individual compared to parasites from different individuals, highlighting the role of allele-specific immunity. We also found that several vaccine candidate antigens, such as SERA5, MSP6, AMA1, etc., differ more than expected by chance in parasites from the same individual compared to parasites from different individuals. SNPs in genes such as *ama1*, *rifin*, and *clag2,* as well as several genes encoding proteins of unknown function, were identified by both analyses, lending further support for their involvement in the development of immunity. We will analyze *in silico* predicted T/B-cell epitope regions in *loci* these genes to understand which regions of these proteins might be immunologically important. Identifying and further analyzing these genomic regions will provide insights into mechanisms involved in acquired immunity and antigenic escape.

1937

THE MIRAGE PROJECT - MALARIA INFECTIOUS RESERVOIR AND GENOMICS, IN SEARCH OF ELUSIVE MALARIA PARASITES IN THE DRY SEASON

Antoine Claessens[1], Benoit Aliaga[1], Sukai Ceesay[2], Sarah Tarr[3], David Conway[3], Teun Bousema[4], Umberto D'Alessandro[2]

[1]*University of Montpellier, Montpellier, France,* [2]*MRC-Gambia, Banjul, Gambia,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*RadboudUMC, Nijmegen, Netherlands*

Malaria in The Gambia is seasonal, with virtually all cases occurring during or just after the four months wet season. As there is very little transmission during the dry season, the reservoir for *Plasmodium falciparum* parasites is thought to be within asymptomatic chronic infections. How the parasite population can switch from a typically high parasitaemia virulent phenotype in the wet season to a 'dormant-like' state in the dry season is not understood. To address this question, at the start of the dry season, we established a cohort with 60 *P. falciparum*-positive asymptomatic Gambian participants who were bled monthly for 6 months. 45% were still carriers at the end of the dry season. We now have a unique dataset of parasite and human serum samples from the same individuals over a 6-month period to investigate how *P. falciparum* establishes a chronic infection. In collaboration with MalariaGEN, parasite genomes are being sequenced to investigate the genetic diversity in the wet and dry seasons. With the Conway lab at LSHTM, we analyse how the parasite senses its environment and adapt to it using (1) Parasite Multiplication Rate assays, and (2) RNA-Seq, to compare parasite transcriptomes across monthly timepoints. Our novel protocol can sequence a whole transcriptome from as few as 1000 parasites. Ongoing data analysis reveals a specific 'transcriptomal signature' of an isolate within its host, stable over time. To the best of our knowledge, this is the first characterization of monthly parasite transcriptomes derived from the same ongoing infection. This

study design, which has the potential to answer a multitude of biological questions, will greatly advance our understanding of the parasite, host and vector interactions, with direct implications for malaria eradication.

1938

SPATIAL ANALYSIS OF PARASITE POPULATION GENOMICS DURING MALARIA ELIMINATION EFFORTS IN EASTERN MYANMAR

Xue Li[1], Grace A. Arya[1], Ann Reyes[1], Aung Myint Thu[2], Gilles Delmas[2], Daniel M. Parker[3], Khin Maung Lwin[2], Kanlaya Sriprawat[2], François Nosten[4], Tim Anderson[1]

[1]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [2]*Shoklo Malaria Research Unit, Mae Sot, Thailand,* [3]*University of California, Irvine, CA, United States,* [4]*University of Oxford, Oxford, United Kingdom*

Early diagnosis and effective antimalarial treatment, combined with mass treatment of "hotspot" villages has proven to be extremely effective in reducing malaria transmission in Kayin State in Eastern Myanmar, an area of multidrug resistance. We describe how genomic surveillance of malaria parasite samples collected during this elimination program can be used to monitor the spread of resistant alleles, to examine patterns of parasite transmission, and to inform control efforts. We prepared DNA from > 3000 blood spots from *Plasmodium falciparum* infected patients collected from > 300 malaria posts in a region of Kayin state spanning ~200km from the northernmost to southernmost village during malaria elimination efforts between 2016 and 2018. We optimized selective whole genome amplification (sWGA) protocols for amplifying low levels of malaria DNA from contaminating human DNA. We are able to use sWGA to recover sufficient malaria DNA for genome sequencing from samples with >24.8 pg malaria DNA as measured by qPCR (approximately one third of the samples) and we have now successfully sequenced >1000 parasite genomes. We are using this dataset, with precise spatial and temporal information for each sample, to examine the spread of resistance alleles under intense selection, to estimate spatial patterns of relatedness (and parasite transmission) using identity-by-descent relationships and landscape features, and to trace mutational changes in clonal lineages of inbred parasites.

1939

SPATIAL-GENETIC ANALYSIS OF *PLASMODIUM FALCIPARUM* IN THE DEMOCRATIC REPUBLIC OF THE CONGO THROUGH MOLECULAR INVERSION PROBES

Robert Verity[1], Ozkan Aydemir[2], Nicholas F. Brazeau[3], Oliver J. Watson[1], Nicholas J. Hathaway[4], Melchior K. Mwandagalirwa[5], Patrick K. Marsh[2], Travis Fulton[3], Madeline Denton[3], Andrew Morgan[3], Jonathan Parr[3], Philip J. Rosenthal[6], Patrick Tumwebaze[7], Julie Gutman[8], William Moss[9], Modest Mulenga[10], Anita Ghansah[11], Benidicta Menseh[11], Antoinette K. Tshefu[12], Azra C. Ghani[1], Steven R. [1]*Imperial College London, London, United Kingdom,* [2]*Brown, Providence, RI, United States,* [3]*University of North Carolina, Raleigh-Durham, NC, United States,* [4]*University of Massachusetts, Worcester, MA, United States,* [5]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo,* [6]*University of California San Francisco, San Francisco, CA, United States,* [7]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [8]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [9]*John Hopkins, Baltimore, MD, United States,* [10]*Tropical Disease Research Centre, Ndola, Zambia,* [11]*Noguchi Memorial Institute for Medical Research, University of Ghana, Noguchi, Ghana,* [12]*Kinshasa School of Public Health, Hôpital General Provincial de Reference de Kinshasa, Kinshasa, Democratic Republic of the Congo*

The Democratic Republic of the Congo (DRC) is estimated to harbor 20% of the global malaria burden. Historically, malaria control efforts have been hampered by the evolution of antimalarial resistance, which is reflected in complex spatial patterns of molecular markers of drug resistance, such as pfcrt and pfdhps. The fine-scale genetic structure that this imposes on the parasite population is currently poorly understood. Using two panels of molecular inversion probes (MIPs), one targeting 1793 SNPs across the genome and one targeting known drug resistance mutations, we carried out the largest nationally representative study of *Plasmodium falciparum* genetic population structure in Africa to date. We used 1951 geo-referenced samples from the 2013 Demographic and Health Survey (DHS) and 435 samples from surrounding countries. PCA showed that parasites in the DRC link traditional East African and West African parasite populations with a Northwest to Southeast cline, consistent with traditional isolation by distance. Subsequent principal components showed population differentiation from both known drug resistance alleles and novel genes not previously characterized. Embedded within these relationships, the high-density SNP genotyping allowed for assessment of highly related pairs of parasites that occurred over distances beyond the expected geographic decay of relatedness. These patterns suggest migration events and gene sharing occurring between Kinshasa and outlying regions in the country. This study provides the first data on fine-scale genetic structure of parasites at a national scale in Africa, and provides a baseline that can be used to study how implementation programs impact parasite populations in the region. The newly implemented MIP platform represents a highly scalable and cost-effective means of providing genome-wide genetic data, without the costs of whole genome sequencing, on large numbers of samples needed for large population surveys. The highly flexible nature of the platform allows it to be rapidly scaled in terms of targets and samples leading it to be applicable across malaria endemic countries.

1940

MALARIA CHEMOPREVENTION WITH MONTHLY TREATMENT WITH DIHYDROARTEMISININ PIPERAQUINE FOR THE POST DISCHARGE MANAGEMENT OF SEVERE ANAEMIA IN CHILDREN AGED LESS THAN FIVE YEARS IN UGANDA AND KENYA: A 3 YEAR, MULTI-CENTER, TWO ARM RANDOMIZED PLACEBO CONTROLLED SUPERIORITY TRIAL

Titus K. Kwambai[1], Aggrey Dhabangi[2], Richard Idro[2], Robert Opoka[2], Simon Kariuki[1], Victoria Watson[3], Nickline Ashitiba[1], Kephas Otieno[1], Aaron M. Samuels[4], Meghna Desai[4], Chandy C. John[5], Bjarne Robberstad[6], Michael Boele van Hensbroek[7], Duolao Wang[3], Kamija Phiri[8], Feiko O. ter Kuile[3]

[1]*Kenya Medical Research Institute, Kisumu, Kenya,* [2]*Makerere University College of Health Sciences, Kampala, Uganda,* [3]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [4]*Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [5]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,* [6]*Centre for International Health, University of Bergen, Bergen, Norway,* [7]*Emma Children's Hospital, Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands,* [8]*School of Public Health and Family Medicine, College of Medicine, University of Malawi, Blantyre, Malawi*

Children hospitalised with severe-anaemia in malaria-endemic areas are at high risk of readmission or death within 6 months post discharge. No strategy specifically addresses this post-discharge period. We conducted a multi-centre, two-arm, placebo-controlled, randomized trial in nine hospitals in Kenya and Uganda to determine if 3 months of post-discharge malaria chemoprevention (PMC) with monthly 3-day treatment courses of dihydroartemisinin-piperaquine (DP) reduced the rate of all-cause readmissions and deaths by 6 months post discharge (primary outcome) compared to a single 3-day treatment course with artemether-lumefantrine provided at discharge (control). Between May 2016 and November 2018, children aged &lt5 years with admission haemoglobin of &lt5g/dL received standard in-hospital care for severe-anaemia and a standard 3-day course with artemether-lumefantrine at discharge. They were randomized two weeks later to receive DP or placebo-DP at 2, 6 and 10 weeks and followed until week 26 inclusive using passive case-detection. Conditional risk set modelling for repeated events (Prentice-Williams-Peterson total-time) were used to obtain hazard ratios

(HR). Overall, 1049 children were randomized (PMC=524, control=525). Between 2-26 weeks post-discharge, there were 189 primary outcome events in the PMC arm and 324 in the placebo arm (HR=0.64 (95% CI 0.53-0.78). The HR during the PMC-intervention period (2-14 weeks) was HR=0.36 (0.27-0.47) and HR=1.17 (0.88-1.55) during the extended follow-up period (14-26 weeks). The median time to the first event was delayed from 47 to 111 days. In areas with intense malaria transmission, three months of malaria chemoprevention in children recently admitted with severe anaemia results in major reductions in all-cause readmissions or death post-discharge.

1941

MATERNAL AND CHILD MALARIA CHEMOPREVENTION TO ENHANCE CHILD DEVELOPMENT: A DOUBLE-BLINDED RANDOMIZED CONTROLLED TRIAL

Paul Bangirana[1], Andrea L. Conroy[2], Robert O. Opoka[1], Margaret Semrud-Clikeman[3], Maria Kroupina[3], Michael Georgieff[3], Grant M. Dorsey[4], Moses R. Kamya[1], Diane Havlir[4], Chandy C. John[2]

[1]*Makerere University, Kampala, Uganda,* [2]*Indiana University, Indianapolis, IN, United States,* [3]*University of Minnesota, Minneapolis, MN, United States,* [4]*University of California San Francisco, San Francisco, CA, United States*

Malaria in pregnancy is associated with adverse birth outcomes like premature birth and low birth weight which often affect neurodevelopment in the developing fetus and child. In addition, childhood severe malaria is associated with 1 in 4 children having long-term cognitive impairment. Prevention of malaria in pregnancy and in young children may thus prevent poor neurodevelopmental outcomes in children in malaria endemic areas. We present neurodevelopmental outcomes of children at age 36 months following chemoprevention in mothers and the children. Three hundred pregnant HIV-uninfected women were randomized at 12-20 weeks of gestation to malaria chemoprevention with either 3 doses of sulfadoxine-pyrimethamine (SP), or 3 doses of dihydroartemisinin-piperaquine (DP), or monthly DP. After birth, the children were randomized to receive DP chemoprevention monthly or every 3 months from 2 to 24 months age. Neurodevelopmental testing was performed using the Bayley Scales of Infant and Toddler Development third edition and parental completion of the Child Behavior Checklist. Monthly DP was associated with a lower risk of maternal and placental malaria compared to SP or 3 doses of DP during pregnancy and with a lower risk of malaria compared to DP every 3 months during infancy. Placental malarial and malaria in pregnancy were associated with poorer language development (mean difference 1.28, 95% CI: 0.12 to 2.45, p=0.03 and mean difference 2.21, 95% CI: 0.72 to 3.70, p=0.004 respectively). Malaria in the first 12 months was associated with poorer motor and language development (mean difference 5.82, 95% CI: 0.38 to 11.26, p=0.04 and mean difference 3.60, 95% CI: 1.24 to 5.96, p=0.003 respectively) at 36 months. Pathway analysis is being conducted to assess whether malaria chemoprevention mediates protection against adverse neurodevelopmental and behavioral outcomes. Placental malaria, malaria in pregnancy in the mother and malaria in the first 12 months of life in the child are associated with worse child neurodevelopmental outcomes at 36 months.

1942

INTERMITTENT PREVENTIVE TREATMENT WITH SULFADOXINE-PYRIMETHAMINE CONFERS NON-MALARIAL EFFECT ON BIRTHWEIGHT: RESULTS FROM A MEDIATION ANALYSIS

Michelle Roh[1], M. Maria Glymour[1], Stephen Shiboski[1], Roly Gosling[1], Anne L'Ianziva[2], Abel Kakuru[3], Richard Kajubi[3], Meghna Desai[4], Julie Gutman[4], Feiko ter Kuile[5], Moses R. Kamya[6], Grant Dorsey[1], R. Matthew Chico[7]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Centers for Disease Control and Prevention (CDC), Kisumu, Kenya,* [3]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [4]*Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, US Centers for Diseases Control and Prevention, Atlanta, GA, United States,* [5]*Liverpool School of Tropical Medicine, London, United Kingdom,* [6]*School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda,* [7]*Faculty of Infectious and Tropical Disease, London School of Hygiene & Tropical Medicine, London, United Kingdom*

The World Health Organization recommends intermittent preventive treatment in pregnancy (IPTp) with sulfadoxine-pyrimethamine (SP) in areas of high to moderate malaria transmission to prevent consequences of malaria infection. Parasite resistance to SP has led researchers to evaluate IPTp with dihydroartemisinin-piperaquine (DP) as an alternative to SP. Three IPTp trials in East Africa have shown DP to be more effective than SP in preventing malaria infection, but not superior at improving newborn birthweight. We conducted mediation analysis using individual-level data from 1,612 HIV-uninfected women enrolled in IPTp trials in Uganda (n=2) and Kenya (n=1) to decompose the non-malarial and antimalarial effects of SP versus DP on birthweight. Treatment was defined as random assignment to SP or DP; the mediator was placental malaria at delivery; the outcomes were birthweight and low birthweight (LBW; <2.5 kg). We accounted for confounders (maternal age, education, household wealth, and gravidity) and interaction by gravidity. Meta-analyses were used to obtain pooled estimates of the total, non-malarial, and antimalarial effects of SP vs DP. Meta-analyses showed SP increased birthweight 73 g [95% CI: 30, 115] compared to DP. This effect was attributed mainly to SP's non-malarial activity (non-malarial effect vs DP=104 g [95% CI: 53, 155]). In contrast, the more potent antimalarial properties of DP produced a modest 34 g [95% CI: -8, 77] increase in birthweight compared to SP via antimalarial mechanisms. DP's antimalarial effect was larger and statistically significant in Uganda, where malaria transmission was higher (74 g [95% CI: 12, 137]). Multigravidae benefited more from the non-malarial effects of SP on birthweight compared to primigravidae (103 g [95% CI: 51, 154] vs 46 g [95% CI: -40, 131]), though differences were seen mainly in Ugandan data. Similar results were observed with LBW. SP appears to have potent, non-malarial effects on birthweight and LBW, independent of its antimalarial activity. Future research should evaluate combining SP with DP for IPTp to prevent both malarial and non-malarial causes of poor pregnancy outcomes.

1943

THE DURATION OF PROTECTION FROM AZITHROMYCIN AGAINST MALARIA, PNEUMONIA AND GASTROENTERITIS WHEN GIVEN ALONGSIDE SEASONAL MALARIA CHEMOPREVENTION: SECONDARY ANALYSIS OF DATA FROM A CLINICAL TRIAL IN HOUNDÉ, BURKINA FASO AND BOUGOUNI, MALI

Matt Cairns[1], **Mphatso Phiri**[2], Issaka Zongo[3], Issaka Sagara[4], Irene Kuepfer[1], Frederic Nikiema[3], Modibo Diarra[4], Amadou Barry[4], Amadou Tapily[4], Paul Milligan[1], Jean Bosco Ouédraogo[3], Daniel Chandramohan[1], Alassane Dicko[4], Brian Greenwood[1]

Mass administration of azithromycin (AZ) is being considered as a strategy to reduce mortality in young children in sub-Saharan Africa, but the potential mechanism by which AZ reduces child mortality is not well characterised. To better understand the nature and extent of protection provided by AZ against common causes of childhood illness, we explored the changing profile of protection against clinical malaria, clinical pneumonia and gastroenteritis by time since administration, using data from a household-randomized, placebo-controlled trial of azithromycin given alongside seasonal malaria chemoprevention (SMC) with sulphadoxine-pyrimethamine plus amodiaquine in Burkina Faso and

Mali. In this study, a cohort of approximately 20,000 children received AZ or placebo with SMC on four occasions during the peak malaria transmission season each year from 2014 and 2016. Poisson regression with a gamma-distributed random effect was used to obtain the incidence rate ratio comparing children given SMC + AZ versus children given SMC + placebo in fixed time strata post-treatment, accounting for the household-randomized design and within-individual clustering of malaria, pneumonia and gastroenteritis episodes. The likelihood ratio test was used to assess evidence for the time-treatment group interaction. The additional protection of SMC + AZ against malaria, relative to SMC + placebo was confined entirely to the first two weeks after administration (Protective efficacy 24.2% (95% CI: 17.8%, 30.1%) P<0.001; suggesting either improved cure of existing infections, or a short-lived contribution to post-treatment prophylaxis. There was evidence of higher initial protection against pneumonia and gastroenteritis, and some evidence of protection beyond the first two weeks post-treatment. We will discuss the possible implications for the mechanism of AZ protection, including the role of curative versus prophylactic effects, and the role of reinfection rates for different pathogens in determining the overall benefit of treatment.

1944

THE EFFECTIVENESS OF SEASONAL MALARIA CHEMOPREVENTION (SMC) IN THE OPERATIONAL PROGRAMMING CONTEXT OF GUINEA

Donal Bisanzio[1], Aissata Fofana[2], Timothée Guilavogui[3], Eugene Kaman Lama[4], Elizabeth Fitch[5], Adam Preston[6], Mamadou Aliou Baldé[2], Jean-Luc Taton[1], Lamine Bangoura[7], Richard Reithinger[1]

[1]*RTI International, Washington, DC, United States,* [2]*PMI StopPalu+ Project, RTI International, Conakry, Guinea,* [3]*National Directorate of Disease Control, Ministry of Health, Conakry, Guinea,* [4]*National Malaria Control Program, Conakry, Guinea,* [5]*RTI International, RTP, NC, United States,* [6]*RTI International, Fort Collins, CO, United States,* [7]*President's Malaria Initiative, US Agency for International Development, Conakry, Guinea*

Seasonal malaria chemoprevention (SMC) is one of the main interventions recommended by WHO to prevent and reduce malaria cases in children under five years of age living in high transmission areas. While the efficacy of SMC in randomized controlled clinical research trials is well established, reports on its epidemiological impact in an operational programming context is more limited. Since 2015, thanks to international support, Guinea's National Malaria Control Program (NMCP) has implemented SMC targeting children ages 3-59 months (CU5) in districts with high malaria incidence. SMC-targeted districts have increased from 8 in 2015 to 13 in 2018. Since 2018, the PMI-funded StopPalu+ project supported the NMCP in implementing SMC in 8 of the countries' 38 districts. We report on the epidemiological impact of the SMC implementation in a context of scaled-up malaria intervention programming, including enhanced case detection and case management, long-lasting insecticidal nets and disease surveillance. Using trend analysis and generalized linear modelling, we compared the trends of malaria test positivity rate (MTPR) in CU5 among SMC and non-SMC covered districts from 2014 (i.e. one year prior to SMC being implemented) to 2018 using data from the routine malaria information system; data included health facility and community-level data. Additionally, we compared MTPR in CU5 to individuals above 5 years of age in SMC districts. Results show that a greater reduction in MTPR in CU5 in SMC districts than in non-SMC districts between 2014 and 2018, with the mean MTPR of CU5 decreasing from 35.1% to 29.8% (15.3% reduction) in SMC districts and from 29.8% to 27.1% (6.8 % reduction) in non-SMC districts ($p<0.05$). Moreover, in SMC districts, the reduction in MTPR in CU5 was 1.4-fold higher than in individuals aged 5 years and above ($p<0.05$). The reduction in MPTR did not show strong heterogeneity among the SMC districts. Our results confirm that—even in an operational programming context—adding SMC to the comprehensive package of malaria interventions yields an epidemiological impact and results in greater reduction in MTPR in CU5.

1945

OPTIMIZING DELIVERY OF SEASONAL MALARIA CHEMOPREVENTION (SMC) FOR CHILDREN UNDER FIVE YEARS OF AGE: VERY HIGH COVERAGE CONSISTENTLY ACHIEVED THROUGH DOOR-TO-DOOR CAMPAIGNS IN BURKINA FASO

Issaka Zongo[1], Jean Bosco Ouédraogo[1], Yacouba Sawadogo[2], Sham Lal[3], Matt Cairns[3], Paul Snell[3], Johanna Stenstrom Johansson[4], Diego Moroso[5], Paul J. Milligan[3]

[1]*Institut de Recherche en Sciences de la Santé (IRSS)/Institut des Sciences et Techniques (INSTech), Bobo Dioulasso, Burkina Faso,* [2]*Programme Nationale Lutte Contre le Paludisme, Burkian Faso, Ouagadougou, Burkina Faso,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*Malaria Consortium, Ougadougou, Burkina Faso,* [5]*Malaria Consortium, Kampala, Uganda*

According to WHO estimates Burkina Faso consistently ranks among the small group of countries contributing the vast majority of the world's malaria deaths each year. To address this public health emergency, SMC was introduced in 2014 and scaled up in subsequent years so that by 2018 SMC was implemented in 65 of the 70 districts in the country, over 4 months during and immediately after the rainy season. A survey in 2016 by ACCESS-SMC showed very high levels of uptake, 99% of eligible children received at least one SMC treatment, and 91% received 4 treatments. That survey was undertaken at the end of the season and relied on caregiver recall for children who did not have an SMC record card or whose card was not completed. To verify the validity of estimating SMC coverage at the end of the season, in 2017 we conducted surveys immediately after each monthly cycle, to compare coverage estimates with retrospective estimates made for the same month in the final survey. 1050 children eligible for SMC were surveyed after the July campaign, and 1567, 1692 and 1776 after the Aug, Sep and Oct campaigns. SMC record cards were available for inspection in 77%, 85%, 79% and 88% of children in each month. The coverage in Jul, Aug and Oct was 95%, 96% and 95%. This compares with retrospective estimates for the same months of 96%, 97% and 96%, obtained in the final survey. The close agreement indicates that coverage can be reliably assessed through a single survey at the end of the season. Coverage in the final month was 96%. 90.5% of children received SMC 4 times. Adherence was high, out of the children who received SMC, the percentage reported to have received all 3 daily doses was 98.2%, 99.5%, 99.5% and 99.6% each month. Out of the children who received a blister pack, the first dose was directly observed each month in 96.8%, 99.2%, 99.1% and 98.5%. Out of those who slept in the household the night before the survey, 95% of children and 92% of all household members slept under an LLIN. SMC is a life-saving intervention. We have shown that very high coverage of SMC can be consistently achieved. This should encourage other countries to investigate barriers to full coverage and take steps to overcome them.

1946

THE EFFECTIVENESS OF REPELLENT DELIVERED THROUGH VILLAGE HEALTH VOLUNTEERS ON MALARIA INCIDENCE IN SOUTHEAST MYANMAR: A STEPPED-WEDGE CLUSTER-RANDOMIZED CONTROLLED TRIAL

Paul Agius[1], Win Han Oo[2], Naanki Pasricha[1], Katherine O'Flaherty[1], Kyaw Zayar Aung[2], Aung Thi[3], Myat Mon Thein[2], Nyi Nyi Zaw[2], Htin Kyaw Thu[2], Wai Yan Min Htay[2], Aung Paing Soe[2], Nicole Romero[1], Zahra Razook[4], Alyssa Barry[4], Angela Devine[5], Julie Simpson[6], Brendan S. In February 2019 the World Health Organization released the guidelines for malaria vector control. Personal repellents have the potential to provide individual protection against mosquito bites, however their deployment in large-scale public health campaigns is not recommended due to the lack of high quality evidence of their public health value. In the Great Mekong Subregion malaria services are typically provided by village health volunteers to ensure access to malaria services in hard to reach populations. In order to provide 'real-world' evidence for the effectiveness of repellent distributed by village health volunteers on *Plasmodium* spp. infection (detected by rapid diagnostic test [RDT] and PCR) we performed a stepped-wedge cluster randomized trial 116 villages in South-east Myanmar over 15 months . *Plasmodium* spp. incidence was low over the duration of the study (0.16%, RDT; 3.2% PCR). We observed a significant decline in *Plasmodium* spp. infection detected by RDT across the study period, independent of the repellent intervention and seasonal variations in incidence which is most likely due to the increased access to malaria services provided by the village health volunteers. However, this decline was not observed for PCR-detectable infection which fluctuated over time. *Plasmodium* spp. detected by both RDT and PCR significantly reduced once villages transitioned into repellent distribution. There was significant heterogeneity observed in the nature of the effect of repellent distribution between villages and the protective effect was greatest for *P. falciparum*, with no protection observed against *P. vivax*. The observed reduction in *P. falciparum* infection incidence after repellent distribution, suggests that the incorporation of repellent into existing malaria services may be an effective strategy in combating malaria in Myanmar and the Greater Mekong Subregion more broadly.

Zika virus (ZIKV) is a mosquito-borne flavivirus that was first isolated from a sentinel macaque in the Zika forest of Uganda in 1947. It caused sporadic human infection throughout Africa and Asia until the first large outbreak on the island of Yap in Micronesia in 2007. The second large outbreak occurred in French Polynesia in 2013. Beginning in early 2015, Brazil experienced a very large outbreak of Zika which rapidly spread throughout the country as well as neighboring countries in Latin America. By the end of 2015, an association between ZIKV infection in pregnancy and microcephaly was established. Due to the devasting effects of congenital Zika syndrome (CZS), a safe and effective Zika vaccine is needed. Scientists at the U.S. NIH have developed the live attenuated Zika vaccine, rZIKV/DEN4Δ30), using a similar approach as that which resulted in the development of the live attenuated dengue vaccine TV003 currently in Phase 3 clinical evaluation. The eventual goal of this program is to develop a pentavalent dengue/Zika vaccine. rZIKV/DEN4Δ30 was developed by substituting the prM and E proteins of ZIKV Paraiba/2015 into the background of the DENV-4 vaccine candidate rDEN4Δ30. The vaccine was evaluated in a Phase 1 clinical trial conducted at Johns Hopkins University and the University of Vermont. Twenty-eight subjects were enrolled (20 received vaccine; 8 received placebo). Subjects received a single subcutaneous dose of vaccine. They were evaluated in the clinic approximately every other day for the first 3 weeks of the trial. At each visit, subjects were evaluated by a clinician and safety laboratory studies were performed. Blood, urine, semen, and cervico-vaginal secretions were collected and tested for the presence of vaccine virus at frequent intervals throughout the study. Blood for serology was obtained on study days 0, 28, 56, 90, 150, and 180. Complete safety, virologic, and serologic responses will be presented.

1948

SAFETY OF A PURIFIED INACTIVATED ZIKA VIRUS VACCINE (PIZV) CANDIDATE IN FLAVIVIRUS PRIMED HEALTHY ADULTS

Htay Htay Han, The ZIK-101 Study Group

[1]*Takeda Vaccines Inc., Cambridge, MA, United States*

Due to the co-circulation of Zika virus (ZIKV) and other flaviviruses (FV) in endemic regions, it is important to evaluate how preexisting immunity to other FV might impact the outcomes of ZIKV vaccines in development. We evaluated the safety and immunogenicity of a two-dose regimen of PIZV at three dose levels (2, 5 or 10 μg) in a two-stage phase 1 study, first in FV-naïve (data not shown) and second in FV-primed healthy adults. This study was conducted at multiple sites in the US and Puerto Rico. The FV-primed healthy adults aged 18-49 years (N=146) were enrolled and randomized into four groups (1:1:1:1) to receive either two administrations of placebo or one of three PIZV dose levels with 28 days interval. Study participants recorded solicited adverse events (AEs) for 7 days, and unsolicited AEs for 28 days after each dose. Serious adverse events (SAEs) were recorded throughout the study period. Safety laboratory parameters were measured at baseline and 7 days post vaccination. Neutralizing antibodies were measured by a plaque reduction neutralizing test (PRNT) before vaccination and 28 days after each dose. Here we report the cumulative safety data from an interim analysis. Out of 146 participants enrolled, 136 received two doses and completed the 28 day post-dose 1 visit and the 7 day post-dose 2 visit, and 99 completed the 28 day post-dose 2 visit. Reported solicited local reactions were higher in PIZV groups compared with placebo. Pain was the most frequently reported reaction, but mostly mild in intensity across all PIZV groups. Reported solicited systemic AEs in PIZV groups were comparable to placebo recipients, generally mild to moderate in intensity across the groups with no apparent increase with increasing dosage. Unsolicited AEs were reported with similar frequencies in all groups; two unrelated SAEs were reported. There were no changes of concern in safety lab parameters across all vaccine groups. Similar safety profiles were observed in all PIZV groups. In summary, the PIZV vaccine was well tolerated with an acceptable safety profile at all dose levels in FV-primed healthy adults. Immunogenicity analyses are being reported later.

1949

ASSOCIATION BETWEEN ZIKA VIRUS MICROCEPHALY IN THE NEWBORN WITH THE RS3775291 VARIANT AT TOLL-LIKE RECEPTOR 3 AND RS1799964 VARIANT AT TNFA GENES

Amélia R. Ribeiro[1], Camilla N. Santos[1], Danielle R. Ribeiro[1], Juliana A. Cardoso[1], Rodrigo A. Cazzaniga[1], Lucas S. Magalhães[1], Mércia S. de Souza[1], Adriana B. Fonseca[1], Ana J. Congenital Zika syndrome (CZS) is a cluster of malformation and the mechanisms that lead to it are still unclear. Seventy women who gave birth to babies with CZS from August 2015 to March 2017, seventy children with CZS, attended to the pediatric service of the University Hospital in Sergipe, Brazil, and twenty-three fathers were recruited to participate in this study. We performed clinical evaluation to confirm the neurological damage and serological tests to exclude other causes that might induce neurological injury, such as microcephaly. According to the World Health Organizations patterns, forty-two of these CZS babies were classified with severe microcephaly (more than 2 standard deviations below the mean for gestational age and sex) and seventeen with microcephaly (more than 3 standard deviations below the mean for gestational age and sex). All parents of these seventy CZS babies were ZIKV IgG positive by ELISA test. Other infections associated to microcephaly were discarded

(Cytomegalovirus, *Toxoplasma gondii*, Rubella virus and Herpes simplex virus). The control group was composed of forty-three mothers who live in the same endemic areas and their healthy babies, born during the same period of the case group. Epidemiological data were obtained by a questionnaire. Among the control group, 15 mothers were ZIKV IgG positive and 28 were negative. Whole blood sample were collected from all participants to obtain DNA, plasm and serum samples. We genotyped DNA samples using TLR3 rs3775291 and TNFα rs1799964 TaqMan® probe by qPCR. This study shows that a Single Nucleotide Polymorphism (SNP) in rs3775291 at TLR3, that trigger to type I interferons antiviral responses, in mothers infected by ZIKV during pregnancy is associated with CZS occurrence. Moreover, the T allele in SNP rs1799964 at TNFα gene in the CZS babies is associated with microcephaly severity.

1950

MAPPING THE ASSOCIATION BETWEEN ZIKA VIRUS INFECTION AND MICROCEPHALY IN BRAZIL

Oliver J. Brady[1], Simon I. Hay[2], Robert C. Reiner[2], Fatima Marinho[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*IHME, University of Washington, Seattle, WA, United States*

Towards the end of 2015, high rates of microcephaly were reported in Northeast Brazil following the first South American Zika virus (ZIKV) outbreak. Despite ZIKV subsequently spreading throughout Brazil, reported rates of microcephaly varied up to ten-fold in different parts of the country. While evidence from a range of laboratory-based and clinical cohort studies have proven the link between ZIKV infection in pregnancy and microcephaly, it remains unclear why microcephaly rates would show such high geographic heterogeneity. Here we merged data from multiple national databases in Brazil to derive an individual-level trimester-specific estimates of ZIKV exposure, in addition to relevant confounders, for 3.6 million pregnancies that occurred during the outbreak. Pregnancies that resulted in births with confirmed microcephaly (cases) were compared against all other births (controls) to derive population-representative estimates of risk. We estimate an absolute risk of microcephaly of 40.8 (95% CI 34.2-49.3) per 10,000 births and a relative risk of 16.8 (95% CI 3.2-369.1) given ZIKV infection in the first or second trimester of pregnancy; however, most pregnant women in Brazil during the ZIKV outbreak will have been subject to lower and more variable risk levels which we map at a high geographic resolution. Statistically significant associations of ZIKV with other birth defects were also detected, but at lower relative risks than that of microcephaly (relative risk < 1.5). This study strengthens the evidence that congenital ZIKV infection, particularly in the first two trimesters of pregnancy, is associated with microcephaly and less frequently with other birth defects. Our estimates of risk given exposure are comparable to previous clinical cohort studies, showing the utility of passive reporting data if analysis can carefully take into account its various biases and gaps. Our maps also suggest that the ZIKV epidemic was much more geographically restricted than previously thought which may imply higher risk of future ZIKV outbreaks in Brazil than previously thought.

1951

MOTOR FUNCTION AT 18 MONTHS AMONG INFANTS FROM THE PEDIATRIC OUTCOMES OF PRENATAL ZIKA EXPOSURE (POPZE) STUDY IN SOUTHERN PUERTO RICO

Luisa I. Alvarado-Domenech[1], Viviana Rosario-Villafañe[1], Nicole M. Pérez-Rodríguez[2], Irelis C. Repollet-Carrer[1], Luzeida Vargas-Lassalle[1], Vanessa Rivera-Amill[2], Mary Rodriguez-Rabassa[2]

[1]*Ponce Health Sciences University, Saint Luke's Episcopal Hospital, Ponce, Puerto Rico,* [2]*Ponce Health Sciences University, Ponce, Puerto Rico*

Zika virus (ZIKV) infection during pregnancy has been associated with adverse birth outcomes known as the Congenital Zika Syndrome (CZS), characterized by microcephaly and central nervous system abnormalities. However, microcephaly is considered the "tip of the iceberg" of this congenital infection. Consequently, children with possible congenital Zika infection born with no apparent clinical findings of CZS must be monitored over time. This study aims to describe the motor function of infants enrolled in the Pediatric Outcomes of Prenatal Zika Exposure (POPZE) cohort study. Infants born to mothers with confirmed (positive Real Time-Polymerase Chain Reaction (RT-PCR) result) or probable (positive Immunoglobulin M Enzyme-linked Immunosorbent Assay (IgM ELISA) result) ZIKV infection at a tertiary hospital in southern Puerto Rico from October 2016 to August 2017 were included. A follow-up visit was conducted at 18 months, where physical and neurologic examinations were performed. The Peabody Developmental Motor Scales (PDMS-2) was used to measure the gross motor development through the Gross Motor Quotient (GMQ) which is comprised by three specific subtests. Descriptive statistics were performed according to sociodemographic characteristics, clinical features, and the GMQ results from this visit. Additionally, comparisons between specific GMQ subtests' standard scores and their corresponding percentiles will be presented. A total of 40 infants were examined, 24 (60%) were females, and 8 (20%) were born preterm (gestational age &lt 36). One infant (3%) had moderate microcephaly at birth. According to GMQ totals, 14 (35%) infants had below average scores compared to age-specific means. Among this group, 3 infants (21%) were hypotonic, and 1 (7%) was not walking independently. Quantifying and describing the gross motor development of infants that are at risk of gross motor delay and tone abnormalities allows early referrals for developmental interventions and may mitigate adverse impacts of this congenital infection on the development of subsequent skills.

1952

ESTIMATION OF ZIKA VIRUS INFECTION RATES IN BLOOD DONORS FOLLOWING THE 2016 EPIDEMIC IN PUERTO RICO USING TWO SEROLOGICAL ASSAYS

Graham Simmons[1], Mars Stone[1], Magelda Montoya Cruz[2], Jasmine Larrick[2], Celine Cheng[1], Inder Singh[1], Honey Dave[1], Phillip Williamson[3], Eva Harris[2], Michael Busch[1]

[1]*Vitalant Research Institute, San Francisco, CA, United States,* [2]*School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [3]*Creative Testing Solutions, Tempe, AZ, United States*

Zika virus (ZIKV) caused a dramatic epidemic in Puerto Rico (PR) during 2016 and 2017, with over 36,000 reported cases; however, overall infections are likely to have been much higher. Estimating the infection rate during the epidemic in this previously naïve population would help establish the likelihood of future outbreaks in PR. Therefore, we performed a serosurvey for anti-ZIKV IgG using two assays that demonstrated strong performance in terms of specificity on blinded arbovirus panel evaluations: the Biotechne ZIKV IgG NS1 ELISA and a ZIKV NS1 blocking of binding (BoB) ELISA assay. We tested six panels of 500 blood bank donor specimens collected in PR prior to the epidemic (March 2015), at the beginning (April), peak (June) and end (October) of the 2016 epidemic, and in March 2017 and April 2018. Initially using the Biotechne ZIKV IgG assay, rates of reactivity, together with mean net OD for only the reactive samples (shown in parentheses), were calculated for each sample set, yielding 0.6% (0.4) in March 2015; 4.1% (1.6) in April 2016; 9.0% (1.6) in June 2016; 17.8% (2.0) in October 2016; 23.0% (1.3) in March 2017; and 16.2% (0.7) in April 2018. Three of the panels were confirmed using the ZIKV NS1 BoB assay, with rates of reactivity for each set of: 2.9% in April 2016; 16.6% March 2017; and 17.4% in April 2018. The peak seroprevalence of 17-23% shortly after the epidemic (March 2017) is consistent with our estimate of 22% seasonal incidence in PR during the 2016 outbreak derived from the yield of ZIKV RNA-reactive blood donors and duration of the NAT detection period. Another interesting finding was the rapid waning of ZIKV Abs between 2017 and 2018, using the Biotechne assay - both in terms of percentage of reactive donations and mean OD signal in reactive samples. This waning was not observed with the NS1 BoB assay, although overall peak seropositivity was somewhat lower. These findings have implications for assay selection, particularly during recurrent outbreaks.

1953

RAPID ACTIVE SEROPREVALENCE (RAS) SURVEYS PERFORMED IN RURAL GUATEMALA DEMONSTRATED A RAPIDLY CHANGING ZIKA DISEASE BURDEN IN 2015-16 AND PROVIDE A USEFUL TOOL TO MEASURE ARBOVIRUS DISEASE BURDEN IN RESOURCE-LIMITED SETTINGS

Daniel Olson[1], Molly Lamb[2], Maria Alejandra Paniagua-Avila[3], Alma Zacarias[3], Neudy C. Rojop[3], Andrea Chacon-Juarez[3], Shekema Hodge[4], Matthew Bonaparte[4], Maria Renee Lopez[5], Celia Cordon-Rosales[5], Edwin J. Asturias[1]

[1]*University of Colorado School of Medicine, Aurora, CO, United States,* [2]*Colorado School of Public Health, Aurora, CO, United States,* [3]*Fundacion para la Salud Integral de los Guatemaltecos, Los Encuentros, Guatemala,* [4]*Sanofi Pasteur, Swiftwater, PA, United States,* [5]*Universidad del Valle de Guatemala, Ciudad de Guatemala, Guatemala*

As new arbovirus vaccines approach public health deployment, rapid, cost-effective tools are needed to estimate the arbovirus disease burden in resource-limited settings. We conducted two cross-sectional Rapid Active Seroprevalence (RAS) Surveys in a dengue-endemic region of Guatemala during the 2015-16 Zika virus (ZIKV) epidemic to determine the age-based seroprevalence of ZIKV and dengue virus (DENV) infection. We used a satellite map-based 2-stage cluster randomization design to perform two cross-sectional RAS surveys over a 200km^2 area in rural southwest Guatemala. RAS Surveys 1 and 2 were completed over 4-6 weeks in Oct-Nov 2015 and Jan-Feb 2016, respectively. All enrolled children <15 years provided demographic, clinical, and epidemiologic data and a serum sample that was tested for DENV by RT-PCR (if fever was present in the preceding week). At study end, remaining samples were tested for ZIKV using microneutralization (MN) and anti-ZIKV NS1 IgG blockade-of-binding (BoB) assays; and for DENV by MN (DENV1-4) and anti-DENV NS1 IgG ELISA. Case definitions were created *a priori* to define ZIKV- and DENV-exposed individuals based on MN testing (Abstract # 2279). A total of 197 (RAS 1) and 186 (RAS 2) children had residual serum for MN, ZIKV NS1 BoB, and DENV NS1 IgG testing, and the two groups were comparable in age (mean 9.9 years) and gender (56% female). ZIKV seroprevalence by MN increased from 1/186 (<1%) to 54/184 (31%), and ZIKV seroprevalence by BoB (titer >10) increased from 20/197 (10%) to 69/184 (38%) between RAS Surveys 1 and 2. DENV seroprevalence by MN remained unchanged from 104/169 (62%) to 109/155 (70%), and DENV seroprevalence by NS1 IgG (titer >50) remained unchanged from 129/147 (88%) to 133/153 (87%) between RAS Surveys 1 and 2. DENV RT-PCR was negative in all 41 febrile cases (ZIKV PCR unavailable). For both ZIKV and DENV, seroprevalence increased with age, and there were no gender differences. These results demonstrate that Rapid Active Sampling (RAS) surveys coupled with currently available diagnostics were able to identify an ongoing ZIKV epidemic over a 3-month period in a highly dengue-endemic region of Guatemala.

1954

DUPLICATIONS, SELECTION AND INTROGRESSION DRIVE THE SPREAD OF RESISTANCE TO ORGANOPHOSPHATES IN WEST AFRICAN *ANOPHELES GAMBIAE*

Xavier Grau-Bove, Edi Constant, Eric Lucas, Dimita Pipini, Arjen van T' Hof, Martin J. Donnelly, **David Weetman**

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The organophosphate pirimiphos methyl is the most important insecticide for indoor residual spraying-based malaria control across Africa. However, organophosphate-resistant *Anopheles* have recently been identified in West Africa, an area where a mutation (G119S) in the insecticide target site, acetylcholinesterase (*Ace-1*) has also been increasing in frequency. Here, from whole genome sequence-based GWAS we establish a clear association between pirimiphos-methyl resistance and copy number of mutated *Ace1* genes in *An. coluzzii* from rice fields in southern Cote d'Ivoire. We establish repeatability of this association in multiple pirimiphos methyl populations from West Africa. Though the mutation appears to have emerged in *An. gambiae* and introgressed to *An. coluzzii*, divergent pathways of duplication have resulted in heterogeneous and homogeneous patterns of copy number variation, both under strong selection. Our results highlight the importance of CNV scanning in in GWAS studies and provide a strongly predictive marker system for monitoring operationally-crucial insecticide resistance in *An. gambiae*.

1955

LLIN EVALUATION IN UGANDA PROJECT (LLINEUP): DATA FROM TWO YEARS OF CROSS-SECTIONAL ENTOMOLOGICAL SURVEILLANCE CARRIED OUT IN 104 HEALTH SUB-DISTRICTS IN UGANDA

Amy R. Lynd[1], Samuel Gonahasa[2], Sarah G. Staedke[3], Ambrose Oruni[1], Catherine Maiteki-Sebuguzi[2], Grant Dorsey[4], Jimmy Opigo[5], Adoke Yeka[2], Agaba Katureebe[2], Mary Kyohere[2], Janet Hemingway[1], Moses R. Kamya[6], Martin J. Donnelly[1]

[1]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [4]*University of California, San Francisco, CA, United States,* [5]*Uganda Ministry of Health, Kampala, Uganda,* [6]*Makerere University College of Health Sciences, Kampala, Uganda*

The primary tool for malaria control in Africa has been the utilization of Long-lasting insecticidal nets (LLINs). The success of these nets is currently threatened by increasing levels of resistance to pyrethroids in the principal vectors of malaria. To overcome this threat nets have been developed that incorporate the synergist, piperonyl butoxide (PBO), which inhibits cytochrome P450 enzymes, one of the main mechanisms of pyrethroid resistance, and so potentially overcoming pyrethroid resistance. However, data on the effectiveness of the PBO treated nets is incomplete. To address this shortcoming a large-scale cluster randomized trial was conducted in Uganda in 2017-2019 to evaluate the impact of long-lasting insecticidal bednets (LLINs), with and without PBO. Entomological surveys were carried out concurrently with community surveys prior to the distribution of LLINs in a national Universal Coverage Campaign and at 6 monthly intervals until 24 months post distribution. The survey was carried out in 104 health sub-districts and included the collection of mosquitoes from 10 randomly selected households from each health sub-district. Up to 50 *Anopheles gambiae s.l.* per health sub-district were investigated for specific insecticide resistance markers to obtain estimates of resistance at baseline, and at 6, 12, and 18 months post distribution. We present the results of these entomological collections over the study period and discuss the changes in frequency of insecticide resistance mutations in relation to the use of PBO-treated LLINs versus pyrethroid-only treated LLINs

1956

METOFLUTHRIN TREATED DEVICES FOR THE PREVENTION OF BITES IN URBAN ENVIRONMENTS: RESULTS OF A FIELD TRIAL IN THE YUCATAN, MEXICO

Wilbert Bibiano Marin[1], Mike Dunbar[2], Pablo Manrique Saide[1], Norma Pavia Ruz[1], Josue Villegas[1], Scott Ritchie[3], Tom Churcher[4], Oselyne Ong[5], Gonzalo Vazquez Prokopec[2], **Gregor Devine**[5]

[1]*Universidad Autonoma de Yucatan, Merida, Mexico,* [2]*Emory University, Atlanta, GA, United States,* [3]*James Cook University, Cairns, Australia,* [4]*Imperial College, London, United Kingdom,* [5]*QIMR Berghofer Medical Research Institute, Brisbane, Australia*

Volatile pyrethroids such as metofluthrin promise the fast and effective coverage of indoor spaces. They volatilise from surfaces at room temperature ensuring rapid diffusion within houses. In tandem with pronounced sub-lethal impacts on mosquito behaviour, they can be used to create "bite-free" spaces for human occupants. We deployed 10% w/w metofluthrin devices (10 x 16 cm) at a rate of 1-2 per room in >100 randomly selected households in Ticul, Mexico. A further 100 households served as untreated controls. The first season's trial ran from April-October 2018. Every three weeks, devices were replaced and Prokopack aspirators

were used to sample mosquitoes from control and treated households. At sporadic intervals, human landing catches were conducted to examine impacts on biting. Aspirated mosquitoes were identified as male, female or blood-fed. *Aedes aegypti* was the commonest species collected (n=9283). Pre-treatment, the mean number of blood-fed females remained similar between control and treatment arms (1.8 and 1.5 respectively, p=0.41). Immediately post-treatment the arms diverged. Treated houses yielded ca. 50% of the blood-fed mosquitoes collected in control houses (1.1 and 2.5 respectively, p=0.02). In terms of reductions in biting rates and potential epidemiological impacts, treated houses yielded landing counts that were 90% lower (0.7/minute) than those in control houses (5.9/minute, p<0.01). An analysis of *kdr* allele frequencies in *Ae. aegypti* from both control and treated households (1138 and 799 individuals respectively) showed that 83% carried at least one copy of the pyrethroid resistant *kdr* mutations F1534C and V1016I and 25% were homozygous for both. Data from "free-flight" chambers and experimental hut trials confirmed that the behavioural impacts of metofluthrin persist in the presence of these alleles. Semi-field trials also demonstrated that the 10% w/w metofluthrin devices did not repel mosquitoes. The burden of bites is therefore not transferred to untreated neighbours. We conclude that these formulations show promise in terms of bite protection and as outbreak response tools for Aedes-borne diseases.

1957

OPTIMIZING TRANSFLUTHRIN TREATED DEVICES FOR DETERRENCE OF MOSQUITOES FROM APPROACHING AND ENTERING PERMETHRIN TREATED TENT

David Oullo[1], James Mutunga[1], Sheila Ogoma[2], Thomas Gilbreath[3], Wes P. McCardle[1]

[1]*U.S. Army Medical Research Directorate - Africa, Kisumu, Kenya,* [2]*Clinton Health Access Initiative, Nairobi, Kenya,* [3]*U.S. Army Medical Research Institute of Infectious Diseases, Maryland, WA, United States*

Long lasting insecticidal nets and indoor residual spraying are among the widely used strategies for mosquito control. However, despite proven efficacy, distribution and usage it still possesses logistical and practical challenges in temporary shelters that do not have substrates for spraying insecticides. Therefore, these tools may not be feasible vector control interventions for refugee camps and temporary military installations in remote areas. Furthermore current strategies target endophagic and endophilic mosquitoes but not outdoor biting vectors. Since there is a need for novel strategies that are field expedient in areas with no structural substrate to spray, this study investigated the spatial protection of transfluthrin-treated devices against mosquito bites in a semi-field environment. All combinations of permethrin treated/untreated tent, transfluthrin-treated burlap strips, transfluthrin-treated Personal Insect Repellent Kits (PIRK) devices at distances of ^{0}m, ^{1}m, and ^{3}m from the tents were tested using a ^{4}x^{4} Latin Square design for five nights each, with a two night period between treatments. Starved, female An. gambiae were released inside the semi-field and collected using human landing catches simultaneously inside and outside the tent. All the treatments significantly reduced mosquito biting inside both treated and untreated tents, with an ^{85}% reduction in treated tents combined with transfluthrin devices. Further studies are warranted to estimate how prolonged exposure to doses of volatile pyrethroids might impact insecticide resistance in natural vector populations and warrant further monitoring and study.

1958

CHARACTERIZING THE IMMUNE PROFILE OF MOSQUITO LARVAE AFTER EXPOSURE TO A NOVEL ESSENTIAL OIL BASED LARVICIDE

Patrick H. Kelly[1], Ju-Lin Weng[1], Michael J. Workman[2], Ivy Hurwitz[2], Marcelo Ramalho-Ortigao[1]

[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*University of New Mexico, Albuquerque, NM, United States*

Synthetic and biological larvicides have been the primary components for larvae source management for many years. However, there are negative environmental issues, development of vector resistance, and substantial cost associated with the use of some of these lavicides. We have developed an environmentally friendly, yeast-encapsulated orange oil larvicide that is effective and inexpensive to produce. This essential oil-based larvicide (EBL) maintains lethality against mosquito larvae at concentrations below 50ppm. Following ingestion and release of the EBL within the larval gut, changes in the expression profiles of genes associated with innate response and epithelial regeneration ensue. These alterations are followed by epithelial damage and sclerotization in 3rd instar *Aedes* and *Anopheles* larvae. Midguts and corresponding carcasses from *Ae. aegypti* exposed to EBL for 4 and 24 hrs demonstrated >20-fold induction of the effector caspases *CASPS7* and *CASPS8*, the midgut epithelial regenerator (*Vein*), and the IMD negative regulator (*Pirk)* compared to control larvae. In addition, 10-fold and 2-fold differences in expression were observed in the inhibitor of apoptosis *IAP1* and *IAP2*, respectively. The activation of apoptotic and necrotic pathways were further assessed by confocal microscopy of EBL-exposed midguts. Larvae exposed to EBL display a pronounced systemic darkening in the cuticle, potentially due to wound healing mechanisms such as melanization that

may be related to the amount of EBL ingested. We are currently assessing the effects of EBL on other innate immune genes and those associated with autophagy, including *ATG1*, *ATG6*, and *ATG8*. The melanization effects observed following ingestion and midgut exposure to EBL are intriguing. Further investigation into this area, specifically between different species of mosquitoes, are ongoing. Our results strongly suggest that EBL effective killing is likely due to induction of apoptosis within the mosquito larva midgut. EBL's amenability for use as part of an integrated vector management makes this novel larvicide a practical approach for mosquito larval control in the future.

SEMI-FIELD TRIALS OF A LOW-COST, DRIED ATTRACTIVE BAIT STATION FOR ADULT *AEDES AEGYPTI* CONTROL

Rachel Sippy[1], Valeria Sanchez[2], Froilan Heras[1], Efrain Ayala[3], Anna M. Stewart-Ibarra[4], Marco V. Neira[5], David A. Larsen[6]

[1]*SUNY Upstate Medical University and University of Florida, Machala, Ecuador,* [2]*SUNY Upstate Medical University, Machala, Ecuador,* [3]*Universidad Técnica de Machala, Machala, Ecuador,* [4]*SUNY Upstate Medical University and University of Florida, Syracuse, NY, United States,* [5]*Pontificia Universidad Católica del Ecuador, Quito, Ecuador,* [6]*Syracuse University, Syracuse, NY, United States*

Illnesses transmitted by *Aedes aegypti* (dengue, chikungunya and Zika) comprise a considerable global burden; options for transmission reduction focus on mosquito control. Current interventions are inadequate and insecticide resistance threatens the effectiveness of these options. We developed a novel mechanism to deliver ingested insecticide to *Ae. aegypti*called a dried attractive bait station (DABS) and tested its impact on *Ae. aegypti*in a series of semi-field trials. The DABS are a high-contrast 28 inch^{2}surface coated with dried sugar-boric acid solution that elicits an ingestion response from *Ae. aegypti*landing on the surface. We released 50 laboratory-reared female *Ae. aegypti*into experimental huts typical of peri-urban tropical communities in South America in six replicates. In Trial Series 1 & 2, the treatment hut contained four DABS and the control hut contained four DABS without the active ingredient. Trial Series 3 had identical DABS placement but an additional food source (100g cut apples) in each hut. Mosquitos were collected with backpack aspirators 24 (Series 1) or 48 hours (Series 2 & 3) after release to calculate mortality (proportion of dead mosquitoes). Mortality was monitored for 48 additional hours in laboratory conditions for Series 1. We used paired t-tests to compare total and 48-hour mortality. In Series 1, total mosquito mortality was 4—18% in the control hut and 54—96% in the treatment hut. There was a difference in mortality in control and treatment huts ($p=0.003$) after 48 hours and in total ($p<0.001$). In Series 2, total mosquito mortality was 2—23% in the control hut and 77—100% in the treatment hut. There was a difference in mortality in control and treatment huts ($p<0.001$). In Series 3, total mosquito mortality was 2—33% in the control hut and 68—100% in the treatment hut. There was a difference mortality in control and treatment huts ($p=0.006$). Our DABS are a promising intervention for control of *Ae. aegypti*and prevention of arboviral disease.

THE IMPACT OF YEAST-ENCAPSULATED ORANGE OIL IN *AEDES AEGYPTI* OVIPOSITION PREFERENCE

Fabiane das Graças Caldeira Brant[1], Bruno Gomes[1], Camila P. Jesus[1], Michael J. Workman[2], Ivy Hurwitz[2], Mariana David[1], Fernando A. Genta[1]

[1]*Fiocruz - Oswaldo Cruz Institute, Rio de Janeiro, Brazil,* [2]*University of New Mexico, Albuquerque, NM, United States*

Aedes aegypti is the main vector for dengue, chikungunya and Zika virus in tropical regions. Mosquito control strategies for aquatic environments aim to stop larvae development by reducing breeding sites and/or the application of larvicides. The larvicide based on yeast-encapsulated orange oil (yeast-OO) is highly active against *Aedes aegypti*larvae (LD_{50}< 50 mg·L^{-1}) presenting an environment friendly alternative to chemical insecticides for mosquito control. Here, we are testing the impact of this novel larvicide in the oviposition of *Aedes aegypti* females. Oviposition assays were carried inside BugDorm-2400 Insect Rearing Tent (W75 x D75 x H115 cm) under laboratory conditions. Ovitraps (black pot + wooden plate) were loaded with 250 mL solution that vary between filtered tap water and a heterogeneous solution with yeast-OO (160 mg·L^{-1}). Two ovitraps of each treatment were placed inside a tent (one trap in each corner) with a diagonal pattern that vary across assays avoiding bias associated with ovitrap location. Mosquito females were artificially fed in human blood. In each assay, one blood fed female (3 - 4 days) was placed inside a tent to infer the amount of eggs laid during 48 h or 72 h. Number of eggs were manually counted in the wooden plate and the solution for each ovitrap. Most females were able to lay eggs in ovitraps under assay conditions providing a high proportion of valid assays (93%). All valid assays had eggs in ovitraps with water whereas only 60% of assays had positive ovitraps with yeast-OO. Moreover, the total number of eggs per ovitrap is significant different between yeast-OO and water (Wilcoxon-ranked test: W = -314, z = -3.57, P< 0.0004). Females seem to lay more eggs in ovitraps without yeast-encapsulated orange oil. This indicates a potential secondary effect for the larvicide based on orange oil position. The repelling action against *Aedes aegypti* oviposition may provide a strategy for reducing egg laying in primary breeding sites that cannot be removed by control agencies.

1961

GEOGRAPHIC INEQUALITY IN CHILDHOOD MORTALITY AND MORBIDITY DUE TO LOWER RESPIRATORY INFECTIONS IN LOW-INCOME AND MIDDLE-INCOME COUNTRIES, 2000-2017

Catherine A. Welgan, Mathew M. Baumann, QuynhAnh P. Nguyen, Brigette F. Blacker, Robert C. Reiner Jr.

Institute for Health Metrics and Evaluation, University of Washington, Seattle, WA, United States

Lower respiratory infections (LRIs) represent the second largest cause of disease burden among children under five in low-income and middle-income countries (LMICs), contributing to more than 336,000 deaths in 2017. Previous work documenting the burden of LRIs across space and time lacks either the spatial breadth or resolution presented here. This study aimed to produce annual estimates of LRI prevalence, incidence, and mortality among children under 5 in 102 LMICs from 2000 to 2017 at high spatial resolution (5-km^2). A Bayesian geostatistical model leveraging data from household surveys and a suite of environmental and socio-demographic covariates was used to generate estimates of LRI burden, which were then calibrated to results reported in the 2017 Global Burden of Diseases, Injuries, and Risk Factors Study. In 2017, the highest estimated mortality rates occurred in administrative subdivisions within South Sudan, Chad, Central African Republic, and Nigeria. Several administrative units in Laos and Guatemala also showed disproportionate LRI burden relative to regional trends. While reductions in LRI prevalence, incidence, and mortality were estimated for most countries, subnational estimates revealed substantial within-country differences in LRI burden. Despite the vaccine-preventable nature of several etiologies of LRIs, this study highlights the persistent burden of childhood morbidity and mortality due to LRIs in numerous countries. The high spatial resolution estimates produced here reveal areas of inequality in both burden and burden reduction over time, illustrating the geographic regions that should be targeted in the implementation of future LRI treatment and prevention programs.

Differentiating the underlying etiology of acute febrile respiratory illness in children is challenging, but has critical implications, given the competing priorities of adequately treating those caused by bacterial infection (i.e. bacterial pneumonia) while thwarting the rise in antibiotic resistance. The challenge stems from the significant overlap in clinical presentation among the common causes of respiratory symptoms (viruses, bacteria, and malaria), a high frequency of mixed infections, and a lack of differential diagnostics. We sought to identify a set of proteins from peripheral blood that could reliably differentiate the main underlying etiology of acute respiratory symptoms, with an emphasis on correctly identifying bacterial pneumonia. Using samples from pediatric patients meeting the WHO case definition for clinical pneumonia (increased respiratory rate and cough or difficulty in breathing, and fever at or within 24 h of admission; n=195) in Mozambique, we used an aptamer-based high dynamic range assay (called SOMAScan) to measure up to 1279 proteins in blood, performed marker selection using a combination of machine learning approaches, and created predictive models to distinguish disease etiologies. Our predictive models met the thresholds of FIND's pediatric pneumonia diagnostic target product profile, for sensitivity (desirable ≥95%, acceptable ≥90%) and specificity (≥90% and ≥80%), in both single etiology and mixed infection samples. Gene ontology and protein pathway analysis revealed that bacterial pneumonia was strongly associated with neutrophil activity, and allowed us to derive a neutrophil blood protein signature. Neutrophil degranulation was one of the top pathways in all analyses, with recurrent degranulation markers including HP, LCN2, LTF, MPO, MMP8, SERPINA1, S100A9, SLPI, PGLYRP1 and RETN. Re-analysis of an independent RNA-sequencing study based on the same sample cohort confirmed our findings. Implemented with an appropriate technology, the markers identified here may provide the basis for a rapid diagnostic for field-based triage for antibiotic treatment of pediatric pneumonia.

WHAT IS A BREATH? WORKING TOWARDS AN IMPROVED REFERENCE STANDARD FOR COUNTING RESPIRATORY RATE TO VALIDATE NEW AUTOMATED PNEUMONIA DIAGNOSTIC AIDS FOR CHILDREN UNDER FIVE

Charlotte Alice Ward, Alice Maurel, Ann-Sophie Stratil, Monica Anna de Cola, Tedila Habte, Kevin Baker

Malaria Consortium, London, United Kingdom

Acute respiratory infections (ARIs), primarily pneumonia, are the leading cause of death from infectious diseases among children under five years of age globally. In low-resource settings, advanced clinical pneumonia diagnostics, such as chest x-rays, are not readily available at the primary care level. Instead, frontline health workers observe the child's chest movements, manually count the number of breaths in 60 seconds using an ARI timer or other timer (mobile, watch) and classify the respiratory rate (RR) as fast or normal. With this method, the observed RR and classification can be inaccurate, which may result in incorrect treatment. New, automated RR diagnostic aids which may be more reliable at counting and classifying RR are becoming available. However, prior to their adoption at scale, their performance needs to be established which requires a suitable reference standard. However, the global health community acknowledges that this is currently lacking. We are aiming to address this gap by building the evidence base around the accuracy of manual video annotation of a child's chest movements. Between April and May 2019 in Southern Nations, Nationalities, and Peoples' Region, Ethiopia, a panel of 10 medical professionals will use video annotation software to annotate 51 videos from two of Malaria Consortium's previous pneumonia diagnostics studies. Three age groups will be equally represented therein (0-<2 months; 2-<12 months and 12-59 months). For each video, five randomly selected reviewers will mark breaths, uncertain breaths (very shallow breaths, incomplete cycles or breaths that are difficult to judge) and distortions (child moving, crying or holding its breath). Based on these counts, upper and lower RR counts will be calculated. Overall agreement between reviewers will be calculated using the intraclass correlation coefficient. The mean time taken to review a video will be calculated and the acceptability of the video annotation tool will be explored through a focus group discussion. Results will be available in June 2019, and these would be the subject of the presentation.

1964

INCIDENCE OF INFLUENZA AND INFLUENZA-LIKE ILLNESS IN HOUSEHOLDS OF PREGNANT WOMEN, POSTPARTUM WOMEN AND INFANTS UNDER SIX MONTHS OF AGE IN BAMAKO, MALI

Nancy Ortiz[1], Adama M. Keita[2], Boubou Tamboura[2], Flanon Coulibaly[2], Uma Onwuchekwa[2], Samba O. Sow[2], Arthur L. Reingold[1], Myron M. Levine[3], Milagritos D. Tapia[3]

[1]*University of California Berkeley, Berkeley, CA, United States,* [2]*Centre pour le Développement des Vaccins-Mali, Bamako, Mali,* [3]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States*

Pregnant women and infants <6 months of age are at high risk for influenza and its complications. However, there is a paucity of information on the burden of influenza illness among pregnant women and their infants, especially in Africa. To determine the incidence of influenza-like-illness (ILI) and influenza in both of these populations, we recruited a cohort of pregnant women and mother-infant pairs and followed them over time, and conducted surveillance for febrile illness. Oropharyngeal and/or nasopharyngeal swabs were tested for influenza by RT-PCR. We accrued 231.6 person-years (PYs) of observation for pregnant women, 701.6 (PYs) for postpartum women, and 720.9 (PYs) for infants <6 months months of age. We observed an incidence of 128.6 ILI episodes per 100 (PYs) and 3.0 cases of laboratory-confirmed influenza (LCI) per 100 (PYs) in pregnant women, and in postpartum women, we calculated 55.9 episodes of ILI per 100 (PYs) and 2.6 cases of LCI per 100 (PYs) Among infants, we observed an incidence of 218.7 ILI episodes per 100 (PYs) and 4.8 cases of LCI per 100 (PYs). Among pregnant and postpartum women, the incidences of ILI and LCI were highest in those <20 years. Women were 2.28 times as likely to develop ILI during pregnancy than during the postpartum period (95%, CI 1.89 - 2.75). While pregnant women had a greater relative risk of LCI than postpartum women, the difference was not statistically significant. Among infants, incidence of LCI and ILI was highest among 4 and 5 month olds. The risk of influenza in adult women was greater in households with a child <5 years of age, compared to households with no children. The risk of a case of influenza in an infant increased with increasing number of children <5 years of age residing in the household, although this difference was not statistically significant. Influenza circulated with defined seasonality and we observed bimodal annual peaks of LCI activity, with cases peaking in October and February. Maternal influenza vaccination administered prior to periods of peak influenza activity may help to prevent LCI in pregnant women, postpartum women and infants under <6 months of age in sub-Saharan Africa.

1965

VIRAL ETIOLOGY OF PNEUMONIA AMONG SEVERELY MALNOURISHED UNDER-FIVE CHILDREN: A PROSPECTIVE CASE-CONTROL STUDY IN AN URBAN HOSPITAL, BANGLADESH

Fahmida Chowdhury, ASM Sayeem Bin Shahid, Probir Kumar Ghosh, Mustafizur Rahman, Zakiul Hasan, Zubair Akhtar, S Mah-E Muneer, Lubaba Shahrin, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

In Bangladesh, pneumonia has a higher mortality among malnourished children aged <5 years. Evaluating pneumonia etiology among malnourished children may help improve empiric treatment guidelines. During April 2015—December 2017, we conducted a prospective case-control study among severe acute malnourished (SAM) children aged <5 years admitted to icddr,b's Dhaka Hospital. We enrolled SAM children with clinical or radiological pneumonia as cases and SAM children without any respiratory symptom in last 10 days before admission as controls. We collected nasopharyngeal wash from both case and control and tested for respiratory syncytial virus (RSV), human metapneumovirus (HMPV), influenza viruses, human parainfluenza viruses (HPIV 1, 2, 3), rhinovirus and adenovirus by singleplex real-time RT-PCR. We enrolled 360 cases and 334 controls. For case and control median age was 8 months (IQR: 5-13) and 11 months (IQR: 6-18) (p=0.001) and 62% and 61% were male (p=0.7) respectively. Weight/age Z-score was -4.3 (SD ±0.7) for cases and -4.1 (SD ±1.1) for controls (p=0.01). Respiratory virus detection was high in cases 251 (70%) compared to controls148 (44%) (p=0.0001). The most frequently detected viruses among cases were rhinoviruses (32%) followed by RSV (13%), adenovirus (9%), HPIV3 (8%), influenza (6%) HMPV (6%). In the controls, rhinoviruses (55%) were most commonly detected followed by adenovirus (18%), HMPV (3%), RSV (2%), HPIV3 (3%), influenza (2%). RSV (OR 12.7; 95% CI: 3.7, 43.3)), influenza (OR 12.9; 95% CI: 2.8, 60.3), HPIV (5.7; 95% CI: 1.8, 18), HMPV (3.4; 95% CI: 1.9, 6) were identified as the independent viral pathogens causing pneumonia. Viral etiology of pneumonia in SAM children were mainly attributable to RSV, influenza, HPIV and HMPV. Our study findings may help in planning further studies to develop improved strategies targeting vaccines or antivirals for the prevention and treatment of pneumonia among SAM children.

1966

OBESITY IMPACT AND THE ROLE OF THE MICROBIOTA IN THE SUSCEPTIBILITY TO TUBERCULOSIS INFECTION

Sandra P. Palma Albornoz, Rômulo S. De Oliveira, Tamara S. Rodrigues, Ana Flávia Gembre, Leandra Z. Ramalho, Daniela Carlos, Vânia L. Bonato

Universidad São Paulo, São Paulo, Brazil

The prevalence of obesity has dramatically increased in recent years and is associated with inflammation and changes of the gut microbiota. Obesity is a major determinant of diabetes, and diabetes is a well-known risk factor for tuberculosis. However, few studies have examined the complex interaction between obesity and tuberculosis (TB). *Mycobacterium tuberculosis* is the causal agent of TB and is responsible for the highest number of infectious disease-related deaths in many low- and middle-income countries. We evaluated whether high-fat diet (HFD)-induced obesity can affect the outcome of TB. C57BL/6 mice were fed with either a low-fat diet (LFD) or high-fat diet (HFD) for ninety days. At 60 days, mice were infected with *M. tuberculosis* by intra-tracheal route. We observed an increase of pulmonary inflammation and susceptibility to infection in mice fed HFD (obese), with an associated augmentation in the frequency of CD4 IFN-γ^+ cells compared to LFD (lean) infected mice. We analyzed changes in intestinal barrier component and gut dysbiosis with an observed increase of Firmicutes and a reduction of Bacteroidetes in obese infected mice. We also found a lung dysbiosis characterized by significant increase of both Firmicutes and Bacteroidetes in infected obese mice compared to infected lean mice. Later, we used fecal microbiota transplantation (FMT) to evaluate the influence of the microbiota in mice with co-morbid obesity/tuberculosis. We found that infected obese mice that received antibiotic treatment before FMT showed a significant reduction of bacterial load and frequency of CD4 IFN-γ^+ cells. Furthermore, when these infected obese mice received FMT from non-infected obese mice, they recovered the bacterial load and the population of CD4 IFN-γ^+ cells. Our findings demonstrate that the obesity associated with dysbiosis is a contributing factor to reduce the resistance to *M. tuberculosis* infection. This study may help to develop novel therapeutic approaches for the treatment of tuberculosis in patients with obesity.

1967

SEVEN-YEAR OUTCOME ANALYSIS OF THE TUBERCULOSIS PROGRAM AT THE CENTRE HOSPITALIER RÉGIONAL SPÉCIALISÉ (CHRS) IN MACENTA, FOREST REGION, GUINEA-CONAKRY

Cornelia J. Staehelin[1], Valérie Schoenbaechler[2], Jean Hébélamou[3], Yakpazouo Guilavogui[3], Sosso Onivogui[3], Catrina Mugglin[2], Hansjakob Furrer[2], Esther Bavogui[3], Cécé Kolié[3], Pévé Zoumanigui[3], Ismaël Béavogui[3], David Leuenberger[3]

[1]*Bern University Hospital, Bern, Switzerland,* [2]*Department of Infectious Diseases, Bern University Hospital, University of Bern, Bern, Switzerland,* [3]*Centre Hospitalier Régional Spécialisé, Macenta, Guinea*

We report population characteristics and treatment outcome of the tuberculosis program between 2010 and 2016 that included 3438 patients (1246, 36.2% female) with a median age of 35 years (interquartile range (IQR) 25-47). Most patients came from Macenta town and surroundings (45.4%). For patients from other places within Guinea, the median distance was 94 km (IQR 73-253 km, max. 608 km), and 106 (3.1%) came from neighbouring countries. Pulmonary tuberculosis was the main presenting form (n=2844, 82.7%), of which 2209 (78%) were sputum positive by microscopy and 635 (22.0%) were sputum negative. Extrapulmonary manifestations of tuberculosis (17.2% of total) were pleural (6.3 %), spinal (5.0%), lymph node (1.9%), peritoneal (1.3%), and other (2.9%). HIV was tested in 88.2% of all patients, 605 (17.6%) tested positive. Among these patients, 331 (54.7%) were already on antiretroviral treatment. Overall treatment success (cured plus treatment completed), according to WHO guidelines, was 74.5%. The main outcome was the percentage of new TB patients (n= 3050) successfully treated: 75.15% (sputum-positive patients 78.4%, all other patients 69.3%). Death occurred in 11.6%, treatment failure in 2.5%, 10.78% of patients were not evaluated or lost to follow-up. In a multivariable regression model, the following factors at treatment start were statistically significantly ($p<0.05$) associated with treatment success: age (per 10 year increase above 15 years) adjusted odds ratio (aOR) 0.87 (95% confidence interval (95% CI) 0.82-0.92); distance from clinic (per 100km further away) aOR 0.94 (0.89-0.99); and HIV status: HIV-positive on antiretroviral treatment (ART) aOR 0.32 (0.24-0.42) and HIV-positive not on ART with aOR 0.28 (0.21-0.38) versus HIV-negative patients. The following factors were not associated with treatment success: sex, year of treatment start, treatment start in years with ongoing Ebola epidemic (ie. 2014 + 2015) or unknown HIV-status. In conclusion, HIV co-infection, distance to clinic and age were factors that contributed to the lack of this TB program to reach WHO goals to achieve >90% treatment success in new patients.

1968

CLINICAL MANAGEMENT OF CHILDREN WITH MALARIA ACROSS EIGHT AFRICAN COUNTRIES: A CROSS-SECTIONAL ASSESSMENT OF NATIONALLY REPRESENTATIVE DIRECT OBSERVATION DATA

Jessica Cohen[1], Hannah Leslie[1], Indrani Saran[2], Guenther Fink[3]

[1]*Harvard School of Public Health, Boston, MA, United States,* [2]*Boston College School of Social Work, Boston, MA, United States,* [3]*Swiss Tropical and Public Health Institute and University of Basel, Basel, Switzerland*

Nearly 300,000 children under age 5 die from malaria in Africa every year. Appropriate clinical management of malaria, including blood test confirmation and recommended antimalarial treatment, are crucial to preventing the progression to severe disease and death. This study estimated rates and predictors of clinically-appropriate malaria management among children under age 5 in sub-Saharan Africa. Cross-sectional analysis of direct observations of outpatient sick child visits in 12 nationally-representative facility surveys, including descriptive and multi-level logistic regression. 5,463 public and private health facilities in 8 countries in sub-Saharan Africa between 2007-2017. 22,100 children under age 5 visiting sampled health facilities for sick child care. Proportion of malaria cases receiving appropriate clinical management, defined as receiving both a blood test diagnosis and a recommended antimalarial. Of 22,100 sick children, 5,313 (24%) were diagnosed with malaria. Only 1,473 children with malaria received clinically-appropriate care (27.7%; 95% CI 25.3% to 30.1%), with 2,836 (53.4%; 50.5% to 56.2%) receiving a blood test and 3,040 (57.2%; 54.4% to 59.9%) prescribed an appropriate antimalarial. 1,135 children diagnosed with malaria (21.4%; 19.3% to 23.4%) received no antimalarial at all. Appropriate management was significantly associated with being seen at a facility with verified malaria testing equipment and treatment available (adjusted conditional marginal effect 0.20, 95% CI 0.14-0.26, p<.01). At well-stocked facilities, only 36.1% (1,340/3,715; 32.8% to 39.3%) of malaria cases received clinically-appropriate care. Appropriate malaria management was higher in the 2013-2017 surveys (1017 of 2718, 37.4%; 95% CI 33.6% to 41.2%) than in the 2007-2010 surveys (430 of 2595, 16.6%; 95% CI 14.2% to 18.9%). In conclusion, this study finds that three-quarters of children with malaria in sub-Saharan Africa received clinically inappropriate care. Renewed policy efforts to improve the clinical quality of care are urgently needed.

1969

AVIAN MALARIA: TROPICAL DEFORESTATION AND HOST SPECIFICITY

Ravinder N. Sehgal

San Francisco State University, San Francisco, CA, United States

The effects of environmental changes on parasite distributions are varied and despite potential consequences to ecosystem health, large-scale studies involving wildlife have been scarce. Here we present data of the effects of rapid deforestation on the prevalence and diversity of mosquitoes and avian blood parasites. In Cameroon, we have initiated a long-term study of mosquitoes, birds and avian malaria to determine how deforestation for the cultivation of palm oil plantations affects parasite transmission. For three years, we have collected samples from the same sites, pre- and post-deforestation. Sampling was done 4 times/year to account for seasonality. By analyzing over 2600 avian blood samples, and about 12000 mosquitoes, we find that habitat degradation leads to altered patterns of parasite prevalence and disruptions in parasite species dominance. The diversity of parasites, birds and mosquitoes changes significantly with deforestation. We also present data on how habitat may affect the evolution of lineage diversity and specialist vs. generalist strategies in avian malaria. Our work incorporates bioclimatic data to quantify differences among collection sites, and predict how microhabitat changes may affect the spread of infections. We have also initiated studies on genes involved in host pathogenicity, with the characterization of the transcriptomes of three parasites; *Plasmodium delichoni*, *P. homocircumflexum* and *Haemoproteus columbae*. We report orthologs of genes known for erythrocyte invasion, and host-specificity, including *msp-1*, *maebl*, *ama-1* and *ron-2*. We also comment on the evolutionary placement of *H. columbae* with respect to *Parahaemoproteus* and avian *Plasmodium* species. With our long-term agenda to discern the interplay between habitat, vector ecology, and genetics on the host-specificity of parasites, we emphasize that influences of land use changes on parasite prevalence are complex, and will require the detailed study of the vector ecology, and habitat effects. This multidisciplinary approach will aid in predicting how habitat changes will influence future scenarios of host-parasite interactions.

1970

LABORATORY QUALITY CONTROL SYSTEM FOR LARGE-SCALE MALARIA SEROSURVEYS: HAITI 2017

Lotus L. van den Hoogen[1], Jacquelin Présumé[2], Ithamare Romilus[2], Gina Mondélus[2], Tamara Elismé[2], Nuno Sepúlveda[1], Gillian Stresman[1], Thomas Druetz[3], Ruth A. Measuring antibody responses to malaria can aid in estimating transmission in a human population. To compare outputs among separate serosurveys, standardized laboratory testing and data collection schemes are required. Here we describe the in-country application and retrospective quality control (QC) of a multiplex bead assay (MBA) to gather antibody data from large malaria surveys in Haiti. Data for IgG against 21 recombinant antigens and peptides were collected for 32,758 participant samples from three separate surveys. The total time for sample processing and IgG data collection in the Haitian national lab was 18 weeks. Titration curves for both a hyperimmune Haitian sera pool as well as the *Plasmodium falciparum* WHO reference standard were included on assay plates. Assay signal data were fit to a 5-parameter logistic regression model, and inspection of the median and interquartile range (IQR) for the y-inflection point of standard curves was used to determine assay precision within and between surveys. Median and IQRs were similar for Surveys 1 and 2 for most antigens, while the IQR for y-inflection points increased for some antigens in Survey 3. Levey-Jennings charts were created for standard curve points for selected antigens to indicate deviation in assay signal and allow a final pass/fail call for each plate. Of 387 assay plates, 13 (3.4%) had aberrant standard values and were repeated. A pass/fail call was determined for each individual sample if IgG binding to the generic glutathione-S-transferase (GST) protein was observed; only 659 (2.0%) of blood samples failed this criterion. An additional 455 (1.4%) of assay wells failed due to low bead numbers (<20/analyte). In total, 609,438 (96.6%) anti-malaria IgG data points from 32,099 persons passed all QC checks. As shown by this experience in Haiti, the MBA can be deployed with high-throughput collection of IgG data and low inter-plate variability. Systematic and efficient antibody data collection can allow for rapid assessment of population exposure and can directly inform decision-making for control and elimination programs.

1971

RISK OF ADVERSE PREGNANCY OUTCOMES IN WOMEN TREATED FOR MALARIA WITH DIHYDROARTEMISININ-PIPERAQUINE OR QUININE IN THE FIRST TRIMESTER OF PREGNANCY IN INDONESIA: A RETROSPECTIVE DATA ANALYSIS

Rukhsana Ahmed[1], Kerryn A. Moore[2], Theda Lukito[3], Andre-Marie Tchouatieu[4], Maud M. Lugand[4], Stephanie Dellicour[1], Feiko O. Ter Kuile[1], Richard N. Price[5], Julie A. Simpson[2], Jeanne R. Poespoprodjo[6]

[1]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [2]*Center for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia,* [3]*Clinesia, Jakarta, Indonesia,* [4]*Medicines for Malaria Venture, Geneva, Switzerland,* [5]*Global and Tropical Health Division, Menzies School of Health Research and Charles Darwin University, Darwin, Australia,* [6]*Timika Research Facility and Department of Child Health, Faculty of Medicine, Universitas, Gadjah Mada, Yogjakarta, Indonesia*

The use of artemisinin for the treatment of malaria in the 1st trimester of pregnancy is restricted due to limited safety data in early pregnancy in humans. Instead, quinine (QN) which is less effective and not well tolerated is recommended for treatment of 1st trimester malaria. In 2006 Indonesia became the first country to introduce artemisinin-based combination therapy (dihydroartemisinin-piperaquine, DP) for the treatment of malaria in the 2nd and 3rd trimesters. We reviewed a decade of retrospective hospital data from Mimika district, Papua province, Indonesia to assess the risk of stillbirth and miscarriage in women treated with either DP or QN in the 1st trimester. Medical records from the emergency room, inpatient, antenatal clinic and delivery unit were linked with laboratory and pharmacy data using hospital identification number, date of birth and name. The date of delivery, date that the drug was dispensed and the estimated gestational age at delivery were used to estimate the gestational age at the time of malaria treatment during pregnancy. The relative risks of stillbirth and miscarriage between the two treatments were analysed by Cox regression. Between 2006-2017, there were 3,766 malaria episodes treated with DP or QN: 869 in the 1st trimester (751 women) of which 203 (23.4%) were with DP (162 women) and 666 (76.6%) with QN (589 women). In the 1st trimester QN group, 10 (1.7%) pregnancies ended in miscarriage and 2 (0.3%) were stillbirths compared to 3 (1.9%) and 1 (0.6%) respectively in the DP group. The hazard ratio for pregnancy loss in the DP group compared with QN alone or QN plus clindamycin was 0.99 (CI 0.31-3.15). Further analysis is being explored on the effect of potential unmeasured confounders such as disease severity. Despite pregnancy loss being rare in our data, our study adds to the growing evidence that DP in the 1st trimester does not increase significantly the risk of pregnancy loss relative to QN.

WHAT HAPPENS WHEN THE SUPPORT ENDS? A COMPARISON OF PRIVATE SECTOR ANTIMALARIAL MARKET SITUATIONS IN MYANMAR

Si Thu Thein[1], Ye Kyaw Aung[1], Phone Si Hein[1], Aung Thi[2]

[1]*Population Services International Myanmar, Yangon, Myanmar,* [2]*National Malaria Control Program, Ministry of Health and Sports, Nay Pyi Taw, Myanmar*

Since 2012, Population Services International Myanmar (PSI) had run Artemisinin Monotherapy Replacement Project (AMTR) to promote quality-assured artemisinin-based combination therapy (QAACT), instead of oral artemisinin monotherapy (oral AMT), among private sector providers. PSI also promoted the use of rapid diagnostic tests (RDT) for malaria before providing any antimalarial treatment. Prompted by funding restraints in 2017, PSI had to drop several AMTR project areas. One year later in 2018, this study aimed to compare private sector antimalarial market situations between 'current' and 'stopped' AMTR areas. From each area, a representative sample of geographic clusters (wards and village tracts) were selected for this cross-sectional quantitative survey of private sector outlets. A total of 143 clusters from current AMTR areas and 110 from stopped areas were included. In each cluster, all private sector outlets with the potential of stocking, selling and distributing antimalarial medicines were screened, and outlets those did any of these activities were interviewed. A total of 9,933 private sector outlets (4,039 from current areas and 5,894 from stopped ones) were screened and 343 were eligible for interviews (164 current, 179 stopped). Availability of QAACT and RDT were higher in current areas compared to stopped ones (52.1% vs 36.3% and 28.7% vs. 7.0% respectively). Availability of oral AMT was lower in current areas than stopped ones (4.8% vs 11.6%), and its market share was 0.4% of the total in current areas but 6.5% in stopped ones. From outlet providers perspective, 43.7% of them in current areas mentioned QAACT as the most effective antimalarial medicine whereas 36.6% from stopped areas said so. Also, 27.4% of providers in current areas said they had reported malaria case data but 22.5% in stopped areas said so. Thus, stopping AMTR program had possible untoward effects on private sector antimalarial markets. Availability of QAACT and RDT were lower but that of oral AMT was higher in stopped AMTR areas compared to current ones. The knowledge of providers had also declined over a year but not as marked as stock situations.

1973

JOINT EFFORTS TO IMPROVE MALARIA CONTROL IN THREE REFUGEE CAMPS IN KIGOMA, TANZANIA: SUCCESSES, CHALLENGES AND LESSONS LEARNED

Shabani Kililwa Muller[1], Juma Ng'akola[1], Zephania Nyakiha[2], Godfrey Smart[3], Goodluck Tesha[1], Jasmine Chadewa[2], Agnes Kosia[2], Zahra Mkomwa[1], Dunstan Bishanga[4], Rita Noronha[2], Lusekelo Njoge[4], Gaudiosa Tibajiuka[4], Chonge Kitojo[5], Erik Reaves[5]

[1]*Path Tanzania, Kigoma, United Republic of Tanzania,* [2]*USAID Boresha Afya Project –Jhiego Tanzania, Kigoma, United Republic of Tanzania,* [3]*Regional Health Management Team-Kigoma, Tanzania, Kigoma, United Republic of Tanzania,* [4]*USAID Boresha Afya Project -Jhpiego Tanzania, Kigoma, United Republic of Tanzania,* [5]*President's Malaria Initiative/United States Agency for International Development, Kigoma, United Republic of Tanzania*

The majority of refugees from Democratic Republic of Congo (DRC) and Burundi arriving in Tanzania are hosted in Kigoma region, where 59.2% of all Tanzanian malaria cases are reported every year. This high proportion of malaria cases is thought to be mostly due to high prevalence rates in three refugee camps, namely Nyarugusu, Mtendeli and Nduta. This article highlights important interventions led by USAID Boresha Afya Program in collaboration with the National Malaria Control Program (NMCP) in the three refugee camps in Kigoma. USAID Boresha Afya provided mentorship and integrated supportive supervisions in the refugee camps in Kigoma region in 2017 and 2018 by following national guidelines. We also conducted meetings with the Regional and District heath management teams to identify and address challenges observed during supportive supervisions. Then, we examined malaria indicators in the District Health Information System (DHIS2) and compared descriptive data before and after the interventions. Following mentorship and supportive supervisions, clinical malaria cases in all refugee camps reduced from 4% in 2016 to 0.1% in December 2018. Malaria reporting rate is now 100% as compared to 41.7% in 2016. Malaria positivity rate has decreased from 59.8% to 54.4% in December 2018. In addition, the proportion of women receiving at least two doses of sulphadoxine-pyrimethamine at antenatal care visits increased from 66.3% in 2016 to 80.8% in December 2018. However, the burden of malaria in refugee camps remains high (54%) as compared to other places. Inaccuracy of data records and management, shortage of staff, and low coverage of long lasting insecticide-treated mosquito nets (63%) are among the major challenges. In addition, non-adherence to a number of recommended government policies and cultural differences hinder the NMCP's efforts to control malaria in refugee camps. Despite these challenges, the malaria burden can be reduced in the refugee camps if multiple interventions are implemented correctly through coordinated stakeholders' efforts.

1974

MMENTORING, A NEW APPROACH TO IMPROVE MALARIA CARE IN BURKINA FASO

Moumouni Bonkoungou[1], Ousmane Badolo[1], Youssouf Sawadogo[1], Stanislas Nebie[1], Thierry Ouedraogo[1], Yacouba Savadogo[2], William Brieger[3], Gladys Tetteh[4], Blami Dao[4]

[1]*PMI Improving Malaria Care Project, Ouagadougou, Burkina Faso,* [2]*Ministry of Health, National Malaria Control Program, Ouagadougou, Burkina Faso,* [3]*Johns Hopkins University, Baltimore, MD, United States,* [4]*Jhpiego Baltimore, Baltimore, MD, United States*

Malaria is the leading cause of consultation (43.3%), hospitalization (44.1%) and death (16.1 %) in Burkina Faso. In the Sahel Region, the case fatality proportion due to malaria is 2% compared to 0.8% for the national average. This region is most affected by malaria than others. Also, the Sahel Region is currently experiencing high levels of insecurity making movement of health teams difficult and unsafe. mMentoring is the use of mobile technology to ensure capacity building and continuing education among health staff. The process started by a workshop to develop messages, and briefing of the main actors. Each week, messages and quizzes (An automatic answer is sent to each quiz) are sent to 753 providers (nurses, midwives, medical doctors) of the 115 health centers in the Sahel Region. Each month, messages are revised by a team at national level before being sent. The messages sent were related to several key malaria prevention and control interventions, such as case definition, parasitological diagnosis, clinical case management of simple and severe cases, intermittent preventive treatment in pregnancy (IPTp), pre-referral treatment with rectal artesunate in children under 5 years, insecticide-treated bed nets. After 10 months of implementation, 64 reinforcement messages on case management and prevention guideline and 63 quizzes were sent. Proportion of correct responses to the quizzes ranged from 43% and 96%. The lowest scores related to topics on management of severe cases while the highest were related to diagnosis of malaria. The participation rate (number of respondents of the 753 targeted health workers) is on average 22% with 71% of participants from primary health facilities. Also, we notice IPT3 increased from 14.8% in the quarter 3 of 2017 to 45.6% in the same quarter of 2018 (with mMentoring). The rate of performance of rapid diagnostic tests (RDTs) rose from 67.5% to 77.8%. The case fatality rate during this quarter of 2017 was 3.3% and 1.8% in 2018. As a real platform for continuing training, it would be wise to extend this approach to other regions of the country and also to other health actors like community health workers.

1975

IMPACT OF ROTAVIRUS VACCINATION VARIES WITH DIFFERENTIAL ACCESS TO PIPED WATER: AN ANALYSIS OF CHILDHOOD CLINIC VISITS FOR DIARRHEA IN PERU, 2005-2015

Miranda J. Delahoy[1], Cesar Carcamo[2], Luís Ordoñez[3], Vanessa Vasquez[2], Benjamin Lopman[1], Thomas F. Clasen[1], Gustavo F. Gonzales[2], Kyle Steenland[1], Karen Levy[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Ministerio de Salud del Perú (Ministry of Health, Peru), Lima, Peru*

Peru has undergone several health and infrastructure developments since 2005, including increased access to piped drinking water and national introduction of oral rotavirus vaccination. We examined whether these factors were associated with the rate of clinic visits for diarrhea in children under five. We fit a negative binomial model investigating the impact of rotavirus vaccination and piped water access on diarrhea rates in the 195 Peruvian provinces from 2005-2015, considering the interaction between these factors, and controlling for long-term and seasonal (El Niño) trends. We compared the "pre-(rotavirus) vaccine" (2005-2009) and "post-vaccine" (2010-2015) eras. Annual percentages of households in each province with access to piped water were analyzed in quartiles. The 2005 childhood diarrhea rate was ~29 annual clinic visits per 100 children and decreased ~3% per year. Higher access to piped water was associated with significantly lower childhood diarrhea rates in the post-vaccine era only. We found no effect of the rotavirus vaccine in the lowest quartile of piped water access. Controlling for long-term trend, compared to the pre-vaccine era, the diarrhea rate was lower in the post-vaccine era by 7% (95% confidence interval (CI): 2-12%), 13% (95% CI: 7-19%), and 15% (95% CI: 10-20%) in the 2nd, 3rd, and 4th quartiles of piped water access, respectively. Diarrhea rates were significantly higher (6%, 95% CI: 4-8%) during moderate or strong El Niño events. Explanations for higher reductions in diarrhea rates from the pre- to post-vaccine era in provinces with better piped water access include: (1) children without piped water may be predisposed to environmental enteric dysfunction, diminishing oral vaccine impact, (2) the etiologic patterns of diarrhea cases may differ by predominant water source, and/or (3) vaccine coverage may be higher in provinces with better piped water access. Improved access to piped water and rotavirus vaccination may operate synergistically to reduce childhood clinic visits for diarrhea in Peru.

1976

SEROPREVALENCE OF ANTIBODIES AGAINST *CHLAMYDIA TRACHOMATIS* AND ENTEROPATHOGENS AND DISTANCE TO THE NEAREST WATER SOURCE AMONG YOUNG CHILDREN IN THE AMHARA REGION OF ETHIOPIA

Kristen Aiemjoy[1], Solomon Aragie[2], Dionna M. Fry[3], Zerihun Tadesse[2], E. Kelly Callahan[4], Sara Gwyn[5], Diana Martin[5], Jeremy D. Keenan[3], Benjamin F. Arnold[6]

[1]*Stanford University, Stanford, CA, United States,* [2]*The Carter Center, Addis Ababa, Ethiopia,* [3]*University of California San Francisco, San Francisco, CA, United States,* [4]*The Carter Center, Atlanta, GA, United States,* [5]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*University of California Berkeley, Berkeley, CA, United States*

Many pathogens follow water-related transmission pathways. Trachoma transmission is associated with water quantity while the transmission of enteric pathogens is associated with both water quantity and quality. We hypothesized that children living further from a water source would have higher levels of exposure to *Chlamydia trachomatis*, the bacterium that causes trachoma, and to enteric pathogens. To evaluate the relationship between proximity to water source and antibody-based measures of pathogen exposure, we used a multiplex bead assay to measure IgG antibody responses to *C. trachomatis*, *Giardia intestinalis*, *Cryptosporidium parvum*, *Entamoeba histolytica*, *Salmonella enterica* (LPS Groups B and D), *Campylobacter jejuni*, enterotoxigenic *Escherichia coli* (ETEC heat labile toxin β subunit) and *Vibrio cholerae* in eluted dried blood spots collected from 2296 children ages 1-9 years in 40 communities in rural Ethiopia. Locations of water sources were recorded using GPS. Linear distances were calculated from the child's house to the nearest water source and divided into quartiles. We derived seroprevalence cutoffs using ROC curves, if available, or by fitting finite mixture models. We used targeted maximum likelihood estimation to estimate differences in seroprevalence according to distance to the nearest water source. Median distance to the nearest water source was 420 meters (IQR 236, 626). The mean seroprevalence among 1-9 year-olds was 42% for *C. trachomatis*, 27% for *S. enterica*, 70% for *E. histolytica*, 54% for *G. intestinalis*, 94.9% for *C. jejuni*, 78% for ETEC, 53% for *V. cholerae* and 94% for *C. parvum*. Children in the quartile living nearest to a water source had a 11% lower prevalence of antibodies to *S. enterica* LPS Group B and D compared to children living in the farthest quartile (p=0.0008). There were no statistically significant differences in seroprevalence for the remaining pathogens with respect to distance to the nearest water source. The absence of heterogeneity in seroprevalence in this high transmission setting may have masked any potential relationships between exposure to enteric pathogens and distance to water.

1977

UNDERSTANDING THE IMPACT OF RAINFALL ON DIARRHEA: TESTING THE CONCENTRATION-DILUTION HYPOTHESIS USING A SYSTEMATIC REVIEW AND META-ANALYSIS

Alicia N. Kraay[1], Olivia Man[1], Morgan C. Levy[2], Karen Levy[3], Joseph N. Eisenberg[1]

[1]*University of Michigan-Ann Arbor, Ann Arbor, MI, United States,* [2]*University of California-San Diego, San Diego, CA, United States,* [3]*Emory University, Atlanta, GA, United States*

Whether rainfall increases or decreases diarrhea rates is unclear based on prior literature. The concentration-dilution hypothesis suggests that the conflicting results might be explained by the background level of rain—rainfall following dry periods can flush pathogens into surface water, increasing diarrhea incidence, whereas rainfall following wet periods can dilute pathogen concentrations in surface water, thereby decreasing diarrhea incidence. In this analysis, we explore the extent to which the concentration-dilution hypothesis is supported by the scientific literature and identify sources of heterogeneity in exposure and study design to understand why the role of rainfall on diarrhea might be context-specific. We queried PubMed, Embase, Web of Science, and the Cochrane collection for articles assessing the relationship between rainfall, extreme rainfall, flood, drought, and season (rainy vs. dry) and diarrhea. A total of 73 articles met our inclusion criteria. Overall, the literature is consistent with the concentration-dilution hypothesis. In particular, extreme rainfall is associated with increased diarrhea following dry periods (IRR=1.04, 95% CI: 1.03, 1.06) but decreased diarrhea following wet periods (IRR=0.88, 95% CI: 0.82, 0.97). Bacterial diarrhea is more common during rainy seasons, providing support for a flushing mechanism, but neither all-cause nor other pathogen-specific diarrhea exhibited this association. This result suggests that concentration-dilution processes might be more relevant in areas where bacterial diarrhea predominates. Diarrhea incidence is highest immediately after a flood but decreases thereafter, with a second spike in transmission two weeks later. This pattern might be explained by an initial increase in exposure, with a delayed later peak due to secondary transmission. There was no association between overall rainfall and diarrheal disease, which might be explained by the lower quality of those studies. Future studies should use standard, clearly defined exposure variables to strengthen our understanding of the relationship between rainfall and diarrheal illnesses.

1978

EVALUATIONS OF THREE DRINKING WATER CHLORINATION INTERVENTIONS IN COX'S BAZAR REFUGEE CAMPS

Mustafa Sikder, Gabrielle String, Danielle Lantagne

Tufts University, Medford, MA, United States

Humanitarian responders provide drinking water to nearly 730,000 refugees in Cox's Bazar, Bangladesh. Multiple water chlorination interventions are implemented in the camps. The aim of this research is to evaluate the effectiveness of three different water chlorination interventions in Cox's Bazar. We applied a mixed-methods protocol and used water quality and reported acceptability to evaluate the programs. We have completed a bucket chlorination (BC) and an in-line chlorination (IC) evaluations. We will evaluate a centrally chlorinated piped network system in April 2019. In the BC intervention, staff dosed chlorine solution into users' water after collection from ringwells. We observed nine chlorination points (CP), conducted 10 KIIs, and led four FGs; enumerators surveyed 148 households. The stock solutions' chlorine varied 0.07-0.34%. Stratified by CP, the mean household free chlorine residual (FCR) varied 0.1-0.5 mg/L, with 28% having no detectable FCR. Furthermore, 73% households had <10 *E. coli* CFU/100mL. Most users believed the intervention made water safe (85%). Recommendations were to increase the concentration of stock solution, prepare solution regularly, use opaque bottles to store chlorine, and provide protective equipment to the staff. In the IC intervention, responders installed automated chlorination devices at handpumps. We observed nine CP, conducted two KIIs, and led two FGs; enumerators surveyed 180 households. At the CP, FCR varied <0.05-3.78 mg/L and *E. coli* were 2-14 CFU/100mL (median <5). Stratified by point, the mean household FCR varied 0.0-0.4 mg/L, with 63% having no detectable FCR. However, 91% of households had <10 *E. coli* CFU/100mL. Many users believed the intervention made the water safe (62%). Recommendations were to replace the devices with adjustable ones and regularly monitor household water quality to determine chlorine dosage. Despite varying modalities, both interventions reduced the *E. coli* and had high acceptance, but struggled to maintain FCR >0.2mg/L. Comparisons of the interventions will help responders make informed decision to select appropriate technology in camps.

1979

IMPACT OF LOW-COST POINT-OF-USE WATER TREATMENT TECHNOLOGIES ON ENTERIC INFECTIONS AND LINEAR GROWTH AMONG CHILDREN IN LIMPOPO, SOUTH AFRICA

Courtney L. Hill[1], Emanuel Nyathi[2], Kelly McCain[3], Joshua N. Edokpayi[2], David M. Kahler[4], Darwin J. Operario[1], James A. Smith[1], Richard L. Guerrant[1], Amidou Samie[2], Rebecca A. Dillingham[1], Pascal O. Bessong[2], Elizabeth T. Rogawski McQuade[1]

[1]*University of Virginia, Charlottesville, VA, United States,* [2]*University of Venda, Thohoyandou, South Africa,* [3]*Emory University, Atlanta, GA, United States,* [4]*Duquesne University, Pittsburgh, PA, United States*

Enteric infections early in life have been associated with poor linear growth among children in low-resource settings. Point-of-use water treatment technologies provide effective and low-cost solutions to reduce exposure to enteropathogens from drinking water, but it is unknown whether the use of these technologies translates to improvements in child growth. We conducted a community-based randomized controlled trial of two water treatment technologies to estimate their effects on child growth in Limpopo Province, South Africa. 404 households with a child under age 3 were randomized to receive a silver-impregnated ceramic water filter, a silver-impregnated ceramic disk (the MadiDrop), a safe-storage water container, or no intervention, and were followed quarterly for two years. Due to unexpectedly high silver concentrations in the treated water, the silver content of the interventions was reduced four times over follow-up. We estimated the effects of the interventions on linear and ponderal growth, enteric infections assessed by quantitative molecular diagnostics, and diarrhea prevalence. The ceramic water filters and silver-impregnated disks consistently achieved more than 1.5 and 2 log reductions, respectively, in total coliform bacteria in drinking water samples. The filters and disks were associated with small, non-significant differences in height (height-for-age z-score differences compared to no intervention: 0.11, 95% confidence interval: -0.12, 0.33 and 0.12, 95% CI: -0.11, 0.34, respectively). There were no effects of the interventions on weight, diarrhea prevalence, or enteric infections, except for a 22% lower (95% CI: 4, 36) prevalence of *Giardia* among children with the filters compared to those with no intervention. While the ceramic water filters and silver-impregnated disks were effective in treating drinking water and potentially limiting transmission of *Giardia*, their use was not sufficient to reduce enteric infections overall or improve child growth. Transformative WASH interventions that better prevent enteric infections are likely needed to improve long-term child growth outcomes.

1980

EFFICACY OF LOCALLY AVAILABLE CLEANING AGENTS AND METHODS TO REDUCE BIOFILMS ON WATER STORAGE CONTAINERS AND TAPS

Gabrielle String, Marta Domini, Patrick Mirindi, Hanaa Badr, Anthonia Oguidupe, Nabila Khandaker, Marlene Wolfe, Daniele Lantagne

Tufts University, Medford, MA, United States

Biofilm growth on surfaces in contact with drinking water can act as a microbial reservoir for *E. coli* and other opportunistic pathogens. A particular concern in water storage containers and taps is bacteria

proliferation inside biofilms on interior surfaces as they can shed and re-contaminate stored water. To our knowledge, in low-income contexts, the efficacy of locally-available cleaning agents and methods for biofilm removal from containers and taps has not been assessed. We completed two laboratory studies growing *E. coli* biofilms on the interior surfaces of 72 jerrycans and 96 taps, respectively. Jerrycans were cleaned with different agents (0.5% NaOCl; pebbles; sand; 0.5% NaOCl and pebbles; 0.5% NaOCl and sand; and, none) and frequencies (every day; every other day; once a week), via shaking. Taps were cleaned with different agents (0.5% NaOCl; recently boiled water; soapy water; and, 5% vinegar) and cleaning methods (flowing the solution through the tap; soaking the tap assembled or disassembled for 60 seconds or 5 minutes; scrubbing the tap assembled or disassemble; scrubbing and soaking the tap disassembled for 5 minutes; and, none). Biofilms were imaged by epifluorescence microscopy and *E. coli* concentrations on the surfaces were enumerated. Imaging and enumeration confirmed *E. coli* biofilm growth on all control jerrycans and taps. Images of jerrycan surfaces cleaned only with pebbles or sand had the densest biofilm growth across all surface areas. Biofilms were thickest on the bottom surfaces of all jerrycans. Images of tap surfaces cleaned with any method using soapy water had large, dense biofilm structures. Cleaning jerrycans with 0.5% NaOCl combined with abrasives inhibited biofilm development across all test combinations. The most efficacious cleaning methods for taps were soaking assembled for 5 minutes (0.5% NaOCl, boiled water), or scrubbing and soaking unassembled for 5 minutes (0.5%NaOCl, vinegar). For jerrycans storing low turbidity water, we recommend daily cleaning with any tested method and daily chlorine water treatment. For taps, we recommend soaking assembled in recently boiled water for 5 minutes.

1981

HOUSEHOLD WATER STORAGE MANAGEMENT AND ASSOCIATED DRINKING WATER QUALITY IN RURAL INDIA

Sarah L. McGuinness[1], Joanne O'Toole[1], Andrew B. Forbes[1], Kavita Patil[2], Asha Giriyan[2], Chetan A. Gaonkar[2], Fraddry D'Souza[2], S. Fiona Barker[1], Thomas B. Boving[3], Allen C. Cheng[1], Karin Leder[1]

[1]*Monash University, Melbourne, Australia,* [2]*The Energy and Resources Institute, Western Regional Centre, Goa, India,* [3]*University of Rhode Island, Kingston, RI, United States*

Intermittent community water supply, related to fluctuations in water availability and electricity, is a reality in rural India. Accordingly, household storage of drinking water is common. Fecal contamination of stored water may occur at the source, during collection or during storage. As part of a trial evaluating a community water intervention in four rural villages in India where open defecation is common, we conducted household-level surveys at six time points. Each survey collected information about water source, storage and treatment, as well as hygiene and sanitation practices. At five of these time points, we also visited a random sample of households to request stored drinking water samples for *Escherichia coli* testing, concurrently observing whether the storage vessel was covered and documenting water access practices. We conducted 12265 surveys amongst 2304 households, and collected 3296 stored water samples from 1739 households. Households frequently reported multiple sources of drinking water (mean 2.7, range 1-7). The majority of water storage vessels were covered (92%); the most common reported (79%) and observed (81%) method used to access stored water was to dip a cup or ladle into the water container. Stored water samples were frequently contaminated with *E. coli* (2277/3296, 69%), and most households contributing two or more samples (745) had intermittently (47%) or persistently (44%) contaminated drinking water. The highest levels of contamination of stored water were observed during the wet season, coincident with the highest levels of river water contamination, which was reported as a primary drinking water source. Until households can be reached with an on premises continuous water supply, the practice of household water storage will continue, coupled with opportunistic use and/or mixing of water supply sources, some of which are likely to be from unprotected sources. These data also show that improvements to the quality of water supply sources will be insufficient to prevent exposure to contaminated drinking water unless attention is given to improving household water storage, hygiene and sanitation practices.

1982

UNDERSTANDING THE REALITY OF MDA FOR TRACHOMA AMONG A MAASAI COMMUNITY IN TANZANIA: APPLICATION OF AN ANTHROPOLOGICAL FRAMEWORK FOR NTD INTERVENTION EFFECTIVENESS

Trachoma, a neglected tropical disease (NTD), is making progress in elimination, yet hard to tackle communities are often marginalized. Neglect encompasses social constructs and livelihoods of a community. Areas in Tanzania, predominantly inhabited by Maasai, remain endemic for trachoma. We assessed the effectiveness of mass drug administration (MDA) using an anthropological framework, drawing on an ethnographic study of trachoma among Maasai. The lead author conducted participant observation during MDA and used household interviews to understand perceptions and experience of MDA, decision-making and migration. Interviews were conducted in Maa and translated into English. A framework method for analysis was used. Five domains were applied. (1) *terrain of intervention*: Human movement during MDA of varied distances and time-frames included seasonal migration, domestic chores, grazing, school and family visits. Encounters with wildlife hindered MDA delivery. (2) *socio-cultural factors and community agency*: Norms to maintain pregnancy secret impeded women of stating their situation to community drug distributors (CDDs). Timing of CDD visits conflicted with attending cattle. Refusals occurred among *ilmurrani* age group and elder women. (3) *strategies and motivation of CDDs*: Maa speaking CDDs were critical to effective delivery of MDA. Maasai CDDs were motivated but challenged by distances, wildlife, and poor compensation. (4) *socio-materiality of technology*: Trust in the drug improved as side effects decreased over years of MDA. Restrictions to swallowing drug and/or water was relevant to post-partum women and *ilmurrani* age group. (5) *political governance*: Whilst perceptions of the program were positive, the community questioned government priorities. People complained of lack of information and involvement of community members. Effective delivery of MDA requires a critical understanding of livelihoods, norms and beliefs and should inform control programs to tailor approaches to delivering to Maasai communities. A critical social science perspective should be imbedded in planning and evaluation of all NTD programs.

1983

TRACHOMA REMAINS HYPERENDEMIC AFTER 10 OR MORE YEARS OF THE SAFE STRATEGY: RESULTS FROM 7 DISTRICT-LEVEL POPULATION-BASED SURVEYS IN AMHARA, ETHIOPIA

Tigist Astale[1], Eshetu Sata[1], Mulat Zerihun[1], Andrew W. Nute[2], Aisha E.P. Stewart[2], Melsew Chanyalew[3], Berhanu Melak[1], Zebene Ayele[1], Demelash Gessese[1], Gedefaw Ayenew[1], Bizuayehu Gashaw[3], Zerihun Tadesse[1], E. Kelly Callahan[2], Scott D. Nash[2]

[1]*The Carter Center, Addis Ababa, Ethiopia,* [2]*The Carter Center, Atlanta, GA, United States,* [3]*Amhara National Regional Health Bureau, Bahir Dar, Ethiopia*

Within trachoma hyperendemic districts, current WHO guidelines recommend 5 years of the Surgery, Antibiotics, Facial Cleanliness and Environmental Improvement (SAFE) strategy for the elimination of trachoma as a public health problem. The Amhara region of Ethiopia was early to scale up with the SAFE strategy and has historically had

many districts hyperendemic for trachoma. This study describes the epidemiological trends of trachoma over a period of up to 11 years in 7 contiguous hyperendemic districts to assess the success of the SAFE strategy as currently recommended. Trachoma impact surveys were conducted in the 7 districts in 2014 after 5-6 years of SAFE, and again in 2019 after 10-11 years of SAFE. At both timepoints a multistage cluster-random sampling design was used to select a population-based sample. All individuals ages 1 year and above were examined for clinical signs of trachoma by certified graders, and conjunctival swabs were collected from children ages 1-5 years to test for Chlamydial infection. The 2014 impact surveys demonstrated that all 7 districts were highly endemic with a trachomatous inflammation-follicular (TF) prevalence among children ages 1-9 years ranging between 36.0% (95% Confidence Interval (CI): 26.3-47.0%) in Kalala district and 56.4% (95%CI: 42.1-69.6%) in Moretina Jiru. The district prevalence of trachomatous inflammation-intense (TI) ranged between 5.3% (95% CI: 2.9-9.5%) and 15.9% (95%CI: 9.5-25.6%) and Chlamydial infection ranged from 2.3% to 33.9% suggesting ongoing transmission. Based on these results, all 7 districts received an additional 5 years of SAFE and were surveyed again in 2019. Although the TF point estimate was lower in all 7 districts in 2019 compared to the earlier survey, the prevalence of TF still ranged from 11.8% (95%CI: 7.6-16.0%) to 36.1% (95%CI: 27.4-44.3%). Infection data will be available soon. These 7 districts appear to constitute a hotspot in the region, and 3-5 more years of SAFE, or more, will be required. The global program should reconsider existing guidelines for hyperendemic districts and should increase research on alternative antibiotic treatment strategies.

1984

TRACHOMA ELIMINATION ENDGAME IN UGANDA: PROGRESS, MILESTONES AND TIMELINES

Gilbert Baayenda[1], Benjamin Binagwa[2], Wangeci Thuo[3], Francis Mugume[1], Edridah Muheki[1], Jeremiah M. Ngondi[4]

[1]*Ministry of Health, Kampala, Uganda,* [2]*RTI International, Kampala, Uganda,* [3]*RTI International, Washington, DC, United States,* [4]*RTI International, Dar Es Salaam, United Republic of Tanzania*

Trachoma is endemic in Uganda where implementation of the surgery, antibiotics, facial cleanliness and environmental improvement (SAFE) strategy started in 2006. We describe: baseline surveys; implementation of SAFE; trachoma impact surveys (TIS) and trachoma surveillance surveys (TSS); and preparation of dossier for validation of elimination. Data were collated from reports of SAFE implementation, scientific manuscripts, water sanitation and hygiene strategies (WASH), and national development plans. The trachoma elimination dossier narrative and data templates were prepared according to the World Health Organization standard operating procedures. From 2006 to 2018, atotal of 57 districts were surveyed at baseline of which 50 were eligible for the AFE components of SAFE.A total of 54,505 trichiasis surgeries were done from 2006 to 2018. Annual mass drug administration (MDA) was undertaken from 2007to 2018in 50 districts. Implementation of facial cleanliness and environmental change (F&E) was targeted to trachoma endemic districts and nationally through WASH programmes. Impact surveys showed that 47 out of 50eligible districts had achieved elimination threshold - trachomatous inflammation-follicular (TF) prevalence of <5%. Surveillance surveys showed that TF prevalence of <5% had been sustained 24 months after the TIS in 38 districts. Three districts are still eligible of for TIS and will require TSS after 24 months if TIS shows TF of <5%. Another set of nine districts require TSS to document sustained elimination of TF. Trachoma dossier preparation has started,and an action plan has been developed with submission of dossier to WHO projected for 2021. Uganda has made steady progress towards elimination of trachoma. The Uganda experience provides important lessons for other national programmes on implementation of SAFE and trachoma elimination.

1985

PHOTOGRAPHING OPERATED TRACHOMATOUS TRICHIASIS (TT) CASES DURING OUTREACH CAMPAIGNS: RESULTS OF A PILOT

Whitney Goldman[1], Assumpta Lucienne Bella[2], Clarisse Bougouma[3], Emilienne Epée[4], Martin Kabore[3], Issouf Bamba[5], Jean-Paul Djiatsa[5], Albert Kiemde[5], Phylippe Bayala[5], Marc Sepama[5], Julie Akame[4], Jules Patrick Evenga[4], Michel Hendji[4], Yannick Nkoumou[4], Carine Fokam Tagne[4], Lauren Johnson[1], Geri Kemper-Seeley[1], Katherine Nerses[1], Stephanie Parker[1], Emily Gower[6]

[1]*Helen Keller International, Washington, DC, United States,* [2]*Ministry of Health, Cameroon, Yaounde, Cameroon,* [3]*Ministry of Health, Burkina Faso, Ouagadougou, Burkina Faso,* [4]*Helen Keller International, Cameroon, Yaounde, Cameroon,* [5]*Helen Keller International, Burkina Faso, Ouagadougou, Burkina Faso,* [6]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Since January 2018 the U.S. Agency for International Development (USAID)'s Morbidity Management and Disability Prevention Project has collaborated with ministries of health in Burkina Faso and Cameroon to pilot photographing operated eyelids during trachomatous trichiasis (TT) surgery and 3-6 month post-operative follow-up exams. The photos were intended to be used as a quality assurance mechanism and to identify potential risk factors for complications. To explore the feasibility of taking high-quality photos of a high proportion of operated cases, photos were taken during routine TT surgery campaigns from Jan. 2018 through Feb. 2019 in Burkina Faso (5 campaigns) and Cameroon (4 campaigns) immediately before surgery, immediately after surgery, one day after surgery, and/or 3-6 months after surgery. Different photographers were used throughout the campaigns. A total of 939 photos were taken, analyzed, and classified. Photos classified as "usable" were those that revealed information about the quality of surgery provided. Photos were also assessed for blurriness, poor lighting, and poor angle. Across all photos, 86% (809/939) were found to be usable: 84% (179/214) in Burkina Faso and 87% (630/725) in Cameroon. Overall, 81% (243/301) of preoperative photos, 88% (260/294) of immediate postoperative photos, 89% (186/208) of Day 1 photos, and 88% (120/136) of 3-6 month photos were usable. The proportion of usable photos ranged from 74% to 95% depending on whether they were taken preoperatively, immediately after surgery, at Day 1, or 3-6 months after surgery. Among photos not classified as usable, image quality issues identified were poor angle (86%), blurriness (43%), and poor lighting (27%). The proportion of usable photos remained above 75% across multiple campaigns and photographers and in different country contexts. These results indicate that photo taking can generate a substantial portion of usable photos revealing information about the quality of surgery provided. Photos of eyelids can therefore be used as a programmatic monitoring tool to document trichiasis surgery and certain post-operative outcomes.

1986

THE GLOBAL BURDEN OF LEPROSY FROM 1980-2017

Harrison Chase Gottlich, Anum Najeem Khan, Taren Gorman, Steph Zimsen, Martina Vargas, Amanda Deen, Elizabeth Cromwell

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Leprosy (Hansen's disease) is an infectious disease with the potential to cause lifelong physical disfigurement and social stigma. The World Health Organization has endorsed the elimination of leprosy as a public health problem by 2020, with an overall objective of reducing the incidence of disability due to leprosy. In this analysis, we estimate the incidence and prevalence of Stage 1 and Stage 2 leprosy from 1990 to 2017 as part of the Global Burden of Disease study. We then model the age and sex-specific distribution to estimate Disability Adjusted Life Years (DALYs). National leprosy reporting data were aggregated and modeled using the Bayesian meta-regression framework DisMod-MR 2.1 under the Global Burden of Disease Study. We present methods for age and sex

adjustment of national reporting data and summarize existing evidence on leprosy-related disability. Overall, the global estimates indicate increasing incidence and prevalence from 1990 to 2000 and decreasing incidence but stable prevalence from 2000 to 2017. We estimate 410,666 (95% Uncertainty Interval (UI): 385,100 to 439,230) prevalent cases (including treated persons with permanent disability) and 101,429 (95% UI: 94,429 to 109,758) incident cases of leprosy in 1990; 519,028 (95% UI: 487,012 to 554,426) prevalent cases and 120,932 (95% UI: 112,878 to 130,511) incident cases of leprosy in 2000; and 518,500 (UI: 487,700 to 552,500) prevalent cases and 48,500 (95% UI: 45,800 to 51,000) incident cases of leprosy in 2017. The prevalence of leprosy is highest among adults ages 50-60 years old, with the majority of total cases estimated in India, Brazil and China, accounting for an estimated 271,760 (95 % UI: 249,565 to 298,280) prevalent cases. Per capita, the burden of leprosy is highest in South Sudan, Madagascar, and Guinea with rates of DALYs per 100,000 DALYs ranging from 2.18 (95% UI: 1.49 to 3.13) to 2.94 (95% UI: 1.93 to 4.14).

1987

LEPROSY POST-EXPOSURE PROPHYLAXIS: AN OPTION TO ACCELERATE LEPROSY ELIMINATION

David J. Blok[1], Arielle Cavaliero[2], Peter Steinmann[3], Jan Hendrik Richardus[1]

[1]*Department of Public Health, Erasmus MC, University Medical Center, Rotterdam, Netherlands,* [2]*Novartis Foundation, Basel, Switzerland,* [3]*Swiss Tropical and Public Health Institute, Basel, Switzerland*

The widespread availability of free multidrug treatment (MDT) has reduced the global leprosy prevalence considerably since the 1980s, but the annual number of newly detected leprosy cases worldwide has stagnated at around 210,000 over the past decade; with about 10% of new diagnoses being children, indicating ongoing transmission. To further curb the case detection rate, a different approach to leprosy elimination, defined as 'zero leprosy', is required. In 2015, the Leprosy Post-Exposure Prophylaxis (LPEP) program launched across eight countries, assessing feasibility and impact of a single-dose rifampicin (SDR) as prevention to eligible contact persons of newly diagnosed leprosy patients. SDR had proven to reduce the risk for these contacts to develop leprosy by over 50%. Household and other contacts were systematically traced, screened for symptoms of leprosy and administered SDR if they did not show signs of leprosy. After an initial increase in new diagnoses due to backlog, the results of LPEP showed a promising downward case detection trend. Since actual long term impact of SDR is difficult to establish during the course of a three-year program such as LPEP, we used the individual-based transmission model SIMCOLEP to predict the potential long-term impact of LPEP on global case detection rates. If LPEP were to continue after three years, our model predicts that it could reduce the case detection rate by 75% in 2030 (15 years after its start), and by over 90% in 2040. Our model further predicts that with the current tools, it would take beyond 2070 to reach a level below 10,000 new cases annually. Implementing LPEP globally would however accelerate that period towards 2057, which means advancing progress towards zero leprosy by more than a decade. LPEP would thereby prevent many new cases. In a nutshell, achieving zero leprosy will take several decades, but LPEP could significantly reduce leprosy transmission. We advise to integrate SDR routinely for contact persons of newly diagnosed patients within national health systems and leprosy programs.

1988

OPTIMIZED GENEXPERT POOLING STRATEGY FOR *CHLAMYDIA TRACHOMATIS* AND *NEISSERIA GONORRHOEAE* REDUCES COST OF MOLECULAR STI SCREENING IN TWO LIMITED RESOURCE CLINICS IN ZAMBIA

Sarah Connolly[1], William Kilembe[2], Mubiana Inambao[2], Ana-Maria Visoiu[2], Tyronza Sharkey[2], Rachel Parker[1], Eric Hunter[1], Susan Allen[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Zambia–Emory HIV Research Project, Lusaka/Ndola, Zambia*

Sexually transmitted infections (STIs) such as chlamydia (CT) and gonorrhea (NG) have been shown to increase the risk of heterosexual HIV-1 transmission. In women, CT and NG are often asymptomatic and undetected by syndromic management. Molecular testing for STIs is highly sensitive, but time and cost restraints preclude implementation of these technologies in resource-limited settings. Pooling samples for testing together in GeneXpert cartridges is one strategy for reducing the cost per individual tested. This project aimed to develop a pooling strategy based on social and demographic factors associated with CT/NG prevalence rates. In a cohort of high-risk women in Zambia, including female sex workers and single mothers with children under the age of five, the prevalence of either CT and/or NG infection was 17%. Data from a 2016 cross-sectional sub-study on intra-vaginal practices was examined to identify associations between various sociodemographic factors, clinical symptoms, sexual behaviors, STI laboratory results, and CT/NG status. Logistic regression modeling was used to predict the probability of a positive CT/NG test result in the presence of the associated factors: city, age, education, long-acting reversible contraception usage, and laboratory results for bacterial vaginosis, *Trichomonas vaginalis*, and incident syphilis on the day of CT/NG testing. Signs and symptoms were not found to be associated. An easy-to-use diagnostic screening checklist was created to categorize women by probability of testing positive on the GeneXpert. An algorithm considering cost of each test and prevalence of disease determined the optimal pool size for each risk category. Pooling women with similar CT/NG predictive factors together, or testing those at highest risk individually, reduced the cost per test. Further implementation of this tool to guide presumptive treatment, in lieu of molecular testing, increases the cost saving potential. The strategies described in this study are applicable to other low-resource clinical settings seeking to bring the accuracy of molecular testing to their clients with a reduced financial burden.

1989

MISSED OPPORTUNITIES FOR VACCINATION EQUITY: TARGETING CHILDREN IN HEALTHCARE FACILITIES

Nicholas Albaugh[1], Joseph Mathew[2], S. Sitaraman[3], Choudhary Richa[3], Tomar Anjali[3], Ishumeet Bajwa[4], **Anita Shet**[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Post Graduate Institute of Medical Education Research, Chandigarh, India,* [3]*Sawai Man Singh Medical College, Jaipur, India,* [4]*Post Graduate Institute of Medical Education and Research, Chandigarh, India*

National vaccination rates frequently obscure inequities in vaccination coverage. Addressing missed vaccination opportunities for children within healthcare systems can increase immunization rates. Using the national immunization schedule as the standard, we aimed to quantify missed vaccination opportunities among hospitalized children in India and identify immunization barriers perceived by caregivers and healthcare providers. Between Nov 2018 and Mar 2019, we screened and enrolled 163 children aged 1-59 months at admission in two public hospitals in northern India. We excluded those with no record or recall of vaccines, and those with vaccine contraindications. We found 55% were under-immunized for their age. Among these 61% were <12 months old, and 3% were 'zero-dose' children (received no vaccines at all). Frequently missed vaccines were hepatitis B birth dose, DTP3 and measles vaccines. Exit interviews and chart reviews at discharge showed that 97% of under-immunized children

were 'missed opportunities' (i.e. received no catch-up vaccines or referral for vaccination services). Significant risk factors for under-immunization included higher birth order (OR 1.8), previous health facility contact (OR 1.8), and father as primary vaccination decision maker (OR 3.2). Immunization barriers noted by healthcare providers included perceived contraindications (child too ill to receive vaccines), physical barriers (vaccines unavailable in the inpatient ward despite availability proximally in the immunization clinic) and policy limitations (staff in the ward not authorized to give vaccines). Over 90% of caregivers supported receiving increased information on vaccination services, and automated reminder services post discharge. Our findings indicate that hospitalized children are more likely to be under-immunized for age compared to national populations, and represent missed vaccination opportunities despite contact at healthcare centers with immunization capacity. Interventions targeting these populations and leveraging existing immunization resources will substantially improve vaccination inequities.

1990

COMPARATIVE EFFECTIVENESS OF STRATEGIES TO IMPROVE PRACTICES OF LAY HEALTH WORKERS IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND BAYESIAN NETWORK META-ANALYSIS

Samantha Rowe[1], Huseyin Naci[2], David Peters[3], Kathleen Holloway[4], Dennis Ross-Degnan[5], Alexander Rowe[1]

[1]*US Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*London School of Economics, London, United Kingdom,* [3]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [4]*Institute of Development Studies, University of Sussex, Brighton, United Kingdom,* [5]*Harvard Medical School, Boston, MA, United States*

Lay/community health workers (LHWs) in low- and middle-income countries (LMICs) often provide inadequate care. A comparison of the effectiveness of strategies to improve LHW practices would be useful for programmatic decision-making. We identified LHW studies from a systematic review on improving health worker performance in LMICs. We focused our analysis on LHW practice outcomes expressed as a percentage (e.g., % of patients treated correctly). Strategy effects were calculated as adjusted risk differences. We estimated mean differences and 95% credible intervals using Bayesian network meta-analysis (NMA) with random effects, adjusting for LHW baseline performance level. We searched 52 databases for published studies and 58 document inventories for unpublished studies up to 2016. We screened 216,477 citations and identified 22 studies that tested 17 strategies. The 22 studies included 30 comparisons: 22 strategy-versus-control and 8 head-to-head comparisons. Most studies (14/22 or 63.6%) had a high risk of bias. The 4 strategies that included the provision of drugs or equipment plus LHW training with or without other intervention components had effects ranging from 8.7 to 57.7 %-points (3 were statistically significant), but all were tested by <3 study comparisons each and thus had results with very limited generalizability. All 5 strategies tested by >3 study comparisons each (whose results were more generalizable) had effects that were relatively small (<6 %-points) and not statistically significant: training only, supervision only, training plus supervision, information and communication technology (ICT) for LHWs only, and provision of equipment plus supervision plus non-supervisory feedback plus ICT. A sensitivity NMA with an expanded definition of LHWs including unlicensed private sector providers had similar findings, except for significant effects for training only (2.8 %-points) and supervision only (13.3 %-points). Despite limitations, our NMA provides evidence that will help decision-makers select strategies to improve LHW performance in LMICs—and potentially avoid relatively ineffective strategies.

1991

EXAMINING THE FEASIBILITY OF COMMUNITY HEALTH WORKER DELIVERY OF SEVERE ACUTE MALNUTRITION TREATMENT USING AN INNOVATIVE SIMPLIFIED LOW-LITERACY PROTOCOL: RESULTS FROM NIGERIA

Olusola B. Oresanya[1], Olatunde Adesoro[1], Prudence Hamade[2], Helen Counihan[2], Patrick Gimba[3], Amina Isah[4], Kolawole Maxwell[1], Naoko Kozuki[5], Bethany Marron[5]

[1]*Malaria Consortium, Abuja, Nigeria,* [2]*Malaria Consortium, London, United Kingdom,* [3]*Nigers State MInistry of Health, Minna, Nigeria,* [4]*State Primary Health Care Development Agency, Minna, Nigeria,* [5]*International Rescue Committee, New York, NY, United States*

Pneumonia, diarrhea, and malaria are leading causes of death among under-fives worldwide. Malnutrition is an underlying cause in half of these deaths. Although integrated community case management (iCCM) is a recognized strategy for increasing access to life-saving treatment, severe acute malnutrition (SAM) is often not included, with treatment only available at outpatient therapeutic centers and delivered using complicated protocols. Using human-centered design, the International Rescue Committee developed a simplified protocol and tools for treating SAM in low-literacy settings, which Malaria Consortium adapted and piloted with community-oriented resource persons (CORPs) providing iCCM services in hard-to-reach areas in Niger State (2017-2018). We trained 67 CORPs and 20 supervisors on the protocol and tools, and 303 children who were in the dark red (9-10.25cm) or pink (10.25-11.5cm) zones on a modified mid-upper arm circumference (MUAC) strip, passed an appetite test and had no symptoms of severe disease were enrolled in the study. We used mixed methods – focus group discussions, in-depth interviews, and data on treatment duration and outcomes for 288 of the enrolled children – to evaluate the feasibility, acceptability and effectiveness of the protocol and tools. A one-sample non-inferiority test conducted against Sphere's 75% standard revealed an overall cure rate of 73.4%, which was non-inferior to the Sphere standard. Results of further analysis showed: median weeks to cure of 6.5; a non-response rate of 4.5%; a default rate of 22%; and referral rate of 14.8%. It also showed that children enrolled in the worst MUAC zone (20.1%) were 29% less likely to recover than their pink zone (79.9%) counterparts and were 50% more likely to be referred. Qualitative data indicated acceptability among CORPs and caregivers. This study demonstrates the feasibility, acceptability and effectiveness of using a simplified protocol for treating SAM via existing iCCM programs being implemented by low-literate CORPs. Community health workers are key to expanding access to SAM treatment if universal health coverage is to be achieved in Africa.

1992

THEMATIC ANALYSIS OF COMMUNICATION BETWEEN PEDIATRIC HEALTHCARE PROVIDERS AND THE SOMALI COMMUNITY

Kristin Maletsky[1], Jibril Mohamed[2], Stephanie Lauden[1]

[1]*Nationwide Children's Hospital, Columbus, OH, United States,* [2]*The Ohio State University, Columbus, OH, United States*

Healthcare providers (HPs) receive variable training in cultural sensitivity despite increasing US refugee populations. Somali refugees face challenges navigating the US healthcare system, yet little is known about how HPs understand or address existing communication barriers. We aimed to understand HPs' perceptions of clinical interactions with Somali patient families, specifically related to communication surrounding pediatric chronic diseases. A convenience sample of HPs (physicians, NPs/PAs, nurses) at an American academic pediatric hospital completed an anonymous, voluntary, online survey in 2019. Demographic data and a self-reported Likert scale (1=no confidence/understanding, 5=could not be more confident/understood) were collected and evaluated using descriptive statistics. HPs completed 3 open-ended questions on their understanding of how the Somali community defines chronic disease and their observations regarding communication and understanding

between HPs and the Somali community. Using Grounded Theory, a qualitative analysis was completed until saturation was theoretically achieved. A total of 162 HPs responded from 16 countries of origin. 45% have served abroad in a healthcare setting. HPs reported some understanding of Somali culture (avg 2.3) and slight confidence in their overall ability to communicate with Somali families (avg 2.8) though less confidence in conversations regarding chronic disease (avg 2.5). 40% reported feeling poorly understood by Somali patient families. Qualitative analysis revealed HP concerns regarding language barriers (34%, n=51), mismatch of expectations between HPs and families (17%, n=26), as well as positive interactions (18%, n=27). Interpreters were described as both integral (18%, n=27) and potentially inaccurate or variable in quality (17%, n=25). 77% (n=115) reported a lack of understanding when asked how the Somali community views chronic disease. Although many positive interactions occur, most HPs lack confidence or understanding regarding communication with our Somali families, presenting a significant opportunity for education and advocacy.

1993

PILOTING EXPANSION OF A PUBLIC SECTOR REPORTING TOOL INTO COMMUNITY-LEVEL PRIVATE SECTOR FACILITIES IN UGANDA

Dorcas Kemigisha[1], Emily A. Briskin[1], Luke Baertlein[1], Alex Ogwal[1], Carol Kyozira[2], Deepa Pindolia[1], Jimmy Opigo[2]

[1]*Clinton Health Access Initiative, Kampala, Uganda,* [2]*Ministry of Health, Kampala, Uganda*

The private sector is an important source of care for sick children in Uganda. With the aims of improving the quality of care and enhancing government awareness and follow-up of fever cases, in August 2018, a pilot group of 108 community-level private facilities in three districts of Uganda were trained to use a government-designed patient register book and to report a set of case count, diagnosis, treatment and stock indicators weekly via the public-sector SMS-based disease surveillance system, mTrac. Data from mTrac flows into the national DHIS-2, increasing oversight and accountability. District and national health authorities met quarterly to review HMIS data submitted by private facilities via mTrac, selecting those with poor reporting or case management to be supervised using a standardized checklist. An observational study was conducted over the six-month pilot, descriptively analyzing routine weekly mTrac data completeness and quality. Further, Mann-Whitney test was used to compare private sector reporting rates to those in the public sector, and linear regression was used to assess trends in private sector reporting rates over time. Results from this pilot period showed that frequency, timeliness, and quality of data reported by private facilities were similar to that of public facilities. With an average weekly reporting rate of 90% in private facilities and 95% in public facilities, the rates were similar, but statistically different ($p<0.01$), suggesting the need for refinement of reporting training and support practices for the private sector. Linear regression analysis showed no effect of time on private sector reporting rate (slope = 0.0, $p=0.62$), suggesting the reporting rate did not decline over the six-month pilot period. The results indicate that private facilities can be expected to report in HMIS via the mTrac SMS-based platform reliably, and that these results can be sustained. To ensure the scalability and sustainability of reporting by private sector facilities, the relevant policies, guidelines, budgets, and national training and support curricula must be updated to integrate the community-level private sector.

1994

EXPLORING COLLABORATIONS BETWEEN A CHILD MORTALITY SURVEILLANCE PROGRAM AND THE INFORMAL HEALTH CARE SYSTEM OF TRADITIONAL BIRTH ATTENDANTS TO IMPROVE DEATH NOTIFICATION

Saquina Cossa[1], Maria Maixenchs[2], Felismina Tamele[1], Zubaida Manhenge[1], John Blevins[3], Inacio Mandomando[1], Quique Bassat[2], Khatia Munguambe[1]

[1]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique,* [2]*ISGlobal, Hospital Clinic, Universitat de Barcelona, Barcelona, Spain,* [3]*Emory Global Health Institute, CHAMPS Program Office, Emory University, Atlanta, GA, United States*

In low income countries like Mozambique, detailed information on deaths occurring in the community is lacking, as >50% of these deaths are not formally reported nor registered. Given that stillbirths and deceased neonates are buried shortly after death, tracing these events is challenging. The Child Health and Mortality Prevention Surveillance Program (CHAMPS) aims to track the Cause of Death (CoD) in children from <5 years old, through collection of clinical data, verbal autopsy, and minimally invasive tissue sampling (MITS). MITS consists of small samples from body tissues and fluids, collected within 24 hours of death. Through community engagement, a strategy was developed to determine how traditional birth attendants (TBA) manage deaths in the community and explore potential links of collaboration for reporting deaths that occur outside health facilities. Snowball sampling was used to select TBAs from Manhiça District (Southern Mozambique). Participatory meetings were held at the neighborhoods from October to December 2017. Field notes, reports and summaries from 18 meetings (engaging 190 TBAs) were introduced into a matrix for data analysis. TBAs explained that they are usually first to confirm stillbirths and deceased newborns in communities, are responsible for informing the traditional authorities about deaths, and in charge of preparing and burying the body in a discreet ceremony, as soon as possible after the death. Despite this limited time window (<1 day), TBAs stated that delaying the ceremony to perform MITS would be possible, provided that families are informed about the procedure's duration. All TBAs stated that they were willing to cooperate with a death notification process in Mozambique. They suggested reporting deaths through a telephone number dedicated for this purpose. Our findings suggest that TBA collaboration in death notification will be very valuable, as they have privileged knowledge about stillbirths and newborn deaths occurring in their areas.

1995

IMPACT OF TRAINING AND SUPPORTIVE INTERVENTIONS ON CASE MANAGEMENT AND REPORTING IN PRIVATE DRUG SHOPS IN TANZANIA

Emily A. Briskin[1], Abdallah Lusasi[2], Felix Lam[3], Richard Silumbe[4], Mathew Mganga[5], Rose Rutizibwa[4], Happy Ndomba[4], Deepa Pindolia[6], Elia Martin[2]

In Tanzania, Accredited Drug Dispensing Outlets (ADDOs) are an important source of care for sick children. Our study aimed to evaluate program interventions designed to improve case management provided by ADDOs for diarrhea, pneumonia, and malaria in children under five. In July 2017, a baseline survey was conducted to measure ADDO dispenser Febrile Illness Management (FIM) knowledge. This informed a training plan in October 2017, where 1467 ADDOs in 4 regions of Tanzania were trained on FIM. The training covered 1) how to assess and treat for diarrhea, pneumonia, and malaria and 2) submission of monthly surveillance data using register books and a mobile text-message-based reporting system.

A holistic package of interventions, including bimonthly SMS reminders, education SMS, performance feedback and targeted quarterly in-person supervision were implemented to reinforce FIM and reporting concepts. In December 2018, a midline survey of a representative sample of ADDOs was conducted to assess their FIM knowledge. We conducted a cross sectional pre- and post-intervention descriptive analysis, which showed that knowledge of appropriate referral for severely ill children increased from 5% at baseline to 76% at midline; knowledge of correct pneumonia and diarrhea treatment increased from 50% to 74% and 50% to 65%, respectively. Reporting rates for November and December 2018 were measured and compared before and after SMS reminders were sent, and differences in reporting rate were assessed using a test of proportions. Results showed that reporting rates increased significantly from 49% to 62% in November and 42% to 59% in December after SMS reminders were sent ($p<0.01$ for both months). The comprehensive set of interventions, including training, educational messages, and targeted supportive supervision, was shown to improve FIM knowledge. SMS reminders were shown to significantly improve reporting rates. SMS reminders should be continued and educational efforts to maintain ADDO dispenser case management knowledge can continue to be systematically modified and assessed to identify practices that maximize FIM knowledge.

1996

A DEEP SEQUENCING APPROACH TO DEFINE BENZIMIDAZOLE RESISTANCE GENE FREQUENCIES IN HUMAN HOOKWORM EGG SAMPLES FROM KPANDAI DISTRICT, GHANA

Santosh George[1], Peter Suwondo[1], Joseph Otchere[2], Lisa M. Harrison[1], Kaya Bilguvar[3], James Knight[3], Adalgisa Caccone[4], Debbie Humphries[5], Michael D. Wilson[2], Michael Cappello[1]

Global control of human hookworm and other STH infections relies on periodic Mass Drug Administration of benzimidazole drugs to high risk groups, regardless of infection status. Our previous studies in Central Ghana demonstrated poor hookworm treatment outcomes with albendazole. In an effort to further assess hookworm response to treatment, we conducted a cross-sectional epidemiological study of hookworm infection in Kpandai District in the Northern Region of Ghana. Participants (n=566) were recruited from 3 rural communities and assessed for STH infection using Kato Katz fecal microscopy. Hookworm-positive individuals were treated with single-dose albendazole(400mg) and re-evaluated after 11-14 days. The prevalence of hookworm was 19.6% and varied significantly by community (range 4.5-33.9%). Response to treatment was at or near WHO effectiveness standards (egg reduction rates 85-94%; cure rates 64-80%). Genomic DNA (gDNA) was extracted from hookworm eggs purified from infected subjects. Three single nucleotide polymorphisms (SNPs;F167Y, E198A and F200Y) corresponding to putative resistance markers within the coding region of the β- tubulin isotype-1 gene of *N. americanus* were characterized in 30 matched pre and post treatment samples using deep sequencing. Each SNP was amplified in two separate PCR reactions, and molecular barcodes were used to label each gDNA fragment and study subject sample. Post sequence analysis revealed 24 million reads, and further *in silico* analysis showed complete coverage of the amplified *loci*. The highest mean alternative nucleotide allele frequency at each position was 0.019 for the F167Y amplicon and 0.131 for the E198A/F200Y amplicon, suggesting minimal genomic variation. There were no samples found to harbor egg DNA with the SNP F167Y marker, while one study subject's sample contained low frequency reads associated with SNPs E198A(3.15%) and F200Y(3.13%). Efforts are underway to compare these results with data from quantitative real-time PCR analysis. This deep sequencing method provides a useful tool to monitor for emerging benzimidazole resistance at the individual and community level.

1997

COMPARISON OF WORLD HEALTH ORGANIZATION AND DEMOGRAPHIC AND HEALTH SURVEY DATA TO ESTIMATE SUB-NATIONAL DEWORMING COVERAGE IN PRE-SCHOOL CHILDREN

Nathan C. Lo[1], Ribhav Gupta[2], David G. Addiss[3], Eran Bendavid[4], Sam Heft-Neal[2], Alexei Mikhailov[5], Antonio Montresor[5], Pamela Sabina Mbabazi[5]

[1]*Stanford University School of Medicine; University of California San Francisco, Stanford; San Francisco, CA, United States,* [2]*Stanford University, Stanford, CA, United States,* [3]*Task Force for Global Health, Decatur, GA, United States,* [4]*Stanford University School of Medicine, Stanford, CA, United States,* [5]*World Health Organization, Geneva, Switzerland*

The key metric for monitoring of deworming programs against soil-transmitted helminthiasis remains WHO-reported national drug coverage. There is increasing interest in using sub-national coverage data as a tracer for equity and to measure within country differences. The Demographic and Health Survey (DHS) potentially offers a readily available source for sub-national data. This study compared deworming coverage reported to WHO and estimated by DHS in pre-school children from Burundi (2016-2017) and Myanmar (2015-2017). WHO provided routinely reported sub-national coverage data, which included the date and coverage of deworming campaigns. We used geospatial, cross-sectional DHS surveys that included mother's report of her child's deworming receipt in past 6 months. DHS survey data were matched to WHO deworming campaigns geographically (at a regional level) and temporally (aligning the survey question recall period with the WHO reporting period). We estimated mean difference in regional deworming coverage between WHO and DHS data and performed sensitivity analyses. We included eligible data on pre-school children from 13 of 18 regions in Burundi (3,585 DHS observations) and 11 of 14 regions in Myanmar (1,656 DHS observations). The reported national deworming coverage in Burundi was 79.8% to WHO and 75.5% by DHS, while in Myanmar coverage was reported as 92.9% to WHO and 47.9% by DHS. In Burundi, the absolute mean regional coverage difference was 10% (range: 1-33%) with a greater WHO coverage in 8 of 13 regions. In Myanmar, the absolute mean regional coverage difference was 45% (range: 24-62%) with greater WHO coverage in 11 of 11 regions. In sensitivity analysis, mean coverage difference was robust to assumptions regarding maternal recall period. WHO and DHS deworming coverage estimates were broadly consistent in Burundi and largely discrepant in Myanmar. These differences may be explained by quality of data reporting and country health information management practices. DHS data can complement WHO deworming coverage data as an independent check on data quality and as a tool to generate sub-national coverage and equity estimates.

1998

PREDISPOSITION AND HOUSEHOLD CLUSTERING OF SOIL-TRANSMITTED HELMINTH INFECTION EVIDENT IN MYANMAR COMMUNITIES THAT HAVE RECEIVED EXTENSIVE MASS DRUG ADMINISTRATION

Julia C. Dunn[1], Martin Walker[1], Alison A. Bettis[1], James E. Wright[1], Nay Yee Wyine[2], Aye Moe Moe Lwin[3], Nay Soe Maung[3], Roy M. Anderson[1]

[1]*Imperial College London, London, United Kingdom,* [2]*London Centre for Neglected Tropical Disease Research, London, United Kingdom,* [3]*University of Public Health, Yangon, Myanmar*

This study analyses the association between demographics, socioeconomic and water, sanitation and hygiene (WASH) factors and prevalence of each STH species in two Myanmar communities that have received repeated rounds of MDA. The study also assesses the degree of

individual and household clustering of infection using longitudinal data, including two MDA rounds, to examine evidence of predisposition and household clustering of infection. For the different STH species, including the individual as a random effect accounted for 8.2-26.3% of the variation in prevalence whereas including household as a random effect accounted for 9.2-19.2% of the variation in prevalence. For any STH and *A. lumbricoides* the best fit models included both individual and household random effects whereas for *T. trichiura* and hookworm the best fit models included only the individual random effect. Factors that were protective for *A. lumbricoides* infection were high socioeconomic status (Adjusted Odds Ratio (AOR)=0.27, 95% Confidence Interval (CI) 0.11-0.69) and being in older age groups (25-39: AOR=0.1 95% CI 0.01-1.29. 40+: AOR=0.11, 95% CI 0.01-1.37). Being male was a risk factor for hookworm (AOR=3.60, 95% CI 1.26-10.28). When accounting for individual predisposition and household clustering, treating household drinking water through chemical and boiling methods was a risk factor for *A. lumbricoides* infection (AOR=2.11, 95% CI 0.91-4.61). This analysis indicates that there are varying patterns of clustering of infection for different STH species. Individual predisposition to infection is evident for all species, but variation in infection with *A. lumbricoides* and when consolidating all species (any STH) is also partially explained by household clustering. The results suggest that, to improve the impact of MDA and possibly achieve transmission interruption, focus needs to be on men and the poorest households in the endemic communities.

1999

EPIDEMIOLOGY OF SOIL-TRANSMITTED-HELMINTHIASIS FOLLOWING TWENTY-ONE ROUNDS OF MASS DRUG ADMINISTRATION IN SEVEN DISTRICTS, BANGLADESH

Sanjaya Dhakal[1], Abdullah A. Kawsar[2], Mohammad J. Karim[2], Michael R. Diaz[1], Alexander J. Jones[1], Rubina Imtiaz[1]

[1]The Task Force for Global Health, Atlanta, GA, United States, [2]Department of Disease Control, Dhaka, Bangladesh

Following WHO guidelines for STH morbidity elimination, Bangladesh conducted 21 rounds of mass drug administration (MDA) targeting school-age children. Children Without Worms (CWW) partnered with the Bangladesh national STH control program to measure the subsequent impact in 7-districts (almost 10% of national population) through surveys using previously described methodology. This paper shares the results of the 7-district concatenated data focusing on parasite- and age-specific prevalence, intensity of morbidity, and treatment history. Integrated Community-based Survey for Program Monitoring (ICSPM), primarily based on TAS-STH were conducted in 7-districts in 2017 - 2018. The surveys, conducted 5-months after the last, and one month prior to the next MDA, collected information at the household and individual levels. Kato-Katz method was used to examine the stool samples. The overall prevalence of any STH was 12.4% per laboratory examination of stool samples (n=7,597). Sunamganj (40.4%) and Sirajganj (26.9%) districts had the highest STH prevalence while Satkhira (2.0%) and Manikganj (3.1%) had the lowest. Moderate to high intensity (MHI) infection of STH was prevalent among 2.9% of overall respondents, while Sunamganj (10.4%) and Sirajganj (7.1%) had the highest prevalence of this surrogate measure for STH morbidity. The similarity in prevalence across all age groups in most districts was unexpected, especially the adults who were not treated through the MOH-conducted MDAs. Systematic intervention resulted in reduction of STH burden in the majority of surveyed districts. However, there were a few smaller areas of high, persistent infection highlighting the need for granular data in advanced programs. STH prevalence was comparable across age groups in spite of several rounds of MDA for SAC only and warrants further investigation. Impact surveys like the ICSPM and TAS-STH, are essential to guide programs that have achieved high, consistent treatment coverage. Additional tools and methods are needed to further map disease clusters in low transmission settings.

2000

FACTORS ASSOCIATED WITH SOIL-TRANSMITTED HELMINTHS (STH) PREVALENCE AND INTENSITY OF INFECTION IN COMÉ, BENIN, WEST AFRICA: FINDINGS FROM A BASELINE PREVALENCE SURVEY OF DEWORM3 STH-ELIMINATION TRIAL

Euripide F. G. A Avokpaho[1], Parfait Houngbegnon[1], Manfred Accrombessi[1], Gilles Cottrell[2], Eloïc Atindegla[1], Fadel Tanimomon[1], Félicien Chabi[1], Innocent Togbevi[1], Firmine Viwami[1], Aurax Fernando[1], Wilfrid Batcho[3], Dorothee A. Kindé-Gazard[4], Achille Massougbodji[1], Andre Garcia[2], Sean Galagan[5], Arianna Means[6], Tim Littlewood[7], Kristjana H. Ásbjörnsdóttir[6], Adrian J. Luty[8], Moudachirou Ibikounle[9], Judd Walson[6]

The DeWorm3 project aims to test the feasibility of interrupting the transmission of STH using a series of cluster-randomized trials in Benin, Malawi and India, using community-wide mass drug administration. From March to April 2018, a baseline STH (Hookworm, *Ascaris* and *Trichuris*) prevalence survey was conducted in Comé, Benin using the Kato-Katz technique. We report the parasitological results and factors associated with the presence and intensity of hookworm infection using mixed effects models. In total 6,139 stool samples were screened. Hookworm was the most prevalent (3.2% of samples), with a higher prevalence in adults than school aged (SAC) and pre-school aged childrend (PSAC) (4.4% vs 2% vs 1% ; p<0.001). In positive samples, we found a median of 4.5 eggs/slide (IQR: 2-13). Males were more infected (4% vs 2.6%; p=0.002) than females. Unadjusted risk factors for hookworm infection were being SAC (OR=2.4, 95%CI:1.03;5.4) or adult (OR=6.98, 95%CI:3.2;15.1), wearing shoes (OR=4.1, 95%CI:1.1;14.4), moisture/vegetation (OR=4.4, 95%CI:2.1;8.8), highest (3rd) tertile of sand fraction (OR=2.7, 95%CI:1.3;5.3) and peri-urban environment (OR:3.8, 95%CI:2.0;7.5). Protective factors were being female (OR=0.57, 95%CI 0.4;0.8), the highest (4th and 5th) quintiles of asset index (OR=0.2, 95%CI:0.1;0.4 and OR=0.2, 95%CI:0.1;0.3), no history of deworming in the past year (OR=0.2, 95%CI:0.1;0.4), improved water (OR:0.4, 95%CI:0.2;0.6), improved sanitation (OR=0.4, 95%CI:0.3;0.7). We found a positive association between the intensity of hookworm infection and being an adult (coeff=3.2, 95%CI:2.0; 4.4), wearing shoes (coeff=2.9, 95%CI:0.5; 5.3), moisture/vegetation (coeff=3.2, 95%CI:1.8; 4.5). A negative association was found with being a female (coeff=-1.2, 95%CI:-1.9; 0.6), no history of deworming in the past year (coeff=-2.87, 95%CI:-3.7;-2.0), improved water (coeff=-2.5, 95%CI:-3.4;-1.5), improved sanitation (coeff=-1.6, 95%CI:-2.5;-0.8). The prevalence of hookworm infection in Comé was generally low, but higher in adults. This could be explained by the national deworming program in Benin that targets only SAC.

2001

IMPACT OF ONCE VERSUS TWICE PER YEAR MASS DRUG ADMINISTRATION WITH DIETHYLCARBAMAZINE PLUS ALBENDAZOLE FOR LYMPHATIC FILARIASIS ON HOOKWORM PREVALENCE AND HEMOGLOBIN LEVELS IN PAPUA NEW GUINEA (PNG)

Brooke Mancuso[1], Nelly Sanuku[2], Samson Satofan[2], Delma Beaso[2], Yao-Chieh Cheng[3], Tobias Muare[2], William Pomat[2], Andrew Majewski[4], James Kazura[5], Gary J. Weil[4], Peter U. Fischer[4], Christopher L. King[5]

[1]Tulane University School of Public Health, New Orleans, LA, United States, [2]Papua New Guinea Institute for Medical Research, Goroka, Papua New Guinea, [3]Temple University School of Medicine, Philadelphia, PA, United States, [4]Washington University St. Louis School of Medicine, St. Louis, MO, United States, [5]Center for Global Health and Disease, Case Western Reserve University School of Medicine, Cleveland, OH, United States

The use of albendazole (ALB) as part of the LF mass drug administration (MDA) program provides the added benefit of treating hookworm and other helminth infections. Its impact on anemia in areas with high hookworm prevalence is poorly understood. Between 2014-18 in East Sepik Province, PNG serial annual cross-sectional sampling for STH by Kato Katz and hemoglobin (Hemacue) testing was conducted with community-based surveys in eight sentinel sites (200-400 participant/site); four sites received MDA 1x/yr and four received MDA 2x/yr to evaluate the impact of annual vs biannual MDA on lymphatic filariasis (LF). This region has high prevalence *Necator americanus* infection with baseline rates of 96% (1x/yr) and 90% (2x/yr). Hemoglobin levels negatively correlated with intensity of infection, especially among women (r^2 = -0.27 P=0.02). Following 3 years of MDA, geometric mean egg per gram (epg) among infected persons decreased significantly, especially among the heavily infected, in both areas; 892 epg (710, 1074, 95%CI) to 391 epg (258, 525) in 1x/yr and from 1060 epg (877, 1244) to 636 epg (468, 805) in 2x/yr sites, with a corresponding decrease in the prevalence of hookworm infection to 81% (1x/yr) and 84% (2x/yr). The decrease in hookworm burden was slightly greater among participants receiving 1x/yr MDA. Prior to MDA anemia (Hb <11g/dL) rates were 45% (1x/yr) and 36% (2x/yr). Following 3 years of MDA the proportion of individuals with anemia changed little 44% (1x/yr) and 42% (2x/yr). However changes in anemia rates varied with respect to age and sex. Anemia rates increased in children <15 years of age (43% to 62% p<0.0001 in females, and 42% to 56% in males p<0.0001). Likewise, the proportion of women ≥15 years with anemia increased (36% to 44%, p=0.06). In contrast, anemia rates dropped in men ≥15 years (40% to 20% p<0.0001, 1x/yr) and (36% to 13%, p<0.0001, 2x/yr). Thus, MDA with ALB for LF decreased hookworm burden, but there was no advantage of biannual relative to annual MDA. Only adult men showed a reduction in anemia rates at year 3.

2002

RELEVANT SPATIAL SCALE FOR EVALUATION UNITS FOR ELIMINATION PROGRAMS FOR SOIL-TRANSMITTED HELMINTHS GIVEN GEOGRAPHY OF SETTLEMENTS AND HUMAN MOVEMENT

Carolin Vegvari, Robert Hardwick, James Truscott, Roy Anderson

Imperial College London, London, United Kingdom

Soil-transmitted helminths (STHs) are the most widespread neglected tropical disease (NTD) infectious agents. The current WHO goal for STHs is morbidity control or the elimination as a public health problem (EPHP). A number of programmes are underway to prove that elimination of transmission of STHs is feasible in defined settings. Current WHO guidelines on evaluating whether EPHP has been achieved are based on sampling school-age children from different ecological zones within implementation units. There are no official guidelines on evaluating the elimination of transmission. The geospatial scale across which EPHP and transmission interruption are to be evaluated is currently not well defined and will depend on, among other factors, the geographical clustering of settlements and human movement patterns. Like other neglected tropical diseases STHs have a tendency to cluster both geographically and within groups of people, typically the most socio-economically disadvantaged. Multiple studies have addressed large-scale heterogeneity in STH prevalence and infection intensity to assist country-wide scale-ups of STH programmes. Local clustering of STH has been identified in all these studies. Here we use geospatial data from three different STH elimination programmes (Tumikia in Kenya, DeWorm3 in India, Benin and Malawi and Geshyaro in Ethiopia) and spatial kernel data characterising human movement in sub-Saharan Africa to define the geospatial scales of evaluation units in which interruption of transmission can be confirmed for the three main STH species, *Ascaris lumbricoides*, *Trichuris trichiura* and hookworm. We present a generalised model that can be applied to STH elimination programmes, regardless of the details of geography and human movement patterns, to determine an adequate spatial scale for evaluation units. This information should be very useful for STH programme managers and implementers.

2003

THE DAMAGE SIGNAL IL-33 PROMOTES A PROTECTIVE IMMUNE RESPONSE TO *TOXOPLASMA GONDII* IN THE BRAIN

Katherine M. Still, Samantha J. Batista, Jeremy A. Thompson, Nikolas W. Hayes, Carleigh O'Brien, Tajie H. Harris

Center for Brain Immunology and Glia, Department of Neuroscience, University of Virginia, Charlottesville, VA, United States

Chronic infection with the parasite Toxoplasma gondii elicits robust immune cell recruitment to the brain which is critical for host survival. We observe clusters of peripherally-derived immune cells, primarily monocyte-derived macrophages and T cells, surrounding replicating parasite in brain tissue. Initial cues which instruct the recruitment and localization of these blood-derived cells is not well understood. One potential mechanism of broad relevance is the incitement of host cell damage. Here we find that IL-33, a nuclear alarmin released upon cell damage, is critical for control of T. gondii parasite burden in the brain. IL-33 is expressed by mature oligodendrocytes and astrocytes during T. gondii infection, and is released into the CSF of infected mice, but not uninfected controls. After its release, IL-33 signaling induces expression of monocyte and T cell chemoattractants and increases adhesion factor expression. We find that IL-33 signaling is required to recruit anti-parasitic immune cells to the brain, including IFN-γ+ proliferating T cells and iNOS+ monocyte-derived cells. Although IL-33 (and most alarmins) signal directly on immune cells in the lung, gut, and skin, we find the relevant responder to IL-33 in the brain during our infection to be radio-resistant, and therefore likely brain resident, using bone marrow chimera experiments. Upon conditionally deleting IL-33's receptor from individual brain cell types, we find that IL-33 signals on multiple cell types in a concerted effort to control of T. gondii infection. These results expand our knowledge of alarmin signaling in the brain, indicating a brain-centric signaling mechanism for IL-33-mediated recruitment peripheral immune cells to sites of T. gondii replication.

2004

BASOPHILS REGULATE HELMINTH-INDUCED INNATE LYMPHOID CELL RESPONSES BY MODULATING NEUROPEPTIDE RECEPTOR EXPRESSION

Juan Inclan-Rico, J.J. Ponessa, C.M. Hernandez, M.C. Siracusa

Center for Immunity and Inflammation, Department of Medicine, Rutgers New Jersey Medical School, Newark, NJ, United States

Type 2 cytokine responses, characterized by the production of interleukin (IL)-4, 5, and 13; promote immunity to helminth parasites, but are also responsible for the immunopathology observed during chronic helminth infections. A growing body of evidence suggests that the coordinated actions of innate immune cell populations and the nervous system promote anti-helminth immunity. However, whether the immune and nervous systems communicate in order to limit type 2 inflammation and promote tissue integrity remains poorly defined. Here we demonstrate

that helminth-induced type 2 innate lymphoid cell (ILC2) responses are exaggerated in the absence of basophils, resulting in increased inflammation and diminished lung function. Further, we show that ILC2s from basophil-depleted mice express reduced levels of neuropeptide receptor that is associated with their enhanced activation. Critically, activation of neuropeptide-signaling pathways reduced infection-induced ILC2 responses, lung eosinophils and parasite clearance. Moreover, neuropeptide signaling was sufficient to reduce IL-5 and IL-13 expression by sort-purified lung ILC2s from control but not basophil-depleted mice. Remarkably, co-culture with basophils was sufficient to enhance neuropeptide receptor expression on ILC2s. Collectively, these data suggest that basophils mediate the ability of ILC2s to respond to neuron-derived signals necessary to limit inflammation and maintain tissue integrity.

2005

DEVELOPMENTAL COMPETENCE AND ANTIGEN SWITCH FREQUENCY CAN BE UNCOUPLED IN *TRYPANOSOMA BRUCEI*

Kirsty R. McWilliam[1], Alasdair Ivens[2], Liam J. Morrison[2], Monica Mugnier[3], Keith R. Matthews[2]

[1]University of Edinburgh, Edinburgh, Scotland, United Kingdom and Ludwig-Maximilians-Universität München, Munich, Germany, [2]University of Edinburgh, Edinburgh, Scotland, United Kingdom, [3]Johns Hopkins School of Public Health, Johns Hopkins University, Baltimore, MD, United States

African trypanosomes use an extreme form of antigenic variation to evade host immunity. This involves the switching of expressed variant surface glycoproteins, antigen exchange being a stochastic and parasite intrinsic process. Parasite development in the mammalian host is another feature of the infection dynamic, with trypanosomes undergoing quorum sensing-dependent differentiation between proliferative slender form and arrested, transmissible, stumpy forms within each parasitaemic wave. Longstanding experimental studies have suggested that the frequency of antigenic variation and transmissibility may be linked, antigen switching being higher in fly-transmissible, developmentally competent, parasites and lower in serially passaged lines. Here, we have directly tested this tenet of the infection dynamic by, firstly, generating lines that inducibly lose developmental capacity through RNAi mediated silencing of components of the stumpy induction signalling cascade ('inducible monomorphs'). Secondly, we have derived de novo lines that have lost the capacity for stumpy formation by serial passage ('selected monomorphs') and analysed their antigenic variation in comparison to isogenic pre-selected populations. Analysis of both inducible and selected monomorphs by in vitro flow-cytometry based VSG switch assays and VSGseq has established that antigen switch frequency does not change regardless of the method used to prevent parasite development. We conclude that changes in antigen switch frequency and developmental capacity can be uncoupled, these independently selected traits being important contributors to the parasite infection dynamic.

2006

MYND AND RNA-BINDING PROTEIN 6 (RBP6) AS MASTER REGULATORS OF *TRYPANOSOMA BRUCEI* DIFFERENTIATION AND MIGRATION IN THE TSETSE

Aitor Casas-Sanchez[1], Lara Lopez-Escobar[1], Aryana Zardkoohi-Burgos[1], Cintia Cansado-Utrilla[1], Lee R. Haines[1], Alistair Darby[2], Samuel Dean[3], Jannah Shamsani[4], Pegine Walrad[4], Alvaro Acosta-Serrano[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Liverpool, Liverpool, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]University of York, York, United Kingdom

To complete its life cycle in the tsetse fly vector and become transmissible to the mammalian host, the parasite Trypanosoma brucei has to undergo a series of migration and differentiation events, ultimately controlled through gene expression. After the bloodstream forms differentiate into the procyclic stage in the tsetse midgut, trypanosomes colonize the fly proventriculus (PV) where they reach the epimastigote stage. These further migrate to the salivary glands to differentiate into the mammalian-infective metacyclic forms which can be transmitted to the host with the tsetse bite. To identify T. brucei genes important for life cycle progression in the tsetse, we compared the gene expression profiles of fly-transmissible PV trypanosomes with that of a strain unable to infect the salivary glands. Among the top upregulated transcripts in fly-transmissible parasites, we identified the RNA-binding protein 6 (RBP6) known to trigger differentiation when overexpressed in vitro, and a new hypothetical protein conserved across kinetoplastids containing a MYND (Myeloid, Nervy and DEAF-1) zinc finger domain. Strikingly, the overexpression of MYND protein in non-transmissible trypanosomes triggered differentiation to the epimastigote stage through a soluble factor in vitro and restored salivary gland infectivity in the tsetse. Pull-down assays revealed that MYND is part of a new protein complex formed by five hypothetical proteins with identifiable zinc finger domains. We found that such complex may interact and stabilize >150 mRNAs encoding RNA-binding, zinc finger and flagellar proteins, among others. In addition, MYND knockout cells presented severe growth and motility defects in vitro and were completely unable to colonize the PV and complete the cycle in the tsetse. On the contrary, RBP6 knockout cells showed no defects except for the inability to differentiate to epimastigotes later in the PV. We hypothesize that the sequential expression of the MYND complex and RBP6 is key to coordinate the developmental progression of T. brucei in the tsetse. Supported by the Wellcome Trust and ITN-FP7 GlycoPar.

2007

A BAR-SEQ FITNESS SCREEN OF LEISHMANIA CRISPR-CAS9 KNOCKOUT MUTANTS SHOWS THE IMPORTANCE OF MOTILITY IN COLONIZATION OF SANDFLIES

Tom Beneke[1], James Smith[1], Edward Hookway[2], Tomas Becvar[3], Jitka Myskova[3], Tereza Lestinova[3], Jovana Sadlova[3], Petr Volf[3], Richard Wheeler[4], Eva Gluenz[1]

The number of fully sequenced Leishmania genomes increases steadily but the function of more than half of the predicted genes remains unstudied. To accelerate dissection of gene function in Leishmania spp. we developed a streamlined pipeline for generation of CRISPR-Cas9 mediated gene knockout in which each mutant carries a unique 17-nucleotide barcode, allowing loss-of-function screens and phenotyping of mutants in mixed populations. To date we have used this method to generate more than 400 null mutants in a knockout screen of the flagellar proteome. This mutant library enables a systematic analysis of the contribution of conserved and kinetoplastid-specific proteins to flagellar motility and function. Individual phenotyping uncovered diverse phenotypes including defects in motility, flagellar assembly, axonemal structure, paraflagellar rod (PFR) integrity and maintenance of cell shape. We show here how pooled fitness screens were used in vitro and in infections of the permissive sand fly vector Lutzomyia longipalpis to determine the effect of flagellar defects on parasite growth and ability to colonise the fly. Promastigotes that were aflagellate, paralysed or uncoordinated swimmers were severely diminished in the parasite population after defecation of the bloodmeal. Dissection of sand flies infected with L. mexicana lines lacking the central pair protein PF16 showed that these paralysed promastigotes did not reach the anterior regions of the fly alimentary tract. These results suggest that motility in Leishmania parasites is vital for colonization of sand flies and show the potential of this method for larger-scale fitness screens of Leishmania mutants.

The phylum Apicomplexa includes several of the most important and prevalent eukaryotic humanparasites, such as the malaria-causing Plasmodium spp. and Toxoplasma gondii that can causesevere neurological disease in the developing fetus. These intracellular parasites enter a host cellby deploying a remarkable machine at their anterior end known as the apical complex (AC), forwhich the phylum is named. At the start of invasion, the AC, including a unique spiral of tubulinbasedfibrils called the conoid, is protruded and secretion events occur from two types of distinctsecretory organelles, capsule-shaped micronemes and club shaped rhoptries. The exact meansby which these various components of the AC coordinate invasion has been largely a mysterydue, in part, to a lack of tools capable of resolving the structure of this extraordinary apparatusin its natural context. To address this need, we are developing a pipeline to image the complexand dynamic structure of the AC to high resolution in parasites devoid of any chemical fixationor staining. This pipeline starts with soft x-ray tomography of plunge frozen parasites to revealthe whole 3D shape of extracellular parasites and the organization of large subcellular organellesinside it. Next, cryo-fluorescence super resolution microscopy and cryo-electron tomography(cryo-ET) are used to precisely localize known apical proteins to the AC subcellular organellesthrough fusion with a photoactivable fluorescent protein, PAmKate, to record fluorescenceoriginating from single molecules. Finally, nano-scale resolution images of these same parasite'sAC are acquired using cryo-electron tomography (cryo-ET) and annotation of the reconstructedtomograms is performed using mixed scale convolutional neural network analysis. Aligning thedata from the three imaging techniques should provide the precise location of the protein whiledisplaying the 3D organization of all the subcellular organelles and uncovering possibleinteractions between them. To start, we have used cryo-ET generated images of unprecedentedresolution of the apical rings, a component of the AC thought to be conserved among allapicomplexan parasites whose structure and function is unknown. Our images reveal that theapical rings exhibit a highly organized structure of repeated units, allowing us to apply techniquesof subtomogram averaging to resolve its structure at nano-scale resolution. To validate ourpipeline, we have endogenously tagged SAS6-L, a protein that was previously shown to localizeat the apical tip of the conoid and are analyzing this line through the methods described above.

The malaria parasite must obtain all nutrients across an interface: the parasitophorous vacuole (PV). Small water-soluble molecules can traverse the PV membrane via channels formed by EXP2, while larger molecules such as hemoglobin can cross via an endocytosis-like mechanism. So far, it is unknown how the parasite maintains lipid homeostasis across the PV lumen. When analyzing electron micrographs of the human malaria parasite, Plasmodium falciparum, to look for lipid transport in the PV lumen, vesicular transport was not evident. However, we found that the distance of the parasite plasma membrane (PPM) to the PV membrane (PVM) appears regulated, demonstrating regions of close membrane "apposition" (~10 nm PVM-PPM distance) and regions of "PV lumen" (20-30 nm PVM-PPM distance). We hypothesized that the exchange of lipids is facilitated in regions of close membrane apposition. To test the hypothesis and localize proteins of known function with respect to PVM-PPM distance, we developed and validated a fluorescent label for the PV lumen (PV-mRuby3) using correlative light electron microscopy. Using this PV lumen label, we found that PV lumen regions co-localize to the nutrient-permeable channel EXP2 (tagged with mNeonGreen) and anti-localize to the lipid transporter PfNCR1 (tagged with GFP). Both proteins appear in patches, but together EXP2 and PfNCR1 complement each other to populate the periphery of the parasite. The set of experiments suggests that regions of close PVM-PPM apposition are sites of lipid exchange. Functionally and structurally, this meets the definition of a membrane contact site. Conceptually, we propose a division of the PV into two distinct domains for the exchange of water soluble and lipidic material as a framework to unravel the functions of this unique organelle.

EARLY IFN-G PRODUCTION BY INNATE LYMPHOID CELLS MEDIATES PROTECTION TO *CRYPTOSPORIDIUM TYZZERI*

Jodi Gullicksrud, Adam Sateriale, Julie Engiles, Christopher Hunter, Boris Striepen

University of Pennsylvania, Philadelphia, PA, United States

From a global health perspective, Cryptosporidium is one of the most important causes of severe diarrheal disease in a variety of epidemiological settings. Similar to other enteric pathogens that are restricted to the epithelium of the intestine, Cryptosporidium invades the villus epithelium, but the role of epithelial cells in pathogen resistance remains unknown. Here we use genetically modified C. tyzzeri, a natural mouse pathogen, and show that intestinal epithelial cell (IEC) derived IL-18 synergizes with IL-12 to drive innate lymphoid cell (ILC) production of IFN-g, which critically limits parasite expansion within the first few days of infection. Further analysis of the NK1.1+NKp46+ population suggests that intestinal ILC1s are a major source of early IFN-g. Transcriptional profiling of IECs from infected mice highlighted the induction of an IFN-g gene signature and specific deletion of STAT1 from IECs resulted in unrestricted parasite growth. Thus, infection with C. tyzzeri has identified ILCs as an innate source of IFN-g and established its downstream impact on ileal epithelial cells. Additionally, C. tyzzeri has provided a model system to demonstrate a critical role of IECs in the induction of protective immunity, where they employ cell extrinsic and intrinsic mechanisms to limit pathogen growth.

COMPARATIVE CHEMICAL GENOMICS IN *BABESIA* SPECIES IDENTIFIES A NOVEL APICOMPLEXAN DRUG TARGET

Caroline D. Keroack, Brendan Elsworth, Jacob A. Tennessen, Cristina K. Moreira, Aditya S. Paul, Manoj T. Duraisingh

Department of Immunology and Infectious Diseases, Harvard T. H. Chan School of Public Health, Boston, MA, United States

Babesiosis is an emerging human zoonosis, and a well-established and widely distributed veterinary infection caused by 100+ species of Babesia parasite. This enormous diversity poses a challenge in identifying broadly effective therapeutic interventions. However, there is also a unique opportunity to leverage the power of comparative analyses in multiple Babesia spp. to explore novel conserved biology, facilitated by the existence of in vitro culture systems. The diversity of Babesia parasites, coupled with the lack of potent inhibitors necessitates the discovery of novel conserved targets. Here, we describe a comparative chemogenomics (CCG) pipeline for the identification of novel and conserved targets. CCG

relies on parallel in vitro evolution of resistance in parallel independent populations of evolutionarily-related Babesia spp. (B. bovis and B. divergens). After screening the MMV Malaria box against both species, we identified a potent anti-babesial inhibitor, MMV019266. This compound is also strongly active in Plasmodium and shows some efficacy in Toxoplasma. We were able to rapidly select for resistance to this compound in two species of Babesia in parallel, achieving 10-fold or greater resistance after six weeks of intermittent selection. After sequencing of multiple independently derived lines in the two species, we were able to identify mutations in a single conserved gene in both species. This gene encodes a predicted membrane-bound metallodependent phosphatase (putatively named phoD^{api}) which is homologous to alkaline phosphatase D in other apicomplexa. Identification of this gene target was greatly facilitated by the comparative approach of utilizing two species. In B. divergens (Bdiv_001570c) we have identified different mutations at the same amino acid residue in the two independent selections (A: C197F, B: C197W). In B. bovis (Bbov_I003300) we were able to identify a mutation (G527S) which is spatially proximal to those found in B. divergens. In both cases, the mutations were found in the phoD-like phosphatase domain, proximal to the ligand binding site. Interestingly, the gene is predicted to contain an apicoplast leader sequence, and the ortholog has been identified in the apicoplast proteome in Plasmodium falciparum, suggesting a potential role in the apicoplast. Strikingly, MMV019266 does not exhibit a delayed death phenotype in Plasmodium, killing in the first cycle. The ability to identify phoD^{api} in two species, and in multiple independent selections, validates the role this gene plays as the etiological driver of resistance to MMV019266 in Babesia spp. Together, these data show the power of CCG to identify not only novel pan-babesiacidal compounds, but also to identify novel conserved apicomplexan biology.

Toxoplasma gondii chronically infects a quarter of the world's population, and can cause life-threatening disease in immunocompromised patients. Acute symptoms of infection result from the rapid proliferation and lysis of host cells by Toxoplasma tachyzoites. Chronic infection is established by slower-growing bradyzoites, which form intracellular cysts resistant to current therapeutics and immune clearance. Differentiation of tachyzoites into bradyzoites can be induced in cell culture through a variety of stress conditions, which has allowed intensive examination of transcriptional differences between these two stages. While this dramatic change in lifestyle is accompanied by widespread morphological, metabolic, and transcriptional shifts, the molecular mechanisms regulating these differences have remained elusive. The inability to isolate Toxoplasma mutants displaying a complete block in differentiation has led to the view that no master regulator of this process exists. Through a combination of Cas9-mediated genetic screening and transcriptional profiling, we have identified and characterized a single transcription factor (BFD1, bradyzoite formation deficient 1) as necessary and sufficient for differentiation. Parasites lacking BFD1 fail to differentiate in cell culture in response to all induction conditions tested and fail to form brain cysts in mice, and these defects are reversed by complementation. Translation of BFD1 is stress dependent, and conditional overexpression of BFD1 induces differentiation in the absence of stress conditions, recapitulating many of the transcriptional changes associated with bradyzoite formation. Profiling the genomic binding pattern of BFD1 revealed preferential binding at transcriptional start sites, particularly within promoters of genes highly upregulated in bradyzoites. BFD1 provides a genetic switch to study and control Toxoplasma differentiation, and will inform prevention and treatment of chronic infection.
