A PHASE IB STUDY TO INVESTIGATE THE ANTIMALARIAL ACTIVITY OF M5717, A FIRST-IN-CLASS INHIBITOR OF *PLASMODIUM* ELONGATION FACTOR 2, USING THE INDUCED BLOOD STAGE *PLASMODIUM FALCIPARUM* MALARIA MODEL

James McCarthy[1], Wilhelmina Bagchus[2], Arnand Odedra[1], Rebecca Webster[1], Claude Oeuvray[3], Aliona Tappert[4], Deon Bezuidenhout[5], Xiaoyan Yin[6], Akash Khandelwal[4], Oezkan Yalkinoglu[4]

M5717 is a first-in-class antimalarial that targets *Plasmodium* elongation factor 2, thereby interrupting protein synthesis. A three cohort single-dose study was undertaken to define the antimalarial activity of M5717 in healthy volunteers using the induced blood-stage malaria (IBSM) model. Doses of 400 mg, 150 mg and 800 mg were successively selected by integrating preclinical data with the emerging human pharmacokinetic (PK) data from the ongoing phase Ia single ascending dose (SAD) study and, where relevant, the antiparasitic effect from the preceding IBSM cohort/s. Administration of 400 mg resulted in a lag of ~48 hrs prior to parasite clearance with a clearance half-life of 3.89 hrs (95% CI: 3.27-4.81). Recrudescence occurred in 2 out of 8 subjects, requiring artemether/lumefantrine rescue 12 days post dosing. Administration of 150 mg M5717 resulted in similar parasite clearance kinetics; the clearance half life was 3.52 hrs (95% CI: 3.12-4.03); recrudescence occurred in 2 out of 6 subjects 10 and 12 days after treatment. Administration of 800 mg M5717 resulted in complete clearance of parasitemia in all 8 subjects, without any recrudescence. PK parameters were similar to those observed in the phase Ia study. A PK/PD model is under development. There were no serious adverse events (SAEs) or severe adverse events (AEs). Clinical and laboratory deviations or AEs were mostly mild to moderate, malaria-related and were all transient in nature. In summary, this study has demonstrated that M5717 has a positive benefit/risk profile and supports its further clinical development of as a single dose treatment of malaria.

2

A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE IB STUDY TO EVALUATE THE SAFETY, TOLERABILITY AND CHEMOPROTECTIVE ANTI-MALARIAL ACTIVITY OF P218 AGAINST CONTROLLED HUMAN MALARIA INFECTION BY DIRECT VENOUS INOCULATION (DVI) OF *PLASMODIUM FALCIPARUM* SPOROZOITE (PFSPZ-DVI) IN NON-IMMUNE HEALTHY ADULT VOLUNTEERS

Mohamed Farouk Chughlay

Medicines for Malaria Venture, Geneva, Switzerland

Globally, malaria causes substantial morbidity and mortality. With increasing drug resistance, there is an urgent need for new anti-malarial drugs for treatment and chemoprotection. P218 is a new candidate anti-malarial drug being developed for chemoprotection against *Plasmodium falciparum* malaria. Its mechanism of action involves selective inhibition of *Plasmodium* DHFR, an enzyme which catalyses the reduction of folates to tetrahydrofolates, essential for DNA biosynthesis in the malarial parasite. P218 demonstrated activity *in vitro* and *in vivo* activity on pyrimethamine *P. falciparum* resistant strains suggesting that this molecule may offer a favourable treatment advantage over pyrimethamine, a drug with similar mechanism of action. The present study which follows the First-In-Human study is investigating P218 (1000mg and 100mg) as a possible chemoprotective agent against *P. falciparum* in a standardised and model, using direct venous inoculation of aseptic, purified, cryopreserved, vialed *P. falciparum* sporozoites (*Pf*SPZ-DVI). Thirty-two healthy men and women aged 18 to 45 years are enrolled in 3 cohorts of 8, 12 and 12 subjects. Subjects are randomized in a 3:1 ratio, to receive two consecutive administrations of either P218 or placebo. Cohorts 1 (safety-1000mg) and 2 (1000mg/*Pf*SPZ) are completed and enrolment in Cohort 3 (100mg/*Pf*SPZ) is ongoing. Subjects are followed-up using a *Plasmodium* 18S rRNA targeted qRT-PCR treatment threshold to initiate rescue treatment after ≥250 estimated parasites/mL are detected. Pharmacokinetic data on P218, safety laboratory data, adverse events and parasite growth kinetics will be assessed. PK/PD modelling will be performed to identify the lowest chemoprotective P218 exposure. Data from the three completed cohorts will be presented. If the P218 activity against *P. falciparum* infection is clinically demonstrated in this study, a long acting injectable depot formulation will be considered, allowing for slow-blood-release of P218 over up to one month following single injection.

3

IDENTIFICATION OF IVERMECTIN METABOLITES

Phornpimon Tipthara[1], Kevin Kobylinski[2], Markus Winterberg[1], Joel Tarning[1]

[1]*Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Preventing transmission is one of the targets in new drug discovery for malaria elimination. Ivermectin (IVM) mass drug administration (MDA) is used for controlling a number of neglected tropical diseases, but is now under consideration for malaria transmission suppression. A recent trial demonstrated mosquito-lethal effects of human venous blood from IVM-treated volunteers, with activity for several days beyond the expected half-life of IVM. This could be due to active IVM metabolites with mosquito-lethal effects. A commercial IVM tablet contains two racemic components. The major form is 25-secondary-butyl (IVM B_{1a}) (> 90%) and the minor form is 25-iso-propyl (IVM B_{1b}) (< 10%). In this study, a quadrupole time-of-flight (Q-ToF) mass spectrometer, coupled to ultra-performance liquid chromatography (UPLC), was used to identify IVM metabolites. Potentially important IVM metabolites were evaluated using *in vitro* techniques (human liver microsomes) and verified using *in vivo* clinical samples from healthy volunteers. Human liver microsomes were incubated with IVM racemic mixture (10 μM), pure IVM-B1a (10 μM), and pure IVM-B1b (10 μM). Metabolite fractions were collected one hour after incubation, and the reaction stopped with the additional of ice cold acetonitrile. Incubation at zero time, incubation without cofactor, and incubation without IVM were used as controls. For the *in vivo* study, whole blood was collected from volunteers after administration of IVM (400 μg/kg). IVM-B1a and IVM-B1b was separated successfully by the developed chromatographic method. Mass spectrometry analysis identified more than 10 potentially important metabolites in *in-vitro* samples. IVM metabolites were primarily oxidation, di-oxidation, and demethylation products. Of these, two were abundant in the blood of volunteers who had ingested IVM. To our knowledge, this is the first detailed description of IVM metabolites in human. Further evaluation of these potentially important metabolites and their mosquito lethal effects are ongoing.

4

PROPHYLACTIC EFFICACY OF POTENT AND BROADLY NEUTRALIZING, NON-CROSS-COMPETING FULLY HUMAN MONOCLONAL ANTIBODIES TARGETING PFRH5

Jonathan Viau, **Lisa Purcell**

Regeneron Pharmaceuticals, Tarrytown, NY, United States

Plasmodium falciparum reticulocyte-binding protein homolog 5 (PfRH5) is remarkably conserved, making it an ideal vaccine target. Passive immunization with monoclonal antibody (mAb) to a conserved epitope on the merozoite could provide protection throughout the malaria season. Human mAbs are ideally suited as therapeutics due to their tolerability and predictable pharmacokinetics. Recombinant PfRH5 protein and purified *Plasmodium falciparum* merozoites were used to immunize mice expressing fully human germline variable segments. We isolated a panel of human mAbs from these VelocImmune®mice that were broadly

neutralizing and potent. The mAbs were effective against both antimalarial drug-susceptible and -resistant laboratory and clinical strains *in vitro*. Both the IgG1 and IgG4 versions of these mAbs were also effective in the presence of human and *Aotus* normal serum. Growth inhibition was enhanced by the combination of mAb with chloroquine (CQ) in CQ-susceptible strains and the mAbs maintained effectiveness under CQ pressure with a CQ-resistant strain. The pharmacokinetic profiles of these mAbs in mice were consistent with that expected of human IgG specific for exogenous target. A six-week *in vitro* study with constant mAb pressure did not result in escape mutants for any one of the isolated mAbs, however, non-cross-competing RH5 mAbs from this panel could be combined to help circumvent the potential emergence of resistant strains. Nonhuman primates were used to assess the dose-dependent, prophylactic effectiveness of one of these mAbs against *P. falciparum* FVO infection. Passive immunization of PfRH5 mAb in the *Aotus* challenge model demonstrates the seasonal protection that could be afforded to humans in malarious regions.

5

DISSECTION OF HAPLOTYPE-SPECIFIC DRUG RESPONSE PHENOTYPES IN MULTICLONAL MALARIA ISOLATES

S**tandwell Nkhoma**, Amel Ahmed, Danielle L. Porier, Sharmeen Zaman, Timothy T. Stedman

ATCC, Manassas, VA, United States

Natural infections of *Plasmodium falciparum* often comprise multiple clonal lineages of the parasite. Drug susceptibility profiles of malaria isolates containing multiple parasite lineages (haplotypes) may yield variable susceptibility patterns depending on the abundance of each parasite haplotype present. We hypothesized that the observed variability in half-maximal drug inhibitory concentration (IC_{50}) of malaria isolates when measured on independent occasions is due to the presence of multiple parasite haplotypes with differing levels of antimalarial drug susceptibility. To test this hypothesis, we studied *in vitro* antimalarial susceptibility profiles of parasite haplotypes cloned from three *P. falciparum* Cambodian isolates (BEI Resources MRA-1236 IPC 3445, MRA-1240 IPC 5202, and MRA-1285 IPC 6403). Parasites were cloned by limiting dilution and typed at 23 highly polymorphic single nucleotide polymorphisms (SNPs) distributed across the *P. falciparum* genome to identify constituent haplotypes. The isolates harbored two to four co-infecting haplotypes. Isolate haplotypes were highly related, sharing up to 21 of the 23 SNPs. Individual haplotypes from two of the three isolates exhibited significant variability ($p<0.05$) in their *in vitro* susceptibility to chloroquine, mefloquine, lumefantrine and piperaquine as measured by standard growth inhibition assays. In most cases, the IC_{50} of the dominant co-infecting parasite haplotype reflected that of the uncloned parental isolate. This suggests that one co-infecting parasite haplotype often dominates the antimalarial susceptibility profile and may mask the effect of minor frequency haplotypes. We conclude that significant variability in the *in vitro* drug response phenotype of a multiclonal infection is often due to the presence of multiple parasite subpopulations with differing levels of susceptibility. We recommend cloning of isolates prior to use for *in vitro* drug susceptibility studies for screening candidate antimalarials. This practice should minimize variability in drug response across independent assays using standardized or clonal parasite lineages.

6

NANOMOLAR POTENCY INHIBITORS OF THE MALARIA PURINE UPTAKE TRANSPORTER KILL *PLASMODIUM FALCIPARUM* PARASITES

Yvett Darcie Sosa[1], Xiaoming Xu[2], Shi-Xian Deng[2], Donald Landry[2], Myles Akabas[1]

[1]*Albert Einstein College of Medicine, Bronx, NY, United States,* [2]*Columbia University, New York City, NY, United States*

Malaria is caused by infection with *Plasmodium* genus parasites. Due to spreading anti-malarial drug resistance, it is imperative to develop drugs with novel targets. One novel target is the purine uptake transporter, the *Plasmodium falciparum* Equilibrative Nucleoside Transporter (PfENT1). Previously, a yeast-based high throughput screen of the GSK compound library identified PfENT1 inhibitors. GSK transferred six hits with diverse chemical scaffolds to our lab as promising starting points for hit-to-lead medicinal chemistry. These compounds killed parasites with IC_{50} values under 15 μM. We focused medicinal chemistry efforts on one compound and synthesized 160 derivatives. 17 of these compounds had IC_{50} values under 50 nM in *P. falciparum* parasite cytotoxicity assays. All compounds killed a variety of drug sensitive and drug resistant *P. falciparum* strains with IC_{50} values between 0.2 to 158 nM. All compounds show efficacy against the *P. vivax* and *P. berghei* ENT1 homologues expressed in yeast. We tested the efficacy of compounds against human erythrocyte purine transporters, hENT1 and the human facilitated nucleobase transporter, hFNT. Four compounds did not inhibit hENT1. All other compounds inhibit hENT1 with IC_{50} values 4 to 12-fold greater than PfENT1. None of the compounds inhibited hFNT. Nine compounds did not display human hepatoma HepG2 cell cytotoxicity. Eight compounds had HepG2 cytotoxicity IC_{50} values between 10 to 30 μM. We demonstrate PfENT1 is a viable target for antimalarial drug development. These inhibitors have nanomolar potency against drug sensitive and resistant *P. falciparum* strains and represent attractive leads for further anti-malarial drug development.

7

ASPARAGINE ETHYLENEDIAMINES AS ANTI-MALARIAL *PLASMODIUM*-SELECTIVE PROTEASOME INHIBITORS

Wenhu Zhan[1], Joeseph Visone[1], Jacob Harris[1], Tierra Ouellette[1], Rong Wang[2], Hao Zang[1], Pradeep Singh[1], John Ginn[3], George Sukenick[2], Tzu-Tshin Wong[3], Judith Okoro[4], Ryan Scales[5], Patrick K. The *Plasmodium* proteasome (Pf20S) recently emerged as a target for antimalarials. Pf20S inhibitors are active at multiple stages of the parasite life cycle and synergize with artemisinins, suggesting that Pf20S inhibitors have potential to be prophylactic, therapeutic, transmission blocking as well as useful for combination therapy. We recently reported asparagine ethylenediamines (AsnEDAs) as human immunoproteasome inhibitors and modified AsnEDAs as selective Pf20S inhibitors. Here we report further structure-activity relationship study of AsnEDAs for selective inhibition of Pf20S over human proteasomes. Additionally, we show a new mutation in the Pf20S β5 subunit (β5A49S) that conferred resistance to AsnEDAs and collateral sensitivity to an inhibitor of the Pf20S β2 subunit, as in our previously identified mutation in the β6 subunit (β6A117D). This resistance could be overcome through the use of structure-guided inhibitor design. Thus, collateral sensitivity to inhibitors of one proteasome subunit can arise from point mutations in multiple other subunits, underscoring the potential value of treating malaria with combinations of inhibitors of different proteasome subunits to minimize the emergence of drug resistance.

Severe dengue is defined by a plasma leak syndrome leading to intravascular volume depletion and shock. The majority of patients with dengue shock recover after a single fluid infusion, however, recurrent shock occurs in approximately 30% and carries a higher risk of poor outcomes. Early Identification of these patients would allow more intensive treatment. The compensatory reserve Index (CRI) is a new physiological parameter that tracks real-time changes in central volume. It is derived from feature analysis of the pulse arterial waveform. Arterial waveform data is processed by an algorithm, giving a CRI value between 1 and 0, where 1 represents normovolaemia and 0 represents decompensated shock (SBP < 80 mm Hg). We investigated the utility of CRI to predict re-shock compared to the current gold standards, including clinical and vital sign parameters in severe dengue. We performed a prospective observational study in the paediatric and adult Intensive Care Units (ICU) at the Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam. Patients were monitored with hourly clinical and vital sign parameters, and continuous recording of the arterial waveform using pulse oximetry. The waveform data was wirelessly transmitted to a laptop where it was synchronized with the patient's clinical data. 90 patients were enrolled, of which 55 had the minimum required dataset for analysis. The median age was 11 years (IQR 8-14 years). CRI had a moderate negative correlation with diastolic and systolic BP. Using logistic regression GEE models, CRI was found to predict shock (defined as PP<20mmHg) up to 5 hours before the event, ranging from the highest risk at 25 minutes prior to shock; OR 1.93, (95% CI 1.49-2.51), P<0.001 and AUC of 0.82, decreasing at 1 hour prior; OR 1.67, (95% CI 1.33-2.11), P<0.001, AUC of 0.77 and at 5 hours prior: OR 1.39, 95% (CI 1.11-2.76), P=0.004 and AUC of 0.68. A CRI cut-off of 0.4 provided the best sensitivity and specificity for predicting shock (0.8 and 0.72 respectively). In summary, CRI is a useful non-invasive method for monitoring intravascular volume status in severe dengue and can predict shock recurrence up to 5 hours before the event.

9

UPDATE FROM PAGODAS: PEDIATRIC ASSESSMENT GROUP OF DENGUE AND AEDES SALIVA TO INVESTIGATE VECTOR-BORNE DETERMINANTS OF *AEDES*-TRANSMITTED ARBOVIRAL INFECTIONS IN CAMBODIA

Rithea Leang[1], Daniel Parker[2], Dara Kong[1], Somnang Man[1], Sokunthea Sreng[1], Sreyngim Lay[1], Kimsour Nang[1], Shaden Kamhawi[3], Michael Fay[3], Emerito Amaro-Carambot[3], Stephen Whitehead[3], Stephen Whitehead[3], Seila Suon[1], Chea Huch[1], Rekol Huy[1], Thomas E. Wellems[3], Jesus G. Valenzuela[3], **Jessica E. Manning**[4]

[1]*National Center for Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia,* [2]*University of California Irvine, Irvine, CA, United States,* [3]*National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States,* [4]*National Institute of Allergy and Infectious Diseases, Phnom Penh, Cambodia*

Dengue virus is a serious public health concern in Cambodia. Defining the burden of dengue disease and the *Aedes aegypti* vector determinants that exacerbate disease transmission are critical for Cambodian public health authorities. In this longitudinal pediatric cohort based in community pagodas, we enrolled 771 healthy Cambodian children aged 2 to 9 years old in July and August 2018 to be followed twice per year (rainy and dry season) for serosurveillance for *Ae. aegypti* salivary gland homogenate antibody intensity determinations as well as dengue seroprevalence through a combination of ELISA and plaque reduction neutralization test (PRNT) assays. Traditional entomological surveys were also performed in 731 houses and 5053 water containers in the community. At baseline, dengue virus seroprevalence was: 19.5% (34/174; 95% CI 13.9-26.2) in 2 – 3 year olds, 22% (45/204; 95% CI 16.6- 28.4) in 4 – 5 year olds, 36.6% (67/183; 95% CI 29.6-44) in 6 – 7 year olds, and 65.8% (n=129/196; 95% CI 58.7-72.4) in 8 – 9 year olds. Full serotyping and PRNT titers will be available by presentation time. As the cohort data collection is still ongoing, initial geospatial analysis will be shown for baseline dengue seroprevalent participants (n=273), asyptomatic dengue cases and acute dengue cases as of October 2019 and their association (or lack thereof) with *Ae. aegypti* anti-saliva antibody intensity at wet and rainy season, mean larval density (from 5053 water containers at 731 houses), and Premises Condition Index (PCI) scoring. Our preliminary findings indicate that: 1) dengue seropositivity increases with age, with most children being seropositive by age 8; and 2) there is spatial overlap between house quality (from PCI), high *Ae. aegypti* salivary responses, and dengue seropositivity.

10

PHARMACOKINETICS OF TKM-130803 IN EBOLA VIRUS DISEASE IN SIERRA LEONEAN PATIENTS

J**anet T. Scott**[1], Raman Sharma[2], Luke W. Meredith[3], Jake Dunning[1], Catrin E. Moore[4], Foday Sahr[5], Steve Ward[2], Ian Goodfellow[3], Peter Horby[6]

[1]*MRC-University of Glasgow Centre for Virus Research, Glasgow, United Kingdom,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*University of Cambridge, Cambridge, United Kingdom,* [4]*Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom,* [534] *Military Hospital, Freetown, Sierra Leone,* [6]*Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom*

TKM-130803 is a specific anti-ebola virus (EBOV) therapeutic comprising of two small interfering RNAs (siRNA) siLpol-2 and siVP35-2. The pharmacokinetics (PK) of these siRNAs was defined in Ebola virus disease (EVD) patients, with reference to efficacy (ET) and toxicology thresholds (TT). The relationship between PK and patient survival was explored. PK and pharmacodynamic (PD) data were available for seven participants with EVD in Sierra Leone who received 0.3 mg/kg of TKM-130803 by intravenous infusion over 2 hours daily for up to 7 days. Plasma concentration of siRNA was compared to survival at 14 days. PK data were fitted to two-compartment models then Monte Carlo simulated PK profiles were compared to ET (Cmax 0.04-0.57 ng/mL and mean concentration 1.43 ng/mL), and TT (3000 ng/mL). Viral loads (VL) were not significantly different at treatment onset or during treatment (p=0.1) in subjects who survived or died. siRNA was in quantitative excess of virus genomes throughout treatment, but the 95% percentile exceeded TT. Plasma concentration of both siRNAs were higher in subjects who died compared to subjects who survived (p<0.025 both siRNAs). The maximum AUC for which the 95% percentile remained under TT was a continuous infusion of 0.15mg/kg/day. TKM-130803 was circulating at concentrations considered sufficient for efficacy but given extremely high viral loads it seems likely that the patients died because they were physiologically beyond the point of no return. Subjects who died exhibited indications of impaired drug clearance, justifying caution in dosing strategies for such patients. This analysis has given a useful insight into the pharmacokinetics of the siRNA in the disease state and illustrates the value of designing PKPD studies into future clinical trials in epidemic situations.

11

HEARING LOSS ASSOCIATED WITH VIRAL HEMORRHAGIC FEVERS

Samuel C. Ficenec[1], Donald Grant[2], Robert Samuels[2], Susan D. Emmett[3], John S. Schieffelin[1]

[1]*Tulane School of Medicine, New Orleans, LA, United States,* [2]*Sierra Leone Ministry of Health and Sanitation, Freetown, Sierra Leone,* [3]*Duke University School of Medicine, Durham, NC, United States*

Hearing loss affects over 1.3 billion people worldwide. Despite well known social, economic, and neurologic consequences, this condition receives little attention. Ebola (EBV) and Lassa Fever (LF) have both been reported to cause hearing loss. However, the true burden of hearing loss secondary to these viruses is likely underestimated due to lack of standardized measurement and reporting. This is a cross-sectional study

of LF and EBV survivors and household controls. Upon recruitment into the study, survivors and controls were screened for hearing loss by determining Pure Tone Averages (PTAs) of air conduction thresholds using an AMBCO audiometer, according to WHO standards. Individuals found to have elevated PTAs were referred to confirmatory testing measuring both air and bone conduction thresholds using a SHOEBOX audiometer to differentiate between sensorineural and conductive hearing loss. As of March 2019, a total of 1329 individuals were recruited for this study, including 301 EBV survivors, 73 LF Survivors and 955 household controls. The mean age of the entire cohort was 25.3 years. Of the 301 participating Ebola survivors, 170 (56.5%) were found to have either bilateral or unilateral hearing loss vs 316 (44.4%, p <0.0001) of EBV controls . In addition, 52 (71.2%) of LF Survivors vs 120 (49.4%, p <0.001) of LF controls were to found have hearing loss on initial screening. Since the addition of confirmatory testing to the study protocol in August 2018, a total of 222 Ebola survivors and 537 contacts have been tested using this methodology. Confirmatory testing reveals 55 (24.8%) EVD Survivors vs 51 (9.5%, p <0.0001) of EVD controls have hearing loss. Confirmatory testing is still ongoing for LF Survivors and controls and will be completed by April 30, 2019.The results of this study demonstrate an association between hearing loss and survival of EVD or LF. Due to the chronic effects of this disability, it is imperative that greater emphasis be placed on characterizing EVD- and LF-related hearing loss not only to decrease the burden of disease and improve the lives of survivors.

12

MACHINE-LEARNING PROGNOSTIC MODELS FROM THE 2014-16 EBOLA OUTBREAK: DATA-HARMONIZATION CHALLENGES, VALIDATION STRATEGIES, AND MHEALTH APPLICATIONS

Andres Colubri[1], Mary-Anne Hartley[2], Mathew Siakor[3], Vanessa Wolfman[3], August Felix[1], Adam C. Levine[4], Pardis C. Sabeti[1]

[1]*Broad Institute, Cambridge, MA, United States,* [2]*University of Lausanne, Lausanne, Switzerland,* [3]*International Medical Corps, Los Angeles, CA, United States,* [4]*Brown University, Providence, RI, United States*

We created a family of prognostic models for Ebola virus disease from the largest dataset of EVD patients published to date. We incorporated these models into an app, "Ebola Care Guidelines", that provides access to recommended, evidence-based supportive care guidelines and highlights the signs/symptoms with the largest contribution to prognosis. We applied multivariate logistic regression on 470 patients admitted to five Ebola treatment units in Liberia and Sierra Leone during the 2014-16 outbreak. The models were then validated with two independent datasets from Sierra Leone. Viral load and age were the most important predictors of death. We generated a parsimonious model including viral load, malaria rapid test result, age, body temperature, bleeding, jaundice, asthenia, dyspnea, dysphagia, and referral time recorded at triage. We also constructed fallback models for when variables in the parsimonious model are unavailable. The performance of the parsimonious model approached the predictive power of observational wellness assessments by experienced health workers and was robust across the validation datasets, with Area Under the Curve (AUC) ranging from 0.75 to 0.83 and overall accuracy of 70% to 78%. Machine-learning models and mHealth tools have the potential for improving the standard of care in low-resource settings and emergency scenarios, but data incompleteness and lack of generalizable models are major obstacles. We showed how harmonization of multiple datasets yields prognostic models that can be validated across different cohorts. Similar performance between the parsimonious model and those incorporating expert wellness assessments suggests that clinically-guided machine learning approaches can recapitulate clinical expertise, and thus be useful when such expertise is unavailable. We also demonstrated with our guidelines app how integration of those models with mobile technologies enables deployable clinical management support tools that facilitate access to comprehensive bodies of medical knowledge.

13

CLINICAL PROFILE AND THERAPEUTIC RESPONSE OF MEROPENEM AND AZITHROMYCIN IN THE TREATMENT OF EXTENSIVELY DRUG RESISTANT (XDR) TYPHOID FEVER IN A LOW-MIDDLE INCOME COUNTRY

S**onia Qureshi**, Tahir Yousafzai, Abdullah Naveed, Khalil Ahmad, Sarwat Ansari, Heeramani Lohana, Farah Naz Qamar

Aga Khan University Hospital, Karachi, Pakistan

Enteric fever due to *Salmonella Typhi* is one of the leading causes of bacterial febrile disease in Pakistan and with the emergence of extensively drug resistant (XDR) *Salmonella Typhi*; it poses an even greater risk. Here we report the clinical manifestations and the treatment response of different antibiotics in treating patients with extensively drug resistant typhoid fever in Pakistan. We retrospectively reviewed the records of culture proven XDR typhoid patients who visited Aga Khan University Hospital, Karachi and Aga Khan Secondary Care Hospital, Hyderabad between April 2017 to June 2018. Only cases with complete records were included in this study. Clinicopathologic data was reviewed to assess antibiotic response used for treatment of XDR typhoid fever and frequency of different clinical symptoms was also documented. 60 patients were enrolled into this study. The two main antibiotics (azithromycin and meropenem) that were used were compared in terms of treatment response by dividing patients into 3 groups; meropenem only (n=10), azithromycin only (n=20) and combination of meropenem and azithromycin (n=30). For patients who were only administered azithromycin, their mean (±SD) time to defervescence was 7.5 (± 3.7) days with 2 treatment failures. Patients who were only administered meropenem had a mean (±SD) time to defervescence of 5.3 (± 3.5) days with 1 treatment failure. Patients who received combination of meropenem and azithromycin had a mean (±SD) time to defervescence of 7.0 (±4.0) days with 2 treatment failures. This observational study showed no significant difference in clinical outcomes when being treated with azithromycin, meropenem or both. Clinical trials are needed for further evidence.

14

HISTOPATHOLOGICAL GRADING OF ENVIRONMENTAL ENTERIC DYSFUNCTION (EED) IN THE SEEM STUDY

N**ajeeha Talat Iqbal**[1], Kamran Sadiq[1], Sana Syed[2], Zubair Ahmad[1], Romana Idress[1], Zehra Jamil[1], Kumail Ahmed[1], Junaid Iqbal[1], Shahida Qureshi[1], Aneeta Hotwani[1], Najeeb Rahman[1], Fayyaz Umrani[1], Sheraz Ahmed[1], Sean Moore[2], Asad Ali[1]

[1]*Aga Khan University, Karachi, Pakistan,* [2]*University of Virginia, Charlottesville, VA, United States*

Environmental Enteric Dysfunction (EED) is an acquired syndrome in children, a poorly defined entity of multi-factorial disease processes that encompasses environmental insults and repeated infections accompanied by structural and functional abnormalities of gut. Impoverished living conditions and inadequate nutrition markedly affect gut function that translates into linear growth faltering. Confirmation of EED requires a rigorous workup of malnutrition, including examination of GI mucosa. These studies are rare and results of few studies are primitive and equivocal. BMGF supported biopsy initiative to find treatable causes of malnutrition, and to characterize EED based on histological scoring. In this study, histological grading of EED is presented in 50 children with chronic malnutrition and failure to nutritional intervention. This longitudinal birth cohort was followed up to two years. Children were selected for upper GI endoscopy, if there was no recovery in growth (WHZ< -2.0) post educational counselling and nutritional rehabilitation. Child was assessed by physicians for further work up. Three punch biopsies were collected from D3/D2 portion of small intestine and were preserved in formalin for H&E. Biological samples were collected for exploratory biomarkers studies. Among several parameters of the grading system, acute and chronic inflammation, villous blunting, presence of IELs and detection of pathogen were analyzed by AKU histopathologists. Of 35 biopsies scored, the Mean

score was 7.0± 2.6 and range was 3 to12. Majority of cases (77%) were scored ≥ 5. *Giardia* and *H. pylori* mixed infection was observed in 18% of cases, H.pylori being most prevalent pathogen (48%), followed by Giardia (40%). Moreover, IELs were raised in 24% of cases. A negative correlation between Leptin (r-0.545; p=0.002) and IGF (r -0.293; p=0.08) were observed with increasing EED score.Further work require correlation of EED biomarkers with severity of disease, and whether EED pathology at site affects systemic or gut inflammatory biomarkers which can be captured through non-invasive EED biomarkers studies.

15

DROP-THE-LOSER ADAPTIVE INTERVENTIONS: AN INNOVATIVE DESIGN FOR FINDING THE OPTIMAL INTEGRATED MALARIA VECTOR CONTROL STRATEGIES

G**uofa Zhou**

University of California Irvine, Irvine, CA, United States

Vector control is the primary means of preventing mosquito-borne disease and has been implemented worldwide. Due to the large number of available and emerging interventions and the heterogeneous and dynamic nature of transmission, an innovative trial design must be developed to test interventions and find the optimal combination. One viable approach may be to build an adaptive design using a sequential multiple assignment randomized trial (SMART). We review the SMART design and highlight its advantages over alternative experimental designs in constructing and revising adaptive interventions. We used malaria vector control as an example to show how the new approach can be used to develop optimal integrated intervention strategies. We conducted the simulation study based on local vector ecology, malaria transmission characteristics, and environmental conditions. The simulated interventions included regular long-lasting insecticidal nets (LLINs), piperonyl butoxide-treated LLINs (PBO-LLINs), indoor residual spraying (IRS) with alternative insecticides, and long-lasting microbial larviciding (LLML). We used a drop-the-loser adaptive design with malaria infection prevalence (MIP) as the outcome measure. The simulation results indicate that, in an area with high pyrethroid resistance and moderate outdoor transmission, a) PBO-LLIN and alternative-insecticide IRS significantly reduced MIP compare to LLINs; b) when alternative-insecticide IRS or LLML were added to existing PBO-LLIN, both were effective in further reducing MIP; c) if only two interventions can be used, PBO-LLIN+LLML would be most effective in reducing MIP; and d) adding LLML on top of PBO-LLIN+IRS (with alternative insecticides) had a significant impact on MIP; however, if PBO-LLIN+LLML has already been implemented, adding IRS may not be recommended. Our simulation example provides a framework or new pathway for informing the optimal integrated intervention. The simulated results are in agreement with existing field trials, and the new strategy can be tested in field trials.

16

EFFECTIVENESS OF COMPLEMENTARY STRATEGIES ON MALARIA BURDEN AND TRANSMISSION: A FOUR-ARMED RANDOMIZED CONTROLLED TRIAL IN KORHOGO AREA, NORTHERN CÔTE D'IVOIRE

Barnabas Zogo[1], Bertin N'Cho Tchiekoi[2], Dieudonné Diloma Soma[3], Anthony Somé[3], Ludovic P. Ahoua Alou[2], Alphonsine A. Koffi[2], Florence Fournet[4], Amal Dahounto[3], Baba Coulibaly[2], Roch Kounbobr Dabiré[3], Lamine Baba-Moussa[5], Nicolas Moiroux[6], Cédric Pennetier[4]

Communication for human behavioral changes, indoor residual spraying and larviciding belong to the vector control arsenal to fight against malaria. However, there are not conclusive evidences that their use in combination with the core vector control tool, long-lasting insecticide treated nets (LLINs) provide additional benefit. To help decision makers in policy making, we conducted a four-armed randomized controlled trial to assess whether the use of these tools in combination with LLINs provide additional protection against malaria in an area of high pyrethroid-resistance. The trial was conducted in 28 villages in Korhogo area, Northern Côte d'Ivoire from September 2017 to July 2018, after one year of baseline survey. We selected the villages based on the population size and a minimum distance between villages of 2 km. Eight villages were randomly allocated to larviciding with *Bacillus thuringiensis israeliensis*, six villages to IRS with pyrimiphos-methyl and six other villages to intensive communication for human behavioral changes. All these villages as well as the remaining 8 villages (control group) were covered with LLINs before the implementation of complementary strategies. We carried out four (4) entomological cross sectional surveys and five (5) epidemiological cross sectional surveys for the measurement of entomological and epidemiological outcomes after the implementation of strategies. The analysis of malaria incidence, prevalence and transmission in Korhogo will be presented.

17

THE DISTRIBUTION AND INSECTICIDE RESISTANCE STATUS OF *ANOPHELES STEPHENSI* IN EASTERN ETHIOPIA

M**eshesha Balkew**

Abt Associates Inc., Addis Ababa, Ethiopia

Anopheles stephensi was detected in the Horn of Africa for the first time in 2012 in Djibouti and in the Somali region of Ethiopia in 2016. To understand the extent of its geographic distribution and insecticide resistance status, the PMI VectorLink project in collaboration with Jigjiga and Diredawa Universities conducted a cross-sectional survey between August and November 2018, in ten urban localities in Eastern Ethiopia: Dire Dawa, Erer, Jigjiga, KebriDehar, Degehabur, Godey, Bati, Gewane, Semera and Awash Sebat Kilo. Adult mosquitoes were sampled using Human Landing Catches (HLCs), Centers for Disease Control and Prevention Light Traps (CDC LTs) and Pyrethrum Spray Catches (PSCs). Larvae and pupae were sampled from potential mosquito breeding sites using standard dippers. Morphology-based species identification was evaluated with sequence analysis at Baylor University. Susceptibility tests against six insecticides: pirimiphos-methyl, propoxur, bendiocarb, deltamethrin, permethrin and alphacypermethrin and synergist tests using piperonyl butoxide were conducted in two of the ten sites, Diredawa and Kebridehar using WHO tube test. The study revealed the presence of *An. stephensi* in all the ten study sites. The survey produced a total of 90 adult-caught and 2,149 larval-collected *An. stephensi* Cisterns, tanks, barrels and tires were found to be important larval habitats in the study areas. The two populations of *An. stephensi* were resistant to all insecticides tested (19-80% mortalities) with the exception of pirimiphos-methyl (100% mortality). Pre-exposure to PBO fully or partially restored *An. stephensi* susceptibility to deltamethrin and permethrin indicating involvement of oxidases as a resistance mechanism. The distribution of *An. stephensi* appeared to be wider than expected, based on the initial finding in one location, and warrants a nationwide survey to understand its spatial distribution in Ethiopia. Further study is also needed to determine physiological resistance, behavioral patterns and its role in malaria transmission in Ethiopia with the goal of design of appropriate vector control interventions.

18

THE PROTECTIVE GAP OF INDOOR RESIDUAL SPRAYING: WALL MODIFICATIONS AFTER SPRAYING AFFECTS ACTUAL COVERAGE AND HAMPERS MALARIA ELIMINATION EFFORTS

M**ercy Opiyo**[1], Charfudin Sacoor[2], Mara Maquina[2], Celso Alafo[2], Pedro Aide[2], Ariel Nhacolo[2], Lucia Fernandez-Montonya[3], Helena Marti[1], Francisco Saute[2], Krijn Paaijmans[4]

Though bednets and indoor residual spraying (IRS) have made a significant contribution to the reduction of malaria transmission in Africa, transmission persists, indicating that these tools alone are not sufficient for this disease. This is under the assumption that tools are implemented to full effect. Whilst the residual effect of IRS insecticides and changes in mosquito traits are being monitored, human behaviors that may affect IRS efficacy such as replastering, painting or washing of treated wall surfaces are never. Yet estimates on the number of people protected, as well as large-scale efficacy studies on the additional effect of IRS on top of nets continue. The purpose of the present study is to quantify the frequency of those human behaviors over time. Together with data on the residual effect of insecticides and information on mosquito bionomics, the protective gap of IRS can be properly quantified, which will allow us to design appropriate mitigation strategies. The study is conducted in two districts in southern Mozambique: Matutuine sprayed with Actellic® (300CS, active ingredient: pirimiphos-methyl, Syngenta) and Boane with SumiShield® (50WG, active ingredient: clothianidin, Sumitomo Chemical). Three hundred households were selected per district, and interviewed monthly using structured questionnaires to collect information related to human behavior. These included factors such as changes made to the walls since spraying, type of wall modification, number of rooms modified, specific rooms modified, adults and children sleeping in such modified spaces, reasons for wall modifications, number of rooms added since spraying, as well our their appreciation of long-lasting insecticide-treated nets, indoor residual spraying and other vector control tools. Preliminary data shows that wall modifications following a successful IRS implementation are common, with people mostly modifying bedrooms and living rooms. Final data are being collected, and will be presented during the meeting in November.

19

THE COST OF MEASURING IMPACT: RANDOMIZED CONTROL TRIAL (RCT) METHODOLOGIES FOR VECTOR CONTROL

Molly Robertson[1], Joe Wagman[1], Rose Zulliger[2], Abuchahama Saifodine[3], Baltazar Candrinho[4], Jason Richardson[5], Laurence Slutsker[6], Carlos Chaccour[7], Francisco Saute[1]

[1]*PATH, Washington, DC, United States,* [2]*President's Malaria Initiative, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Maputo, Mozambique,* [3]*President's Malaria Initiative, US Agency for International Development, Maputo, Mozambique,* [4]*Programa Nacional do Controlo da Malaria, Maputo, Mozambique,* [5]*Innovative Vector Control Consortium, Liverpool, United Kingdom,* [6]*PATH, Seattle, WA, United States,* [7]*ISGlobal, Barcelona Centre for International Health, Research Hospital Clínic - Universitat de Barcelona, Barcelona, Spain*

To estimate the cost-effectiveness of combining third generation indoor residual spraying with long-lasting insecticidal bed net universal coverage campaigns, a cluster randomized control trial (RCT) was conducted over two years in Mopeia district, Mozambique from Nov 2016 - Oct 2018. The trial measured malaria burden and the effect of seasonal IRS campaigns conducted by PMI/Abt Associates using five methodologies: entomological monitoring, a monthly infection incidence cohort of ~1,500 children under 5 years old at enrollment, yearly, all-age cross-sectional surveys with parasite prevalence measured through rapid diagnostic tests, enhanced routine passive case surveillance linked to each study cluster, and costing. All of the methodologies help shape an understanding of malaria burden and the cost-effectiveness of the intervention in different ways. Some results closely aligned, for example, there were similar trends in decreased monthly vector densities as well as decreased cohort infection incidence and passive case incidence rates in communities that received IRS. But there was some discordance between the incidence and prevalence trends: during the first five months of the study incidence rates of new malaria infections in the cohort and confirmed malaria cases from district health facilities both declined significantly in IRS communities but there was no corresponding difference in malaria infection prevalence measured between IRS and non-IRS communities during the 2017 cross sectional survey. While the use of complementary impact measures provides nuanced and in-depth understanding of the effectiveness of the IRS intervention, each measure also has important analytical and cost implications. This talk will describe the details and contribution of each approach to overarching project objectives and discuss the decision, in the continuation of the study to a 3rd year, to alter the methodology. Given the cost of each method, and of RCTs in general, this discussion is important for others considering which strategies to employ when conducting studies to estimate the public health impact of vector control interventions.

20

LESSONS LEARNED, CHALLENGES AND IMPLICATIONS FOR DECISION-MAKING AFTER A DECADE OF EXPERIENCE MONITORING THE IMPACT OF INDOOR RESIDUAL SPRAYING IN BENIN, WEST AFRICA

M**artin Akogbeto**

Cotonou Research Entomology Center, Cotonou, Benin

Benin has performed Indoor Residual Spraying (IRS) in 19 communes since 2008: 4 communes in southern Benin (2008-10) and 9 communes in Atacora (2011-16) and 8 communes in Atacora, Alibori, and Donga (2017-18) in northern Benin. However, Benin still struggles with questions about IRS' costs, benefits, and epidemiological impact. We discuss lessons learned and challenges from 10 years of IRS in Benin. CREC has assessed entomological parameters in IRS districts since 2008. Compared to controls, significant decreases in *Anopheles gambiae* human biting rate*, An. gambiae* carrying *Plasmodium falciparum* in salivary glands, blood feeding, and entomological inoculation rate (EIR) occurred in all IRS districts. This encouraging 80-90% reduction in EIR should be observed with caution because: (i) it may be insufficient to decrease epidemiological indicators given the residual EIR in IRS districts was still higher than in some regions of stable malaria; (ii) it is based on comparisons with control districts, but it is difficult to select control areas with the same environmental characteristics as intervention areas; and (iii) half of all mosquitoes that entered IRS-treated houses still succeeded in taking human blood meals. Further, human behaviors limit IRS efficacy. Recent data show that >90% of Benin citizens are not fully protected by IRS from 7-10 PM because they remain outside and that most people are not fully protected from mosquito bites after 10 PM because they either sleep outside without IRS protection or inside without an ITN. People also have large amounts of items hanging on walls where mosquitoes rest, avoiding IRS-treated walls. Finally, three other issues are important to consider: (i) Vector resistance management strategies are sometimes poorly understood. Management aims to prevent the emergence of resistance; this is different from replacing an insecticide by another after resistance emerges. (ii) Before IRS begins, communities should be informed that IRS will not be a permanent measure. Clear communication and expectations are important. (iii) African countries should prepare to finance IRS and other vector control interventions themselves.

21

COST-EFFECTIVENESS OF COLLABORATING WITH THE TOGOLESE ARMED FORCES FOR LONG-LASTING INSECTICIDE-TREATED MOSQUITO NET (LLIN) MASS DISTRIBUTION CAMPAIGN

T**chaa A. Bakai**[1], Tchassama Tchadjobo[1], Josée Gnamien-Koudou[1], Jean-Emmauel Julo-Réminiac[2], Stéphane d'Almeida[3], Komi Kusiaku[3], Komla D. Kadzahlo[1], Agnidouféyi Aawi[1], Aféignitou Boukpessi[1], Batoma Tombegou-Pana[1], Esso-Kilina Tako[1], Kossi Yakpa[1], Ahoefan Djossou[1], Kansame Labarboré[1], Ley-Bawé Tchamoussa[1], Bana Botcholi[1], Batawa Akakpo[1], Kokoe D. d'Almeida[1], Afolabi Eliassou[1], Tinah Atcha-Oubou[1]

[1]*National Malaria Control Program, Lome, Togo,* [2]*HRH*[2030]*-Capacity Building for Malaria, Chemonics International, Arlington, VA, United States,* [3]*Global Fund Project Management Unit (PMU), Lome, Togo*

Malaria is the primary cause of premature death in Togo (Global Burden of Disease 2017). Aiming to maintain progress in universal coverage, Togo's National Malaria Control Program (NMCP) initiated their 2017 national long-lasting insecticide-treated mosquito net (LLIN) mass distribution campaign. The NMCP sought to distribute 4,770,250 LLINs acquired by the National Coordination Committee (NCC) with contributions from the Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM) (64%), the Against Malaria Foundation (26%), and the national government (10%). Due to prolonged procurement processes, unavailable or inadequate central warehouse space and distribution vehicles, and socio-political instability and insecurity, the NMCP estimated that 85% of LLINs would need to be distributed directly to the districts. By engaging high-level State authorities including the President, the NMCP facilitated a collaboration with the Togolese Armed Forces (FAT). The NCC and Ministry of Defense and Veterans Affairs signed of a memorandum of understanding with the Prime Minister (Principal Recipient of GFATM), the World Food Program (WFP) and the FAT. This allowed for the requisition of WFP-managed, State-owned warehouses for interim LLIN storage at the central level. Using army trucks staffed with one military driver and three additional soldiers, the FAT successfully transported 3,668,200 LLINs from the central warehouses to 37 district-level warehouses. The collaboration with the FAT for the LLIN distribution campaign achieved substantial savings of 186,166,637 FCFA in storage and transportation costs (more than $300,000 USD). The Alliance for Malaria Prevention lauded the Togo NMCP for this initiative with a special innovation award at its 2019 annual meeting in Geneva. Resource-constrained disease programs could benefit from considering Togo's approach to collaborate with non-health actors to strengthen the State's involvement in the fight against malaria.

22

DISSECTING THE MECHANISMS OF MALARIA INDUCED ANEMIA IN RODENT MALARIA MODELS

Keyla C. Tumas[1], Jian Wu[1], Sittiporn Pattaradilokrat[1], Lu Xia[1], Yu-Chih Peng[1], Timothy G. Myers[2], Xin-zhuan Su[1]

[1]*National Institutes of Health, Rockville, MD, United States,* [2]*National Institutes of Health, Bethesda, MD, United States*

Plasmodium parasites cause human malaria infections with symptoms ranging from no complications to deadly complications including severe anemia. Malaria induced severe anemia is likely multifactorial, arising from clearance of infected and uninfected red blood cells and an inhibition in erythropoiesis, the production of new red blood cells. However, the exact molecular mechanisms of malaria induced anemia are still largely unknown. Using *Plasmodium yoelii* N67C and 17XNL strains in C57BL/6 mice as models, we are dissecting the molecular mechanisms of malaria induced anemia and stimulation of hematopoiesis. From microarray analysis, mice infected with N67C strain have decreased expression of erythropoietic associated genes at day 4 post infection. In contrast, those infected with 17XNL strain have an initial inhibition of erythropoietic associated genes but later in the infection had an increase in expression. Using flow cytometry analysis of cells from bone marrow and spleen, where production of new red blood cells occurs during malaria infections, we found differences in progenitor cell populations of erythropoiesis. In particular, the N67C strain had decreased cell frequencies for proerythroblast and other early cell stages of erythropoiesis on day 4 post infection. In contrast, mice infected with 17XNL strain had increased cells of erythropoiesis in the spleen and bone marrow, including reticulocytes, 10 days post infection. The uninfected red blood cells from 17XNL infected mice were removed at a faster rate than those of N67C by phagocytic cells, which may explain production of more reticulocytes in the 17XNL infected mice. Future studies will aim to elucidate the molecular mechanisms contributing to the changes in erythropoiesis and red blood cell clearance, ultimately to advance our understanding of malaria induced anemia.

23

EXPERIMENTAL MALARIA IN PREGNANCY IS ASSOCIATED WITH NEUROPSYCHIATRIC DISORDERS IN OFFSPRING IN A DISEASE SEVERITY-DEPENDENT MANNER

A**ndrea Weckman**[1], Vanessa Tran[2], Chloe R. McDonald[2], Kevin C. Kain[3]

[1]*University of Toronto, Toronto, ON, Canada,* [2]*Sandra Rotman Centre for Global Health, University Health Network-Toronto General Hospital, Toronto, ON, Canada,* [3]*Sandra Rotman Centre for Global Health, University Health Network-Toronto General Hospital, Tropical Disease Unit, Department of Medicine, University of Toronto, Toronto, ON, Canada*

Each year ~125 million pregnant women are at risk for malaria infection. Malaria in pregnancy (MiP) has a profound impact on mother-child health, including delivery of low birth weight (LBW) infants. Even in the absence of LBW, epidemiological studies show a link between maternal infection and increased susceptibility of offspring to neuropsychiatric disorders later in life. There is preclinical evidence for a correlation between severity of maternal immune activation and severity of psychiatric outcome. The two-hit hypothesis of neuropsychiatry posits that a first "hit" (i.e. maternal infection) primes offspring for increased susceptibility to psychiatric disease in response to a second "hit" (i.e. stress) later in life. The impact of malaria exposure *in utero* on long-term vulnerability to psychiatric disease has not been reported. We hypothesize that exposure to MiP will prime offspring to an increased risk of psychiatric disorders in a disease severity-dependent manner. We used the established experimental mouse model of MiP (EMIP) with *Plasmodium berghei* ANKA (PbA). Uninfected adult offspring of dams infected with PbA underwent a battery of standardized behavioural tests. Exposure to EMIP *in utero* induced anxiety-like behaviour and hypersensitivity to amphetamine, and deficits in prepulse inhibition compared to unexposed offspring ($p<0.05$). In dams with less severe EMIP, which was characterized by lower parasitemia and lower maternal IL-6 ($p=0.01$), only offspring exposed to both EMIP plus a second hit of stress in puberty exhibited increased anxiety-like behaviour and hypersensitivity to amphetamine compared to EMIP alone ($p<0.05$). While exposure to more severe EMIP induced psychiatric disease in offspring alone, less severe EMIP acted synergistically with stress in puberty to induce a deficit. Our data implicate MiP as a modifiable risk factor for psychiatric disorders in offspring, even in instances of less severe disease. This concept represents a paradigm shift in our understanding of mental illness in malaria-endemic settings and may shift global health priorities from costly rehabilitation to prevention.

24

COMPARATIVE TRANSCRIPTOMICS IDENTIFIES PHENOTYPIC SIMILARITIES BETWEEN MOUSE MODELS AND HUMAN SEVERE MALARIA

A**thina Georgiadou**[1], Pablo Soro Barrio[1], Claire Dunican[1], Hyun Jae Lee[2], Michael Levin[1], Myrsini Kaforou[1], Aubrey Cunnington[1]

[1]*Imperial College London, Section of Paediatrics, London, United Kingdom,* [2]*Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia*

Mouse models are widely used in severe malaria research. However, the relevance of these models to human severe malaria (SM) pathophysiology is frequently disputed. New approaches are needed to objectively quantify and improve the translational relevance of mouse models. Comparative transcriptomics provides an unbiased assessment of similarities of biological processes between species.We performed RNA-sequencing on whole blood of C57BL/6 mice infected with each of 5 commonly-used rodent malaria parasites (*Plasmodium berghei* ANKA, *P. berghei* NK65, *P. yoelii* 17XL, *P. yoelii* 17XNL, and *P. chabaudi* AS). We identified differentially expressed genes (DEGs) in the whole blood transcriptomes between uninfected or early stage infections vs. late stage infections. In corresponding analyses in multiple datasets from African children we identified DEGs between healthy controls or uncomplicated malaria (UM) vs. different SM phenotypes including hyperlactatemia and / or cerebral malaria (CM). Unsupervised clustering analyses on orthologous DEGs in humans and mice revealed that *P. yoelii* 17XL was the most similar to human hyperlactatemia at a transcriptomic level, whilst *P. berghei* ANKA (experimental CM) infection was the most similar to human CM. However in both cases similarities between human and mouse were not absolute, with both concordant and discordant DEGs noted. No mouse model of hyperlactatemia has previously been reported, therefore we investigated blood lactate concentrations in each model and found that *P. yoelii* 17XL infection caused extreme hyperlactatemia (18-21mmol/L) with similar concentrations to the maximum values observed in human SM, whilst other models induced only modest or no increase in blood lactate. These findings demonstrate the potential of unbiased comparative transcriptomics to identify the most relevant mouse models for translational research. Concordant and discordant differential gene expression may be used to efficiently identify mechanisms and therapeutic targets for translational investigations in mouse models, and to exclude those which are unlikely to have translational relevance.

25

EXPRESSION PROFILING PATIENT SAMPLES IDENTIFIES GAMETOCYTE-COMMITTED RING BIOMARKERS

S**urendra K. Prajapati**[1], Ruth Ayanful-Torgby[2], Michelle C. Barbeau[1], Festus K. Acquah[2], Elizabeth Cudjoe[2], Courage Kakaney[2], Jones A. Amponsah[2], Evans Obboh[3], Benjamin K. Abuaku[2], Linda E. Amoah[2], Kim C. Williamson[1]

[1]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [2]*Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana,* [3]*University of Cape Coast, Cape Coast, Ghana*

The sequestration of immature stage *Plasmodium falciparum* gametocytes (stages I-IV) has made it challenging to track gametocyte development in peripheral blood samples and complicated the analysis of factors that contribute to *in vivo* gametocytogenesis. This challenge could be overcome by developing a gametocyte committed (gc)-ring biomarker. To identify potential markers, we used our *ex vivo* gametocyte culture assay to evaluate gc-rings in Ghanaian malaria patients (n=367) from 2015-2018 and observed a wide range of gametocyte conversion rates (GCR: sexual- to asexual-ring ratio) from 0 to 78%. Microarray analysis of the day 0 (D0) ring stage parasite transcriptome from high GCR (~3-66%; n=9) and low GCR (0%; n=8) samples revealed increased transcripts from only 8 genes (FDR=<0.045) in the high GCR samples. These 8 genes included a transcription factor (*ap2-g),* three enzymes *(hda1, lshd* and *arom),* and four proteins predicted to be exported to the RBC (3 *surfins* and one uncharacterized exported protein). *In vitro,* the ratio of the relative abundance of transcripts in ring stages and gametocytes was high (>11) only for *ap2-g* and two *surfins*, suggesting potential as specific biomarkers. Further *in vitro* testing using gametocyte-deficient and -producer strains demonstrated a correlation between the D0 RNA levels and D8 gametocyte production as well as D8 *pfs25* or *pfs230* RNA levels (R^2=0.56-0.77). The expression levels of all 3 genes are tightly correlated (R^2=0.99) and both *surfin*s were found to be AP2-G-dependent using an AP2-G inducible line. Importantly, in D0 RNA harvested from 224 malaria patient blood samples, the relative abundance of transcripts for all three genes correlated with the patient's D8 GCR (R^2=0.41-0.68) as well as *pfs230* transcript levels in D8 *ex vivo* culture (R^2=0.63-0.711). Further, transcripts for these genes were detectable in asymptomatic carriers. Together this work suggests these three genes are reliable early gametocyte biomarkers to study *in vivo* gametocyte production and, potentially, to use as a tool to predict malaria transmission 10-12 days before the circulation of mature gametocytes in the peripheral blood.

26

HEPATOCYTE BINDING PEPTIDE HP1 TARGETS *PLASMODIUM* SPOROZOITE-HEPATOCYTE INTERACTION

Sung-Jae Cha, Marcelo Jacobs-Lorena

Johns Hopkins University, Baltimore, MD, United States

Previously, using a phage peptide display library, our group has identified *Plasmodium* parasite ligands and corresponding host cell receptors important for ookinete-mosquito midgut interaction, sporozoite-mosquito salivary gland interaction and sporozoite-Kupffer cell interaction in the mammalian liver. Here we report on a phage display library screen for peptides that bind to hepatocytes, the sporozoite target for infection of the liver. We hypothesize that such peptides may be mimotopes (structural mimics) of *Plasmodium* sporozoite ligands for hepatocyte interaction. A prime candidate peptide from this screen - HP1 - binds to a ~25 kDa hepatocyte membrane protein (a candidate receptor) and an anti-HP1 antibody recognizes a ~45 kDa sporozoite surface protein (a candidate ligand). Immunization with HP1 protected 50 % mice from *P. berghei* challenge. Significantly, anti-HP1 antibody inhibited *P. falciparum*-human hepatoma cell (HepG2) interaction by 87 % compared to control antisera. This sporozoite ligand is a potential vaccine antigen targeting malaria liver invasion.

27

RISK OF READMISSION IN UGANDAN CHILDREN WITH SEVERE MALARIAL ANEMIA

Samina Bhumbra[1], Gregory S. Park[2], Robert O. Opoka[3], Dibyadyuti Datta[1], Chandy C. John[1]

[1]*Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Office of the Vice President for Research, University of Minnesota, Minneapolis, MN, United States,* [3]*Department of Paediatrics and Child Health, Makerere University, Kampala, Uganda*

Post discharge morbidity from severe malarial anemia (SMA) remains significant for survivors. As many as 16% of children diagnosed with SMA who survive are readmitted or die by 6 months. Identification of biomarkers predictive of recurrent severe malaria in children with SMA could help to define pathophysiologic factors that put children at risk for recurrent severe malaria. We assessed plasma concentrations of 25 pro- and anti-inflammatory cytokines and chemokines, markers of endothelial activation, and hematopoietic/vascular growth factors by cytometric bead assay in a cohort of Ugandan children aged 18 months to 12 years with severe malarial anemia (n=119). We then compared plasma concentrations of these factors in children with recurrent severe malaria (RSM, n=12) vs. no recurrent severe malaria (n=107) in the 6 months following the SMA episode. Children with RSM had lower baseline levels of PDGF bb (median [IQR], 429.15 pg/mL [269.93-649.47]), VEGF (33.43 pg/mL [19.12-49.93]), and EPO (2717.57 mU/mL [968.68-3410.17]) compared to children who

did not have RSM (PDGF bb 1193.30 pg/mL [508.68-2114.47], VEGF 67.5 pg/mL [34.2-102.94], EPO 4974.0 mU/mL [2979.7-10353.1]; all P<0.05). Children with RSM also had an increased Ang-2:Ang-1 ratio, an indicator of endothelial dysfunction associated with higher mortality in severe malaria (0.60 [0.47-1.13]), than children without RSM (0.31 [0.13-1.05], P=0.0477). Suppression of factors associated with angiogenesis (PDGF-bb, VEGF) and erythropoietic drive (EPO), and an increase in the Ang-2/Ang-1 ratio, leading to endothelial dysfunction, may put children with SMA at higher risk for recurrence of severe malaria.

28

MALIAN CHILDREN WITH SEVERE MALARIA SUBTYPES HAVE DISTINCT ANTIBODY GAPS TO VIRULENT PFEMP1S

M**ark A. Travassos**[1], Paul Han[1], Drissa Coulibaly[2], Albert E. Zhou[1], Antoine Dara[1], Biraj Shrestha[1], Rie Nakajima[3], Aarti Jain[3], Omid Taghavian[3], Algis Jasinskas[3], Matthew B. Plasmodium falciparum erythrocyte membrane protein-1 (PfEMP1) antigens play an important role in parasite sequestration and host immune system evasion. Acquired antimalarial immunity is at least partially due to antibodies directed against highly variable antigens like PfEMP1 that are present on the erythrocyte surface. PfEMP1 antigenic domains that drive immune-mediated protection in severe malaria have not been identified. We hypothesized that Malian children with severe malaria subtypes have lower seroreactivity to subsets of non-CD36-binding PfEMP1s containing domain cassettes (DCs) associated with severe malaria pathogenesis compared to matched uncomplicated malaria controls. We developed a custom protein microarray including 158 PfEMP1 fragments from the 3D7 reference genome and 78 fragments from PfEMP1s associated with severe malaria, including DCs 1, 5, 8, 13, and 15 from the IT4, HB3, and DD2 reference strains and DC8- and DC13-containing Malian PfEMP1s sequenced from field isolates. We measured serological responses for 34 cerebral malaria cases, 18 severe malarial anemia cases, and 9 cases of both cerebral malaria and severe malarial anemia, as well as age-matched controls who had uncomplicated malaria. Compared to controls, children with cerebral malaria had lower seroreactivity to PfEMP1s featuring DC1, DC5, DC8, DC13, and CIDRα1.7, but not to any 3D7 PfEMP1s known to bind CD36. In contrast, children with severe malarial anemia had lower seroreactivity to PfEMP1s featuring DC1, DC4, DC5, DC6, DC8, DC13, and CIDRα1.7, as well as several 3D7 CD36-binding PfEMP1s. Interestingly, children with both cerebral malaria and severe malarial anemia did not differ in PfEMP1 seroreactivity with controls, although low numbers preclude definitive conclusions. Acute and convalescent serologic comparisons for severe malaria are ongoing. These results suggest that immune-mediated protection against cerebral malaria may overlap with immune-mediated protection against severe malarial anemia, but the two are not identical, a finding that should be accounted for in severe malaria vaccine and treatment development.

Loa loa, known also as eye worm, is a filarial disease in which adult nematodes can migrate through subcutaneous tissues for many years, producing microfilaria that circulate in blood at concentrations of up to 100,000/mL, yet generally without triggering profound inflammation. The regulatory mechanisms involved in this paragon of immunological tolerance have nevertheless received almost no attention. Monocyte-like (M-) and polymorphonuclear (PMN-) myeloid-derived suppressor cells (MDSCs) are capable of displaying immunosuppressive features and play important roles in regulating the immune response against cancer and some infectious diseases. Here we compared the magnitude and immunosuppressive phenotype of M-MDSC and PMN-MDSC populations by flow cytometry in the peripheral blood of *L. loa* microfilaremic (MF+) and non-microfilaremic (MF-) subjects in an ongoing cross-sectional study in Moyen-Ogooué province in Gabon. The functional immunosuppressive activity of PMN-MDSC was assessed using *in vitro* T cell proliferation assays. We also assessed the dynamics of MDSCs in MF+ subjects undergoing treatment with albendazole. Our primary results show that (i) PMN-MDSC but not M-MDSC numbers are higher in MF+ than in MF- subjects; (ii) PD-L1 expression on PMN-MDSC, but not M-MDSC, is higher in MF+ than in MF- subjects; (iii) PMN-MDSC from these subjects show patent suppressive effects on T cell proliferation *in vitro*; (iv) PMN-MDSC but not M-MDSC numbers show a transient increase during albendazole treatment, followed thereafter by a decrease to below baseline. PMN-MDSC thus appear to be key players in the critical balance between anti-parasitic effector responses and immunopathology in chronic loiasis. The molecular pathways by which they are induced by this parasite and their relative cost/benefit to the host, including e.g. bystander effects on immune responses against other prevalent pathogens, remains to be determined.

30

MICROFILARIAE TRIGGER MURINE AND HUMAN EOSINOPHIL EXTRACELLULAR TRAPS IN A DECTIN-1-DEPENDENT MANNER

A**lexandra Ehrens**[1], Benjamin Lenz[1], Anna Lena Neumann[1], Samuela Giarrizzo[1], Stefan J. Frohberger[1], Wiebke Stamminger[1], Benedikt C. Bürfent[1], Frederic Fercoq[2], Coralie Martin[2], Daniel Kulke[3], Achim Hoerauf[1], Marc P. Hübner[1]

[1]*University Hospital Bonn, Bonn, Germany,* [2]*Muséum National d'Histoire Naturelle, Paris, France,* [3]*Bayer Animal Health GmbH, Monheim, Germany*

During primary filarial infection, eosinophils mediate protection against adult worms and microfilariae, but not against infective third-stage larvae. A recently described defense mechanism by eosinophils is the production of extracellular DNA traps (EETosis), a form of cell death where intracellular DNA is explosively released, entrapping pathogens and supporting their killing. The results of the present study demonstrate that microfilariae, but not third-stage larvae of the filarial nematode *Litomosoides sigmodontis*, trigger DNA release by eosinophils as analyzed by scanning electron microscopy, confocal microscopy and quantitative fluorescence DNA assay. *In vitro*, these eosinophil DNA traps, consisting of nuclear and mitochondrial DNA, inhibit microfilariae motility in a DNA- and direct cell contact-dependent manner. Eosinophils isolated from the gut of naïve and gut and pleura of filariae-infected-mice demonstrate an enhanced microfilariae motility reduction compared to bone-marrow-

derived eosinophils, whereas gut- and pleura-derived eosinophils primed during *L. sigmodontis* infection and gut-derived eosinophils from naïve animals showed comparable DNA-trap-dependent microfilarial motility reduction. *In vitro* assays further reveal that microfilariae-induced EETosis is independent of the presence of antibodies. Dectin-1 recognition was identified as the underlying signaling pathway involved in triggering the microfilariae-induced EETosis. DNA-dependent inhibition of microfilariae motility and microfilariae-induced DNA release by eosinophils appears to be a conserved mechanism since murine as well as human eosinophils respond to microfilariae derived from the rodent filarial nematode *L. sigmodontis* and the canine heartworm *Dirofilaria immitis*. *In vivo* studies reveal an increase in local DNA concentration upon *L. sigmodontis* infection in mice. Intravenous microfilariae injection raised systemic DNA concentrations, which is partly mediated by eosinophils, indicating a potential role of EETosis as an *in vivo* effector mechanism as well.

31

A PARASITE-ENCODED HUMAN IL-10 RECEPTOR ANTAGONIST REVEALS A NOVEL STRATEGY USED TO MODULATE THE HOST RESPONSE IN FILARIAL INFECTIONS

A**lessandra Ricciardi**, Thomas B. Nutman

Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

IL-10 has been shown to be the primary immunoregulatory cytokine driving the modulation of the host response in filarial infections. To determine whether parasite-derived molecules could modulate the host IL-10/IL-10R pathway, we performed solid-phase immobilization of human IL-10Rα followed by binding assays with *Brugia malayi* (Bm) adult antigen extracts. Bm proteins that bound to human IL-10Rα were eluted and analyzed by liquid chromatography-tandem mass spectrometry. Our analysis identified 5 Bm molecules that bound human IL-10Rα. The top hit, Bm5539, a 114kDa GTPase activator, contains PH, Rho-GAP, and SH3 domains as well as coiled coil motifs. Using a structural alignment program, we identified a 164 amino acid sequence from Bm5539 that shared high structural homology with the human IL-10 functional dimer. This truncated sequence was also structurally similar to EBV- and CMV-encoded viral IL-10. Furthermore, predicted functions using COFACTOR and COACH included cytokine receptor binding as well as growth factor receptor binding. Sequence comparisons revealed that other filarial parasites (*Wuchereria, Loa, Onchocerca*) possess Bm5539 orthologues with 80-90% homology. Moreover, the truncated IL-10-like sequence is conserved among these other filarial species. Using a baculovirus-expressed truncated form of Bm5539, we examined its ability to signal through the human IL-10R, using phosphorylation of STAT3 (pSTAT3) in human monocytes by flow cytometry as the readout. Despite its ability to bind to human IL-10R, Bm5539 did not induce pSTAT3. In contrast, when we incubated monocytes in the presence of both rBm5539 and human IL-10, we observed an 88% decrease in pSTAT3. Furthermore, this effect was Bm5539 dose-dependent. Thus, *in vitro*, recombinant truncated Bm5539 abrogated IL-10 signaling through its receptor, which demonstrates that Bm5539 acts as an IL-10R antagonist most likely through competitive binding to the human receptor. This class of parasite-encoded cytokine receptor agonists and antagonists provides an additional lens through which parasite-induced modulation of the host immune response can be examined.

INTERLEUKIN-4 SIGNALING PLAYS A MAJOR ROLE IN UROGENITAL SCHISTOSOMIASIS-ASSOCIATED BLADDER CARCINOGENESIS

Evaristus C. Mbanefo[1], Chi-Ling Fu[2], Christina P. Ho[3], Loc Le[1], Kenji Ishida[1], Michael H. Hsieh[1]

[1]*Biomedical Research Institute, Rockville, MD, United States,* [2]*Pharmacyclics, Sunnyvale, CA, United States,* [3]*Children's National Medical Center, Washington, DC, United States*

Urogenital schistosomiasis (UGS) is a class 1 carcinogen, but the exact mechanism of schistosomiasis-induced bladder carcinogenesis is largely unknown. Although the mechanistic role of IL-4 signaling and the IL-4 inducing principle from schistosomes eggs (IPSE) in driving the type-2 granulomatous chronic inflammatory and fibrotic pathogenesis due to urogenital schistosomiasis is well recognized, we are yet to demonstrate the important causative role or otherwise of IL-4R signaling in driving bladder carcinogenesis. Using our previously described intramural bladder wall injection-based mouse model of urogenital schistosomiasis, we examined the mechanistic role of IL-4 signaling in the induction of bladder pathogenesis and carcinogenesis during urogenital schistosomiasis. Readouts include histopathological comparison, assessment of urothelial proliferation and urothelial chromosomal structural abnormalities between intramural bladder wall egg-injected IL-4 receptor alpha knockout (IL-4RαKO) mice versus wildtype BALB/c. To further assess the role of IL-4 in these oncogenic urothelial changes, we assessed the role of exogenous IL-4 on urothelial cell (HCV-29) proliferation, including assessment of phosphorylation pattern of downstream regulators in the IL-4 signaling pathway. Our results show that IL-4 receptor signaling is required for the recapitulation of the pathogenic features of urogenital schistosomiasis. There was significant decrease in the size and intensity of granulomatous response to the bladder-wall injected parasite eggs in the IL-4RαKO group (p= 0.0347). Next, we showed parasite egg-induced urothelial proliferation, including evidence of urothelial hyperdiploidy in wildtype mice following bladder wall egg injection. Again, these urothelial changes were found to be dependent of IL-4 receptor signaling. We further observed features consistent with oncogenesis following urothelial exposure to IL-4 and showed that IL-4 induces urothelial cell proliferation changes and potentially bladder carcinogenesis mainly via PI3K/AKT signaling cascade.

33

TARGETING THE HEDGEHOG PATHWAY IS A NOVEL THERAPEUTIC STRATEGY TO TREAT SCHISTOSOMIASIS FIBROSIS AND PORTAL HYPERTENSION

Thiago de Almeida Pereira[1], Paula Vidigal[2], Izabela Voieta[2], Vivian Resende[2], Rafal Witek[3], Anil Jegga[4], Joseph Arron[5], Satish Madala[4], José Roberto Lambertucci[2], Anna Mae Diehl[6], Thomas Wynn[7], Philip Beachy[1]

[1]*Stanford University, Stanford, CA, United States,* [2]*Federal University of Minas Gerais, Belo Horizonte, Brazil,* [3]*Thermo Fisher Scientific, Frederick, MD, United States,* [4]*Cincinatti Children's Hospital Medical Center, Cincinatti, OH, United States,* [5]*Genentech Inc., South San Francisco, CA, United States,* [6]*Duke University, Durham, NC, United States,* [7]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States*

IL13 and Hedgehog (Hh) signaling pathways have both been implicated in the pathogenesis of fibrosis. Our aims were to determine if there is cross-talk between IL13 and Hh pathways and if Hh pathway inhibitors could be used as anti-fibrotic therapy in schistosomiasis mansoni. Hh/IL13 signaling were investigated by qRT-PCR, immunohistochemistry and ELISA in uninfected healthy transplant donors (n=22), infected hepatointestinal schistosomiasis patients (liver granulomas, low fibrosis, n=17), infected hepatosplenic patients (advanced fibrosis and portal hypertension n=72); in *Schistosoma mansoni* infected mice (wild-type, IL13Rα1-/- and TKO (IL-10-/- IL12p40-/-IL13Rα2-/-) treated with anti-IL13 antibody, Hh

pathway inhibitors (Vismodegib or AsO3 or HPI1-4) or vehicle; in mice overexpressing IL13 (plasmid) and in human liver cells stimulated with recombinant IL13 (rIL13) and treated with STAT6 siRNA or Vismodegib. Hh signaling is upregulated in human schistosomiasis and correlates with IL13, fibrosis stage and severity of portal hypertension. Overexpression of IL13 (plasmid, infected TKO mice, rIL13) induced Hh ligand production/pathway activation; lack of IL13 signaling (IL13Rα1-/- infected mice, anti-IL13 antibody, STAT6 siRNA) implicated in reduced Hh pathway, indicating that Hh signaling is dependent on IL13. STAT6 Chromatin Immunoprecipitation assay further demonstrated that STAT6 directly bind to the promoter region and regulate the transcription of Hh ligands (Ihh, Dhh) and transcription factors (Gli1, Gli2, Gli3). Smoothened antagonist Vismodegib effectively blocked fibrosis during acute schistosomiasis but failed to inhibit Hh signaling/fibrogenesis when treatment was initiated in chronic phase due to Smoothened-independent IL13-mediated Gli2 activation. Gli2 inhibition with AsO3 or HPI1-4 in the chronic phase impaired Hh signaling, fibrogenesis and inflammation. Activation of the Hh pathway in schistosomiasis is highly dependent on IL13-mediated signaling. Targeting Hh pathway with Gli2 antagonists may be a novel therapeutic strategy to treat schistosomiasis fibrosis and portal hypertension.

Schistosomiasis often evades common control efforts, in part due to poor understanding of the spatial distribution of inherent transmission risk. While praziquantel effectively clears infection, it does not provide prophylactic protection and humans are re-infected when they return to the same waterbodies. According to WHO, administration of praziquantel covers less than 10% of the at-risk population in Senegal, where the logistics of mass drug administration preclude effective implementation. To address this, we present preliminary data revealing an innovative approach using remote sensing technology and artificial intelligence to schistosomiasis vector hotspots to facilitate geographically-targeted schistosomiasis control. Previous work across 16 villages in northern Senegal, conducted seasonally from summer 2016 to present, found that the removal of submerged vegetation at water access sites resulted in a 103- and 16-fold reduction in *Bulinus* and *Biomphalaria* snails, respectively, relative to controls. This suggests that mapping locations of *Ceratophyllum demersum* via remote sensing can identify hotspots of transmission risk. Through a grant from the Digital Globe Foundation (WorldView-2 imagery) combined with fine scale drone imagery of open water, *C. demersum,* other submerged vegetation, and emergent vegetation at the study sites, we developed the ability to discriminate submerged vegetation from open water and emergent vegetation, allowing for aerial identification of schistosomiasis habitats using image classification and training tools within ArcMap 10.6. These abilities were enhanced when spectral signatures (mean RGB values and NDVI scores) for sampled sites with *C. demersum* and many vector snails and those with *C. demersum* but few (less than 10) to no vector snails were compared, with preliminary analyses indicating significant differences between the mean RGB values and NDVI scores. Ongoing analyses are identifying specific signatures to interpolate over new locations in order to identify additional productive snail habitats. The resulting model is set for ground validation in the summer 2019 field season.

35

THE ROLE OF IRRIGATED AGRICULTURE IN SCHISTOSOMIASIS RISK IN A DAMMED LANDSCAPE IN WEST AFRICA

Andrea Lund[1], David Rehkopf[1], Susanne Sokolow[2], Nicolas Jouanard[3], M. Moustapha Sam[3], Assane Fall[3], Gilles Riveau[3], Jason Andrews[1], Giulio De Leo[2], David Lopez-Carr[4]

[1]*Stanford University, Stanford, CA, United States,* [2]*Hopkins Marine Station, Stanford University, Pacific Grove, CA, United States,* [3]*Centre de Recherche Biomedicale - Espoir Pour La Sante, Saint-Louis, Senegal,* [4]*University of California Santa Barbara, Santa Barbara, CA, United States*

Since dam development in the late 1980s, the Senegal River remains hyperendemic for schistosomiasis. The dams were conceived in response to a decade-long drought and designed to improve food security in an arid region vulnerable to climate change. The expansion of irrigated agriculture, while economically beneficial, is offset by a high burden of debilitating disease. This study investigates whether the choice to pursue irrigated agriculture at the household level affects risk for schistosomiasis. Presence and intensity of re-infection following treatment were discerned from urine samples from 1414 school-aged children (SAC) in 16 study villages in February 2017. Household surveys were conducted the preceding August in the 655 households where the 1414 SAC lived. Use and characteristics of agricultural land were self-reported for each household, along with demographic and socio-economic indicators. Logistic and Poisson regression were used to determine the relationship between agricultural livelihoods and infection presence and intensity, respectively, controlling for age, sex, geographic location, domestic water contact, wealth and the presence of other high-risk occupations. Area of irrigated land was marginally significantly associated with the presence of urinary schistosome infection (odds ratio = 1.04, p = 0.057), after controlling for covariates listed above. Area of irrigated land was positively and significantly associated with the intensity of urinary schistosome infections (rate ratio = 1.05, p < 0.001). The risk of urinary schistosome infection is elevated in children living in households actively pursuing irrigated agriculture. In particular, infection intensity appears to increase with increased agricultural activity, after controlling for a number of covariates. These results suggest that the schistosomiasis risk may be as much a result of the economic choices made at the household level as a result of landscape-scale environmental change, supporting the notion that people in this setting face a trade-off between health and livelihoods.

36

DEVELOPMENT AND APPLICATION OF A COMPLETE TRI- AND TETRAMER REPEAT MICROSATELLITE CATALOG TO BRAZILIAN AND KENYAN *SCHISTOSOMA MANSONI* POPULATIONS

J**effrey D. Kovach**[1], Lúcio M. Barbosa[2], Luciano K. Silva[3], Ana Rafaela Kruemmel[4], Mitermayer G. Reis[3], Ronald E. Blanton[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Bahiana School of Medicine and Public Health, Salvador, Brazil,* [3]*Oswaldo Cruz Foundation, Gonçalo Moniz Institute, Salvador, Brazil,* [4]*Georgia State University, Atlanta, GA, United States*

Analysis of population structure is necessary for understanding how schistosomes respond to control measures. Microsatellites remain a central tool for population genetics due to their high information content, low cost, high throughput and good resolution for most questions of diversity and differentiation. Issues that remain are which markers are best and how many are needed. A majority of the published >290 microsatellites are dinucleotide repeats, which are problematic for our approach of genotyping pooled eggs from feces. A literature review identified 52 tri- and tetramer repeat microsatellites, but many were never validated. Based on previous work and new assays using clones and lab strains, this list was refined to 28 markers that produced easily read peaks, were polymorphic for lab strains and were single locus. Markers were localized to all autosomal chromosomes, nevertheless, not all of these markers were successful for all field populations. Infrapopulations from

two rural Brazilian communities (n=354) were identified that had >85% amplification success using 25 markers. To determine the ideal marker number, random sets of 5, 10, 15, and 20 markers were used to calculate differentiation between infrapopulations (Di), component populations (Dc) and between each infrapopulation and component population (Dic). As marker number increased, variance markedly decreased between 10-15 markers for all measures. We developed a Dic Assignment Ratio Test that successfully assigned infrapopulations to geographic locations only 6 km apart (98% accuracy). Assignment score variance decreased with 15-20 markers. PCA of Dic values that included a Kenyan population could assign origin 100% correctly, including between the 2 neighboring Brazilian populations. This further validated the ability of the markers and the approach to identify epidemiologically and biologically relevant features. It was difficult to infer a marker's potential usefulness prior to genotyping based on characteristics of the lab strains or any distantly related population. However, using between 10-20 randomly selected markers give results near true values.

37

IMPACT OF BIANNUAL COMMUNITY-WIDE AND SCHOOL-BASED TREATMENT ON UROGENITAL SCHISTOSOMIASIS IN NIGER

Anna E. Phillips[1], Neerav Dhanani[2], Amadou Garba[3], Amina A. Hamidou[4]

[1]*Imperial College, London, United Kingdom,* [2]*Schistosomiasis Control Initiative, London, United Kingdom,* [3]*World Health Organisation, Geneva, Switzerland,* [4]*Riseal Niger, Niamey, Niger*

This was a five-year cluster-randomized trial that compared the impact of treatment strategies in areas with high and moderate *Schistosoma haematobium* prevalence. Each village was randomly allocated to one of six possible combinations of annual or biannual community-wide treatment (CWT) or school-based treatment (SBT). Data was collected annually among children aged 5-to-8 years in first-year of school, school-aged children 9-to-12-years and 50 adults (aged 20-to-55). In total, data was collected from 167,500 individuals across 225 villages in nine districts within the Niger River valley. Overall, treatment resulted in a decrease in prevalence of infection from baseline (15.7%) to Year 5 (8.85%) across all arms. The proportion of heavily infected was low but reduced from 1.46% to 0.76% over five years. The only significant difference between study arms was seen between annual and biannual SBT in areas with a high starting prevalence. Interestingly, although adults were not targeted for treatment in SBT, a statistically significant decrease in prevalence among adults was seen in moderate prevalence areas receiving biannual SBT (10.7% to 4.8%). Although treatment was successful in reducing the burden of active infection, there was no statistically significant difference between arms with once- and twice-yearly CWT or SBT in areas with low *S. haematobium* endemicity, despite high treatment coverage. There was, however, a significant impact on infection reduction from biannual versus annual treatment in areas of moderate prevalence. These findings are an important consideration for control programs that are considering elimination, as scaling up the frequency of treatment is a commonly proposed strategy in areas of low prevalence. These findings support the idea that preventive chemotherapy alone will not eliminate schistosomiasis. Interestingly, the finding that prevalence decreased among adults in SBT arms suggests that transmission in the community can be reduced, even where only school children are being treated, which could have logistical and cost-saving implications for the national control programmes.

38

SCHISTOSOMIASIS AT DELIVERY IS ASSOCIATED WITH A HIGHER RISK OF SMALL-FOR-GESTATIONAL AGE AT BIRTH AND INFANT'S WEIGHT DURING THE FIRST YEAR OF LIFE IN BENIN

Gino C. Agbota[1], Frank T. Wieringa[2], Maiza Compos-Ponce[3], Nadine Fievet[4], Manfred Accrombessi[1], Emmanuel Yovo[1], Clémentine Roucher[5], Achille Massougbodji[1], Michel Cot[4], Valérie Briand[4], Katja Polman[5]

[1]*CERPAGE/UMR*[216]*/IRD, Cotonou, Benin,* [2]*Nutripass, UMR*[204]*, IRD, Montpellier, France,* [3]*Vrije University, Amsterdam, Netherlands,* [4]*UMR*[216]*/IRD, Paris, France,* [5]*Institute of Tropical Medicine, Antwerp, Belgium*

Schistosomiasis represents one of the most prevalent and disabling parasitic infection in sub-Saharan Africa (SSA). While schistosomiasis has been related to anemia, stunting, neurocognitive disorders in infancy, little is known about the effect of schistosomiasis during pregnancy on birth and postnatal outcomes. In animal models, maternal schistosomiasis has been associated with an increasing risk of anemia, preterm birth and low birthweight. This study aims to assess the effect of maternal schistosomiasis on the risk of small-for-gestational age (SGA) and child's weight growth from birth to year one. From 2014 to 2018, in Benin, women were followed from the pre-conception period until delivery (RECIPAL study). A sub-sample of their children was followed from birth to year one (SEPSIS study) with weight measurements at birth and each quarter. Gestational age was accurately determined by ultrasound at the 1st trimester. Maternal schistosomiasis was defined as a urinary detection of *S. haematobium* eggs at delivery. In the child, SGA was defined according to the INTERGROWTH-21st standards and the postnatal growth was assessed using weight variation from birth to year one. A logistic and mixed linear regression models were used to assess the effect of maternal schistosomiasis on child growth at birth and during the first year of life, respectively. A total of 127 mother-child pairs were included. The prevalence of schistosomiasis at delivery was 11.8%. At birth, 20.5% of newborns were SGA. From birth to year one, the mean (standard deviation) child's weight increased from 3056 (397) to 8384 (1158) g. After adjustment for potential maternal and infant confounding factors, maternal schistosomiasis was significantly associated with a higher risk of SGA (adjusted odds ratio=4.8, [1.4; 16.5], p=0.014). From birth to year one, maternal schistosomiasis was significantly associated with a lower child's weight (adjusted β= -548 g [-973; -123], p=0.011). In conclusion, these results highlight the importance of maternal schistosomiasis in SSA and reinforce the need for the preventive strategies before and during pregnancy.

39

A THEATRE-BASED APPROACH FOR ASSESSING AND INFLUENCING HIGH-RISK WATER CONTACT BEHAVIORS OF SCHISTOSOMIASIS-ENDEMIC COMMUNITIES IN ETHIOPIA AND TANZANIA

May N. Sule[1], Safari M. Kinung'hi[2], Teshome Imana[3], Emma Bewley[1], Justina Mosha[2], Teckla Angelo[2], Kamran Rafiq[4], Alex Dower[4], Feleke Zewge[3], Michael R. Templeton[1]

[1]*Imperial College London, London, United Kingdom,* [2]*National Institute for Medical Research, Mwanza Centre, Mwanza, United Republic of Tanzania,* [3]*Addis Ababa University, Addis Ababa, Ethiopia,* [4]*Acting for Health, London, United Kingdom*

This study aimed to assess the effectiveness of a theatre-based behaviour change technique to reduce high-risk water contact behaviour in schistosomiasis-endemic communities. The study was carried out in three communities: Kemise in Ethiopia; Kigongo and Mwakalima in Tanzania. Initial baseline data on knowledge, perceptions, and behaviours of the communities used mixed quantitative and qualitative research methods including questionnaires, in-depth interviews and focus group discussions. For each theatre workshop, the cohort included 18-20 community representatives, occupationally exposed people (fishermen, paddy

farmers and horse cart men), and regional government representatives participating for 4 or 5 days. The Acting for Health methodology involves drawing out the disease 'complex' i.e. everything associated with schistosomiasis; this includes the life cycle, symptoms, treatment, beliefs, water contact, use of alternative safe water supplies and improved sanitation. Findings from the complexes progressed into solutions for the prevention and control of schistosomiasis, which were then developed into sketches and scenes with relevant messaging. Characters were created from among the cohort, who developed the narrative. The play was rehearsed and performed for the local community. Questionnaires were conducted with the cohort before and after the workshops, to measure changes in perceptions and understanding. The cohort made plans for peer education and communal dissemination of the workshop messages. There is ongoing cohort follow-up through monthly community visits and social media platforms. Quantitative and qualitative surveys will be repeated in the communities after three months (in June 2019) and results will be compared against the initial baseline data to assess changes in perception and behaviours towards water contact and alternative safe water supply. The conclusions from this study will provide information to identify effective and sustainable behaviour change communication strategies to accompany water and sanitation interventions that will reduce transmission of schistosomiasis.

40

ADAPTIVE STRATEGIES FOR SCHISTOSOMIASIS CONTROL AND ELIMINATION IN HETEROGENEOUS ENVIRONMENTS: A MODEL-BASED ANALYSIS OF PUBLIC HEALTH GUIDELINES

David Gurarie[1], Charles H. King[1], Nathan C. Lo[2], Qimin Huang[1], Emily Li[1]

[1]*Case Western Reserve University, Cleveland, OH, United States,* [2]*Stanford University, Stanford, CA, United States*

Schistosoma infection is endemic in many parts of the world, and WHO has made its control and elimination a high priority. Recently, a large-scale trial and multiple country control-surveillance programs have been conducted, including SCORE (Schistosomiasis Consortium for Operational Research and Evaluation, U. Georgia) and SCI (Schistosomiasis Control Initiative, Imperial College, London). The 5-year SCORE trial explored several control strategies with different target age groups and drug regimens. However, these studies have yielded mixed results in seemingly similar settings; whereas some communities achieved substantial gains, others deemed "hotspots" were highly resilient to the effects of mass drug treatment (MDA). We developed a simulation-based study with dynamic transmission models to investigate how complex environmental and life cycle aspects (e.g. host demographics, in-host biology, transmission environment, and host-vector interactions) can drive the differential response to MDA seen in SCORE and country programs, and compared new adaptive decision making strategies (updating strategy based on initial treatment response) to current WHO guidelines and targets. The models were fit to datasets from SCORE villages and related studies. Our model-based analysis revealed many key predictors of response to MDA, including those of intermediate snail host biology and infection dynamics. The new set of adaptive strategies achieved more rapid control of schistosomiasis with fewer treatment rounds compared to WHO guidelines. Finally, an adaptive strategy that included an integrated approach (MDA + snail control with molluscicide) was found to be optimal in control.This study found that across a broad range of host communities and environmental settings that adaptive decision making with integrated strategies (MDA + molluscicide) could achieve control of schistosomiasis in shorter time periods compared to current WHO guidelines and targets. Future policy decisions should consider adopting adaptive decision making to address "hot spot" settings.

41

CEREBRAL SPINAL FLUID IN SUBARACHNOID NEUROCYSTICERCOSIS IS CHARACTERIZED BY PROINFLAMMATORY CYTOKINES AND CHEMOKINES THAT FAIL TO FULLY NORMALIZE FOLLOWING CURE

Elise M. O'Connell, Sarah Harrison, Theodore E. Nash, Thomas B. Nutman

National Institutes of Health, Bethesda, MD, United States

When treatment for racemose subarachnoid neurocysticercosis (SANCC) commences or other factors cause breakdown of the parasite integrity, an exuberant inflammatory response ensues that drives the majority of pathology, including hydrocephalus, vasculitis, and cranial nerve damage. The standard of care for SANCC includes global immune suppression with high doses of corticosteroids and concomitant anthelmintics, both often required over months to years after initial diagnosis. As an improved understanding of both the mediators required for parasite control and those primarily responsible for the host damage is necessary, we sought to measure the major pro- and anti-inflammatory cytokines and chemokines in SANCC. To this end, 16 patients with active SANCC and 16 patients with cured SANCC had CSF and serum subjected to multianalyte profiling on a Luminex™ platform. Likewise, 9 normal patients' CSF was tested in 3 pools of 3. When levels of proinflammatory cytokines/chemokines from those with SANCC were compared to CSF from healthy individuals the Th1- (IFNy, IL-12p40, IL12-p70) and Th2- (IL-10, IL-13) associated cytokines, along with GM-CSF, IL-1ra, IFN-α2b, VEGF, and the chemokines eotaxin-1, IL-8, IP-10, MIP-1α and MIP-1β were significantly elevated. Moreover, all but 4 of these same analytes (eotaxin-1, VEGF, MIP-1α and MIP-1β) were found at significantly higher levels in the CSF than in the serum from the same patients. In assessing paired CSF samples from patients before and following cure, while all analyte levels fell significantly following cure (average of 133 days post anthelmintics, range 0-452 days), IL-12p40 and IL-10 still remained statistically significantly elevated compared with normal CSF. These data suggest that neuroinflammatory processes underlie SANCC. Moreover, we have identified multiple pathways that could be targeted by specific cytokine/chemokine inhibitors reduce the pro-inflammatory milieu seen in the CNS of those with active SANCC. These findings also raise questions about the influence of persistent neuroinflammation in the pathology associated with SANCC.

42

COMBINED USE OF ANTIBODY AND ANTIGEN DETECTION TO IMPROVE THE ACCURACY IN THE DIAGNOSIS OF VIABLE INFECTION IN PATIENTS WITH PARENCHYMAL CEREBRAL CYSTICERCOSIS

G**ianfranco Arroyo**[1], Javier A. Bustos[1], Andres G. Lescano[1], Pierre Dorny[2], Erika Perez[3], Yesenia Castillo[1], Isidro Gonzales[3], Herbert Saavedra[3], E. Javier Pretell[4], Saul Santivañez[5], Robert H. Gilman[6], Armando E. Gonzalez[7], Hector H Garcia[1]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Institute of Tropical Medicine, Antwerp, Belgium,* [3]*Cysticercosis Unit, Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [4]*Department of Neurology, Hospital Nacional Alberto Sabogal, Callao, Peru,* [5]*Instituto Peruano de Parasitología Clínica y Experimental, Lima, Peru,* [6]*Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States,* [7]*School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru*

Anthelmintic therapy in parenchymal neurocysticercosis (NCC) depends on a proper diagnosis of viable cysts by neuroimages, and is confirmed by serology. The EITB assay detects serum antibodies and is highly sensitive, but poorly specific to differentiate old from viable infections, whereas antigen-detection discriminates viable cyst infections, although its performance is lower compared to EITB. Nonetheless, their combined use may improve diagnostic accuracy for viable parenchymal NCC. Neuroimages (magnetic resonance [MR] and computed tomography [CT]), and sera of 222 patients with parenchymal NCC were evaluated. Cases

were classified with viable parenchymal NCC according to neuroimages. Sera were processed by EITB and ELISA for antibody and Ag-detection. We assessed the performance of different EITB-positive cutoffs (≥1, ≥3, and ≥4 bands), alone or combined with Ag-detection in terms of their accuracy to diagnose viable parenchymal NCC (ROC-curve areas, sensitivity, and specificity) using logistic regression models. A total of 135 cases (60.81%) had viable parenchymal NCC. Adding ELISA Ag-detection to a EITB diagnosis with ≥1 reactive bands improve its accuracy to discriminate viable cyst infections (ROC-areas 0.84 versus 0.72, $p<0.001$), and a similar effect was obtained for EITB diagnosis with ≥3 reactive bands (ROC-areas 0.87 versus 0.77, $p<0.001$). Also, specificity levels significantly increased when Ag-detection was added to EITB cutoffs ≥1 bands (82.75 versus 52.87, $p<0.001$), and ≥3 bands (85.06 versus 64.37%, $p=0.001$), whereas sensitivity levels were not significantly affected. Using an EITB cutoff ≥4 bands, the addition of Ag-detection did not improve assay performance. In patients reacting to 1 to 3 bands on EITB, the addition of ELISA Ag-detection improves the accuracy to diagnose viable parenchymal NCC by increasing specificity levels in 30% or more. Combined use of antibody and antigen detection may serve to correctly diagnose NCC in patients that require anthelmintic therapy, and in rural settings to identify cases that require further neuroimaging assessment.

43

RISK FACTORS FOR BREAKTHROUGH SEIZURES IN PATIENTS WITH EPILEPSY DUE TO CALCIFIED NEUROCYSTICERCOSIS

Javier A. Bustos[1], Gianfranco Arroyo[1], Isidro Gonzales[2], Herbert Saavedra[2], Robert H. Gilman[3], Armando E. Gonzalez[1], Hector H. Garcia[1], for the Cysticercosis Working Group in Peru[1]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [3]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Neurocysticercosis is one of the main causes of epilepsy in endemic areas. Viable brain cysts follow a degenerative progression and finally resolve completely or leave a calcified scar. Some patients develop epilepsy and receive antiepileptic drugs (AED), however a proportion of these patients would still present breakthrough seizures. We performed a prospective cohort study to assess the incidence and associated risk factors of breakthrough seizures in adult patients with epilepsy and calcified NCC under AED treatment. At baseline, patients had a clinical examination, EEG test, and EITB Western Blot. Participants were under AED as indicated by their attending neurologist. Then Patients had a clinical evaluation every three months and the study team contacted them by phone every two weeks. All reported seizure events were classified according to the ILAE guideline. 210 patients that fulfilled inclusion criteria composed the final cohort and 101 of them presented new seizure during the follow-up. Maximum follow-up time was 69 months with a median of 11 months. Mean age was 36.34 (SD 13.04) years and 48.57% were males (102/210). The time-to-event analysis shows that 35.5% (95% CI 27.2%-46.5%) remains free of seizure and most of the events occurred within the first 2 years of follow-up (93%, 94/101). In the bivariate Cox analysis we found as protective factors: being male (HR: 0.67 p=0.05), history of antiparasitic treatment (HR 0.68 p=0.06), and to remain free of seizures during the last two years (HR: 0.38 p=0.001) and as risk factors: history of 10 or more seizures (HR: 1.65, p=0.01) and to present an abnormal EEG (HR: 2.52 p=0.03 On multivariate analysis, we found the same tendencies, but only a history of ten or more seizures (HR: 1.68 p=0.02) and abnormal EEG (HR 2.22 p= 0.06) remain as significant risk factors and be seizure free in previous 2 years is protective factor (HR: 0.49 p=0.02). Seizures control in calcified NCC is poor. Only 35.5% of patients remain remains free of seizure in a 5-years follow-up time, and the main risk factors are having a history of ten or more seizures, having an event within the previous 2 years and an abnormal EGG at enrolment.

44

MOVING TOWARDS IMPLEMENTATION: A COMMUNITY-BASED PARTICIPATORY RESEARCH PILOT TO PROMOTE CYSTICERCOSIS PREVENTION AND RING SURVEILLANCE IN NORTHERN PERU

M**ichelle Beam**[1], Angela G. Spencer[1], Ruth Atto[2], Roberto Camizan[2], Lauralee Fernandez[1], Ian Pray[1], Brian Garvey[1], Percy Vilchez[2], Claudio Muro Ecca[2], Ricardo Gamboa[2], Luz Maria Moyano[2], Josefina Coloma[3], Hector H. Garcia[4], Seth E. O'Neal, for the Cysticercosis Working Group[1]

[1]*Oregon Health & Science University, Portland, OR, United States,* [2]*Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*University of California Berkeley, Berkeley, CA, United States,* [4]*Universidad Peruana Cayetano Heredia, Lima, Peru*

Taenia solium is a common cause of preventable epilepsy. Ring treatment (RT), a control strategy that targets treatment for taeniasis to households in close proximity to heavily infected pigs, has been shown to be effective when surveillance is carried out by research teams. We carried out a two-year mixed-methods pilot study in 4 intervention villages (pop. 819) in Peru to promote community participation in RT, using participatory research methods previously effective for dengue prevention in Nicaragua. The intervention included a workshop in which villagers observed cyst evagination with microscopes, as well as 3 focus groups and 16 working groups in which community-identified leaders worked with study staff to design and adapt RT for their village. In 3 control villages (pop. 992), the same surveillance, reporting, and response structures were implemented without participatory development of local champions or workgroups. Key measurements included augmented knowledge, attitudes and practices (KAP) survey administered in all study households every 4 months, audio-recorded and transcribed focus groups analyzed with *in vivo* thematic coding, and seroincidence in pigs measured using EITB LLGP. The community-engaged RT intervention was effective, achieving 40% decrease in seroincidence among pigs over 16 months vs. 4% increase in the controls. Household survey results demonstrated *T. solium* lifecycle knowledge of human-to-pig transmission and pig-to-human transmission improved among adults who attended the evidence workshop compared to non-attendees, OR=2.67 (CI=1.23-5.78) and OR=3.50 (CI=1.76-6.9), respectively. Preliminary analysis of the KAP survey also demonstrated community-level behavior change. In this pilot study, we showed that surveillance and reporting can be successfully managed by community members in partnership with local health posts, when supported by research teams. Final results, salient lessons learned, and plans to refine, scale up, and test community-based RT strategy regionally through implementation research will be presented.

45

PROLONGED CYSTICIDAL TREATMENT AND CONTROL OF INFLAMMATION LEADS TO SUSTAINED INACTIVE DISEASE IN SUBARACHNOID RACEMOSE NEUROCYSTICERCOSIS

Theodore E. Nash[1], Elise M. O'Connell[1], Dima A. Hammoud[1], Lauren Wetzler[1], JeanAnne M. Ware[1], Siddhartha Mahanty[2]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*The Peter Doherty Institute for Infection and Immunity, University of Melbourne and The Royal Melbourne Hospital, Melbourne, Australia*

Subarachnoid racemose NCC (SUBNCC), the most morbid form of NCC, is caused by an aberrant proliferative form of *Taenia solium* that grows and invades the subarachnoid spaces of the brain and spinal cord. The best way to treat this form of NCC is unclear. Here we summarize the clinical course and outcomes of 34 SUBNCC patients evaluated and treated at the National Institutes of Health employing prolonged cysticidal and anti-inflammatory regimens and long term follow up. The median ages at the time of first symptom, diagnosis and enrollment were 29.7, 35.6 and 37.9 yrs, respectively. Twenty participants (58.8 %) were male and 28 (82.4%) Hispanic. The median time from immigration to development of symptoms (minimal incubation period) was 10 yrs, with an estimated median

incubation period of 22.2 yrs. Other NCC involvement was detected in half, including 20.6% with ventricular cysts, 8.8% with parenchymal cysts and 44.1% with parenchymal calcifications. Hydrocephalus, shunt insertions, infarcts and symptomatic spinal disease occurred in 55.9%, 41.2%, 17.6% and 14.7 %, respectively. Thirty required prolonged treatment with albendazole (88.2%, median duration of 0.55 yr) and/or praziquantel (61.8%; median of 0.96 yr), high dose corticosteroids (88.2%, median of 1.09 yr.), methotrexate (50%, median of 1.37 yr.), and etanercept (34.2%, median of 0.81 yr.), which led to inactive disease in 29 of the 30 treated (96.7%) a median of 4.2 yrs post treatment (range of follow up: 15 for ≥4 yrs, 20 ≥ 2 yrs, 26 > 1 yrs, 3< 1 yrs). Three patients had successfully retreated recurrent disease and 1 has continuing infection. Normalization of CSF parameters and cestode antigen levels guided treatment decisions. None of the 15 patients who reached undetectable cestode antigen values had recurrent disease. There were no deaths and, in general, moderate morbidity. Corticosteroid related side effects were common, avascular necrosis of joints (8 of 33, 24.2 %) being the most long lasting. Prolonged cysticidal treatment combined with effective control of inflammation led to good clinical outcomes and sustained inactive disease, which is likely curative.

46

PREDICTORS FOR THE DEVELOPMENT OF RESIDUAL CALCIFICATIONS AFTER ANTIPARASITIC TREATMENT OF PARENCHYMAL BRAIN CYSTICERCOSIS

J**avier A. Bustos**[1], Gianfranco Arroyo[1], Percy Soto-Becerra[1], Robert H. Gilman[2], Isidro Gonzales[3], Herbert Saavedra[3], Armando E. Gonzalez[1], Hector H. Garcia[1], for the Cysticercosis Working Group in Peru .[4]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Instituto Nacional de Ciencias Neurologicas, Lima, Peru,* [4]*Universidad Peruana Cayetano heredia, Lima, Peru*

Neurocysticercosis (NCC) is a main cause of secondary epilepsy in endemic areas. Along the natural course of evolution or as a effect of antiparasitic treatment the host´s inflammatory response leads to cyst degeneration, which in some cases ends as a calcified scar. This study assessed the proportion of residual calcification at one year in cerebral cysts that resolved after antiparasitic treatment. We evaluated data of 220 adult patients with 1 to 20 viable parenchymal NCC from three previous clinical trials were patients received standard Albendazol (ABZ-S 15mg/kg/d), increased ABZ (ABZ-I 22.5mg/kg/d) or ABZ-S plus Praziquantel (PZQ 50mg/kg/d), and corticosteroids. Patients had MRI exams at baseline and at day 180 to assess cyst resolution and a CT scan at day 360 to assess calcification. We selected cases with completed follow up (MRI at day 180 and CT at day 360). We used Poisson regression with random intercepts adjusted by covariates at the patient and cyst levels to estimate risk ratios of calcification. A total of 495 cysts in 147 patients were assessed, with an overall percentage of calcification of 38.2% (189/495 95%CI 33.9%-42.6%). Main positive predictors of cyst calcification were more than 24 months with seizures (RR: 1.24 p=0.004) and presence of perilesional edema at baseline (RR: 1.40 p=0.013). Protective factors included a higher dose of dexamethasone (RR: 0.73 p=0.032 for >6.5 mg/day), using combined antiparasitic treatment (ABZ + PZQ) (RR: 0.91 p<0.58 compared to ABZ-S and RR: 0.77 p=0.001 compared to ABZ-I), re-treatment in patients with partial cure who need an additional course of antiparasitic treatment after 6-month MRI evaluation (RR: 0.64 p<0.001 compared to patients with complete cure who do not need retreatment and RR: 0.68 p=0.024 compared to patients with incomplete cyst cure and not re-treated). This study defined factors associated with frequency of residual calcifications. These factors (such as to enhance corticosteroids dose, use of combined treatment (ABZ+PZQ), or additional courses of antiparasitic re-treatment) could be targeted in future studies intended to decrease the proportion of calcification.

47

SEASON PATTERNS IN RISK FACTORS FOR *TAENIA SOLIUM* TRANMISSION: A GPS TRACKING STUDY OF PIGS AND OPEN HUMAN DEFECATION IN NORTHERN PERU

Ian W. Pray[1], Claudio Muro[2], Percy Vilchez[2], Ricardo Gamboa[2], Hector H. Garcia[3], Seth E. O'Neal[1]

[1]*Oregon Health and Science University, Portland, OR, United States,* [2]*Center for Global Health Tumbes, Tumbes, Peru,* [3]*Universidad Peruana Cayetano Heredia, Lima, Peru*

Taenia solium (cysticercosis) is a parasitic cestode that is endemic in rural populations where open defecation is common and pigs are allowed to graze on human feces. The purpose of this study was to examine the roaming patterns of free-range pigs, and identify areas where *T. solium* transmission could occur via contact with human feces. We did this by using GPS trackers to log the movement of 108 pigs in three villages of northern Peru. Pigs were tracked for 6 days each, and tracking was repeated in the rainy and dry seasons. Maps of pig ranges were analyzed for size, distance from home, land-type, and contact with human defecation sites, which were assessed in a community-wide defecation survey. Consistent with prior GPS studies and spatial analyses, we found that the majority of pigs remained close to home during the tracking period and had contact with human feces in their home areas - pigs spent a median of 79% (IQR: 61-90%) of their active roaming time within 50 meters of their homes, and 60% of contacts with open defecation within 100 meters of home. Extended away-from-home roaming was predominately observed during the rainy season; and, overall, home range areas were 61% larger during the rainy season compared to the dry season (95% CI: 41-73%). Both home range size and contact with open defecation sites showed substantial variation between villages, and contact with open defecation sites was more frequent among pigs with larger home ranges, and pigs living in higher density areas of their village. Our study builds upon prior work showing that pigs predominately roam and have contact with human feces within 50-100 meters of the home, and that *T. solium* transmission is most likely to occur in these concentrated areas of contact. This finding, therefore, supports control strategies that target treatment resources to these areas of increased transmission. Our finding of a seasonal trend in roaming ranges may be useful for control programs relying on pig interventions, and in the field of transmission modeling, which require precise estimates of pig behavior and risk.

48

PARENTERAL ARTEMISININS ARE ASSOCIATED WITH REDUCED MORTALITY AND IMPROVED LONG-TERM BEHAVIORAL OUTCOMES BUT INCREASED HOSPITAL READMISSION IN UGANDAN CHILDREN WITH SEVERE MALARIA

A**ndrea L. Conroy**[1], Robert O. Opoka[2], Paul Bangirana[2], Richard Idro[2], Chandy C. John[1]

[1]*Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Makerere University, Kampala, Uganda*

In 2011 the World Health Organization recommended injectable artesunate as the first-line therapy for severe malaria (SM) due to its reduction of mortality compared to quinine. From 2008-2013, we enrolled 718 children in a prospective cohort study to assess long-term neurocognitive and behavioral outcomes following cerebral malaria or severe malarial anemia. Behavior was assessed one week after discharge and at 6, 12 and 24 months after discharge by the Child Behavior Checklist (CBCL) and Behavior-Related Inventory of Executive Function (BRIEF). Higher scores indicated poorer behavioral outcomes. Artemisinin use increased gradually from 0% to 91.9% from 2008 to 2013, with 156 children with severe malaria (31.1%) receiving parenteral artemisinins. Children receiving quinine vs. artemisinins were similar in demographics. All analyses including adjustment for potential confounding factors. Children receiving artemisinins compared to quinine had reduced in-hospital mortality (3.9% vs. 8.4% adjusted odds ratio (aOR) [95%

confidence interval (CI)] 0.25 [0.09, 0.72]) and reduced neurologic deficits at discharge (23.7% vs. 41.7%, aOR 0.25 [0.12, 0.54]) but no differences in neurologic deficits in follow-up. However, children receiving artemisinins compared to quinine were more likely to be readmitted to hospital multiple times (incidence rate ratio 2.01 [95% CI, 1.28-3.17]). Artemisinin compared to quinine treatment was associated with improved total behavior scores on the CBCL (beta, 95% CI: -0.28, -0.47, -0.09, p=0.004), and improved global executive function (beta, 95% confidence interval (CI): -0.36, -0.62, -0.10, p=0.007), and metacognition scores (beta, 95% CI: -0.34, -0.61, -0.08, p=0.012) on the BRIEF in children ≤5 years of age, over 24-month follow-up. No differences were observed in children over five years of age. Artemisinin compared to quinine treatment of severe malaria is associated with reduced mortality and improved long-term behavioral outcomes but increased risk of hospitalization readmission. Additional studies are needed to understand how artemisinins may increase risk of recurrent hospitalizations.

49

ACUTE KIDNEY INJURY DURING AN EPISODE OF SEVERE MALARIA IS ASSOCIATED WITH RECURRENT SEVERE MALARIA IN UGANDAN CHILDREN

Ruth Namazzi[1], Robert Opoka[1], Richard Idro[1], Paul Bangirana[1], Dibyadyuti Datta[2], Andrea Conroy[3], Chandy John[3]

[1]*Makerere University College of Health Sciences, Kampala, Uganda,* [2]*Indiana University School of Medicine., Indianapolis, IN, United States,* [3]*Indiana University School of Medicine, Indianapolis, IN, United States*

Severe malaria is associated with high post discharge morbidity and mortality. Few studies have examined the burden and risk factors for repeated malaria episodes in children discharged after an episode of severe malaria. 600 children ages 6-48 months with severe malaria (SM), and 120 age-matched healthy community children (CC) were enrolled and followed for 12 months post discharge at two hospitals in Uganda. These children were assessed for malaria whenever they presented to the hospitals with a complaint of fever or had an axillary temperature of ≥37.5˚C. Among all the enrolled children, there were a total of 2144 sick visits over the 12 months follow-up period of which 950/2144 (44.3%) were positive for malaria. Of these, 625/950 (65.8%) were severe episodes requiring hospitalization. The incidence of malaria (episodes per 100 person-years) was 0.46 for children with SM, compared to 0.29 for CC, yielding an incidence rate ratio (IRR) of 1.57 (95% confidence interval (CI) 1.29, 1.93, p<0.0001) for malaria episodes in children with SM compared to CC. The incidence of severe malaria (malaria requiring hospitalization, episodes per 100 person-years) was 0.32 for children with SM compared to 0.13 for CC (IRR, 2.47, 95% CI 1.85, 3.37). In a model that included site, age, sex, nutritional status (weight-for-age and height-for-age z scores), severe anemia, hyperparasitemia, coma, acute kidney injury (AKI), and hyperlactatemia, site and AKI at enrollment was associated with an increased risk recurrent SM in children with prior SM (IRR, 1.64; 95% CI, 1.23-2.19, p=0.0008). When analyses were stratified by site, AKI remained an independent risk factor for recurrent SM in both the low transmission site (IRR, 1.76; 95% CI, 1.09-2.86, p=0.022) and high transmission site (IRR, 1.45; 95% CI, 1.02-2.07, p=0.040). Children with SM in malaria endemic areas are at high risk for recurrent SM, and AKI at the time of first SM episode is associated with increased risk of recurrent SM. Future studies should assess how AKI and other factors lead to an increased risk of recurrent SM, to allow for prevention of future SM episodes in these children.

50

ATOVAQUONE-PROGUANIL EXPOSURE IN PREGNANCY AND RISK FOR ADVERSE FETAL AND INFANT OUTCOMES

Julie R. Gutman[1], Clinton Hall[2], Zeina G. Khodr[2], Anna T. Bukowinski[2], Gia R. Gumbs[2], Ava Marie S. Conlin[3], Natalie Y. Wells[4], Kathrine R. Tan[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Naval Health Research Center, Deployment Health Research Department and Leidos Inc., San Diego, CA, United States,* [3]*Naval Health Research Center, Deployment Health Research Department and Innovative Employee Solutions, San Diego, CA, United States,* [4]*Naval Health Research Center, Deployment Health Research Department, San Diego, CA, United States*

Malaria infection in pregnancy can lead to maternal and fetal complications. Only chloroquine (CQ) and mefloquine (MQ) are recommended for chemoprophylaxis in pregnancy, but parasite resistance and contraindications may leave some women with no recommended options. Limited data suggest atovaquone-proguanil (AP), a highly effective antimalarial, might be suitable for malaria prevention in pregnancy, but more evidence is needed. Data for pregnancies and live births among active duty women, 2003-2014, from the Department of Defense Birth and Infant Health Research program were linked with pharmacy data to determine antimalarial exposure, defined as a drug dispensation date in pregnancy. Multivariable Cox and logistic regression models were used to assess the relationship between antimalarial exposure and fetal and infant outcomes, respectively. Among 199,017 pregnancies, 51 were exposed to AP, 159 to MQ, and 133 to CQ. Overall, 15.1% of unexposed pregnancies and 27.5%, 13.8%, and 4.5% of pregnancies exposed to AP, MQ, and CQ, respectively, ended in miscarriage (adjusted hazard ratios [aHR]=1.72, 95% confidence interval [CI]=1.02-2.90; aHR=1.03, 95% CI=0.68-1.57; and aHR=0.38, 95% CI=0.17-0.85, respectively); similar results were seen for the outcome "fetal loss," which included both miscarriage and stillbirth. Among 160,944 live births, 36 were exposed to AP, 130 to MQ, and 122 to CQ. Compared with unexposed infants, there was a statistically insignificant increased risk for a composite poor live birth outcome (preterm birth, low birthweight, or small for gestational age) among AP exposed infants (adjusted odds ratio=2.02, 95% CI=0.88-4.60), but not MQ or CQ exposed infants. Birth defects were seen in 3.0% of unexposed and 5.6%, 0.8%, and 0.8% of infants exposed to AP, MQ, and CQ, respectively. The small number of AP exposed pregnancies highlights the difficulty in assessing safety. While definitive conclusions are not possible, these data suggest further research of AP exposure in pregnancy and fetal loss is warranted.

51

AETIOLOGIES OF ACUTE FEBRILE ILLNESS AMONG CHILDREN IN A CONTEXT OF DECLINING MALARIA TRANSMISSION

T**echalew Shimelis Woldkiros**[1], Birkneh Tilahun Tadesse[2], Fitsum Belay[2], Gill Schierhout[3], Susana Vaz Nery[1], John Kaldor[1]

[1]*University of New South Wales, Sydney, Australia,* [2]*Hawassa University, Hawassa, Ethiopia,* [3]*The George Institute, Sydney, Australia*

The introduction of rapid malaria rapid diagnostic tests greatly improved malaria case management and reduced unnecessary anti-malaria drug prescription. However, the management of non-febrile illnesses, which now represent a higher proportion of cases, remains problematic in resource-constrained countries where laboratory facilities are limited, with a particular issue being over-prescription of antibiotics. In Ethiopia, the relative importance of various infectious causes of non-malaria febrile illnesses is unknown. This study aimed to assess aetiologies of fever (temperature of ≥37.5 ^{0}C or a history of fever in the past 48 hours) in children aged ≥2 months and <13 years presenting to Hawassa University Hospital, southern Ethiopia from May 2018 to February 2019. Clinical and demographic data were gathered from 433 participants using a clinical case report form. Various samples (blood, urine, stool, throat swab, CSF) were analysed using culture, microscopy and rapid diagnostic tests (RDTs) to identify pathogens. In addition to fever, the most common symptoms

were cough (53.1%, 230/433) and diarrhoea (18.3%, 79/433). Malaria and HIV infection were diagnosed in 3.2% (14/431) and 0.7% (3/431) of children, respectively. Blood stream bacterial infections were detected in 5.5% (23/421) of children, with *S. aureus* (3.8%, 16/421) the leading isolate. Urinary bacterial pathogens were isolated in 18.2% (73/402) of children, with *E. coli* (9.2%, 37/402) and *Klebsiella* species (4%, 16/402) predominant. Among 56 children with gastroenteritis from whom stool specimens were obtained, there were findings of rotavirus/adenovirus (17 cases, 30.4%) by RDT, intestinal parasites (9 cases, 16.1%) by microscopy and *Salmonella/Shigella* (2 cases, 3.6%) by culture. Group A *Streptococci* (16.1%, 28/174) and *S. pneumonia* (16.9%, 30/178) antigens were detected via RDTs in children with acute respiratory illness. This study represents the first systematic investigation of fever causes in children in Ethiopia, and supports the need for improved access to routine laboratory services to ensure appropriate management of specific pathogens.

52

ALGORITHM IN THE DIAGNOSIS OF FEBRILE ILLNESS USING PATHOGEN-SPECIFIC RAPID DIAGNOSTIC TESTS

Sunil Pokharel[1], Lisa J. White[2], Ricardo Aguas[2], Olivier Celhay[2], Karell G. Pelle[3], Sabine Dittrich[3]

[1]*Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [2]*Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [3]*Foundation for New Innovative Diagnostics (FIND), Geneva, Switzerland*

Acute Undifferentiated Febrile Illnesses (AUFI) caused by malaria, dengue, scrub typhus, typhoid and other aetiologies are common presentations in developing countries. In the lack of clinical expertise and reliable laboratory tests, patients are empirically treated with antimicrobials. Rapid diagnostic tests (RDTs) are increasingly available and used but lack optimal diagnostic accuracy. There are no guiding protocols and algorithms for the application of these tests. Using prevalence data of five common febrile illnesses from India and Cambodia and performance characteristics (sensitivity and specificity) of relevant pathogen-specific RDTs, we used a mathematical model to predict the probability of correct identification of each disease when diagnostic testing occurs either simultaneously or sequentially in various algorithms. We developed a web-based application of the model to visualise and compare output diagnostic algorithms when different disease prevalence and test performance characteristics are introduced in the model (https://moru.shinyapps.io/diagnostic-algorithm-app/). Diagnostic algorithms with appropriate sequential testing predicted better diagnostic outcomes in both settings when compared to simultaneous testing. The best performing sequential diagnostic algorithms were different in India and Cambodia due to varying disease prevalence. Simultaneous testing is not appropriate for diagnosis of AUFIs with presently available tests, which discourages the unsupervised use of multiplex diagnostic tests. The implementation of adaptive algorithms can predict better diagnosis and add value to the available RDTs. The web application of the model can serve as a tool to identify the optimal diagnostic algorithm in different epidemiological settings, whilst taking into account local epidemiological variables and accuracy of available tests.

53

AN EPIDEMIOLOGICAL STUDY OF *TOXOCARA* SPECIES IN HOUSTON PARKS USING A NOVEL PCR-BASED METHOD

David McCormick[1], Timothy Erickson[1], Donna L. Tyungu[2], Rojelio Mejia[1]

[1]*Baylor College of Medicine, Houston, TX, United States,* [2]*The University of Oklahoma Health Sciences Center, Oklahoma, OK, United States*

Toxocariasis is a parasitic infection caused by *Toxocara* species that can lead to visceral and ocular migrans and cognitive impairment. These parasites are found in the feces of dogs (*T. canis*) and cats (*T. cati*) and excreted into the soil, where they can survive for many years. Toxocariasis is an underdiagnosed neglected parasitic infection in the United States. Persons living in low socioeconomic communities are at increased risk. We examined soil samples from 15 urban and suburban parks in Houston, Texas using molecular methods. Approximately 30-70 grams of soil collected from the upper centimeter of dirt in two separate locations for each park. Soils were concentrated and DNA extracted using a novel method. Including mechanical disruption in a bead-beating device, and then processed using the MP FastDNA spin kit for soil preparation. Multi-parallel real-time quantitative PCR (qPCR) was performed using primers specific to *T. canis* and *T. cati* qPCR performed in duplicate for all samples, and a positive control with known amounts of *T. canis* and *T. cati* eggs used for each experimental run. *Toxocara canis* DNA was detected in 20% of parks located in the zip code with the lowest median income ($22,424/year). No *Toxocara* spp DNA was identified from parks located in zip codes with median income >$50,000/year. No samples contained DNA from *T. cati.* This study suggests that *T. canis* is an environmental contaminant in public spaces in Houston and associated with the socioeconomic status of the surrounding population. Use of a novel molecular method will allow for rapid screening of soil samples to further characterize this public health problem. Further studies will include a total of 45 parks and school playgrounds with quantification of the contamination burden. Environmental data will be cross-referenced to patient chart records with toxocariasis at Texas Children's Hospital and Harris Health systems. Comparisons of the socioeconomic status of those infected to the presence of *Toxocara* contamination will further show how parasites unequally affect those living in poverty.

54

EFFECTS OF IVERMECTIN ON INTRAOCULAR MICROFILARIAE IN PERSONS WITH ONCHOCERCIASIS IN EASTERN GHANA

Hong Augustine[1], Nicholas O. Opoku[2], Charles W. Goss[1], Christopher L. King[3], Gary J. Weil[1], Michael E. Gyasi[4]

[1]*Washington University School of Medicine, St. Louis, MO, United States,* [2]*University of Health and Allied Sciences, Hohoe, Ghana,* [3]*Case Western Reserve University, Cleveland, OH, United States,* [4]*St. Thomas Eye Hospital, Accra, Ghana*

Ivermectin (IVM) is widely used for treatment for onchocerciasis. We performed a prospective cohort study in Ghana to assess the kinetics of microfilarial (Mf) clearance from the eye after IVM 150 ug/kg in 261 patients with palpable nodules and Mf-positive skin snips. This study is the first to use optical coherence tomography (OCT) in the setting of onchocerciasis. OCT is analogous to an optical ultrasound that composes microscopic, high-resolution cross-sectional images of the retina. Skin Mf counts (geo mean Mf /mg and range) were 12.6, 2-86 at baseline and 0, 0-11 at 3 months. 28.5% of participants had at least 1 Mf in their anterior chambers (MfAC, total for both eyes, range 1-150) at baseline, and 3.2% of patients had at least 1 MfAC three months after treatment. 97.8% of participants with 1-9 MfAC and 95% of those with at least 10 MfAC at baseline had complete clearance at 3 months. No Mf were observed in the posterior segment. MfAC counts were correlated with baseline skin Mf counts ($p<0.001$). 52.1% of persons with high skin Mf counts (at least 30 Mf/mg) had MfAC compared to 26.5% of subjects with skin Mf counts between 1 and 10 Mf/mg. 84% of participants experienced at least one adverse event (AE) after IVM, with itching skin (46.4%), headache (28.6%) and joint or muscle pain (26%) being most common. Ocular itching (9.4%), eye pain (5.7%) and watery eyes (1%) were the most common ocular AEs. No severe or serious AEs were observed. OCT was useful for evaluating and monitoring glaucoma, chorioretinal atrophy, retinal edema and retinal anatomy. Subjects with severe eye disease or media opacities were excluded prior to enrollment. Among enrolled participants, baseline eye diseases (not including uncorrected refractive error) included glaucoma (7.3%), macular degeneration (2.3%), macular scarring (3.1%), severe cataract (1.9%), unexplained vision loss (1.5%), central corneal scarring (1.1%), and other (2.7%). Minimal changes occurred in ocular anatomy following IVM. In conclusion, our study demonstrated that IVM is safe and effective for reducing MfAC counts at 3 months; 6 month data will be presented at the meeting.

55

CHIKUNGUNYA VIRUS DISSEMINATION FROM THE MIDGUT OF *AEDES AEGYPTI* - INSIGHTS INTO THE MECHANISM

Alexander W.E. Franz, Yingjun Cui, Asher M. Kantor, DeAna G. Grant, Tommi A. White

University of Missouri, Columbia, MO, United States

The mosquito, *Aedes aegypti*, is a vector for emerging arboviruses such as chikungunya (CHIKV). The midgut epithelium is the initial tissue of the mosquito to be infected with an arbovirus following its oral acquisition from a vertebrate host. Following its replication within the midgut epithelium, the virus disseminates to secondary tissues including the salivary glands. The tissue barrier separating the midgut epithelium from the hemocoel, the midgut escape barrier, is an important determinant of mosquito vector competence for arboviruses. The midgut epithelium is surrounded by a multi-layered basal lamina (BL) composed of collagen IV and laminin. In ultrastructural (TEM and FIBSEM) time course studies, we showed that CHIK virions accumulated at the BL around 24 h pbm and were found between BL strands until 32 h pbm. However, at 48 h pbm, virions no longer strongly amassed towards the BL. This indicates that there is a time window post-bloodmeal acquisition during which CHIKV is disseminating from the midgut. An accompanying SEM time course study indicated that following bloodmeal acquisition, the midgut tissue and the BL were overstretched and partly damaged, which could be critical factors allowing virions to escape the midgut through the BL. We now show that fluorescent dye conjugated gold nanoparticles with a 5 nm diameter efficiently diffused through the BL of midguts dissected from sugarfed and BSA-fed mosquitoes. In contrast, 50 nm (approximate virion size) gold nanoparticles diffused only through the BL of those midguts that were obtained from BSA-fed mosquitoes. Importantly, one week after receiving the BSA meal, the midgut BL was still permissive for both 5 and 50 nm gold nanoparticles, whereas midguts of sugarfed mosquitoes, independent of their age, remained permissive for 5 nm gold nanoparticles only. These findings suggest that although the overall midgut structure relaxes during gradual meal digestion, the pore size exclusion limit of the BL remains (at least 10x) increased for a prolonged period following complete meal digestion.

56

SAFETY OF THE MEASLES-VECTORED CHIKUNGUNYA VACCINE (MV-CHIK) IN HEALTHY VOLUNTEERS PREVIOUSLY EXPOSED TO CHIKUNGUNYA VIRUS

Katrin Ramsauer[1], Clemente Diaz[2], Irma Febo[2], James Powell[2], Aileen Rivera Maldonado[2], Raimund Vielnascher[1], Paul B. Keiser[3]

[1]*Themis Bioscience GmbH, Vienna, Austria,* [2]*University of Puerto Rico, San Juan, Puerto Rico,* [3]*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

The pathophysiology of chronic chikungunya is not well understood but several mechanisms have been proposed including immunopathology triggered by chikungunya antigens. The vaccine candidate MV-CHIK consists of a measles vaccine Virus expressing the polyprotein gene of chikungunya, resulting in production of chikungunya virus-like particles. We have recently shown safety and immunogenicity of the vaccine in phase 1 and phase 2 clinical trials. In anticipation of field trials and vaccination campaigns in areas of on-going or previous chikungunya transmission, we sought to evaluate the safety of MV-CHIK among subjects primed by natural infection. The study was conducted in Puerto Rico, which has a relatively high seroprevalence of chikunugunya following an epidemic in 2014 but negligible chikungunya transmission during the study period. A total of 34 healthy volunteers ages 21 to 50 were enrolled. After openly cohorting by baseline chikungunya IgG (16 seropositive and 18 seronegative) volunteers were randomized to receive either MV-CHIK or MMR in a 4:1 ratio. Adverse events (AEs) were solicited for 28 days after each of two intramuscular doses and unsolicited AEs were collected for a full year. The percentage of individuals reporting solicited AEs by unblinded cohort was not significantly higher in subjects previously exposed to chikungunya: fatigue (31% among pre-exposed vs 33% of unexposed), malaise (13 vs 44%), headache (31 vs 72%), diarrhea (19 vs 33%), nausea/vomiting (0 vs 28%), joint pain (31 vs 22%) and injection site pain (19 vs 61%). There were no related clinically significant laboratory abnormalities and no grade 3 or serious adverse events. C-reactive protein levels after the first vaccination did not increase significantly in either cohort suggesting that vaccine-induced inflammation was negligible. This study supports the safety of MV-CHIK in healthy volunteers primed by prior chikungunya infection. Additional studies to assess the safety of MV-CHIK in previously exposed populations are planned.

57

AEDES AEGYPTI SIALOKININ I MODULATES SIGLEC-1 EXPRESSION ON HUMAN MONOCYTES AND MACROPHAGES DURING CHIKUNGUNYA VIRUS INFECTION

Siew-Wai Fong[1], Jeslin J.L Tan[2], Vaishnavi Sridhar[1], Tze-Kwang Chua[2], Siti Naqiah Amrun[2], Guillaume Carissimo[2], Fok-Moon Lum[2], Kini R Manjunatha[1], Lisa F.P Ng[2]

[1]*National University of Singapore, Singapore, Singapore,* [2]*Singapore Immunology Network, Agency for Science, Technology and Research, Singapore (A*STAR), Singapore, Singapore*

Chikungunya virus (CHIKV) infection is initiated by the bite of infected female *Aedes* mosquitoes when viruses along with saliva are released below the skin of human host. Several reports have indicated that mosquito bites can enhance arbovirus infection and enhancement is attributed to proteins in the mosquito saliva. The saliva of female *Aedes aegypti* mosquito contains a 1400-Da Sialokinin peptide with vasodilatory properties typical of a tachykinin. Here, the effect of Sialokinin I was studied in primary human monocytes and monocyte-derived macrophages (MDMs). The expression of Siglec-1 (or CD 169) on human monocytes/macrophages is critical for activation of immune responses to viral infections in the human host. Increased expression of Siglec-1 on peripheral CD14+ monocytes was observed in CHIKV-infected patients. Interestingly, Sialokinin I significantly down-regulated Siglec-1 expression in both primary human monocytes and MDMs. The modulation effect of Siglec-1 expression by Sialokinin I was abrogated by antagonism of human neurokinin receptors of which the nonpeptide neurokinin receptor antagonists (CP-96345 and GR-159897) potently restricted downregulation of Siglec-1 expression by Sialokinin I on both monocytes and MDMs. Collectively, our findings reveal a novel role for Sialokinin I, which regulates Siglec-1 expression on monocytes/macrophages, affecting human host immune response to CHIKV infection. Modulation of Sialokinin I activity and neurokinin receptors may offer a new approach to the design of anti-CHIKV therapy.

58

RISK FACTORS FOR INFECTION WITH CHIKUNGUNYA AND ZIKA VIRUSES IN A COMMUNITY-BASED COHORT STUDY IN SOUTHERN PUERTO RICO

Laura E. Adams[1], Liliana Sanchez-Gonzalez[1], Robert Rodriguez Gonzalez[2], Kyle Ryff[1], Dania M. Rodriguez[1], Chelsea Major[1], Emma M. Little[1], Olga Lorenzi[1], Mark Delorey[1], Freddy A. Medina[1], Manuela Beltran[1], Jorge L. Muñoz-Jordán[1], Stephen H. Waterman[1], Marianyoly Ortiz[3], Vanessa Rivera-Amill[2], Gabriela Paz-Bailey[1]

[1]*Division of Vector-borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States,* [2]*Ponce Health Sciences University, Ponce, PR, United States,* [3]*Puerto Rico Vector Control Unit, San Juan, PR, United States*

Communities Organized for the Prevention of Arboviruses (COPA) is a cohort study in southern Puerto Rico, initiated in 2018 to measure arboviral disease risk and provide a platform to evaluate interventions. Chikungunya virus (CHIKV) caused a large outbreak in Puerto Rico in 2014, followed by a Zika virus (ZIKV) outbreak in 2016. To identify risk factors for infection, we assessed previous CHIKV infection and recent ZIKV infection among COPA participants. Participants aged 1-50 years

(y) were recruited from randomly selected households in study clusters. Each participant completed an interview and provided a blood specimen, which was tested by anti-ZIKV IgM MAC-ELISA assay and anti-CHIKV IgG ELISA assay. We assessed individual, household, and community factors associated with a positive result for CHIKV or ZIKV after adjusting for confounders. Preliminary results are presented. During 2018-2019, 3,422 participants were enrolled; 59% were female and median age was 30y (IQR: 18-42). Among 3,176 participants tested for ZIKV, 462 (15%) had evidence of recent infection. Infection risk increased with older age, from 7% among 1-10y olds up to 18% among 41-50y olds (OR 3.1; 95% CI 1.9-5.1). Males had an increased risk of Zika infection compared with females (OR 1.4; 95% CI 1.1- 1.7). Participants with home screens (OR 0.6; 95% CI 0.5-0.8) and air conditioning (OR 0.6; 95% CI 0.6-0.9) were at lower risk for ZIKV infection compared to those without. ZIKV infection also decreased with higher income and later recruitment dates. Among 1,542 participants tested for CHIKV, 491 (32%) had evidence of previous infection. CHIKV infection did not differ by age or sex. Lower CHIKV infection was associated with home screens (OR 0.5; 95% CI 0.3-0.6) and air conditioning (OR 0.5; 95% CI 0.4-0.6). CHIKV infection also varied by study cluster of residence, employment status, and insurance type. Different infection patterns were observed for recent ZIKV infection and previous CHIKV infection by age, sex, time of specimen collection, and study cluster. However, the presence of screens and air conditioners in the home decreased infection risk from both viruses by as much as 50%.

59

SAFETY AND IMMUNOGENICITY OF A REPLICATION DEFICIENT SIMIAN ADENOVIRAL VECTORED CHIKUNGUNYA VACCINE: A PHASE I, FIRST-IN-HUMAN, DOSE ESCALATION TRIAL

P**edro M. Folegatti**[1], Kate Harrison[1], Fernando Ramos Lopez[1], Mark W. Tilley[1], Cesar Lopez-Camacho[1], Young C. Kim[1], Lorena Preciado-Llanes[1], Shannan L. Rossi[2], Ian Poulton[1], Daniel Jenkin[1], Mehreen Datoo[1], Yrene Themistocleous[1], Alison Lawrie[1], Rachel Roberts[1], Katie Ewer[1], Eleanor Berrie[1], Adrian Hill[1], Arturo Reyes-Sandoval[1]

[1]*University of Oxford, Oxford, United Kingdom,* [2]*University of Texas Medical Branch, Galveston, TX, United States*

Chikungunya virus (CHIKV) is an alphavirus, transmitted by *Aedes* mosquitoes. The disease consists of an acute illness characterized by fever, rash, myalgia and generally symmetrical, peripheral, and often incapacitating polyarthralgia and/or polyarthritis, which lasts weeks to months. The most cost-effective means of controlling the spread of CHIKV is by vaccination. There is currently no licensed vaccine against CHIKV and although there are several candidates in pre-clinical development, only a few have entered clinical trials. Replication deficient vectors, as opposed to recombinant replication competent live attenuated viruses, avoid the risks of disseminated disease in immunocompromised hosts while maintaining the advantages of native antigen presentation, elicitation of T cell immunity and the ability to express multiple antigens. We developed a chimpanzee adenoviral vector expressing the structural polyprotein cassette of CHIKV (ChAdOx1 Chik) and conducted a Phase I, first-in-human, clinical trial. Twenty-four participants received a single intramuscular injection at 3 escalating doses in Oxford, UK. The trial is now fully recruited and is expected to be completed within 6 months. Preliminary data shows that ChAdOx1 Chik was well tolerated at all doses with no serious adverse events related to the vaccine reported to date. All local and systemic adverse events were self-limiting and short-lived, although higher reactogenicity has been observed at the top dose. A single unadjuvanted dose of ChAdOx1 Chik was immunogenic, eliciting high neutralising antibody titres and an increase in antibody levels was seen at D28 and D56 post vaccination compared to D0 in all groups. Responses against the structural CHIKV antigens show significant increases in IFN-γ levels, peaking at D14 post vaccination and there were no significant differences in ELISpot responses between dosage groups. The safety, cellular and humoral immunogenicity results up to 6 months post vaccination will be presented at the meeting. The results of this trial support a subsequent Phase Ib clinical trial of ChAdOx1 Chik in an endemic region.

60

ROBUST IMMUNOGENICITY OF 1- AND 2-DOSE SERIES OF AN ADJUVANTED VLP-BASED CHIKUNGUNYA VACCINE

Sean R. Bennett[1], Jason Mendy[2], Lisa Bedell[1], Kelly L. Warfield[3], Paul Shabram[2], Paul-Andre deLame[3]

[1]*Emergent BioSolutions, Inc., Redwood City, CA, United States,* [2]*Emergent BioSolutions, Inc., San Diego, CA, United States,* [3]*Emergent BioSolutions, Inc., Gaithersburg, MD, United States*

Rapid and durable protection against Chikungunya is highly desired, but currently no licensed vaccine exists. An unadjuvanted Chikungunya virus-like particle (CHKV-VLP) candidate vaccine has previously demonstrated a good safety profile and robust immunogenicity in phase 1 and 2 trials in both CHKV-naive and CHKV-exposed adults. Here we report interim results of a phase 2 trial of alum-adjuvanted CHKV-VLP. Healthy US adults 18 to 45 years of age (n=415) were given a 1- or 2-dose series at doses of 6 to 40 mcg over a 2- or 4-week period. Serum neutralizing antibody (SNA) was assessed by a luciferase-based assay and 80% neutralization titers (NT80s) were calculated. All regimens were well-tolerated, with mostly mild or moderate injection site pain in 21% to 49% of subjects, and no vaccine-related severe (Grade 3 or higher) or serious adverse events or discontinuations. Seroconversion occurred in 74% to 98% of subjects by 7 days after 1 dose, and in all subjects by 28 days after the last dose (the primary endpoint). Peak NT80s were similar to those seen after natural CHKV infection. The immune response was persistent, with mean NT80s of 196 to 457 through 6 months. Long-term follow-up is ongoing. These findings strongly support the potential utility and continued development of an alum-adjuvanted VLP-based vaccine for the prevention of CHKV infection, including future studies in a wider age range.

61

CHIKUNGUNYA: PHASE 1 CLINICAL DEVELOPMENT OF A SINGLE-SHOT LIVE-ATTENUATED VACCINE

Nina Wressnigg, Romana Hochreiter, Andrea Fritzer, Robert Schlegel, Andreas Meinke

Valneva, Vienna, Austria

VLA1553 is a live-attenuated Chikungunya virus (CHIKV) vaccine candidate designed for active immunization of the general population living in endemic regions, as well as serving as a prophylactic measure for travelers to endemic areas or areas at risk for an upcoming outbreak. The replicating CHIKV vaccine comprises a deletion of 60 amino acids in the nsP3 gene encoding the non-structural replicase complex protein leading to attenuation of the virus *in vivo*. VLA1553 is based on the La Reunion strain of the East Central South African genotype, is produced in Vero cells and purified by centrifugation, ultrafiltration, batch-chromatography and sucrose gradient centrifugation. In preclinical models of CHIKV disease (mice and non-human primates) the vaccine candidate demonstrated to be highly attenuated as evidenced by the absence of clinical manifestations typically associated with wild-type CHIKV infections in addition to strongly reduced viremia and inflammatory cytokine levels. Moreover, VLA1553 was highly immunogenic, induced a strong and long-lasting as well as protective neutralizing antibody response against a high dose wild-type CHIKV challenge. A blinded, randomized phase 1 clinical study investigating the safety and immunogenicity of three dose levels administered intramuscularly as a single-shot immunization designed to elicit long-term immunological memory is currently ongoing (NCT: NCT03382964). Initial blinded data across all dose groups up to Day 28 after a single immunization showed an excellent immunogenicity profile with 100% seroconversion rates (proportion of subjects achieving a CHIKV-specific neutralizing antibody titer of NT50≥20) and a high GMT of 648. The safety profile is acceptable supporting further development: no serious adverse events or adverse events of special interest occurred

up to Day 28. Further analysis of safety and immunogenicity up to Month 6 including a homologous challenge will elucidate the optimal dose for further development of the vaccine and at the same time provide an early indication of efficacy paving the way to late stage clinical development.

62

VACCINATION WITH A *TRYPANOSOMA CRUZI* CYCLOPHILIN 19-DELETION MUTANT CONFERS COMPLETE PROTECTION AGAINST ACUTE CHAGAS DISEASE IN MICE

B**ijay Kumar Jha**[1], Sanjay Varikuti[1], Nicholas Bishop[1], Gregory Pedroso dos Santos[2], Manjusha Kulkarni[1], Sergio Schenkman[3], Abhay Satoskar[1], Bradford Scott McGwire[1]

[1]*The Ohio State University, Columbus, OH, United States,* [2]*Universidade Federal de São Paulo, Estado de Sao Paulo, Brazil,* [3]*Universidade Federal de São Paulo, São Paulo, Brazil*

Human infection with *Trypanosoma cruzi* causes Chagas disease, a major public health problem that affects up to 8 million people world-wide and causes 10,000 deaths per year. Chronic infection with this parasite is the leading cause of heart failure in Latin America. There are no therapeutic or prophylactic vaccines for this infection, however they are urgently needed since the incidence of Chagas is increasing and there are only two drugs approved for treatment of the infection. Previously, we described that *T. cruzi* the cis-prolyl isomerase, cyclophilin 19 (Cyp19), binds to and neutralizes antimicrobial peptides promoting parasite survival and potentiating parasite infectivity. We have also recently found that Cyp19 is expressed in and secreted by all parasite stages. In order to understand the potential role of this protein in parasite virulence we generated a double allelic deletion mutant in Cyp19. This mutant replicates slowly *in vitro* and generates more abundant metacyclic trypomastigotes than wildtype parasites. Mutant metacyclics are complement-resistant as are wildtype parasites, but fail to infect host cells *in vitro* and cannot establish a productive infection. High-dose inoculation of mutant parasites does not produce infection in either immunocompetent A/J mice or in immunocompromised STAT-1$^{-/-}$ and STAT-4$^{-/-}$ mice which are normally hyper-susceptible to *T. cruzi* infection. Importantly, despite the inability to replicate in mice repeated inoculation produces escalating anti-parasite immunity. These immunized mice are protected from developing tissue parasitization, clinical infection and death from high-dose wildtype parasite challenge. These results indicate that *T. cruzi* Cyp19 is important for the infectivity of *T. cruzi* and that this mutant parasite line is a promising potential vaccine candidate for Chagas disease.

63

CHEMICAL CARTOGRAPHY OF HOST-PARASITE-MICROBIOME INTERACTIONS REVEALS NEW MECHANISMS OF DISEASE TOLERANCE IN AMERICAN TRYPANOSOMIASIS

Ekram Hossain[1], Chaoyi Wu[1], Sharmily Khanam[1], Danya A. Dean[1], Adwaita Parab[1], Shelley Kane[1], Karina Flores[1], Sharon Lostracco-Johnson[2], Diane Thomas[2], Danyang Li[3], Christine Woelfel-Monsivais[1], Mitchelle Katemauswa[1], Camil Gosmanov[1], Krithivasan Sankaranarayanan[1], **Laura-Isobel McCall**[1]

[1]*University of Oklahoma, Norman, OK, United States,* [2]*University of California San Diego, La Jolla, CA, United States,* [3]*Beijing Normal University, Beijing, China*

American trypanosomiasis (Chagas disease) is a neglected parasitic infection caused by *Trypanosoma cruzi* parasites. Over 7 million people worldwide are *T. cruzi*-positive, but only 30-40% of infected individuals will develop cardiomyopathy, megaoesophagus and/or megacolon. The mechanisms leading to symptomatic Chagas disease are still poorly understood, particularly for gastrointestinal (GI) manifestations. To address this issue, we implemented a novel integration of 3D mapping, analytical chemistry (liquid chromatography-tandem mass spectrometry), microbiome science and big data analytics ("chemical cartography") to systematically determine the local impact of *T. cruzi* infection throughout the GI tract, in a mouse model of Chagas disease. Increases in the magnitude of disturbance in local tissue metabolism were observed in the oesophagus and in the colon during the transition from acute to chronic stage, while only limited impact on chronic-stage metabolism was observed in the stomach and small intestine, sites not associated with GI Chagas symptoms. Infection also altered local microbiota composition and diversity. Major infection-associated chemical differences include increases in specific members of the acylcarnitine family of molecules, and changes in short-chain acylcarnitine distribution. Based on these observations and our prior data on acylcarnitine alterations in cardiac Chagas disease, we then directly investigated the role of carnitine in Chagas disease pathogenesis. Strikingly, treatment of infected mice with 1.3% carnitine in drinking water prevented infection-related mortality with no changes in parasite burden, indicating that carnitine supplementation induces disease tolerance in Chagas disease. Overall, these results significantly expand our understanding of Chagas disease pathogenesis, with potential for the development of new therapeutic regimens. More broadly, these results highlight the ability of chemical cartography approaches to provide insight into tropical disease pathogenesis, with translational applications for infectious disease drug development.

64

THE ROLE OF MONOCYTE MOBILIZATION IN RESPONSE TO SAND FLY BITES IN INCREASED TRANSMISSION FROM MAMMALIAN HOSTS TO THE SAND FLY VECTOR

Andrea Paun, Joanna G. Valverde, David L. Sacks

National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States

Mammalian hosts in areas endemic for leishmaniasis can be exposed to multiple and repeated bites from sand flies over a short period of time. Previous work in our laboratory has shown that prior exposure of *Leishmania donovani*-infected hamsters to sand fly bites results in an increased rate of parasite transmission during subsequent exposure to a new set of sand sand flies after 24 hours. By artificial feeding, parasites could be picked up from both the skin and the blood, though only transmissions from the blood correlated with the direct feeding. Building upon these observations we describe a mobilization of monocytes, including parasite-infected cells, neutrophils and lymphocytes into the blood in the 24 hours following the fly bite. The magnitude and cellular composition of this systemic response was found to differ between naïve and *L. donovani*-infected animals; monocytes being preferentially mobilized in infected animals compared with a greater neutrophil response in naïve animals. These differences suggest that there is a host-vector-parasite interaction that the parasite takes advantage of in order to increase its potential transmission to new hosts. We are now utilizing *L. donovani*-infected mice in order to gain a better understanding of the mechanisms underlying the host response to vector bites that promotes the cyclical transmission of *Leishmania*.

65

MYELOID AND LYMPHOID IMMUNE EXHAUSTION PROFILE DURING MURINE VISCERAL LEISHMANIASIS

Diogo Valadares[1], Richard E. Davis[2], Ellen Kiser[1], Mary Wilson[1]

[1]*University of Iowa, Iowa City, IA, United States,* [2]*University of Utah, Salt Lake City, UT, United States*

Leishmaniasis is a chronic disease of reticuloendothelial organs that is usually controlled by TH1-type CD4 T cells. Anti-microbicidal responses are ineffective during disease progression, and it is reported that T cells in humans and dogs with visceral leishmaniasis (VL) express markers of cell exhaustion. We hypothesized that myeloid cells provide counter-receptors for inhibitory receptors on T cells at the local sites of *Leishmania infantum* infection, inhibiting T cell effector functions. We therefore examined inhibitory receptors PD1, LAG3, CTLA4 and TIM3 on lymphoid cells, and counter-receptors PDL1, MHCII, CD80 and Galectin 9 on myeloid cells using flow cytometry, throughout 5 weeks of infection. In livers and spleens of infected BALB/c mice, significant increases in myeloid cells

expressing PD-L1 and lymphoid cells expressing PD-1 were detected. In livers of infected mice, an increased population of neutrophils with DC features (CD11c+MHCII+) expressing PD-L1 and IL-10 was also observed. In all infected samples an increased DC subset with a reduced expression of MHCII, CD80 and CCR7 and higher expression of Galectin 9, PD-L1 and IL-10, suggesting a pro- T cell exhaustion profile of those cells in infected mice. Furthermore, CD4 and CD8 T cells in infected mice expressed higher levels of the exhaustion markers LAG3, CTLA4 and PD-1 than uninfected mice, with greater proportions of CD8 than CD4 T cells in livers and blood demonstrating the exhausted phenotype. Using PEPCK tetramers and CD11b and CD49d surface markers to identify antigen (Ag)-experienced cells, the majority of Ag-experienced CD8 T PD-1+ cells in liver and spleens produced IL-10, whereas most Ag-experienced CD4 T PD-1+ cells produced IFN-γ at the time points studied[MW1] . The data suggest either CD8 T cells assume an exhausted phenotype earlier than CD4 T cells, or CD8 T cells are the predominant exhausted T cells. Data also suggest that both DC and neutrophil subsets could represent a pro-exhaustion myeloid population that may influence the unresponsiveness of lymphocytes in infected tissues during visceral leishmaniasis.

66

SUBNATIONAL MAPPING OF UNDER-FIVE MORTALITY AND ITS DETERMINANTS IN KENYA SINCE 1965

P**eter M. Macharia**[1], Emanuele Giorgi[2], Pamela Thuranira[1], Noel K. Joseph[1], Benn Sartorius[3], Robert W. Snow[4], Emelda Okiro[1]

[1]*Kenya Medical Research Institute-Wellcome Trust Research Programme, Nairobi, Kenya,* [2]*Lancaster Medical School, Lancaster University, Lancaster, United Kingdom,* [3]*Public Health Medicine, School of Nursing and Public Health, University of KwaZulu-Natal, Durban, South Africa,* [4]*Kenya Medical Research Institute-Wellcome Trust Research Programme, Nairobi, Kenya and Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom*

Kenya did not achieve MDG 4 despite substantial health funding and significant declines in under five mortality (U5M) since 2000. The launch of SDG 3 to ensure healthy lives and wellbeing calls for approaches to quantify variations in U5M and its determinants at sub national units of decision making to inform *what* interventions are needed and *where* needed. We characterized spatio-temporal variation and inequalities in child survival and its determinants since 1965 at decentralized health planning units (counties) in Kenya. Household surveys and census data undertaken between 1989 and 2015 were assembled and aligned to the respective counties. Demographic techniques and Bayesian spatio-temporal Gaussian process regression were applied to estimate annual U5M per county between 1965 and 2015. Bayesian spatio-temporal areal level models were applied to produce reliable estimates for key determinants between 1990 and 2015 due to insufficient sample size at county level. 23 surveys and 3 censuses were assembled between 1989 and 2015. Nationally, U5M reduced by 62%, from 1965 to 2015. However, the decline was heterogeneous ranging between 19% and 80% across the counties. Inequalities in child survival declined significantly between counties but, disparities continued to persist by 2015. The progress towards meeting international developments goals on U5M was sub-optimal. The coverage of most the health interventions such as household bed net coverage and Vitamin A supplementation increased over time while major risk factors e.g. malaria risk declined. Changes observed in intervention coverage and risk factors were uneven across time and between counties with varying rates of change. These results form a baseline for tracking local (county) targets under the decentralized governance and the SDGs. In spite of significant progress made in child survival, U5M in Kenya remains high and heterogeneous across counties. Focused allocation and targeted interventions are required to achieve further improvement in child survival and continued decline in subnational inequalities.

67

A SYSTEMATIC REVIEW OF PROACTIVE CASE DETECTION BY COMMUNITY HEALTH WORKERS FOR THE MANAGEMENT OF COMMON CHILDHOOD ILLNESSES

Caroline Whidden[1], Julie Thwing[2], Julie Gutman[2], Clemence Leyrat[1], Kassoum Kayentao[3], Ari Johnson[4], Brian Greenwood[1], Daniel Chandramohan[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*University of Sciences Techniques and Technologies of Bamako, Bamako, Mali,* [4]*University of California San Francisco, San Francisco, CA, United States*

Many low- and middle-income countries (LMICs) are scaling Community Health Worker (CHW) programs as an evidence-based strategy to improve child health, but the expected benefits are often not realized. Proactive case detection by CHWs may overcome barriers to access seen with a conventional community-based approach. We systematically reviewed the evidence of the effects of proactive case detection by CHWs in LMICs on access to care, morbidity, and mortality for common childhood illnesses. Published studies were identified via electronic health databases from 1978 to 2017. We included randomized, non-randomized, controlled before-after, and interrupted time series studies and assessed their quality for risk of bias. We reported measures of effect the same way study investigators reported them and synthesized by outcomes of mortality, disease prevalence, hospitalization, and access to treatment. We calculated risk ratios (RRs) as a principal summary measure, with confidence intervals adjusted for cluster design effect. We identified 14 studies of 11 interventions from nine LMICs that met inclusion criteria. There was considerable diversity in intervention design and implementation, comparison, choice of outcomes, and study quality, which precluded meta-analysis. There was low quality evidence that proactive case detection may reduce neonatal (RR 0.43 - 1.07) and infant mortality (RR 0.52 - 0.94), increase access to effective treatment (RR 1.24 - 1.29), and have little or no effect on wasting and stunting (RR 0.61 - 1.16). There was very low quality evidence that it may reduce mortality among children under five years of age (RR 0.04 - 0.80), prevalence of infectious diseases (RR 0.06 - 1.02), hospitalization (RR 0.38 - 1.26), and increase access to prompt treatment (RR 1.00 - 2.39). Proactive case detection by CHWs may reduce child mortality, morbidity, and improve access to care. This review calls for more rigorous study designs in operational research around proactive case detection, standardization of outcomes and their measurement, and more complete reporting of complex intervention design and implementation.

68

USING PARTNERSHIPS AND EXISTING SYSTEMS TO IMPROVE THE QUALITY OF INTEGRATED SERVICES FOR SICK CHILDREN AT PATENT AND PROPRIETARY MEDICINE VENDORS IN TWO STATES IN NIGERIA

Kate E. Gilroy[1], Abimbola Olayemi[2], Adedeji Onayade[3], Olujide Arije[3], Miranda Gyang[2], Felix Ogaga[4], Chinwe Nweze[5], Olusegun Afolabi[3], Abimbola Phillips[3], Michel Pacqué[1]

[1]*MCSP/JSI, Washington, DC, United States,* [2]*MCSP/JSI, Abuja, Nigeria,* [3]*Institute of Public Health, Obafemi Awolowo University, Ile-Ife, Nigeria,* [4]*MCSP/JSI, Lokoja, Nigeria,* [5]*MCSP/JSI, Abakaliki, Nigeria*

Patent and Proprietary Medicine Vendors (PPMVs) are a significant source of treatment for sick children in Nigeria, although concerns are widespread that PPMVs provide poor quality services. The Maternal and Child Survival Program, in close coordination with public and private state and national-level stakeholders, worked to improve and assess the quality of integrated community case management (iCCM) services for childhood malaria, diarrhea, and pneumonia that PPMVs provide. The "Enhancing Quality iCCM through PPMVs and Partnerships (EQuiPP)" approach supported 833 registered PPMVs to improve service quality in 4 local government areas in Kogi and Ebonyi states through initial iCCM training and joint supervision, with supervisors from the public primary health centers and peers within

PPMV associations. Coordination with suppliers, wholesalers, and PPMV associations aimed to improve the availability of essential commodities at PPMV shops through market forces. To evaluate EQuiPP, we conducted baseline (March 2018), midline (July 2018), and endline (November 2018) assessments that included direct observation of services provided to sick children with clinical re-examination and inventory audits at a sample of 176 PPMV shops in each assessment. EQuiPP improved the availability of essential stocks: 30% of PPMV shops had rapid diagnostic tests (RDTs) on the day of the survey at baseline, improving to 83% at endline. The availability of artemisinin combination therapies, zinc and amoxicillin dispersible tablets (AmoxDT) at PPMV shops improved by 20%, 52% and 91% points between baseline and endline, respectively. Among febrile children, only 11% received an RDT to confirm malaria status at baseline, compared to 95% at endline. The percent of children with cough and fast breathing (suspected pneumonia) given AmoxDT was 0% at baseline and 66% at endline. EQuiPP is a promising approach to improve availability of medications and quality of child health services at PPMV shops. Improvements observed after initial training were sustained at endline; future studies should examine trends in the quality of PPMV services over longer periods.

69

PREVALENCE OF CHILD MARRIAGE IN RURAL BANGLADESH AND ASSOCIATIONS WITH ADVERSE PREGNANCY OUTCOMES

Kyu Han Lee[1], Atique I. Chowdhury[2], Qazi S. Rahman[2], Sanwarul Bari[2], Shams El Arifeen[2], Emily S. Gurley[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*ICDDRB, Dhaka, Bangladesh*

Bangladesh has one of the highest rates of child marriage in the world with an estimated 18% of girls married by the age of 15 and 52% married by the age of 18. Early marriage is a primary health concern as they lead to pregnancies in children and are associated with adverse pregnancy outcomes and poor health outcomes among newborns. We used data from an ongoing demographic surveillance system to examine annual trends in child marriage in Baliakandi, a rural subdistrict of Bangladesh. Further, we examined whether early pregnancies were associated with adverse pregnancy outcomes. Starting in September 2017, we visited households in Baliakandi every 2-4 months to identify pregnancy outcomes and child deaths. Married women provided their marriage date through a pregnancy history questionnaire. We used generalized estimating equation models to examine the association between maternal age and 1) stillbirths or spontaneous abortions and 2) neonatal mortality among singleton pregnancies. We identified a total of 49,794 marriages from 1990-2018. During this period, the proportion of marriages to children decreased from 72% to 54%, largely due to a reduction among girls <13 years (23% to <1%). However, marriages among older adolescents (16-17 years) became more prevalent (17% to 29%) and a notable increase was observed from 2017-2018 among girls 13-15 years (19% to 24%). In girls <16 years, 13% of singleton pregnancies resulted in stillbirths compared to 8% in older adolescents and 6% in adults 18-34 years. Neonatal deaths occurred in 1% of live births in girls <16 years compared to 6% in older adolescents and 2% in adults. The odds of stillbirth and spontaneous miscarriage were significantly higher among older adolescents (OR: 2.3, 95% CI: 1.3-4.2) and the odds of neonatal death were significantly higher among girls 16-17 (OR: 2.5, 95% CI: 1.5-4.2). Although child marriage has become less common among young girls, it remains common practice for older adolescents. Given the associated risks with child health and the Bangladesh government's commitment to ending child marriage, regular assessments should be made on legal protections against child marriage.

70

FACTORS ASSOCIATED WITH CONSENT FOR MINIMALLY INVASIVE TISSUE SAMPLING (MITS) TO IDENTIFY THE CAUSE OF DEATH FOR STILLBIRTHS AND CHILDREN UNDER THE AGE 5 IN BANGLADESH

S**hahana Parveen**[1], Farzana Islam[1], M. Saiful Islam[1], Hossain M. Sazzad[1], Farhana Hasnat Khan[1], Md. Al-Mamun[1], Mahadi Hasan[1], Safiur Rahman[1], Salim Reza[1], Sazzad Hossain Khan[1], Tonmoy Sarkar[1], Kamal Ibne Chowdhury[1], Dalia Yeasmin[1], Kyu Han Lee[2], Sanwarul Bari[1], Shams El Arifeen[1], Emily S. Gurley[2]

[1]*International Centre for Diarrhoeal Diseases Research, Bangladesh (icddr,b), Dhaka, Bangladesh,* [2]*John Hopkins University, Baltimore, MD, United States*

Minimally invasive tissue sampling (MITS), is a post-mortem procedure, can be used to determine the etiology of death, especially in countries with sparse data. However, people often confuse MITS with full autopsies, and many families may not provide consent for the procedure. Our objective was to identify factors associated with MITS consent in the Child Health and Mortality Prevention Surveillance study. From September 2017 to March 2019, we identified stillbirths and deaths among children <5 years in Baliakandi, a sub-district, Bangladesh, and approached their parents for MITS consent. Consent rates were compared by family involvement and maternal factors using χ^2. P-values <0.1 were considered meaningful differences. Later, we conducted in-depth interviews with 39 families to explore the factors that contributed their decisions about MITS. We approached to the parents of 78 stillbirths and child deaths for MITS consent and 35 (45%) of them agreed. Consent was more common among parents when the deceased child was multiparous (56% vs. 39%, p=0.080) and among parents who had a history of miscarriage and/or child loss (67% vs 40%, p=0.051). We also found death type (57% stillbirth vs 40% child death, p=0.18) and mother or maternal relatives' involvement in decision making (54% vs 36%, p=0.11) had some influence on consent. In-depth interviews, all respondents mentioned that they consented for MITS for the benefit of the society. Nearly two-thirds of families who consented to MITS did so to learn the cause of death and how to prevent it. The reported reasons for disagreement were an aversion to needle punctures in the body (39%), a lack of attentiveness to listen the content due to emotional vulnerability (30%) and a desire to hurry home to begin burial activities (30%). Findings suggest that prior child loss experience drove parents' interest in learning why their child died and for future prevention. Encouraging the mother and maternal relatives to participate in the decision-making, psychological support and sharing MITS result to families with further prevention measure may promote MITS acceptance and thereby prevent further child mortality.

71

INVOLVING COMMUNITY VOLUNTEERS FOR REAL-TIME IDENTIFICATION OF STILLBIRTHS AND UNDER-5 CHILD DEATHS IN A CHILD HEALTH PROGRAM IN RURAL BANGLADESH

A**bdullah Al Masud**[1], Shahana Parveen[1], Saiful Islam[1], Faruqe Hussain[1], John Blevins[2], Ahoua Kone[2], Kyu Han Lee[3], Qazi Sadeq-ur Rahman[1], Palash Mutsuddi[1], Sanwarul Bari[1], Shams El Arifeen[1], Emily S. Gurley[3]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Rollins School of Public Health, Emory University, Atlanta, GA, United States,* [3]*John Hopkins University, Baltimore, MD, United States*

The Child Health and Mortality Prevention Surveillance (CHAMPS) Network is ongoing at sites in 7 countries in Africa and south Asia, including in Baliakandi, a rural sub-district in Bangladesh (population 220,000), that aims to identify specific causes of stillbirths and deaths among children under 5. CHAMPS uses minimally invasive tissue sampling (MITS) to provide information about the cause of death. MITS must be conducted shortly after death, before burial. Since many children die at home, receiving death notifications in a timely manner is a major challenge.

Therefore, 870 male and female community volunteers from 261 villages within the CHAMPS surveillance site were recruited to quickly identify stillbirths and deaths occurring in the community. Community volunteers were oriented to CHAMPS activities, including information about MITS procedure and were asked to report stillbirths and deaths of children under 5 to CHAMPS hotline number. Community volunteers were paid different amounts of incentives range from 0.5 to 2.3 USD for the each notification they provided within 4 hours to 1 month. The amount of which was inversely proportional to the elapsed time from the time of death to notification. We analyzed data from the first 8 months of the community volunteer engagement (August 2018 to March 2019) to understand the effectiveness of involving community volunteers to notify stillbirths and deaths of children under 5 in the community within a timeframe to allow for MITS consent. Among the 254 death notifications received by CHAMPS during the 8 month period, 98 (39%) notifications were received from community volunteers. Among those, 37% were received within 3 hours of death, 21% were received within more than 3 to 8 hours of death and 42% were received more than 8 hours after death. Death or stillbirth occurred at home was 37%, occurred at heath facilities was 54% and occurred on the way to the hospital was 9%. The use of community volunteers to notify deaths in real-time was shown to be a valuable approach that could be used in other public health programs through proper motivation, incentives, periodical performance monitoring and refresher training.

72

MINIMALLY INVASIVE TISSUE SAMPLING AMONG HOSPITAL-BASED CHILD DEATHS IN BLANTYRE, MALAWI: THE ROLE OF SOCIAL RELATIONSHIPS AND POWER DYNAMICS

D**ave Mankhokwe Namusanya**[1], Sarah Lawrence[2], Andrew Hamuza[1], Cornelius Huwa[3], Maureen Kelley[4], Sassy Molyneux[4], Wieger Voskuijl[5], Donna Denno[2], Nicola Desmond[1], Dennis Chasweka[3]

[1]*Malawi Liverpool Wellcome Trust, Blantyre, Malawi,* [2]*University of Washington, Seattle, WA, United States,* [3]*University of Malawi, College of Medicine, Blantyre, Malawi,* [4]*University of Oxford, Oxford, United Kingdom,* [5]*Global Health Child Group, Amsterdam University Medical Care, University of Amsterdam, Amsterdam, Netherlands*

Undernutrition is an underlying cause in almost 45% of child deaths globally. Case fatality among children hospitalized with acute malnutrition remains high even with guideline-based care. Cause of death (CoD) is often unknown. Minimally invasive tissue sampling (MITS) using needles to obtain post-mortem samples for histopathological and microbiologic investigation is increasingly being utilized to improve child and adult CoD attribution. "MITS in Malawi" employs standard MITS and a novel post-mortem endoscopic intestinal sampling approach to better understand CoD among children with acute illness and/or malnutrition enrolled in a parent study who die during hospitalization. This formative study aimed to understand sociocultural factors that may impact MITS acceptability in this setting in Malawi. We conducted eight focus group discussions with various hospital cadres and community members to explore attitudes towards MITS and to inform consent process design. We used thematic content analysis drawing on a conceptual framework developed from prior MITS acceptability work. Social relationships at hospital, as well as at community and individual levels, emerged as important factors likely to inform MITS acceptability. Feelings of power over decision-making, trust in healthcare systems facilitated by active involvement of caretakers in child's treatment, and content of communication about MITS were also important dimensions informing acceptability. Other facilitating factors included the potential for MITS to add CoD information to aid in sense-making of death, to reduce witchcraft accusations in communities, and to contribute to medical knowledge and new interventions. The findings informed how we developed an appropriate and contextualised consent approach within a hospital-based cohort study. They further highlight that understanding social relationships and power dynamics within healthcare systems, community social and cultural contexts, and how MITS is placed within existing parent studies are critical components to consider in consent processes and acceptability of MITS in facility-based settings.

73

H-IPSE, A PATHOGEN-SECRETED HOST NUCLEUS-INFILTRATING PROTEIN (INFILTRIN), HAS A LIMITED RANGE OF TARGET CELLS

Olivia Lamanna[1], Evaristus Mbanefo[2], Kenji Ishida[2], Luke Pennington[3], Theodore Jardetzky[3], Franco Falcone[4], Michael Hsieh[1]

[1]*Children's National Medical Center, Washington, DC, United States,* [2]*Biomedical Research Institute, Rockville, MD, United States,* [3]*Stanford University, Stanford, CA, United States,* [4]*The University of Nottingham, Nottingham, United Kingdom*

IPSE (IL-4 Inducing Principle from *Schistosoma mansoni* Eggs) is one of the most abundant egg secreted proteins of the *Schistosoma* parasite. IPSE has been shown to interact with IgE on the surface of basophils to induce IL-4 secretion, trigger Breg cell activation, and, as an infiltrin, translocate into host cell nuclei to alter host transcription. This suggests that IPSE is an important immunomodulator. IPSE binds to DC-SIGN and the mannose receptor, suggesting it may have specific cellular receptors. Our objective was to determine extracellular versus intracellular localization of H-IPSE (a *Schistosoma haematobium* ortholog of IPSE) in various cell types. H-IPSE variants H03 and H06 were conjugated to Alexa-488 fluorophore and incubated with urothelial, endothelial, immature dendritic (iDC), hepatocyte, and neuronal cells. Flow cytometry was used to quantify cells that were IPSE positive. Trypan blue (TB) quenching of extracellular Alexa-488 was used to measure intracellular H-IPSE signal. When urothelial, endothelial, and iDC cell lines were incubated with 2ug/mL of H03 for 24 hrs, the percentage of cells positive for intra/extracellular H03 was 69, 46, and 90%, respectively. Upon TB quenching, intracellular signal was 65, 42, and 84%, respectively. H03 was internalized by hepatocytes at a reduced rate and was not internalized by neurons. These results were similar for both H03 and H06 regarding urothelial cells and iDCs. However, H06 was less efficient than H03 in extra/intracellular localization with endothelial cells. H-IPSE's minimal internalization by hepatocytes suggests that IPSE may not be hepatotoxic, contradictory to previous findings. Our unpublished data showing that IPSE alleviates capsaicin receptor-mediated pain, led us to postulate that IPSE acts through the capsaicin receptor on nociceptive neurons. However, our findings indicate that IPSE does not interact with neurons and is inducing its effects through an alternative pathway. Additional research is underway on IPSE's internalization mechanisms to provide further insights into its therapeutic potential and role in the pathogenesis of schistosomiasis.

74

VACCINATION WITH CATHEPSIN B USING A YS1646 *SALMONELLA ENTERICA* TYPHIMURIUM VECTOR PROTECTS MICE AGAINST *SCHISTOSOMA MANSONI* CHALLENGE

Adam Hassan, Nicholas H. Zelt, Dilhan J. Perera, Brian J. Ward, Momar Ndao

Research Institute of the McGill University Health Centre, Montreal, QC, Canada

Schistosomiasis is among the most important neglected tropical diseases and *Schistosoma mansoni* threatens hundreds of millions of people in >50 countries worldwide. *S. mansoni* resides adjacent to mucosal tissues as adult worms. Several candidate vaccines are in pre-clinical and clinical development, but none is designed to elicit a mucosal response. We have repurposed an attenuated *Salmonella enterica* Typhimurium strain (YS1646) to produce such a vaccine. We have initially targeted cathepsin B (catB), a digestive enzyme important for both juvenile and adult worms. Using a series of plasmid constructs that exploit the type 3 secretory system of *Salmonella*, the expression of catB was screened in monomicrobial culture and in RAW 264.7 cells. Two strains bearing promising promoter-secretory signal pairings were selected for *in vivo*

evaluation (nirB_SspH1 and SspH1_SspH1). Female C57BL/6 mice were immunized twice, 3 weeks apart. Serologic (IgG) responses to catB were monitored by ELISA and, three weeks after the second dose, mice were challenged with 150 *S. mansoni* cercariae. Mice were sacrificed 7 weeks later to assess adult worm and egg burden (liver and intestinal tissue), granuloma size and egg morphology. Responses were highest in the animals immunized with the nirB_SspH1 YS1646 followed by catB IM. All vaccinated animals had reduced worm and egg burden in both the intestines and liver. In the nirB_SspH1 + catB IM group, the worm and intestine/liver egg burden were reduced 93.1% and 79.5%/90.3%. Granuloma size was reduced most significantly in the nirB_SspH1+ catB IM group (34.74 ± 3.35 μm^2 versus 62.22 ± 6.08 μm^2 in the saline controls. Many of the eggs in the granulomas of vaccinated animals had abnormal morphology. Furthermore, preliminary data shows elevated cathepsin B-specific IgA levels in mice immunized with the nirB_SspH1 strain. Targeting the digestive enzyme catB using a multimodality approach elicits both systemic and mucosal immune responses and provides protection against *S. mansoni* challenge. These novel YS1646-vectored candidate vaccines show considerable promise to address the need for a *S. mansoni* vaccine.

75

USE OF BODIPY LABELLED ATP ANALOGUE IN THE DEVELOPMENT AND VALIDATION OF A KINASE BINDING ASSAY FOR SCREENING OF KINASE INHIBITORS

Bernardo Pereira Moreira[1], Tom Armstrong[2], Izabella Cristina Batista[1], Naiara Clemente Tavares[1], Camilla Valente Pires[1], Marina de Moraes Mourão[1], Franco Falcone[3], Lodewijk Dekker[4]

[1]*Rene Rachou Research Centre/CPqRR - FIOCRUZ, Belo Horizonte, Brazil,* [2]*School of Chemistry, University of Nottingham, Nottingham, United Kingdom,* [3]*School of Pharmacy, Division of Molecular Therapeutics and Formulation, University of Nottingham, Nottingham, United Kingdom,* [4]*School of Pharmacy, Division of Biomolecular Science and Medicinal Chemistry, University of Nottingham, Nottingham, United Kingdom*

Human schistosomiasis is a neglected tropical disease that affects more than 230 million people worldwide. It is caused by a parasitic trematode that can survive for years or decades in the mammalian host. As a key strategy to survive in the host, *Schistosoma* integrates specific extracellular signals to generate an appropriate cellular response in order to inhibit or modulate host immune responses. One of the families of proteins involved in such processes are the eukaryotic Protein Kinases (ePK), which regulate tissue-specific biological activities such as cell proliferation, differentiation and survival. The primary catalytic function of PKs is based on the binding of ATP and phosphorylation of specific substrates. Hence, the ATP binding pocket is considered one of the main focuses for inhibitor design, with an increasing number of inhibitors now approved as drugs. Based on that information and considering the need for simple single-tool assay technologies with which one could assess 'all' kinases, we developed a fluorescence polarization-based assay to screen PKs against a library of small molecules predicted to block its ATP binding site. We used BODIPY ATP-y-S as probe to measure the shift in the polarization of a light beam when passed through the sample. We were able to optimize the assay using commercial Protein Kinase A (PKA) and H7 efficiently inhibited the binding of the probe when added to the reaction. Furthermore, we were able to employ the assay to validate in silico screening of a library of more than 80000 small-molecule compounds predicted to dock into the ATP binding site of PKA. Additionally, the assay was also employed to assess the binding activity of heterologous *S. mansoni* c-jun N-terminal kinase (JNK). Thus, this polarization assay is suitable to assess the binding capabilities of PKs as well as to screen larger libraries of compounds that may target PKs by blocking the ATP binding site.

76

HEADS OR TAILS? DIFFERENTIAL TRANSLATIONAL REGULATION IN CERCARIAL HEADS AND TAILS OF SCHISTOSOME WORMS

James R. Hagerty, Emmitt R. Jolly

Case Western Reserve University, Cleveland, OH, United States

Schistosomes are responsible for over 218 million cases of human schistosomiasis in 78 countries. Infection occurs when free-swimming cercariae penetrate host skin and initiate developmental progression into adult worms. Transcriptomic studies of cercariae reveal abundant mRNAs associated with energy metabolism and host invasion. However, the cercaria is mostly transcriptionally quiescent, suggesting that most mRNAs are primed prior to cercarial escape from the snail host. The use of transcriptomics to understand protein functionality presumes that transcription and translation are functionally coupled and the cercarial stage has categorically been treated as a single unit for -omic analysis. Per contra, the relationship between transcription and translation in infectious cercariae has not been described. To understand the correlation between transcription and translation in cercariae, we separately measured nascent translation levels in cercarial heads, cercarial tails and in the developing schistosomula, the next life cycle stage. The loss of the cercarial tail is essential for the transformation from a cercaria to a schistosomulum. We observed that translation increases during the first 72-hours after tail loss and that translational inhibitors such as anisomycin had little effect on the viability of the cercaria though some showed behavioral changes. When we tested nascent translation in cercarial heads, cercarial tails, and whole cercariae we found that translation is significantly upregulated in the cercarial tail when compared to the cercarial head and that translation was undetectable in heads using immunofluorescent image quantification ($p=.0005$). These data represent a major shift in how we understand the cercarial stage. The cercarial head is mostly transcriptionally and translationally quiescent while being sufficient for progression into a schistosomulum. In addition, transcription and translation are not linked in S. mansoni cercaria. Thus, our current conceptual approach of treating the cercaria as a single functional unit for -omic studies may be insufficient to understand cercarial development.

77

COMPARING CATHEPSIN B VACCINE FORMULATIONS IN A PRE-CLINICAL SCHISTOSOMIASIS MODEL

Dilhan J. Perera[1], Adam Hassan[1], Yimei Jia[2], Michael McCluskie[2], Risini Weeratna[2], Momar Ndao[1]

[1]*Research Institute McGill University Health Center, Montreal, QC, Canada,* [2]*National Research Council Canada; Human Health Therapeutics Research Center, Ottawa, ON, Canada*

Schistosomiasis (Schisto) is one of the most important helminthic parasitic diseases in the world with >700 million people at risk, and >200 million infected. Liver cirrhosis can also occur, due to egg deposition and granuloma formation in hepatic tissues. Our lab has shown effective vaccine candidates using *Schistosoma mansoni* cathepsin B (SmCB) as an antigen (Ag) in combination with either CpG dinucleotides (CpG) or Montanide ISA VG 720 (Montanide), reducing parasite burden up to 70% in initial formulations. The goal of this project is to screen other vaccine adjuvants and test their ability to protect from a *S mansoni* infection. Seven vaccine formulations were tested in a mouse model of schisto, each consisting of 20 ug of recombinant SmCB protein with adjuvant. The adjuvants tested included Montanide, aluminum hydroxide (alum), alum/CpG, sulfated lactosyl archaeol archaeosomes (SLA), and alum/monophosphoryl lipid A (alum/MPL). After immunization, vaccines formulated with Montanide, and alum/CpG demonstrated the highest Ag-specific total IgG titers as well highest IgG2c antibodies. Vaccine groups SLA, and alum/MPL produced the highest Ag-specific IgG1 antibodies. Previous data suggests that mixed antibody response, IgG1 and IgG2c, results in higher parasite reduction upon challenge. After challenge, adult worm reductions of 78.9%, 68.5%, and 68.5% were found in the

Montanide, SLA, and Alum/MPL groups respectively. Hepatic eggs were reduced the greatest by Montanide (75.5%), SLA (59.2%), and Alum/MPL (78.7%), and intestinal eggs were reduced the greatest by Montanide (78.9%), SLA (77.1%), and Alum/MPL (77.7%). The data obtained suggests that a vaccine formulated with several of the adjuvants tested could surpass the WHO's minimum threshold of 40% for an effective vaccine.

78

THE HUMAN TELOMERASE REVERSE TRANSCRIPTASE, HTERT IS ABSENT IN *SCHISTOSOMA MANSONI*: EFFECT OF INFECTION AND DRUG TREATMENT ON GENE EXPRESSION OF THE *BIOMPHALARIA GLABRATA* ORTHOLOG IN THE HOST-PATHOGEN RELATIONSHIP

Nana Adjoa Pels, Swara Yadav, Olayemi Akinyele, Freddie Dixon, Carolyn Cousin, Matty Knight

University of the District of Columbia, Washington, DC, United States

The human telomerase reverse transcriptase, commonly known as hTERT, is the vital catalytic sub-unit of telomerase. Together with telomerase RNA, the enzyme complex plays a significant role in the maintenance of telomeres at the ends of chromosomes. Regulation of hTERT is closely linked to cell growth states governing either malignancy or senescence. For this reason, hTERT is a target in developing anti-cancer therapy to block elevated hTERT activity in order to inhibit cell proliferation in cancer. We recently hypothesized that malignant cancer is a parasite in its host and, therefore, the snail host/parasite relationship serves as a good animal model to examine the regulation of cancer related transcripts, including the snail homolog of hTERT in the *Biomphalaria glabrata/Schistosoma mansoni* animal model. To test this hypothesis, we utilized an *in silico* approach to identify the snail hTERT ortholog. The human hTERT amino acid sequence was identified and utilized to interrogate the *B. glabrata* genome in NCBI. Results revealed a significant match with a *B. glabrata* hTERT ortholog (E-value of $2e^{-86}$). Further searches using the compatible parasite *Schistosoma mansoni* of *B. glabrata* as the query showed that unlike the snail host, the parasite lacks an hTERT ortholog. To determine the regulation of the snail hTERT ortholog in relation to the host-pathogen relationship, Gene Specific Primers were utilized for end- point PCR analysis. Results revealed the amplification of a 400bp amplicon at 2hr post- exposure of *B. glabrata* to *S. mansoni* miracidia. In addition, from real time qPCR analysis, results showed that the transcript encoding the snail hTERT ortholog was upregulated in *B. glabrata* at 2hr post-exposure to *S. mansoni.* To further validate whether hTERT plays a role in the snail host:schistosome relationship an anti-telomerase drug BPPA was utilized to block schistosomiasis in the snail host. Other anti-telomerase drugs are being evaluated in the snail-schistosome interaction to test the hypothesis that this host-pathogen relationship is a good model to study malignant cancer as a parasitic disease.

79

DUAL TRANSCRIPTOMICS PROFILING OF THE MOUSE BLADDER WALL INJECTION MODEL OF *SCHISTOSOMA HAEMATOBIUM* INFECTION

Kenji Ishida[1], Evaristus Mbanefo[1], Nirad Banskota[1], James Cody[1], Loc Le[1], Neil Young[2], Michael Hsieh[1]

[1]*Biomedical Research Institute, Rockville, MD, United States,* [2]*The University of Melbourne, Victoria, Australia*

Schistosoma haematobium parasitic flatworms have been estimated to infect over 100 million people. Symptoms include bloody urine, bladder pain, and other bladder dysfunction, and the infection is also associated with the development of bladder cancer. Additionally, animal models to study bladder pathology associated with *Schistosoma haematobium* infection are limited. Here, we use the mouse bladder wall injection model to profile the transcriptome of both the host bladder and parasite eggs to better understand the genes and pathways associated with the infection. We injected 6000 *S. haematobium* eggs into the bladder wall of BALB/c mice and performed RNA-seq on the egg-injected bladders after 4 days. In conclusion, we found 325 differentially expressed host mouse genes ($p < 0.05$) involved in 82 regulatory/signaling pathways when comparing egg-injected bladders with vehicle-injected control bladders. Top pathways include cell migration and fibrosis. Further experiments are planned to identify differences in the transcription profile of the parasite eggs.

80

THE INTERRUPTION OF TRANSMISSION OF ONCHOCERCIASIS BY AN ANNUAL MASS DRUG ADMINISTRATION (MDA) PROGRAM IN PLATEAU AND NASARAWA STATES, NIGERIA

Frank O. Richards[1], Abel Eigege[2], John Umaru[2], Barminas Kahansim[2], Solomon Adelamo[2], Jonathan Kadimbo[3], Jacob Danboyi[4], Hayward Mafuyai[5], Yisa Saka[6], Chukwuma Anyaike[6], Michael Igbe[6], Lindsay Rakers[1], Emily Griswold[1], Thomas Unnasch[7], Bertram E. Nwoke[8], Emmanuel Miri[2]

[1]*The Carter Center, Atlanta, GA, United States,* [2]*The Carter Center, Jos, Nigeria,* [3]*Plateau State Ministry of Health, Jos, Nigeria,* [4]*Nasarawa State Ministry of Health, Lafia, Nigeria,* [5]*University of Jos, Jos, Nigeria,* [6]*Federal Ministry of Health, Abuja, Nigeria,* [7]*University of South Florida, Tampa, FL, United States,* [8]*Imo State University, Owerri, Nigeria*

The 30 districts (Local Government Areas-LGAs) of Plateau and Nasarawa states, located in central Nigeria, have received annual mass drug administration (MDA) with ivermectin for onchocerciasis for a period of 8-26 years. Depending on the LGA, during 8- 11 of these years ivermectin was combined with albendazole as treatment for lymphatic filariasis. Serial assessments during this time in hypermesoendemic sentinel villages showed reduction of onchocerciasis prevalence to near zero. In 2017 serological and entomological assessments were undertaken to determine if MDA could be stopped in accord to World Health Organization onchocerciasis elimination guidelines. Bistate evaluations were conducted in 39 sites located in 22 of the 30 LGAs. The sites selected for assessments were 'first line villages' locate near rivers and having conditions favoring *Simulium* vector breeding. IgG4 response to the OV16 antigen was determined by ELISA in 5-<10 year old resident children. *Simulium damnosum* s.l. collected in or around those same villages either by human landing capture or by Esperanza trap were tested by PCR for determination of the presence of infective *Onchocerca volvulus* L3 larvae. Only 2 (0.03%) of 6,262 children tested were positive. A total of 19,056 vectors heads were tested in pools of 100 flies and were PCR negative. Both states met WHO guidelines of an infection rate in children <0.1% (with 95% confidence) and the rate of infective black flies of <1/2000 (with 95% confidence). The Federal Ministry of Health concluded that transmission of onchocerciasis has been interrupted and approved halting 2.2 million ivermectin treatments in 2018. Post Treatment Surveillance was immediately launched with an emphasis on entomological collections near borders with other onchocerciasis endemic states still being treated. This was the first stop MDA decision for onchocerciasis in Nigeria and among the largest reported to date. The apparent positive impact of LF treatments on hypoendemic onchocerciasis areas will be discussed.

81

RESURGENT LYMPHATIC FILARIASIS IN THE SAMOAN ISLANDS: TIME FOR CHANGE IN SURVEILLANCE STRATEGIES AND THRESHOLDS FOR VALIDATION OF ELIMINATION?

C**olleen L. Lau**[1], Sarah Sheridan[2], Therese Kearns[3], Take Naseri[4], Robert Thomsen[4], Saipale Fuimaono[5], Tautala Mauala[6], Helen Mayfield[1], Brady McPherson[1], Kelley Meder[1], Gabriela Willis[1], Benjamin Dickson[1], Meru Sheel[1], Kimberly Won[7], Katherine Gass[8], Patricia Graves[9]

[1]*Australian National University, Canberra, Australia,* [2]*University of New South Wales, Sydney, Australia,* [3]*Menzies School of Health Research, Darwin, Australia,* [4]*Samoa Ministry of Health, Apia, Samoa,* [5]*American Samoa Department of Health, Pago Pago, American Samoa,* [6]*Samoa Red Cross, Apia, Samoa,* [7]*Centers for Disease Control and Prevention, Division*

of Parasitic Diseases and Malaria, Atlanta, GA, United States, [8]Task Force for Global Health, Atlanta, GA, United States, [9]James Cook University, Cairns, Australia

Samoa and American Samoa, two adjacent South Pacific island groups, had high circulating filarial antigen (Ag) prevalence (4.5% and 16.5% respectively) in 1999, when baseline surveys were conducted through the Pacific Programme to Eliminate Lymphatic Filariasis (LF). After 6-7 rounds of mass drug administration (MDA) with diethylcarbamazine (DEC) and albendazole from 1999-2006 with reported adequate population coverage, Ag prevalence in all ages reduced to 1-2%. American Samoa passed two Transmission Assessment Surveys (TAS) of 6-7 year-old children in 2011 & 2015. Samoa conducted four additional MDA rounds during 2008-2017, and passed TAS in two of three evaluation units (EUs) in 2013, but failed TAS in all EUs in 2017. Population representative household surveys found that overall Ag prevalence had risen to 6.2% (95% CI 4.5-8.6%) in American Samoa in 2016, and 4.9% (95% CI 4.0-5.9%) in Samoa in 2018. Ag prevalence in 6-7 year-old children was 0.7% (95% CI 0.3-1.8%) and 1.5% (95% CI 1.0-2.1%) respectively, indicating ongoing transmission. Overall, 15-25% of Ag-positive (Ag+) persons were microfilaraemic, including children as young as 5 years. Ag+ persons were identified throughout American Samoa (2016) and Samoa (2018) in all EUs, but village-level Ag prevalence varied significantly, ranging from 0% to 45%. Significant household clustering of Ag+ persons was found in both Samoas. The results indicate that neither Samoa nor American Samoa had interrupted transmission by 2011-2013 despite passing TAS thresholds, and both are now experiencing resurgence. In areas with highly efficient vectors (e.g. Polynesia), programmatic guidelines may need to be revised to ensure interruption of transmission is sustained. Potential strategies include: 1) reducing Ag prevalence thresholds for stopping MDA and validating elimination; 2) because Ag prevalence increases with age, increasing the target age groups for surveillance to improve the sensitivity for detecting any residual transmission; and 3) screening household members of Ag+ persons. Both Samoas are implementing nationwide triple drug MDA (DEC, albendazole, ivermectin) in 2018-2019.

82

ANNUAL VERSUS SEMI-ANNUAL MASS DRUG ADMINISTRATION WITH DIETHYLCARBAMAZINE PLUS ALBENDAZOLE FOR ELIMINATION OF LYMPHATIC FILARIASIS IN EAST SEPIK PROVINCE, PAPUA NEW GUINEA

Michael C. Payne[1], Philip Lus[2], Nelly Sanuku[2], Brooke Mancuso[1], James Suamani[2], Delma Beaso[2], Gary J. Weil[3], Peter U. Fischer[3], Moses Laman[4], Leanne J. Robinson[5], Daniel J. Tisch[1], Christopher L. King[1]

[1]*Case Western Reserve University, Cleveland, OH, United States, [2]Papua New Guinea Institute of Medical Research, Maprik, Papua New Guinea, [3]Washington University School of Medicine, St. Louis, MO, United States, [4]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [5]Burnet Institute, Melbourne, Australia*

Papua New Guinea (PNG) has over 5.4 million people at risk of lymphatic filariasis (LF) with some of the highest infection rates in the world. Modeling studies based on data from Ghana and India suggest that semi-annual mass drug administration (MDA) could accelerate LF elimination. The aim of this study was to compare the impact of annual and semi-annual MDA for clearance of microfilaremia (Mf) and circulating filarial antigen (CFA) in highly endemic areas in PNG. Repeated annual cross-sectional surveys were conducted in 8 sentinel villages (~300-400 individuals/site) in the Dreikikir District, East Sepik Province; 4 sentinel sites in communities received semi-annual MDA with DEC plus albendazole (ALB) at 6 month intervals for 3 years (total of 5 rounds), and 4 sentinel sites received 3 rounds of annual MDA with the same medications. Filarial test strips (FTS) evaluated the presence and levels of CFA and Mf was assessed by microscopic examination of 60 µl night blood smears. Approximately 1,400 persons were surveyed for each treatment area each year. Baseline Mf and CFA prevalence were similar in annual and semi-annual MDA communities (26% Mf+ and 51% CFA+ vs. 26% Mf+ and 53% CFA+). Clearance of Mf and CFA was assessed annually for 3 years after baseline. Mf prevalence decreased dramatically over 3 years from 26% to 0% after annual MDA and from 26% to 0.3% after semi-annual MDA. Declines in CFA prevalence were also comparable (from 51% to 29% after annual MDA, and 53% to 35% after semi-annual MDA). In conclusion, MDA with DEC + ALB was highly effective for clearing microfilaremia from communities but less effective for clearing CFA. Additional work is needed to understand the significance of persistently high CFA prevalence in these communities. Semi-annual MDA was not superior to annual MDA. We recommend that LF elimination programs conserve resources by focusing on delivery of a single round of high quality MDA per year.

83

ONCHOCERCIASIS ELIMINATION IN LOW-ENDEMIC SETTINGS: MATHEMATICAL MODELLING TO ASSESS THE REQUIRED DURATION OF MASS DRUG ADMINISTRATION OF IVERMECTIN

Wilma A. Stolk, Anneke S. De Vos, David J. Blok, Luc E. Coffeng, Sake J. De Vlas

Erasmus MC, Rotterdam, Netherlands

Onchocerciasis is targeted for elimination in Africa by mass drug administration (MDA) of ivermectin. Many low-endemic areas have not yet been treated, as MDA programmes historically focussed only on meso- and hyperendemic areas for morbidity control. We used the ONCHOSIM simulation model to assess how many rounds of MDA are needed to eliminate onchocerciasis from low-endemic areas. We simulated annual MDA for settings with 0%-40% baseline microfilaria (mf) prevalence and varying local transmission conditions (annual biting rate, inter-individual variation in exposure to flies, and rate of infection importation from other areas). The number of MDA rounds to bring mf prevalence below 1.4% (the assumed critical threshold) depends on baseline endemicity, coverage, trends in infection importation, and the stability of transmission without importation. If importation rates remain constant until the start of MDA, it would take 5, 11, 14 and 15 annual MDA rounds, respectively, to reduce mf prevalence to <1.4% in areas with 0-10%, 10-20%, 20-30% and 30-40% baseline mf prevalence. Shorter durations are expected if the importation rates start declining before introducing MDA, thanks to treatment in surrounding areas. In some areas, infection transmission can only persist thanks to importation from surrounding higher-endemic areas. Treating the surrounding areas - leading to reduced importation - is then sufficient for elimination, although elimination can be accelerated by also treating the low-endemic area. In conclusion, the number of MDA rounds required to eliminate onchocerciasis from hypo-endemic areas varies strongly. Under some conditions as many as 15 annual MDA rounds may be required to bring mf prevalence below the assumed <1.4% threshold, and acceleration strategies may have to be considered (e.g. treating biannually). The assumed 1.4% threshold is subject to uncertainty. The actual threshold depends on local transmission conditions, and further work is needed to understand where more lenient threshold can be used or more stringent threshold are needed.

84

FEASIBILITY OF ONCHOCERCIASIS ELIMINATION USING A "TEST-AND-NOT-TREAT" STRATEGY IN *LOA LOA* CO-ENDEMIC AREAS

David J. Blok[1], Joseph Kamgno[2], Sebastien D. Pion[3], Hughes C. Nana-Djeunga[2], Yannick Niamsi-Emalio[2], Cedric B. Chesnais[3], Charles D. MacKenzie[4], Amy D. Klion[5], Daniel A. Fletcher[6], Thomas B. Nutman[5], Sake J. de Vlas[1], Michel Boussinesq[3], Wilma A. Stolk[1]

[1]*Department of Public Health, Erasmus MC, University Medical Center, Rotterdam, Netherlands, [2]Centre for Research on Filariasis and other Tropical Diseases (CRFilMT), Yaoundé, Cameroon, [3]IRD UMI [233]-INSERM U[1175]-Montpellier University, Montpellier, France, [4]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [5]Laboratory of Parasitic*

Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [6]Department of Bioengineering and the Biophysics Program, University of California, Berkeley, CA, United States

Mass drug administration (MDA) with ivermectin is the main strategy for onchocerciasis elimination. Ivermectin is generally safe, but has been associated with serious adverse events in persons with high microfilarial densities (MFD) of *Loa loa.* Therefore, ivermectin MDA is not recommended in areas where onchocerciasis is hypoendemic and *L. loa* is co-endemic. To eliminate onchocerciasis in those areas, a test-and-not-treat (TaNT) strategy has been proposed. Using the Loascope, a mobile video-microscope, people with high *L. loa* MFD can be identified and excluded from ivermectin treatment. While TaNT was successfully piloted in Cameroon, it remains unclear whether onchocerciasis elimination is possible using this strategy. We used the established individual-based model ONCHOSIM to assess whether onchocerciasis can be eliminated using TaNT in *L. loa* co-endemic areas and what the required duration until elimination would entail in comparison to MDA. We simulated pre-control onchocerciasis microfilarial prevalence (MFP) levels ranging from 1-50%. The impact of TaNT was simulated under varying levels of participation rate, systematic non-participation and exclusion from ivermectin due to high *L. loa* MFD. We predict that in areas with a pre-control MFP of 30-40% it normally takes around 10 and 14 years to bring onchocerciasis MFP below 1.4% using MDA, if the participation rate is 80% and 65%, respectively. These durations would increase with about 1 year, if 2.5% of the population is randomly excluded from ivermectin treatment due to TaNT. This increase can be up to about 5 years if systematic non-participation is assumed, and if participation rates are lower and pre-control MFP higher. Although the chosen elimination threshold is provisional, our model predicts a high probability of achieving true elimination after reaching this threshold. In conclusion, onchocerciasis can be eliminated using TaNT in areas co-endemic for *L. loa*. The required treatment duration of TaNT until elimination is only slightly longer than in areas with MDA, if participation is good.

85

ENVIRONMENTAL FACTORS ASSOCIATED WITH CONTRASTING GEOGRAPHICAL DISTRIBUTIONS AND HOTSPOTS OF ONCHOCERCIASIS AND LOIASIS IN KONGO-CENTRAL, DEMOCRATIC REPUBLIC OF CONGO

Xavier Badia-Rius, Hannah Betts, **Louise A. Kelly-Hope**

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Onchocerciasis and loiasis are important filarial diseases in the Democratic Republic of Congo (DRC), and the Kongo-Central region has shown to have contrasting geographical distributions, which may be driven by the ecological niche of the *Simulium* and *Chrysops* vectors. To better understand environmental factors associated with geographical patterns and potential hotspots, REMO and RAPLOA survey data from 335 villages available from the ESPEN portal were examined. Maps were developed using ArcGIS 10.5.1 and prevalence distributions examined for spatial clustering using the Getis Ord Gi* statistic. Environmental factors including annual mean temperature (°C), annual precipitation (mm), elevation (m), tree canopy coverage (%) and tree canopy height (m) were obtained from publicly available sources, and data extracted for each village and analysed using statistical methods with a significance level of $P < 0.05$. Overall, mean environmental measures for both diseases were similar (temperature 31.6-32.1°C; precipitation 1287-1290mm, elevation 23.5-23.7m, canopy coverage 30.2-32.7%, canopy height 7.3-11.3m). Prevalences were found to be positively correlated with temperature, and negatively with precipitation. However, onchocerciasis prevalence was significantly negatively correlated with canopy coverage (r=-0.30) and canopy height (r=-0.16), whereas loiasis was significantly positively correlated with coverage (r=0.50) and height (r=0.26). For onchocerciasis, 86 villages were identified as hotspots and clustered near the Congo River with mean temperature 28.2°C; precipitation 1184mm, elevation 22.0m, canopy coverage 16.4%, and canopy height 5.6m. In contrast for loiasis, 57 villages were identified as hotspots and clustered in the forested region with mean temperature 24.7°C; precipitation 1165mm, elevation 18.5m, canopy coverage 63.6%, and height 13.4m. This study provides insights into the environmental parameters of transmission, which may help to delineate high and low risk, and target intervention strategies for filariasis control and elimination.

86

EVALUATION OF RESPONDENT-DRIVEN SAMPLING TO ESTIMATE LYMPHATIC FILARIASIS MORBIDITY BURDEN IN HAITI

Alexia Couture[1], Luccene Desir[1], Ernest Jean Romuald[1], Madsen Beau De Rochars[2], Brittany Eddy[1], Karen E. Hamre[3], Michelle A. Chang[3], Katherine M. Gass[4], Caitlin M. Worrell[3], Jean Frantz Lemoine[5], **Gregory S. Noland**[1]

[1]*The Carter Center, Atlanta, GA, United States,* [2]*Department of Health Services Research, Management and Policy, College of Public Health and Health Professions, University of Florida, Gainesville, FL, United States,* [3]*Division for Parasitic Diseases and Malaria, Center for Global Health, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Neglected Tropical Diseases Support Center, Task Force for Global Health, Decatur, GA, United States,* [5]*Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti*

More than 36 million people suffer from lymphatic filariasis (LF)-related limb swelling (lymphedema) or urogenital swelling (hydrocele). The World Health Organization requires LF-endemic countries to document the number of lymphedema and hydrocele cases in all historically endemic districts, yet there is no agreed methodology for assessing morbidity burden. Case reporting is hindered by the social stigma and isolation associated with LF. Respondent driven sampling (RDS) is a method developed for accessing hidden populations through recruitment of a limited number of starting 'seeds' followed by successive waves of participant referral. We evaluated the feasibility of RDS for estimating LF morbidity burden in four districts in Haiti classified as high, medium or low burden based on baseline antigen prevalence at mapping in 2001 (range: 1%—44%). We compared RDS burden estimates with those derived from recent cross-sectional household surveys (HHS) conducted in the same areas. From July 2018-January 2019, approximately 20-25 individuals per condition (lymphedema or hydrocele) identified from local health facility records were enrolled as seeds and asked to refer others in the community with the same condition. A total of 179 confirmed lymphedema cases (52% male) and 238 hydrocele cases (100% male) were enrolled through RDS across four districts. The number of referral waves directly correlated with antigen prevalence classification for both lymphedema (r^2=0.88) and hydrocele (r^2=0.97). Surprisingly, a greater number of waves were achieved for hydrocele than for lymphedema in every district. District-level RDS prevalence estimates calculated with successive sampling - population size estimation (SS-PSE) and a flat prior ranged from 0.2% (95% CI: 0.15%—0.21%) to 1.4% (95% CI: 0.4%—2.1%) for lymphedema and from 0.4% (95% CI: 0.20%—0.50) to 1.5% (95% CI: 0.7%—1.9%) for hydrocele. The 95% confidence intervals for RDS and HHS overlapped in three of four districts for hydrocele, but only one or four districts for lymphedema. Results suggest that RDS may offer a viable option to efficiently obtain LF morbidity burden data.

87

HEALTH CARE PROVIDERS AND CAREGIVERS' VIEWS ON THE FEASIBILITY, USABILITY AND ACCEPTABILITY OF LUNG ULTRASOUND FOR DIAGNOSING PEDIATRIC PNEUMONIA IN MANHIÇA DISTRICT, MOZAMBIQUE

Olga Cambaco

Manhica Health Research Centre, Vila da Manhica, Mozambique

In Mozambique, pneumonia is a leading cause of death among children under 5 years of age, yet its diagnosis remains a challenge. Although chest radiography (CXR) remains the recommended diagnostic method, existing evidence from other suggests that CXR it is often unavailable, costly and

exposes children to hazardous radiation. Lung ultrasonography (LUS) is a promising diagnostic method due to its high sensitivity in detecting diseases such as pneumonia. This is the first study to date to explore the anticipated acceptability and usability of LUS for diagnosing pediatric pneumonia among health care providers and caregivers in Mozambique. We conducted a qualitative study in the Manhiça district Hospital (MDH), in southern Mozambique, from April to May 2018. Semi-structured interviews were conducted among health care providers (10) and caregivers (10) combined with direct observations of ultrasound utilization. Data were analysed following a combination of content and thematic analysis. This study showed a high level of acceptability of LUS among caregivers and health care providers in our setting. We identified the following acceptability factors: LUS is perceived to be precise to diagnose, portable, easy to use, and non-invasive. Despite this, participants expressed some reservations. Caregivers were concerned with battery life limitation and device's susceptibility to dropping and breaking down. On the other hand, health care providers were concerned about the potential cost of the devices, poor conservation and management and the language of the software. These findings anticipate potential reasons for acceptability and advances recommendations to overcome the perceived limitations that are important to take into account prior to any future implementation of LUS for pneumonia diagnosis.

88

AWARENESS AND WILLINGNESS TO USE PREP AMONG FEMALE SEX WORKERS IN DAR ES SALAAM

Diana Faini[1], Mucho Mizinduko[1], Samuel Likindikoki[1], Alexander Mwijage[1], Melkizedeck Leshabari[1], Neema Makyao[2], Kåre Moen[3], Germana H. Leyna[1], Claudia Hanson[4], Patricia Munseri[1], Elia J. Mbagga[1]

[1]*Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania,* [2]*National AIDS Control Program, Dar es Salaam, United Republic of Tanzania,* [3]*University of Oslo, Oslo, Norway,* [4]*Karolinska Institutet, Stockholm, Sweden*

Tanzania is implementing a demonstration project on pre-exposure prophylaxis (PrEP) to female sex workers (FSW) whose HIV prevalence is five times higher than the general population. While PrEP has demonstrated to be an effective biomedical intervention in reducing HIV incidence, no data is available on the extent of PrEP awareness and willingness to use among FSW in Tanzania. Understanding the level of awareness, the extent of willingness to use PrEP and identifying factors associated with PrEP awareness could inform the ongoing country efforts to roll-out PrEP. FSWs were recruited in the integrated bio-behavioral surveillance in December 2017 using responded-driven sampling method. Face-to- face interviews were conducted to collect information on awareness and willingness to use PrEP as well as factors associated with PrEP awareness. Weighted bivariate and multivariable logistic regression models were used to estimate factors associated with PrEP awareness. We recruited 958 FSW, their median age was 26 (IQR 22-32) years. Among self- reported HIV negatives(n=751), 228 (31%) reported having heard of PrEP. PrEP awareness was higher among those aged 25 years or more compared to 18-24 years (33% vs 26%, P=0.02), but did not differ by education levels [none/primary vs secondary/tertiary (24% vs 30%, P=0.26)]. Contact with peer educator in the past 12 months (aOR 1.48,95%CI 1.06-2.06), HIV testing at a health facility (aOR 1.65, 95%CI 1.03-2.66) or research project (aOR 3.41, 95%CI 1.74-6.68) compared to testing in the community were strongly associated with higher PrEP awareness.Substance use (aOR 0.64, 95%CI 0.41-1.00) and having >10 partners in the past month (aOR 0.65, 95%CI 0.43-0.96) were associated with lower PrEP awareness. Nearly all of the self-reported HIV negative women 96% (n= 710/751) were willing to use PrEP. Despite the low PrEP awareness, there is a great willingness to use PrEP among FSW in Dar es Salaam. PrEP implementation programs should focus on increasing PrEP knowledge among younger FSW. Peer educators and HIV testing opportunities could be seized to raise PrEP awareness.

89

A BASELINE ASSESSMENT EVIDENCE INFORMED DECISION MAKING NETWORK IN THE HEALTH SECTOR IN MALAWI USING SOCIAL NETWORK ANALYSIS AND A PROSPECTIVE CASE STUDY

Melody Sakala[1], Kate Gooding[1], Jenny Hill[2], Linda Nyondo Mipando[3], Bertie Squire[2]

[1]*Malawi Liverpool Wellcome Trust, Blantyre, Malawi,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*College of Medicine, Blantyre, Malawi*

Despite the steady progress in health-related research only a limited number of that research translates into policy and impact. Global advocacy for evidence-based decision making is recognized both nationally and internationally and there has been recent global initiatives to ensure use of research findings in decision making processes. To further support research evidence use in Malawi, all the main actors in the space of knowledge translation and evidence use have joined efforts to establish a formal Network for Evidence-Informed Decision-Making in Health Policy & Practice in Malawi (EvIDeNt).The overall objective of this study is to conduct a baseline assessment of key indicators and processes of EvIDeNt in supporting use of research outcomes and to inform the evaluation of the network at a later stage. In achieving this, the baseline will assess the connectivity of the networks in terms of membership and structure, its health in terms of resources and internal systems. Social network analysis will be used to examine the networks existing ties among members and to assess network efficiency and a case study on use of findings from a malaria trial, to trace specific effects of EvIDeNt and identify aspects of the research and policy context that affect research uptake. Methods for data collection will employ a desk review analysis to capture the overall structure, systems and resources of the network. Key informant, interviews will be used to clarify on the mapped intended outcomes. The study intended outcomes aims to support evidence informed health policy by strengthening EvIDeNt and advancing understanding of factors influencing research uptake.

90

GEOSPATIAL MAPPING OF TIMELY ACCESS TO COMPREHENSIVE EMERGENCY OBSTETRIC CARE IN KENYA

Paul Ouma, Robert Snow, Mike English, Emelda Okiro

KEMRI-Wellcome Trust, Nairobi, Kenya

Ensuring access to comprehensive emergency obstetric care (CEmOC) can reduce maternal mortality by 85%. In many African countries, access to these services is poor, partly due to inadequate hospital capacity and long distances to the few hospitals that can provide care. This study aimed to assess readiness to provide CEmOC services and combine with population data to define county level geographic access to CEmOC hospitals in Kenya. We assessed hospital readiness to provide caesarean deliveries and blood transfusion which are the two key indicators needed to provide CEmOC services, using data from nationwide service availability assessments. This included collecting information on availability of operating theatres, blood transfusion, medical doctors, nurses and basic surgical equipment, all which are needed to provide safe CEmOC. We then assembled road networks, elevation and land use at high spatial resolution to formulate a cost friction surface. This surface was then combined with location of CEmOC hospitals to estimate population living more than two hours from the nearest CEmOC hospital at county level. In 2018, 512 public and private hospitals were assessed and indicator availability were; operating theatres (n=295), blood transfusion (n=318), medical doctor availability (n=443), nurse availability (n=512) and surgical equipment (n=290). There were 228 hospitals that provide CEmOC services, seven of which could perform caesarean deliveries without blood transfusion. Approximately 19% of Kenya's expectant women in 2018 were living more than 2 hours from the nearest CEmOC hospital, with significant variations at county level. These ranged from as high as 75% in Turkana to less than 5% in Nairobi, Kisii, Kiambu, Kisumu, Nyamira and Vihiga

counties. The results show a substantial variation in access to CEmOC services at county levels, highlighting the need for targeted investments to bridge the inequities.

91

COST OF DENGUE ILLNESS IN INDONESIA

Oliver J. Brady[1], Lauren Carrington[2], Emilie Hendrickx[1], Dinar D. Kharisma[3], Ida S. Laksanawati[4], Kathleen O'Reilly[1], Donald S. Shepard[5], Cynthia Tschampl[3], **Nandyan N. Wilastonegoro**[6], Laith Yakob[1], Wu Zeng[3]

[1]*London School of Tropical Medicine & Hygiene, London, United Kingdom,* [2]*Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam,* [3]*Brandeis University, Waltham, MA, United States,* [4]*Dr. Sardjito General Hospital, Yogyakarta, Indonesia,* [5]*Heller School for Social Policy and Management, Waltham, MA, United States,* [6]*Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia*

There has been a shift in the global burden of disease from communicable non-communicable disease. Interestingly, global dengue cases have been increasing over the decades. Prognosis of dengue varied from asymptomatic to fatal cases with outbreaks often occurred. As a consequence, the economic burden due to dengue is a threat to endemic countries. We estimated the cost of dengue illness in Indonesia using mix approach of macro- and micro-costing. We gathered financial and utilization data of health facilities (hospitals and primary cares) and interviewed respondents' cases for hospital, ambulatory and non-medical cares in Yogyakarta City. We analyzed the cost per patient and the portion of that paid by households and other paying mechanisms. To obtain the estimation of dengue cases and cost in Indonesia, part of our study produced consensus estimates using statistical and mathematical modeling. We summed the total cost of dengue illness and multiplied to our estimation of dengue cases to obtain the estimated national cost. Dengue cost per case for hospital, ambulatory and non-medical treatments were US$ 318.36 (95%UI 243.93-392.79), US$ 23.03 (95%UI 14.45-31.62) and US$ 7.53 (95%UI 2.37-12.68), respectively. There was a total of 7.535 million (95%UI 1.319-16.513 million) dengue cases in 2017 and our national estimate suggests that the economic cost of dengue in Indonesia was US$ 666.83 million (95%UI 531.57-802.08 million). To this figure, about 37%, 20%, 25% and 18% paid by the households, social contributors, Indonesian National Health Insurance Program (*Jaminan Kesehatan Nasional*/JKN) and other parties, respectively. In conclusion, the cost of dengue illness will be useful in Indonesia and in other countries. This economic analysis is informing out-of-pocket expenditures and direct and indirect costs within three different treatment settings. Hence there are needs for refinement of dengue policy options to existing and promising interventions e.g. vaccine and Wolbachia technologies which are attributed to lowering economic burden.

92

HEALTH CARE OPTIONS AND FACTORS INFLUENCING HEALTH SEEKING BEHAVIOR IN A RURAL NIGERIAN COMMUNITY

Paul W. Okojie

Liberty University, Lynchburg, VA, United States

There is an urban and rural disparity in health care infrastructure in Nigeria. With over 60% of its population living in rural communities, there is an opportunity for addressing the root causes of the poor health status of rural populations. The paper aimed to analyze sociodemographic factors influencing health-seeking practices in a rural community setting. A cross-sectional study of 380 rural dwellers in Utese, Southern, Nigeria was done using interviewer-administered questionnaires. Data were analyzed with SPSS version 25 software. Chi-square test was used to find the association between sociodemographic characteristics and health-seeking practices. Comparable proportions (43.4%, 42.9%) of the respondents fell within the younger age categories of 10-29 and 30-49 years, respectively. Self-reported factors influencing the choice of health care were: Promptness of care (41.8%), cost (22.4%), professionalism (16.8%), distance (15.8%), and cultural belief (3.2%). Patent medicine store was the most utilized source of health care (42.1%). 140 (36.8%) respondents sought health care in the hospital. The hospital was utilized by 41.8% of respondents with secondary education; 34.9% with tertiary education; 31.7% primary and 26.1% with no formal education, respectively. Females tended to seek healthcare from hospitals (40.2%) and patent medicine store (43.7%) compared to males (33.3% and 41.0%). There was a significant association between educational attainment and healthcare options utilized ($P<0.05$). Less than half of rural dwellers utilize minimum standard health care mainly due to cost and timeliness of health care. Education is the key to influencing health-seeking practices in rural communities.

93

MATERNITY WAITING HOMES IN LIBERIA: RESULTS OF A 5-YEAR COUNTRY-WIDE MULTI-SECTOR SCALE-UP

Alphonso W. Kofa[1], Joseph E. Perosky[2], Aloysius Nyanplu[1], Cheryl A. Moyer[3], Jody R. Lori[4]

[1]*Liberia Ministry of Health, Phebe, Liberia,* [2]*Michigan State University College of Human Medicine, East Lansing, MI, United States,* [3]*University of Michigan Medical School, Ann Arbor, MI, United States,* [4]*University of Michigan School of Nursing, Ann Arbor, MI, United States*

Maternity waiting homes (MWHs) are small structures built adjacent to a healthcare facility where women can stay prior to giving birth. In 2010, a cohort study of 10 rural primary health facilities (5 with and 5 without a MWH) was conducted in Bong County, Liberia to evaluate their impact on maternal and newborn outcomes. Results showed a decrease in maternal and perinatal mortality in communities with a MWH compared to those without one. Following this study, the Liberian Ministry of Health identified MWHs as one component of continuing health system strengthening efforts to improve maternal and newborn outcomes. In the ensuing eight years, an additional 114 MWHs have been constructed in 14 of the 15 counties in Liberia for a total of 119 MWHs by an array of funders and implementers. Of these 119, 54 (45.4%) are open and functional, 8 (6.7%) are currently under construction, 35 (29.4%) were started but construction ceased prior to opening, 15 (12.6%) have been repurposed mainly for staff quarters, and 7 (5.9%) MWHs were opened and later abandoned. There were various funders and implementers involved in the scale up of MWHs including 72 (60.5%) by NGOs, 35 (29.4%) by the local community, 6 (5.0%) by the United Nations H6 consortium, 4 (3.4%) by Individuals, and 2 (1.7%) by the local Liberian government. One hundred fifteen focus groups were conducted with community members (Chiefs, Community Leaders, Women of Reproductive Age, Traditional Birth Attendants (TBAs), Women currently staying at a MWH, and Male Partners) as well as 113 interviews with health care providers providing services at the health care facilities associated with a MWH. Nearly all communities hold the following three beliefs: MWHs 1) reduce home deliveries; 2) reduce maternal deaths; and 3) improve relationships between health facility staff, TBAs, and communities. The data also revealed the following challenges and barriers to sustainability and scalability of MWHs in Liberia: 1) lack of initial community engagement; 2) lack of community awareness; 3) food security; 4) inadequate capacity; 5) lack of development of a self-governance model; and 6) lack of on-going support/resources.

94

PRECISION PUBLIC HEALTH AND PANDEMIC PREPAREDNESS: QUANTIFYING TRAVEL TIME TO HEALTH CARE AND LOCATIONS AT RISK FOR PATHOGEN TRANSMISSION

E**rin Hulland**[1], Kirsten Wiens[1], Shreya Shirude[1], Beth Bell[2], Peter Rabinowitz[3], Judith Wasserheit[2], Daniel Weiss[4], Simon Hay[1], David Pigott[1]

[1]*Institute for Health Metrics and Evaluation, Seattle, WA, United States,* [2]*Department of Global Health, University of Washington, Seattle, WA,*

United States, [3]Department of Global Health and School of Public Health, University of Washington, Seattle, WA, United States, [4]Big Data Institute, Nuffield Department of Medicine, Oxford, United Kingdom

Infectious disease threats exist even in places without evidence of past events, and without clear preparedness plans to prevent, detect, and respond to such threats, outbreaks can easily overwhelm fragile health systems. Recent emphases on developing National Action Plans have required subnational evaluations of vulnerable communities, and precision public health using geospatial resources have provided a method to quantify observed heterogeneities. In early stages of an outbreak, proper diagnosis and treatment are essential for containment and care, and proximal access to a health facility is vital, but just as the risk of infectious disease is not homogeneous across the world, neither is health care accessibility, leaving gaps in coverage. Moreover, many of those regions at higher risk are often those that also lack accessibility to care. Here we mobilized large, open-source geospatial resources including a travel-time friction surface, geolocated health facility information, and pathogen environmental suitability maps to quantify health facility accessibility and pathogen suitability transmission to any location within a given country. Noting significant cross-border migration and previous disease transmission stemming from such movements, such as the detection of Ebola cases at the Uganda border with the Democratic Republic of Congo (DRC), we considered the pathogen suitability of neighboring countries and calculated the time it would take to travel to any point in-country. For Uganda, much of the border with DRC was within five hours of locations with known Ebola suitability. Finally, we developed methods to identify areas where additional resources directed to health facility development would be most impactful. Together, these maps highlight existing preparedness gaps and sub-national risk of infectious disease and demonstrate the potential for precision public health resources to inform preparedness activities. With the development of comprehensive, geolocated health facility lists, these maps can be used as one tool among a set of many in-country to ensure preparedness for the next public health threat.

95

BURDEN OF NON-COMMUNICABLE DISEASES IN A KENYAN CASUALTY DEPARTMENT

Gladys Wambua[1], Mugane Mutua[1], **Daniel Rafiki Owambo**[2], Morgan Muchemi[3], Thomas Kedera[4], Kipkoech Rop[5], Benjamin Wachira[6], Christine Ngaruiya[7]

[1]*Kenyatta National Hospital, Nairobi, Kenya,* [2]*Narok County Referral Hospital, Kenya, Narok, Kenya,* [3]*PCEA Chogoria Mission Hospital, Chogoria, Kenya,* [4]*Kakamega County Referral Hospital, Kakamega, Kenya,* [5]*Kilifi County Referral Hospital, Kilifi, Kenya,* [6]*Aga Khan University Hospital, Nairobi, Kenya,* [7]*Yale School of Medicine, New Haven, CT, United States*

Non-communicable diseases (NCDs) account for 41 million deaths annually. Low and Middle-Income countries (LMICs) suffer 75% of this global NCD death burden. In Kenya, these deaths have risen from 35% in 2003 to 45% in 2010. However, limited primary data exists on this burden. Resource-limited health systems unable to capture data describing patients presenting for acute care impede early detection and treatment of NCDs. This study assesses NCDs and associated risk factors in a Kenyan Casualty Department to provide knowledge to inform development of protocols, policies and educational interventions on their management. Data was collected using the WHO STEPwise approach and PHQ-9 questionnaires. We targeted patients at the Kenyatta National Hospital Casualty Department aged 18-69. Sample size was 2400; 10% of the total estimated presentations. Majority (53.6%) of respondents were male, with a mean age of 35y. 11% of respondents smoke tobacco with 8% doing so daily. The mean starting age for smoking was 20y. 36% of participants are exposed to second-hand smoke from their homes and work-places. 51% of participants reported engaging in alcohol use while less than 5% have attempted to stop drinking upon medical recommendation. 21% of respondents are hypertensive but only 11% are on medication. 10% of respondents reported symptoms of angina and 7% reported elevated blood sugar. A high burden of NCDs exists in the Casualty Department, yet treatment is minimal. Overlooking this risks loss of productivity and escalation of healthcare costs. This emphasizes the need for interventions unique to this population.

96

TRASH TO TREASURE: COLLECTING TRASH FOR PROFIT TO REDUCE VECTOR BREEDING SITES IN KWALE COUNTY, KENYA

Gathenji B. Njoroge

University of California Berkeley School of Public Health, Berkeley, CA, United States

Plastic pollution harms the environment, promotes zoonoses, and promotes vector-borne diseases (VBD) like dengue, chikungunya, and Zika which are transmitted by *Aedes aegypti*. Community-based methods to control this vector rely on a continuous stream of external funding and are rarely sustainable. Some of the most productive *Aedes aegypti* habitats worldwide and in Kwale County, Kenya (Kwale) are synthetic containers, such as recyclable plastic containers, tires, and trash. Recognizing individuals may not be incentivized to clean up their environment to improve health if basic needs are not met due to poverty, we aim to assess the potential for community-based recycling that engages aspiring entrepreneurs to repurpose trash for profit in Kwale. Our goals are to improve health by reducing VBD and to alleviate poverty by generating income. We will empower and train aspiring entrepreneurs to repurpose trash for profit in Kwale (9.1% unemployment). We hypothesize profitable businesses which motivate community members to remove trash from the community will reduce vector breeding containers. We plan to measure pre- and post-intervention: vector abundance (ovitraps), and visual presence of trash; and during the process: volumes of trash collected, and profits generated. We are currently engaging local entrepreneurs, policy makers, community leaders and NGO's. We have identified 14 target communities, are 7 engaging community leaders and 2 NGOs to mobilize entrepreneurs, and have mapped the landscape of trash volumes and market opportunities through key-informant interviews and 10 spatial video geonarratives. Interest from Kenyan entrepreneurs exists to reuse plastics and some programs are already collecting and sorting trash and making items such as building materials and art. Creating demand will be a challenge. Our next step is to pilot the entrepreneur incubator program to remove trash from the environment by inviting interested individuals to apply to participate in a social entrepreneurship program to create and execute business plans.

97

HEALTHCARE UTILIZATION IN PATIENTS WITH SUSPECTED ENTERIC FEVER

Alexander T. Yu[1], Rajani Shakya[2], Caryn Bern[3], Bikram Adhikari[2], Dipesh Tamrakar[2], Krista Vaidya[2], Caitlin Barkume[4], Denise Garrett[4], Stephen Luby[1], Isaac Bogoch[5], Jason Andrews[1]

[1]*Stanford University, San Francisco, CA, United States,* [2]*Dhulikhel Hospital, Kathmandu University Hospital, Dhulikhel, Nepal,* [3]*University of California San Francisco, San Francisco, CA, United States,* [4]*Sabin Institute, Washington, DC, United States,* [5]*University of Toronto, Toronto, ON, Canada*

We used a hybrid approach, combining population-based, age-structured health care utilization data with facility-based typhoid surveillance, to produce age-adjusted burden estimates in an urban and peri-urban setting in Nepal. We conducted a randomized cluster-based healthcare utilization survey in the catchment areas of Kathmandu Medical College Hospital (urban Kathmandu) and Dhulikhel Hospital (peri-urban areas of Kavrepalanchok district), where prospective typhoid surveillance has been ongoing since September 2016. Data on healthcare seeking behavior, socioeconomic status and symptom severity were collected for each household member with an episode of fever ≥ 3 days in the previous 8 weeks. From January 2017 to October 2018, we enrolled 24,515

households, representing 81,369 individuals (47,198 in Kathmandu, 34,171 in Kavrepalanchok) with a median age of 27 years (IQR 18-40). Household period prevalence of fever ≥ 3 days was lower in Kathmandu (5.7% vs 15.4%, p<0.01). Children <5 had the highest period prevalence (13.9%) while adults 22-45 had the lowest (2.1%). The period prevalence of fever was lower in the rainy season compared to drier winter months (4.9% vs 6.4%, p<0.01). Higher SES and education was associated with lower fever prevalence. The majority with fever sought medical care (87.7%), most commonly from pharmacies. Only a small proportion presented to the surveillance facility (6.2% in Kathmandu, 12.6% in Kavre). Fever lasted a median 4 days (IQR 3-7) and kept participants from activities for a median 3 days (IQR 1-5). Those taken to a facility had a longer mean duration of fever (5.8 vs 4.7 days, p<0.001) and spent more time in bed on the worst day of illness (13.1 vs 11.7 hrs, p<0.001). In conclusion, more than 85% of individuals with suspected enteric fever sought medical care, most frequently at pharmacies. Although our surveillance facilities are major medical centers, only a small proportion of those with febrile illness presented to them, highlighting the importance of adjusting for healthcare utilization to produce accurate estimates of disease burden.

98

ESTABLISHING AN URBAN HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM IN A SEMI-INFORMAL SETTLEMENT, INITIAL EXPERIENCES AND FINDINGS OF FIRST TWO YEARS, MANYATTA KISUMU

Thomas Misore, Maurice Ombok, David Obor, Peter Otieno, Stephen Liech, Leonard Oyuga, Janet Agaya

Kenya Medical Research Institute (KEMRI), Kisumu, Kenya

Health and demographic surveillance systems (HDSS) are important sources for health planning and policy implementation in many low and middle income countries. They provide longitudinal data regarding health and vital statistics in countries where vital registration systems perform poorly. Most HDSS sites are set up in rural settings. Through the support of the Child Health and Mortality Prevention Surveillance network, the Kenya Medical Research Institute set up an urban HDSS in Manyatta informal settlement area of Kisumu town, western Kenya. The HDSS was set up primarily to assist in identifying child deaths, provide denominators for cause specific mortality as well as follow up on public health interventions. We present experiences and findings of the first two years of setting up and operation. Manyatta site was mapped and numbered into 121 villages. Consent was obtained from household heads before the enumeration exercise. . Household data was collected by trained Community Interviewers and Community Health Volunteers. Supervisors conducted random, repeat interviews in 5% of households for quality checks. Half yearly cohort follow-ups were conducted to record information on vital events. Flexible working hours allowed for households visits. Data analysis was conducted using Stata 14. Baseline enumeration registered a population of 77,061, distributed in 31,000 households. Females made up 39,221 (50.9%).Sex ratios were 96 males per 100 females. The average household size was 3. There were 11,699 (15%) under five years children. Refusal rate stood at 0.03% and revisits 11% .Observing working time flexibility, security, respect for diverse cultures and religion is key. In conclusion, findings demonstrate feasibility of setting up and operating a HDSS and to collect accurate and reliable data in an informal urban setting such as Manyatta. The urban setting has unique characteristics and challenges that require flexibility and modification of strategies that ordinarily apply in rural settings.

99

INTERRATER RELIABILITY OF AN ADAPTED AND TRANSLATED VERSION OF THE MULLEN SCALES OF EARLY LEARNING (MSEL) IN RURAL GUATEMALA

Alison M. Colbert[1], Molly M. Lamb[1], Desirée Bauer[2], Sara Hernández[2], Maria Alejandra Martínez[2], Paola Arroyave[2], Alejandra Paniagua-Avila[2], Daniel Olson[1], Mirella Calvimontes[2], Guillermo A. Bolaños[2], Hana M. El Sahly[3], Flor M. Muñoz[3], Edwin J. Asturias[1], Amy K. Connery[1]

[1]*University of Colorado School of Medicine, Aurora, CO, United States,* [2]*Center for Human Development, Fundación para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala,* [3]*Baylor College of Medicine, Houston, TX, United States*

Prenatal Zika virus (ZIKV) and chikungunya virus (CHIKV) infections have been associated with long-term neurodevelopmental sequelae, though the impact of early post-natal infection on neurodevelopment in children in low- and middle-income countries (LMICs) is less clear. This paucity of knowledge is exacerbated by the lack of standardized, performance-based neurodevelopmental assessment tools for LMICs. We evaluated the reliability of an adapted and translated version of the Mullen Scales of Early Learning (MSEL) in a rural, resource-limited region of Guatemala highly endemic for arboviruses. MSEL administration interrater reliability was calculated from an audit conducted during a prospective cohort study of the effects of postnatal ZIKV infection. Guatemalan psychologists were trained by Spanish-speaking US neuropsychologists to administer the MSEL. Twenty consecutive MSEL administrations by trained Guatemalan psychologists were independently live double-scored by US neuropsychologists (*mean*child age = 21 months; *range*= 6-62 months). Interrater reliability for each MSEL subscale (gross and fine motor, visual-reception, receptive and expressive language) and composite score were excellent (*ICC* = 0.99, *p*< .001). Additionally, 32 MSEL administrations (*mean*child age = 20 months; *range*= 6-63 months) by trained Guatemalan psychologists were independently live double-scored by another trained, Guatemalan psychologist. Interrater reliability was excellent for each MSEL subscale (*ICC* = 0.99, *p*< .001) and composite score (*ICC* = 0.98, *p*< .001). These results suggest our training model was effective, administration instructions were clear, and child performance was similarly interpreted by examiners. This, along with previous work supporting the construct validity of this version of the MSEL, provides support for MSEL use in this resource-limited population in Guatemala. Our findings indicate that rigorous neurodevelopment assessment tools with strong psychometric properties can be applied in LMICs when carefully translated, adapted and applied.

100

ENGAGING YOUNG PEOPLE AS AGENTS OF CHANGE: A SCHOOL-BASED INTERVENTION TO REDUCE ARBOVIRUS TRANSMISSION – ONE YEAR FOLLOW-UP INTERVIEWS

Arielle M. Kempinsky[1], Jenna E. Forsyth[2], Emilia J. Ling[1], Catharina J. Alberts[3], Francis Mutuku[4], Lydiah Kibe[5], A. Desiree LaBeaud[6]

[1]*Stanford University School of Medicine, Stanford, CA, United States,* [2]*Emmett Interdisciplinary Program on Environment and Resources, Stanford University, Stanford, CA, United States,* [3]*International Agency for Research on Cancer, World Health Organization, Geneva, Switzerland,* [4]*Technical University of Mombasa, Mombasa, Kenya,* [5]*KEMRI-Wellcome Trust Programme, Kilifi, Kenya,* [6]*Lucille Packard Children's Hospital at Stanford University School of Medicine, Stanford, CA, United States*

Creating sustainable behavior change is a necessary step in reducing the burden of *Aedes aegypti* mosquito-borne diseases in rural Kenya. Without the ability to cure these diseases or to implement insecticide-based control, we must focus on source reduction. Intentions and perceptions directly impact the degree to which households adopt source reduction. This study aims to better understand the impetus for or against behavior change following a school-based educational intervention. The goal of the curriculum was to provide targeted behavioral recommendations based

on container types, including covering any with standing water, removing old containers, and turning over unused containers. From a sample size of 500, 17 adopter households (those who decreased the number of improperly managed containers) and 17 non-adopters were randomly selected for inclusion. Field research assistants conducted structured interviews with mothers of children in the intervention to synthesize why households did or did not change their behavior, along with the effect of these choices. Using images to rank their mosquito related priorities, respondents showed that container behaviors ranked second of five after bed nets. We found nine adopters ranked container management in their top two, as compared with five non-adopters. Respondents prioritized covering cooking and drinking water, but seemed less inclined to cover laundry water. The interviews also revealed barriers in the non-adopters. The most common extrinsic obstacle that mothers faced was the behavior of other family members, while the most common intrinsic barrier was lack of time. Questions about project efficacy in both groups showed us the most common knowledge increase surrounded maintaining a trash-free, clean compound. Since children used old containers and tires as toys, respondents in both categories reported difficulty discarding these items, even when water tended to pool inside of them. Long-term behavior change may require empowering local community members to create structural changes from within.

101

UNDERSTANDING THE CONTEXT OF DEATH OF UNDER-FIVE CHILDREN IN RURAL GHANA USING VERBAL POST MORTEM NARRATIVES

Samuel Afari-Asiedu, Charles Zandoh, Edward Anane Apraku, Mahama Abukari, Felix Boakye Oppong, Wisdom Adeapena, Samuel Harrison, Kwaku Poku Asante

Kintampo Health Research Centre/Ghana Health Service, Kintampo, Ghana

Globally, under-five deaths have decreased by 58% but still high in Africa. Compared to global estimate of 39 deaths, under-five deaths in Ghana was 49 per 1000 live births in 2017. Verbal Post Mortem (VPM) is vital for understanding the context of death at the community level. This paper reports on the context and health seeking behavior for under-five deaths in rural Ghana. Fifty (50) VPM narratives, 5 from each year (2006 to 2015) were randomly selected. VPM transcripts were imported into Nvivo 12 for coding and analysis. The multidimensional approach to health was used as a framework to develop themes of interest and their relationships using a mind map. Data were presented as narratives with quotes to substantiate the findings. Narratives of under-five deaths were based on symptoms experienced prior to death including fever, diarrhea, anal sore, convulsion, swollen stomach and feet and anaemia. Some carers treated their children with orthodox medicine and others used both orthodox and traditional/herbal medicine. Carers who used orthodox medicine initiated treatment by obtaining medicine from over-the-counter sellers. Children were sent to the community-based health planning and services compound/heath centers in their communities and subsequently to the district hospital when the illness did not resolve. There was no clear sequence of health seeking for carers who used both orthodox and traditional/herbal medicine. It was observed that some carers initiated treatment with traditional/herbal medicines at home and continued with orthodox medicine when the illness did not resolve. Others started with orthodox and later with traditional/herbal medicine. It emerged that some carers believe certain illnesses including convulsion and body swellings are not "hospital illnesses" and requires traditional/herbal medicine. There was no clear trajectory for the management of under-five illness. Cultural beliefs influences health seeking behaviour for under-five illnesses. Continues public health education is needed to encourage early care seeking at health facilities and to discourage self-medication to reduce under-five deaths.

102

QUALITY OF CARE FOR FEBRILE CHILDREN: AN ANALYSIS OF NATIONAL HEALTH FACILITY SURVEYS FROM MALAWI AND TANZANIA

Cameron Taylor, Jehan Ahmed, Wenjuan Wang

ICF, Rockville, MD, United States

The WHO Global Malaria Program's T3: Test. Treat. Track initiative recommends that every suspected malaria case is tested, every confirmed case is treated, and the disease is tracked by surveillance systems. To investigate the quality of care for febrile children and adherence to the "test" component of the T3 initiative, we examined data from the observation of sick child consultations and the exit interview of caretakers from the 2013-14 Malawi Service Provision Assessment (SPA) and the 2014-15 Tanzania SPA which are nationally representative health facility surveys. We identified essential elements of febrile clinical care for sick children recommended by the WHO that are also available in the SPA surveys. These included 1) the provider asking about fever, 2) child was felt for temperature, had their temperature taken with a thermometer, or checked for pallor by looking at palms, and 3) provider instructed child to see another provider or laboratory for a finger or heel stick for blood testing. As a proxy for severe malaria, children were excluded from the analysis if they presented in hospitals or were referred/admitted at end of the consultation. Among children who had a fever in the past two days according to the caretaker, 25% (N=2,698) in Tanzania and 43% (N=1,368) in Malawi received all three essential elements of febrile clinical care. We assessed facility, provider, and patient factors that might explain variations in febrile patient quality of care, using random-effects logit regressions. In both Malawi and Tanzania the results showed that facility readiness for malaria services including availability of mRDTs and microscopy supplies, were significantly associated with children receiving all three essential elements of febrile clinical care ($p<0.10$). Provider and patient factors were not significant except child's age. In both countries, these findings show the importance of malaria service readiness for providing high quality of care for febrile children. Having facilities with diagnostic capabilities will help ensure that providers adhere to the WHO T3 initiative.

103

SMS FOR LIFE, A DIGITAL SOLUTION TO IMPROVE THE AVAILABILITY OF ESSENTIAL MEDICINES IN NORTHERN ZAMBIA

Marcel Braun, Nadine Schecker, Viviam Patricia Canon

Novartis Social Business, Basel, Switzerland

By 2017, the population of Zambia was 17.4 m, life expectancy at birth was 66.3 y for females and 60.4 y for males. Despite the advances in diagnostic and treatments and the 63% reduction in mortality compared to 2007, HIV/AIDS is still the first cause of death. Tuberculosis and malaria mortality increased compared to 2007 and represented the 4th and 7th cause of death respectively. Timely and sustained availability of diagnostic tools and first-line treatment for those diseases is crucial. Interruption of HIV or TB treatments increases the risk of failure and selection of resistance. Lack of availability of rapid diagnostic test (RDT) and/or malaria treatment increase the risk of adverse outcomes mostly in young children. SMS for Life in Zambia is a Novartis initiative started in 2018 as a public-private partnership with the MoH, Right to Care/EQUIP and Vodacom. Objectives: 1) demonstrate that visibility of weekly stock levels of essential commodities will promote actions to reduce or eliminate stock-outs, 2) Demonstrate that simple customized digital solutions may be successfully implemented in remote areas and 3) demonstrate the benefit of public-private partnerships in public health. The items surveilled included RDT (13), malaria treatments (4), HIV medicines (4 ARV, 1 prophylaxis), and TB (1 first-line treatment, 1 prophylaxis). One hundred eighty-six (186) health care facilities across three provinces of Zambia (Luapula, Muchinga and Northern) were included, covering approx. 3.2 million people. SMS for life works with SIM card equipped tablets, smartphones, feature phones

and a widely available telecommunications technology. Health care workers are trained and enabled to track stock levels of essential tests/medicines and send notifications to district officers every week. A report on the availability of commodities is generated as needed. A public-private partnership allows SMS for Life to provide visibility of stock levels of essential medicines using simple technology. The system has the potential to facilitate the provision of stock and alleviate the restricted availability of drugs in rural or under-resourced areas.

104

SOCIAL MEDIA USE IN EMERGENCY RESPONSE TO NATURAL DISASTERS: A SYSTEMATIC REVIEW WITH A PUBLIC HEALTH PERSPECTIVE

Kamalich Muniz-Rodriguez[1], Sylvia K. Ofori[1], Kadiatou Diallo[1], Manyun Liu[1], Jessica S. Schwind[1], Gerardo Chowell[2], Isaac Chun-Hai Fung[1]

[1]*Jiann-Ping Hsu College of Public Health, Georgia Southern University, Statesboro, GA, United States,* [2]*School of Public Health, Georgia State University, Atlanta, GA, United States*

Natural disasters affect the lives of thousands of people every year. The damages caused by these events call for a multiagency response, where effective communication and coordination are essential. Previous research has explored the usefulness of social media analysis during a natural disaster as a tool to guide response efforts with a focus on geography and computational methods. The purpose of our research is to study the implications of social media use during natural disaster specifically focusing on the public health implications in the response phase of the emergency. We conducted a systematic literature review on natural disasters and social media use during the emergency response phase. Three databases, PubMed, IEEE Xplore, and Web of Science were searched in September 2018 using three different keyword combinations. Articles that complied with our inclusion criteria were independently reviewed, and their findings were analyzed to answer our research questions. A total of 47 full-text articles were included in our study. Analyses of social media data were performed at a wide range of spatial and time scales ranging from countries, states, or cities, and measured from minutes, hours, and days. Twitter was the most analyzed platform, followed by Facebook. Social media was used as a tool to identify areas in need of relief operations by using self-reported location. Researchers identified individuals in need of medical assistance, areas without water supply and electricity. One of the most common uses of social media data is map development for location, needs, direction of relief operations, and disaster intensity. Twitter was mostly identified as a broadcasting tool, and platforms like Facebook were recognized as a two-way communication tool. The identification of social media platforms as a broadcasting tool presents an opportunity for public health agencies to address rumor control during a natural disaster. In retrospective analyses, social media analysis shows promise as an opportunity to reduce the time of response and to identify the individuals' location. However, further research is needed to evaluate the use in real-time.

105

THE VALUE-ADD OF PARTICIPATORY RESEARCH TECHNIQUES TO INFORM ZIKA PREVENTION PROGRAMS: A QUALITATIVE STUDY IN THE DOMINICAN REPUBLIC

Tilly Gurman, Anne Ballard, Gabrielle Hunter

Johns Hopkins University, Baltimore, MD, United States

A challenge in Zika prevention efforts is the need to promote multiple behaviors (e.g. using repellent/condoms during pregnancy, cleaning water storage containers, removing standing water). While epidemiological data and quantitative surveys offer important information for Zika-related programs aiming to foster behavior change, data elicited from novel qualitative participatory techniques (e.g. free listing, pile sorting) can inform even more comprehensive programs. The current qualitative study (n=88) used three participatory techniques in focus group discussions (FGDs) and in-depth interviews (IDIs) to explore Zika-related perceptions among pregnant and non-pregnant women (ages 18-30) and male partners of pregnant women in the Dominican Republic. First, using free listing, individuals met with an interviewer and listed, top-of-mind, the behaviors that people in their community perform to prevent Zika. Second, FGDs employed pile sorting to categorize and prioritize Zika-related behaviors according to perceived effectiveness/feasibility. Finally, participants simulating the cleaning of water storage containers via drawings and physical demonstrations spurred group discussion about common cleaning practices. Data analysis also included a participatory process with local stakeholders that yielded contextually relevant themes. Free listing findings indicated that no single behavior was mentioned by a majority of respondents. From pile sorting activities, multiple insights surfaced. Participants associated health/well-being with cleanliness—the concern for Zika only existing during outbreaks or when given attention by media/government. Participants further noted that responsibility for vector-control behaviors fell to community groups/local authorities. The cleaning simulation activities found that people valued the use of bleach, although the amount and technique varied. The current study contributes insights about perceptions of Zika-related behaviors and highlights the value-add of using participatory research techniques to inform behavior change programs for Zika or other arboviruses.

DETERMINANTS OF VACCINE COVERAGE IN A COHORT OF CHILDREN IN OSHIKHANDASS, A NORTHERN PAKISTANI VILLAGE

Alexandra Jamison[1], Elizabeth Thomas[1], Ejaz Hussain[1], Iqbal Azam[2], Wasiat Shah[1], Benjamin McCormick[1], Zeba Rasmussen[1]

[1]*Fogarty International Center, National Institutes of Health, Bethesda, MD, United States,* [2]*Aga Khan University, Karachi, Pakistan*

Pakistan initiated its Expanded Programme on Immunization (EPI) in 1978, but the incidence of vaccine preventable disease remains among the highest in the world. We describe vaccine completeness, timeliness and determinants of coverage from a cohort study (2012-2014) in a rural northern Pakistani village. Health workers compiled vaccination history using EPI vaccine cards along with maternal report and Lady Health Worker registries. Vaccination was complete if all doses were received according to the EPI schedule and timely if doses were not ≤3 days early or > 28 days late. Univariate chi-squared tests and a multivariable logistic regression were used to examine factors associated with completeness; variables included parental education and age, household income and assets, distance from the vaccine dispensary and the total number of children in the family. Of 1104 children followed to 12 months, 73% (802) had full vaccination histories: of these, 514 (64.1%) were fully vaccinated, 245 (30.5%) partially vaccinated and 43 (5.4%) unvaccinated. Coverage was highest for the BCG vaccine (94.1%) and lowest for measles (74.7%). Timeliness declined with subsequent doses, for example, 80.8% received their first dose of OPV on time, but only 42.6% received a fourth dose on schedule. Overall, only 18.5% of those fully vaccinated received all doses on schedule. The child's birth order, total number of children in the family, parental education and the year of family's migration to the village were all significant in univariate analysis of coverage. Adjusting for other variables, only the total number of children in the family remained statistically significant (OR=1.45, 95%CI=1.12, 1.88). Our results highlight three key points: (i) coverage decreases for vaccines with multiple or later doses. (ii) Drivers of vaccine coverage are multifactorial, but after adjusting for child and family factors, the more children in the family the more likely that a child is fully vaccinated. (iii) Despite implementing the EPI with greater coverage than the national average, disappointingly few vaccines were timely, potentially undermining their effectiveness.

107

COLLABORATIVE IMPROVEMENT APPLIED TO MALARIA SURVEILLANCE DATA QUALITY IN UGANDA: A COMPARISON OF OUTCOMES REPORTED BY INTERNAL QUALITY IMPROVEMENT TEAMS VERSUS AN INDEPENDENT EVALUATION IN UGANDA

Nelli Westercamp[1], Sarah Staedke[2], Catherine Maiteki-Sebuguzi[3], Simon Kigozi[3], John Michael Okiring[3], Alexander K. Rowe[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Infectious Disease Research Collaboration, Kampala, Uganda*

Transforming malaria surveillance into a core intervention is a pillar of the Global Technical Strategy for Malaria but ensuring high quality of routinely collected data remains a challenge. Collaborative improvement (CI) is an innovative quality improvement method that encourages shared learning and continuous assessment of performance indicators by health facility (HF) based teams. Evidence suggests CI is promising; however CI effectiveness has been evaluated primarily through data self-reported by internal CI teams, which may be subject to bias. In 2015-16, we evaluated whether CI could improve the quality and accuracy of malaria surveillance data in 5 HFs in Kayunga, Uganda. Data accuracy was measured by comparing the number of individual malaria cases recorded monthly in the outpatient register to aggregated numbers reported in monthly summary reports. The relative difference in these numbers (the accuracy indicator) was determined by internal CI teams and an external team of independent evaluators. Comparisons were made with Pearson's correlation and mean differences. Overall, Pearson's correlation was 0.43 for the accuracy indicator across all 5 sites, ranging from -0.06 to 0.99 for each individual HF. Mean differences in the self-reported accuracy by CI teams compared to the evaluation data were -2 %-points for all sites, ranging from -15 %-points to -3 %-points for higher level (larger, complex) HFs and 4-6 %-points for lower level HFs. Negative values here indicate that CI teams found greater reductions in discrepancies between the data sources, and thus a greater improvement in accuracy of data, compared to evaluation results. The correlation between the CI team and evaluation data was moderate, with considerable variations across different HFs. Our results suggest that in higher level HFs, internal CI teams may have overestimated the impact of CI on data accuracy. Improving quality of malaria surveillance data is a high priority. Additional research of the effectiveness of CI on improving data quality is needed. Future studies of CI should include an independent evaluation to ensure the impact evaluation is valid and unbiased.

108

THE INFLUENCE OF TRAINING ATTRIBUTES ON THE EFFECTIVENESS OF TRAINING TO IMPROVE HEALTH WORKER PRACTICES IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW

Alexander Rowe[1], Samantha Rowe[1], David Peters[2], Kathleen Holloway[3], Dennis Ross-Degnan[4]

[1]*US Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Institute of Development Studies, University of Sussex, Brighton, United Kingdom,* [4]*Harvard Medical School, Boston, MA, United States*

Health worker (HW) performance in low- and middle-income countries (LMICs) is often inadequate, and in-service training is a common strategy for improving performance. To explore how training attributes influence training effectiveness (and thus identify ways to increase training impact), we identified training studies with HW practice outcomes expressed as a percentage (e.g., % of patients treated correctly) from a systematic review on improving HW performance in LMICs. Effect sizes were calculated as adjusted risk differences. To estimate the effect of training attributes, we examined head-to-head studies that directly compared different training approaches, and we used random-effects linear regression modeling on studies of training with different approaches versus a control group. We searched 52 databases for published studies and 58 document inventories for unpublished studies up to 2016. We screened 216,477 citations and identified 179 eligible studies for this analysis. Most studies (105/179 or 58.7%) had a high risk of bias. Training tended to be more effective when it was at least partly conducted where HWs routinely work (by 9.4–10.9 %-points), tailored to a HW's stage of readiness to change (23.3 %-points; only 1 study), taught a protocol (versus allowing HWs to use their discretion, by 8.4 %-points; only 1 study), or used clinical practice (6.7–7.5 %-points). The mean effect of training without supervision tended to decrease over time after training (0.8–1.0 %-point decrease per month), but this decay was not seen when training was combined with supervision. Attributes such as training duration, training with computers or interactive lectures, training via live video interactive sessions, and pedagogical background of trainers had little influence (effects of 4.3 %-points or less). The effect of training group size and having trainers with content expertise was unclear because of conflicting results from different analyses. In conclusion, although many knowledge gaps remain, there is promising evidence that several approaches might increase the effectiveness of training courses to improve HW practices in LMICs.

109

EXPANDED FEVER SURVEILLANCE AMONG PROVINCIAL HOSPITALS IN THE LAO PEOPLE'S DEMOCRATIC REPUBLIC

Jose A. Garcia[1], Vilada Chansamouth[2], Matthew Robinson[2], Paul Newton[2]

[1]*US Navy, Phnom Penh, Cambodia,* [2]*Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic*

With declining *Plasmodium falciparum* malaria in the Lao PDR (Laos), there is an urgent need to determine the causes of fever in order to guide optimal empirical therapy and to determine key diseases for enhanced surveillance. Presently, there remain gaps in information from Southeast Asia to provide a comprehensive assessment. An ongoing two-year study is currently being conducted in three hospitals in the Luang Nam Tha, Xieng Khuang and Salavan provinces located in northern, central and southern Laos, respectively, to obtain evidence on the causes of fever and address this information gap. From August 2017 until February 2019, a total of 2,899 subjects who met the minimum case definition of body temperature ≥37.5°C were enrolled. The majority of the enrolled subjects were adults (>15 years), with 1,740 (60%) being within the median age of 23 (4-50) while 1,508 (52%) were male. Preliminary data shows that of the 2,899 subjects, 125 (4.3%) were confirmed to have dengue fever, followed by bacteremia (84, 2.9%) and Japanese encephalitis virus infection (9, 0.3%). This study to date has demonstrated important differences in the aetiology of fever among the northern, central and southern regions of Laos with there being 48% and 71% more febrile cases detected in the southern region (121/218, 55.5%) when compared against the northern (63/218, 28.8%) and central regions (35/218, 16%) respectively, with dengue fever being the most prevalent. Thus paving the way to initiate more in-depth resistance profiling surveys to address if differences exist in the presence of antimicrobial resistance among both viral and bacterial pathogens within these areas.

110

PILOTING A NON-VERBAL COGNITIVE ASSESSMENT BATTERY, THE LEITER INTERNATIONAL PERFORMANCE SCALE, THIRD EDITION (LEITER-3), IN HEALTHY UGANDAN CHILDREN AND ADULTS

Erika S. Phelps Nishiguchi[1], Shubaya K. Naggayi[2], Mary Nyakato[2], Jacqueline Nakitende[3], Megan S. McHenry[4], Robert O. Opoka[3], Paul Bangirana[3], Chandy C. John[4]

[1]*University of Washington, Seattle, WA, United States,* [2]*Global Health Uganda, Kampala, Uganda,* [3]*Makerere University, Kampala, Uganda,* [4]*Indiana University, Indianapolis, IN, United States*

As global pediatric health priorities shift from surviving to thriving, there is need for globally relevant language-independent developmental assessment tools. The Leiter International Performance Scale, 3rd Edition (Leiter-3) evaluates nonverbal cognitive abilities through ten sub-tests explained using pantomimed instructions. It is promoted as a culturally fair, language-neutral assessment. To assess feasibility, validity, and acceptability of the Leiter-3 in the Ugandan population, a pilot study will be conducted in two phases: 1) training and 2) psychometric evaluation and acceptability. Three experienced Ugandan psychology research assistants (RAs) were trained to administer the Leiter-3. The training, clarification, and adaptation process took place over 2 months. This included roleplaying and field testing with volunteer children and adults. The RAs worked with a trainer and a representative from the test's publisher to clarify instructions, develop responses to participants' behaviors, and adapt pantomimes for poorly understood sub-tests. Qualitative feedback was sought from RAs and volunteers. Administration consistently required 90-120 minutes, longer than the published 20-45 minute duration. The RAs reported initial discomfort with the manual's instructions, with administering the test in silence, and with managing challenging behaviors. The next phase is to pilot the Leiter-3 in 40 healthy Ugandan children and young adults. The pilot will include administration of previously validated verbal tools, the Kaufman Assessment Battery for Children, 2nd edition (KABC-II) and Ugandan Neuropsychology Battery (UNPB), to enable psychometric evaluation of the Leiter-3. Face validity and acceptability will be assessed through semi-structured interviews of pilot participants. Inter-rater reliability will be calculated, and RAs will be interviewed at the beginning and end of the pilot period to assess acceptability of test administration. We expect these efforts to provide a comprehensive understanding of the strengths and limitations of using the Leiter-3 in the Ugandan setting.

111

LESSONS LEARNED IN HEALTH INFORMATION SYSTEM STRENGTHENING: WHAT WORKED FOR THE DEMOCRATIC REPUBLIC OF THE CONGO

Lavanya Gupta[1], Scott McKeown[1], Johanna Karemere[2], Olivier Kakesa[2], Ramine Bahrambegi[3]

[1]*MEASURE Evaluation, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*MEASURE Evaluation, ICF, Kinshasa, Democratic Republic of the Congo,* [3]*MEASURE Evaluation, ICF, Rockville, MD, United States*

Since 2014, MEASURE Evaluation has helped the National Malaria Control Program (NMCP) of the Democratic Republic of the Congo (DRC) to streamline and improve routine malaria data collection, reporting, management, and use at all levels of the health system to facilitate intervention targets. We have supported the rollout of the electronic health information platform—DHIS 2—in all 178 health zones and 77 health facilities in 9 PMI-targeted provinces; the integration of malaria indicators in DHIS 2; the training of more than 400 staff in monitoring and evaluation, data collection, analysis, and use; the development of health information system (HIS) management resources; and the implementation of data review and data quality check mechanisms. We sought to document the outcomes of our work with the NMCP and identify effective HIS strengthening interventions for health data including malaria, by conducting in-depth interviews with staff members at the national, provincial, and health facility levels. Interviews included questions about engagement with MEASURE Evaluation, any trainings attended, and perceived facilitators of and barriers to a strong HIS. From the audio-recorded interviews we developed in-depth notes and analyzed them with thematic coding. The data analysis yielded three primary themes: access to DHIS 2 supported capacity building in data collection and reporting; the capacity to oversee and participate in data quality assurance practices facilitated more timely and complete routine data; and the establishment of data review mechanisms at all levels of the health system provided opportunities for stakeholders to make key data-informed decisions. Each of these contributions has improved data quality and data use, thus improving overall HIS performance in the DRC. Although respondents noted that some challenges remain, these observations demonstrate the interventions' effectiveness. Our approaches represent best practices in HIS strengthening that could be adapted and implemented in other disease and country contexts.

112

DESCRIPTIVE ANALYSIS OF VACCINE-PREVENTABLE DISEASES IN THE DOMINICAN REPUBLIC: IS PUBLIC MEDIA COUNTERACTING THE PUBLIC HEALTH EFFORTS?

Priscilla M. Abate[1], Jose A. Duran[2], Paola Peña[3], **Leandro Tapia**[2], Robert Paulino-Ramirez[2]

[1]*Centro Medico Otorrino, Santo Domingo, Dominican Republic,* [2]*Institute for Tropical Medicine and Global Health - Universidad Iberoamericana, Santo Domingo, Dominican Republic,* [3]*Centro de Gastroenterologia Avanzada, Santo Domingo, Dominican Republic*

The Anti-vaccination movement has dominated media; meanwhile public health policies are being conducted to counteract declining vaccination rates. Despite the efforts made, in recent years there has been an increase in vaccine preventable diseases, especially in tropical and sub-tropical regions. These diseases have caused outbreaks in the Caribbean and low-income countries. The aim of this study is to characterize vaccine preventable diseases in the Dominican Republic from 2012-2018. Data of cases of Vaccine Preventable Diseases included in the Governmental Immunization Program and their demographic characteristics were extracted from the Ministry of Health Weekly Reports (digepi.com.do) in order to establish prevalence and describe demographic patterns. A total of 777 cases were analyzed, of which *B. pertussis*, represented a total of 411 cases, 48% females, and a, mean age of 128 days (3 days - 16 years); *C. tetani*, a total of 329 cases, 88% males with a, mean age of 41 yo. On the neurological related preventive illnesses, those caused by *S. pneumoniae*, a total of 27 cases, 59% males and 41% females, with a mean age of 8 years (73 days - 76 years). Mortality rates related to those illnesses accounted for 41% related to meningitis, 27% for tetanus, and 5% related to pertussis. In animal-transmitted preventable vaccination Rabies accounted for a total of 10 cases, in the majority affecting males (70%), and a mortality rate of a 100% in mid-age individuals (mean age 12 yo). Vaccine preventable diseases seem to have a major impact in public health, especially *B. pertussis*. Mortality by vaccine preventable diseases constitutes an important part of reported cases. Counteracting measures to increase intake of vaccines and reinforcement of vaccine coverage are still needed, many questions remains from the local perspective, are this lower coverage induced by lack of education, or the negative impact of media, case-control and infectious disease modeling are needed to estimate the real impact of communicable diseases prevented by current interventions in the DR.

113

CHARACTERIZATION OF SIERRA LEONEAN VILLAGES USING SATELLITE IMAGERY AND OBJECT IMAGE RECOGNITION TECHNOLOGIES

Jeffrey G. Shaffer[1], Katherine L. McKeon[2], Christian J. Geneus[2], Seydou O. Doumbia[3], Frances J. Mather[2]

[1]*Tulane University, Harahan, LA, United States,* [2]*Tulane University, New Orleans, LA, United States,* [3]*University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali*

Field research in Africa often necessitates the characterization of community-level attributes such as populations, household sizes, population densities, and proximity to water bodies. Field-based characterization approaches such as door-to-door censuses and data capture with global positions system devices is commonly impractical due to resource limitations. This work focuses on remote characterization techniques through feature extraction from satellite imagery through the joint use of the ENVI (Broomfield, CO) image analysis application and the ArcGIS geographic information system (Redlands, CA). Prior efforts in Africa utilizing satellite imagery in this sense have focused on (through alternative approaches) capturing census data and developing sampling frames in Ethiopia and Malawi, respectively. Here we detail an approach for characterizing Sierra Leonean villages according to population size, household size, and household distances to roads and water bodies. Supervised classification methods were applied using the ENVI Feature Extraction Module classifying features according to village housetops, roads, and water bodies. Vector-based shapefiles were generated these features and were summarized using the ArcGIS application. Summary statistics were generated for the number of households in each village, and village populations were determined by calculating the number of housetops and multiplying by a factor proportional to housetop sizes. Average distances between households to streams or roads were determined using spatial joins. Village population densities were estimated using the ArcGIS Nearest Neighbor Tool. Summary population statistics were generated for an entire Sierra Leonean chiefdom and compared with the Sierra Leone 2015 Population and Housing Census. Village characterization using the ENVI/ArcGIS approach described here has great utility for carrying out research in remote areas and may provide a viable alternative or complementary approach to more costly field-based methods.

114

SOCIAL DETERMINANTS OF HEALTH ASSOCIATED WITH LEPTOSPIROSIS IN A RURAL POPULATION IN CÓRDOBA-COLOMBIA

Virginia C. Rodríguez, Ana M. Castro, Alfonso Calderón, Maria F. Yasnot, Isabel Arcila, Luis F. Urango

Universidad de Córdoba, Monteria, Colombia

Leptospirosis is a zoonotic bacterial disease of worldwide importance, caused by pathogenic species of the genus *Leptospira*. Despite the great negative impact that it have on public health, little is known about the environmental and social conditions that are important for its development in Alto Sinú in Córdoba (Colombia). A cross-sectional descriptive study was carried out from May to October 2018. By a randomized sampling 324 individuals from the localities of Crucito and Frasquillo of the municipality of Tierralta-Córdoba were included in the study. The informed consent and the epidemiological record with articulated questions about the structural and intermediate social determinants that could be related to the disease were completed by the participants. A microagglutination test (MAT) was performed on blood samples, and the seroprevalence was determined. A univariate analysis of the information, associated tests and statistical significance were performed. The majority of the population was male adults residing in scattered, rural areas of low socioeconomic status without fixed income and under the legal monthly minimum wages. The largerst part of the population (95.5%) have not waste disposal or solid waste management services and only 9.6% had an aqueduct service. The existence of the disease was 58.3% and 27.47% had titers greater than 1:400. A risk association was determined for the presence of leptospirosis in the waters of the dam in which the population engage in recreational activities, bathe or fish. The environment where the population developed has characteristics that act as coadjutants in the development of leptospirosis. For example, inadequate basic sanitation conditions, close coexistence with the animals, low level of schooling, difficult access to the services of health and consumption of untreated water are all factors that can increase the risk of contracting leptospirosis. The contact with water from the dam is a risk factor that can actively participate in the dissemination or development of contagious leptospirosis in the analyzed population.

115

GENETIC DIVERSITY OF *BARTONELLA* SPP. IN VAMPIRE BATS IN BRAZIL

Marcos Rogério André[1], Ricardo Gutierrez[2], Priscila Ikeda[1], Renan Amaral[1], Keyla Sousa[2], Yaarit Nachum-Biala[2], Luciana Lima[3], Marta Teixeira[3], Rosangela Machado[1], Shimon Harrus[2]

[1]*Universidade Estadual Paulista (UNESP), Jaboticabal, Brazil,* [2]*Koret School of Veterinary Medicine, The Hebrew University of Jerusalem, Rehovot, Israel,* [3]*Universidade de São Paulo (USP), São Paulo, Brazil*

Recently, an increasing number of *Bartonella* species have emerged to cause human diseases. Among animal reservoirs for *Bartonella* spp., bats stand out due to their high mobility, wide distribution, social behavior, and long-life span. Although studies on the role of vampire bats in the epidemiology of rabies have been extensively investigated in Latin America, information on the circulation and genetic diversity of *Bartonella* species in these bat species is scarce. In the present work, 208 vampire bats, namely *Desmodus rotundus* (the common vampire bat; n=167), *Diphylla ecaudata* (the hairy-legged vampire bat; n=32) and *Diaemus youngii* (the white-winged vampire bat; n=9) from 15 different states in Brazil were sampled. DNA was extracted from liver tissue samples and submitted to real-time PCR and conventional PCR assays for *Bartonella* spp. targeting five genetic *loci*, followed by phylogenetic and genotype network analyses. Fifty-one out of 208 liver samples (24.51%) were positive for *Bartonella* DNA in the ITS real-time PCR assay: 40 (78.43%) of them were from *D. rotundus* from 11 states, and 11 (21.57%) samples from *D. ecaudata* from three states. Eleven genotypes were found among the obtained *gltA* and *rpoB* sequences. Several ITS sequences detected in the present study clustered within the lineage that includes *B. bacilliformis* and *B. ancachensis*. The Bayesian phylogenetic inference based on the *gltA* gene positioned the obtained sequences in six different clades, closely related to *Bartonella* genotypes previously detected in *D. rotundus* and associated ectoparasites sampled in Latin America. On the other hand, the *Bartonella rpoB* genotypes clustered together with the ruminant species, *B. schoenbuchensis* and *B. chomelii*. The present study describes for the first time the molecular detection of *Bartonella* spp. in *D. ecaudata* bats. It also indicates that *Bartonella* spp. of vampire bats are genetically diverse and geographically widespread in Brazil.

116

INVESTIGATION OF THE EMERGENCE OF TYPHUS GROUP *RICKETTSIA* IN CENTRAL TEXAS

Leigh E. Preston[1], Rebecca Fischer[1], Kristy Murray[2], Sarah Hamer[3], John Midturi[4], Rodion Gorchakov[2], Bonnie Gulas-Wroblewski[5], Jennifer Horney[1]

[1]*Texas A&M University School of Public Health, College Station, TX, United States,* [2]*Baylor College of Medicine, Houston, TX, United States,* [3]*Texas A&M University College of Veterinary Medicine, College Station, TX, United States,* [4]*Baylor Scott & White Health, Temple, TX, United States,* [5]*Texas A&M University Department of Wildlife and Fisheries Sciences, College Station, TX, United States*

Typhus group rickettsiosis (TGR) is a vector-borne disease caused by *Rickettsia typhi* or *Rickettsia prowazekii*, transmitted via flea and thought

to circulate among small mammals. TGR may present as non-specific and resemble other febrile illnesses. Little is known about TGR in Texas, but evidence of its recent emergence and spread highlights knowledge gaps about its clinical and epidemiologic features. This study sought to describe TGR clinical disease and risk factors, as well as identify animal hosts in central Texas. Medical record abstractions were done on patients referred for TGR testing at Baylor Scott & White (BSW) hospitals and clinics from Jan 2012 to Aug 2018. Odds ratios (OR; 95% CI) are reported for factors associated with laboratory confirmed TGR. PCR for *R. typhi* was performed on banked animal specimens collected in central Texas from Apr 2012 to May 2018. Of 384 patients referred for testing, 16 (4%) had TGR, 69 (18%) had Rocky Mountain spotted fever (RMSF), and 299 (78%) had neither. The number of TGR cases increased from 0 in 2012 to 5 in 2018 ($p<0.001$). Most TGR patients were febrile (87.5%) and suffered acute liver injury (68.8%). Compared to RMSF patients, TGR patients were older (OR: 1.06, per year; 1.01-1.10) and more likely to have liver signs (OR: 8.60; 2.06-35.96) and systemic inflammation (OR: 6.58; 1.21-35.89). RMSF patients more often had heart disease (OR: 0.13; 0.02-0.77). TGR patients lived on a farm, ranch, or wooded area (OR: 31.05; 4.01-240.17) more often than patients without rickettsiosis. *R. typhi* was not detected in animals (238 skunks, 196 canines, 7 opossums, 6 rodents, 2 raccoons). This study confirms TGR as an emerging zoonosis in central Texas, making clinician education on rickettsial diseases a critical next step. While no specific animal was found to harbor *R. typhi*, it remains vital to explore what species are involved in maintenance of transmission cycles in the region. This study also revealed important discrepancies in diagnostic criteria for clinical, surveillance, and research purposes, which likely contributes to under-reporting and missed diagnoses, ultimately to an underestimation of disease.

117

"STOPPING THE ITCH": MASS DRUG ADMINISTRATION FOR SCABIES OUTBREAK CONTROL FOR OVER 15 MILLION PEOPLE IN THE AMHARA REGION OF ETHIOPIA

Wendemagegn Embiale Yeshanehe[1], Tariku Baynie[2], Ashenafi Ayalew[3], TekileHaimanot Gebrehiwot[3], Tesfa Getanew[3], Alie Ayal[3], Rony Zachariah[4]

[1]*Bahir Dar University, Bahir Dar, Ethiopia,* [2]*Amhara Health Bureau, Bahir Dar, Ethiopia,* [3]*Amhara Public Health Institution, Bahir Dar, Ethiopia,* [4]*UNICEF/UNDP/World Bank/WHO Special Programme for Research and Training in Tropical Diseases (TDR), World Health Organization, Geneva, Switzerland*

Scabies is a Neglected Tropical Disease (NTD) of public health importance. The Amhara region in Ethiopia is one of the scabies endemic area with public health intervention since 2015. In June 2018 following screening of more than 15 million people in house to house census intervention was planned. This study was ubdertaken to describe the implementation of mass drug administration campaign for scabies outbreak control and community prevalence in the Amhara region of Ethiopia. Cross sectional descriptive study using routine monitoring data from the Mass Drug Administration (MDA) campaign. The study has included all individuals screened for scabies during the MDA campaign in the region. The study looked in to the numbers screened and identified with scabies (cases and contacts); the proportion of detected scabies stratified by treatment sub-groups. We used descriptive statistics to present the finding. From May 14 to June 20 on the campaign planning 15701907 residents were screened which has registered 718597 cases and 956017 contacts in 142 administrative districts. While the follow up treatment campaign from July 2 to August 26, 2018, has treated 815065 scabies cases and 1055071 contact. The regional mean scabies prevalence of 9 % (ranging 0.1 to 40.4%). 55.2% of cases are under 18 years old and 3.7 % of those are below 2 years old. While Ivermectin was used to treat 93.7% of scabies cases and 95.2% of contact the rest treated by Permethrin. There were about 202 health workers per 100,000 population involved in the MDA campaign and in each district the campaign has taken in average 6 days. In conclusion, the campaign has screened over 15 million people, delivering an Ivermectin based MDA for 1.87 million scabies cases and their contact successfully. The experience will contribute to the WHO initiative of development of scabies control framework.

118

THE POSSIBLE POLYMICROBIAL ETIOLOGY OF ALZHEIMER'S AND RELATED DEMENTIA

Remi L. Landry[1], Shiva K. Gadila[2], Monica E. Embers[3]

[1]*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States,* [2]*Tulane University National Primate Research Center, Covington, LA, United States,* [3]*Tulane University School of Medicine, New Orleans, LA, United States*

Observational and pathological studies have generated evidence for the complexity and possible polymicrobial causality of dementia-inducing diseases. It is thought that microbes and pathogens can act as triggers and interact with genetic factors to initiate neuronal loss, progressive synaptic dysfunction, the accumulation of amyloid-β peptide parenchymal plaques, tau protein neurofibrillary tangles, and inflammation in the brain. There is parallel concern regarding the role of persistent pathogens in the development of chronic Lyme neuroborreliosis. Conversely, review articles have suggested that Alzheimer's disease (AD) could be a neurospirochetosis. Evidence indicates that *Borrelia burgdorferi, Chlamydophila pneumoniae,* and *Candida albicans* are able to infect and evade the immune system and consequently are prevalent in the AD brain. To examine the possibility that microbes are contributing to Lyme and AD neuropathology, we will probe post-mortem brain tissues from patients with a history of neurologic Lyme disease, Alzheimer's disease, and non-dementia controls. This broad approach will include immunofluorescent staining with two separate antibodies and fluorochromes per pathogen, RNA *in situ* hybridization to identify targets and assess their viability, PCR with degenerate primers, and DNA and RNA next-generation sequencing. Samples of the hippocampus, frontal and parietal cortices, and the inferior temporal cortex will be sectioned for molecular detection and pathogen-specific staining. We will employ a target enrichment approach by utilizing oligonucleotides containing conserved species-specific sequences prior to sequencing. Pathology in the form of inflammatory lesions and AD plaques will be used as a road map for pathogen detection. Non-human primate samples spiked with pathogen or free of infection will serve as positive and negative controls, respectively. By completing this study, we expect to have a comprehensive understanding of the roles of persisting pathogens in both AD and Lyme disease.

119

SYSTEMATIC REVIEW OF SCRUB TYPHUS DRUG EFFICACY STUDY LANDSCAPE

Kartika Saraswati[1], Brittany Maguire[2], Sauman Singh[2], Nicholas P. Day[3], Philippe J. Guérin[2]

[1]*Eijkman-Oxford Clinical Research Unit, Eijkman Institute for Molecular Biology, Jakarta, Indonesia,* [2]*Infectious Diseases Data Observatory (IDDO), Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [3]*Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand*

One billion people are at risk of scrub typhus. Considering the magnitude of this public health problem, the evidence available to optimise treatments and disease control is sparse. Existing data collected from past clinical trials and longitudinal observational studies could be a source of information to address research priorities and knowledge gaps. Meta-analysis using an individual participant-level data (IPD) approach can produce a more representative secondary analysis because it facilitates the use of data from observational studies as well. We conducted a systematic review to assess the characteristics of scrub typhus clinical studies, the strength of evidence supporting current recommendations and to explore the feasibility of developing a scrub typhus IPD platform. Six databases and two clinical trial registries were searched for clinical trials and longitudinal

observational studies conducted between 1998 and 2018. Variables for extraction include treatment tested, patient characteristics, diagnostic methods, geographical location, outcome measures, and statistical methodology. The literature searches identified 5,163 citations, of which 2,647 unique articles were independently screened by two reviewers. A total of 95 studies (7 clinical trials and 88 observational studies) met the pre-specified inclusion criteria. The studies have been conducted in 11 countries and enrolled a total of 9,010 patients. Although there were only a few scrub typhus clinical trials found, there are substantially more data available from observational studies. Understanding the landscape of scrub typhus treatment studies allows assessment of the feasibility of addressing research questions using IPD meta-analysis method as well as research gap analysis.

MOLECULAR CHARACTERIZATION OF *BARTONELLA* SPECIES IN ECTOPARASITES COLLECTED FROM DOMESTIC ANIMALS, CUZCO, PERU

Carmen Flores-Mendoza[1], Steev Loyola[1], Ju Jiang[2], Mariza Lozano[1], Michael Fisher[1], Allen L. Richards[3]

[1]*U.S. Naval Medical Research Unit No. 6, Callao, Peru,* [2]*Medical Research Center, Silver Spring, MD, United States,* [3]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States*

Rickettsiae and bartonellae are Gram-negative bacteria that cause zoonotic and human diseases and are vectored by hematophagous arthropods such as mites, ticks, lice, sandflies, and kissing bugs. In the Americas, rickettsioses and bartonelloses have reemerged as a significant public health threats. A total of 222 domestic animals representing 8 different species of domestic animals (donkeys, horses, cattle, pigs, goats, guinea pigs, sheep and llamas) were sampled. Ectoparasites (n=1,697) collected from 122 of the animals were identified: 1657 lice, 39 ticks, and 1 flea. A total of 600 (35%) samples were DNA extracted for qPCR from the following ectoparasite species: *Tunga penetrans* (1), *Bovicola caprae* (3), *Haematopinus eurysternus* (3), *Bovicola equinus,* (8), *Bovicola bovis* (8), *Linognathus stenopsis* (15), *Haematopinus suis* (22), *Otobius megnini* (35), and *Melophagus ovinus* (505). All samples tested were negative for rickettsial DNA. A total of 173 (28.8%) DNA samples were screened for *Bartonella* by a genus-specific qPCR assay (StepOne Plus). *Bartonella* positive samples (n=91) were identified with threshold (Ct) values ranging 14.7 to 29.8 (mean: 21.4). For *Bartonella* species identification, PCR primers targeting *gltA*, *rpoB*, *ftsZ*, *rrs* and *groEL* genes fragments were used. *Bartonella bacilliformis* served as the PCR positive control. Seven PCR products were sequenced using Big Dye terminator kit and 3130XL genetic analyzer sequencing. According to Mega Analysis Software (version 7.O.21) and multilocus sequence typing analysis (MLST) *gltA*, *rpoB*, *ftsZ*, *rrs* and *groEL* gene sequences were found to matched to two *Bartonella* species: *Bartonella* melophagi and and an *Bartonella bovis*-like agent. *Bartonella* species are associated with disease in humans and animals. *B. melophagi* has been found in human blood but we do not know the roll of *Bartonella* bovis-like agent in human disease. Human and veterinary clinicians should be aware of the potential for louse-borne disease due to these *Bartonella* species. Research is on-going to determine the identity of the *Bartonella bovis*-like agent.

INVESTIGATING THE PREVALENCE OF PREVIOUS SPOTTED FEVER GROUP RICKETTSIA EXPOSURE ALONG THE SOUTHERN BORDER OF MONGOLIA

Michael E. von Fricken[1], Matthew A. Voorhees[2], Carmen Asbun[1], Brandon Lam[3], Paul Kuehnert[2], Jeffrey W. Koehler[2], Barbara Qurollo[4], Dulamjav Jamsransuren[5], Dolgorkhand Adiyadorj[5], Uyanaga Baasandagwa[5], Battsetseg Jigjav[5], Randal J. Schoepp[2]

[1]*George Mason University, Fairfax, VA, United States,* [2]*United States Army Medical Research Institute of Infectious Diseases (USAMRIID), Fort Detrick, MD, United States,* [3]*Johns Hopkins School of Medicine, Baltimore, MD, United States,* [4]*North Carolina State University, Raleigh, NC, United States,* [5]*National Center for Zoonotic Diseases, Ulaanbaatar, Mongolia*

Ticks are second only to mosquitoes as vectors of disease. Human tick-borne disease occurs through the bite of an infected tick, thus outdoor occupations in tick habitats are put humans at a higher risk of disease exposure. In Mongolia, 26% of the population relies on nomadic herding, which places them in contact with ticks and tick-borne diseases like rickettsia. This study was undertaken to investigate the extent of rickettsia exposure occurring in the nomadic population a total of 1,926 human serum samples were collected from southern Mongolia in 2013-2014, across five aimags (provinces) including Bayankhongor, Dornogovi, Govi-Altai, Khovd, and Ömnögovi. Immunofluorescence assays (IFA) were used at an initial screen of 1:100 to detect previous rickettsia exposure compared to *R. rickettsii* and *R. conorii* controls. Of the 506 slides screened thus far, 114 (22%) had antibody evidence of previous exposure. Additional analysis pending to determine hotspots of disease and the full extent of previous exposure. Rickettsia exposures are occurring along the southern border of Mongolia at a high rate based on antibody prevalence. Known species of spotted fever group rickettsia detected in ticks collected in Mongolia include *R. raoultii*, *R. sibirica*, and *R. sibirica mongoloitimonae*, with *Candidatus R. tarasevichiae* endemic in the north. These preliminary findings align with previous work in other parts of Mongolia that found ~20% seroprevalence, suggesting exposure occurs frequently and across a wide geographic range.

122

IMPROVING THE MOLECULAR DIAGNOSIS OF SCABIES USING A PCR ASSAY TARGETING HIGH COPY NUMBER REPEATS IDENTIFIED IN THE PARASITE GENOME

Cielo Pasay[1], Lena Chng[1], Deborah Holt[2], Katja Fischer[1], Matt Field[3], Josh Francis[4], Dev Tilakaratne[5], Zuleima Pava-Imitola[1], Kate Mounsey[6], Asha Bowen[7], Tony Papenfuss[8], Bart Currie[2], James McCarthy[1]

In recent years, considerable advances have been made in molecular diagnostic methods for many pathogens. This escalation in interest has occurred in parallel with data indicating inaccuracy of scabies diagnostics using currently available methods. With the recent availability of the scabies genome, we have developed two pilot diagnostic PCR assays targeting abundant repetitive DNA elements. These two abundant repetitive sequences were identified from Next Generation Sequencing (NGS) of scabies mite genomes: a >400bp satellite sequence and a 606bp LTR sequence. These targets generated > 200 and 300 BLAST hits respectively, across datasets assessed. The sensitivity of these new assays is being compared against a published reference assay targeting the Cox1 gene. To enhance assay performance, a mite DNA extraction method is also being optimised using a non-invasive (flocked swabs) sample collection methodology and will be tested against the standard skin scraping method. Results of assay optimisation and of qPCR sensitivity and specificity will be presented. A more sensitive and specific diagnostic assay for scabies would greatly assist clinical management, epidemiological studies and ease the conduct of trials to assess new acaricides.

123

SCRUB TYPHUS-AN EMERGING ETIOLOGY OF ACUTE FEVER WITH JAUNDICE IN ADULTS PRESENTING TO A TERTIARY CARE HOSPITAL IN NORTH INDIA

Vikas Suri, Mandeep Singh, Ajay Duseja, Manisha Biswal, Mini P Singh, Kamran Zaman, Ashok k Pannu, Kapil Goyal, Ashish Bhalla, Rk Ratho, Sanjay Jain, Savita Kumari

PGIMER, Chandigarh, India

Fever with jaundice or tropical jaundice is a common presenting feature of the patients visiting for emergency medical care.140 adult patients (more than or equal to 14 years of age) with acute fever (body temperature > 101°F of 14 days or less in duration) without any localized source of infection on initial clinical evaluation accompanied with jaundice (hyperbilirubinemia ≥ 1.5 mg/dl or elevation of aspartate aminotransferase or alanine aminotransferase more than three times upper limit of the reference range) were enrolled. All these patients with fever and jaundice were evaluated on the basis of a standard proforma and were evaluated for malaria (peripheral smears/rapid diagnostic kits), scrub typhus(PCR / IgM ELISA),leptospirosis(IgM ELISA), enteric fever by blood cultures and dengue by dengue (NS1 antigen test and IgM ELISA),Hepatitis(IgM ELISA of EBV/HSV, IgM ELISA of HAV/HEV and HBsAg with IgM HBc ELISA if HBsAg positive)59.5% were males and 40.5% were females. The mean duration of fever before the presentation was 7.75 ± 3.58 days.7 patients (5%) died. 133 patients (95%) improved with treatment and were discharged. Scrub typhus 30 (21.4%), Hepatitis E 18 (12.8%), malaria 9 (6.4%), dengue fever, enteric fever, hepatitis A and leptospirosis in 12 (8.5%), 2 (1.4%), 4 (2.2%) patients and 1 (0.7%) patient respectively were the prominent etiology a patient presenting with fever and jaundice . Probable sepsis (Fulfilling SIRS criteria with a negative culture) accounted for 40 patients. Conjunctival suffusion (OR=22.17), severe anemia (OR=5.5), respiratory crepitations (OR=5.27), thrombocytopenia (OR=1.14), hepatomegaly (OR=1.04), normal INR (OR=0.29) and altered mentation (OR=0.25) were significant predictors of a diagnosis of scrub typhus in patients with fever and jaundice. Severe anemia (Hb<8), Hypoalbuminemia, severe thrombocytopenia (Platelet count <50,000) and a near normal INR at admission were predictors of a malarial vs a viral etiology of Tropical jaundice. Co-infection with scrub typhus and malaria was seen in 4 patients (vivax-3 and falciparum-1) and viral hepatitis A & E was observed in 3 patients.

124

MOLECULAR DETECTION OF SELECT MOSQUITO- AND TICK-BORNE DISEASES IN BELIZE

Lynne Sloan[1], Elitza Theel[1], Dane Granger[1], Gerhaldine Morazan[2], John W. Wilson[1], Nicole Achee[3], John Grieco[3], Bobbi Pritt[1]

[1]*Mayo Clinic, Rochester, MN, United States,* [2]*Central Medical Laboratory, Belize City, Belize,* [3]*University of Notre Dame, Notre Dame, IN, United States*

The prevalence of vector-borne diseases (VBDs) is not routinely monitored in resource-limited countries such as Belize. As a component of a collaborative effort with the Mayo Clinic, University of Notre Dame and Belize Ministry of Health, we aimed to determine the value of PCR testing for 4 mosquito- and 11 tick-borne pathogens in conjunction with serology in acutely-ill patients suspected of having a VBD. Sera were collected from Belizean patients with suspected acute VBD (1-5 days post-symptom onset) during 3/2017-12/2018. Nucleic acid was extracted (Roche MagNAPure) and PCR testing was performed (Roche LC instruments) for 15 VBD pathogens: *Anaplasma phagocytophilum, Ehrlichia* chaffeensis, *Ehrlichia ewingii*, *Ehrlichia muris, Babesia microti, Babesia divergens, Babesia duncanii, Borrelia miyamotoi, Borrelia hermsii, Borrelia parkeri, Borrelia turicatae,* West Nile virus (WNV), Dengue virus (DENV), Zika virus (ZIKV), and Chikungunya virus (CHIKV). PCR for 15 VBD pathogens was performed on sera from 77 patients (1155 analyses). Patients comprised 42 women, 31 men, 4 unknown; median age was 27 years (range 1-59). Among PCR tests for mosquito-borne pathogens, only 1 specimen was DENV PCR positive, while the remaining 76 were negative. In comparison, serologic testing performed on 42 of the 77 specimens revealed 2 specimens with possible past DENV infection (IgM-/IgG+/NS1 Ag-), 11 presumptive and 1 possible positive ZIKV IgM positive and 1 Flavivirus, NOS positive results. No specimens were positive for antibodies to WNV and CHIKV. All PCR tests for tick-borne pathogens were negative. In comparison, serology performed on 44 of the 77 specimens showed seropositivity rates of 14% for *B. microti*, 14% for *E. chaffeensis,* and 9% for *A. phagocytophilum*. Molecular testing has been previously shown to play an important but limited role in detection of acute VBD. Our results support this finding, with the detection of only a single positive PCR result (DENV) among 77 patients with suspected acute VBD. These results may be used to shape VBD testing programs in Central American countries such as Belize where testing resources are limited.

125

NUCLEIC ACID-BASED ASSAYS FOR DETECTION OF TICK-BORNE *ANAPLASMA PHAGOCYTOPHILUM* AND *BORRELIA MIYAMOTOI*

Scott Meredith, Hong Zheng, Victoria Majam, Sanjai Kumar

Food and Drug Administration, Silver Spring, MD, United States

Tick-borne pathogens present a significant public health problem and a risk to blood safety in the United States and elsewhere. Two such pathogens, *Anaplasma phagocytophilum* and *Borrelia miyamotoi*, are rapidly emerging and represent a matter of concern for U.S. blood safety; both pathogens are transmitted by the black-legged tick species (*Ixodes scapularis* and *I. pacificus*) and have been observed to survive in blood products. *A. phagocytophilum* has caused at least 10 cases of transfusion-transmitted human granulocytic anaplasmosis (HGA), while *B. miyamotoi*, a causative agent of tick-borne relapsing fever (TBRF), has been observed to be transmissible by blood in animal models. Despite this, no FDA-licensed tests for diagnostic or donor screening exist for either agent. To support the development of these assays, we are developing nucleic acid amplification test (NAT) for both pathogens. Protocols for culturing both bacteria have been designed based on methods from the published literature, which allows careful development of the NAT reference panel at low bacteria densities. Methods for purification, amplification, and detection of pathogen nucleic acids are currently under development. Primer sequences for amplification of an appropriate target gene have been designed for both pathogens. These target genes, the 16S rRNA sequence or *GlpQ* in *B. miyamotoi* and *msp2* in *A. phagocytophilum*, have been previously identified and evaluated in the literature. Throughout the development of the NAT assays, other promising amplification targets may be identified by analysis of purified gDNA or cDNA; in this case, new primers may be developed and evaluated for their effectiveness in diagnostic and detection assays. The NAT reference panel will be evaluated by qPCR with SYBR Green I fluorescent dye. Sequence-specific probes may be designed for newly identified amplification targets throughout the course of assay development. The results of NAT assays for *A. phagocytophilum* and *B. miyamotoi* will be presented.

126

MOLECULAR DETECTION OF KNOWN < POTENTIALLY NEW *BARTONELLA* SPECIES IN ARTHROPOD VECTORS CIRCULATING IN PERU

Giovanna Mendoza, Victor Alberto Jimenez- Vasquez, Yanina Zarate-Sulca

Instituto Nacional de Salud-Perú, Lima, Peru

Nine out of 32 recognized species of *Bartonella* genus, are known as human diseases agents transmited by different arthropod vectors. However the transmission of unidentified Bartonella sp is still poorly understood, especially in rural areas of peruvian andean valleys. The aim of the study was the molecular identification of *Bartonella* sp in arthropod vectors from endemic localities in Peru. We collected ticks, pet fleas, and sheep flies from cats, dogs, guinea-pigs, in 10 sites. We extracted DNA from 677

arthropod pools and designed nested PCR primers to amplified ITS region. DNA sequences obtained by Sanger sequencing, were aligned with other Gen Bank sequences and a maximum likelihood (ML) tree was stimated. We successfully detected *Bartonella* in 29.5% of samples. Our ML tree generated clades according with all species included in the alignment with supported nodes. The identified species were: *B.henselae, B.clarridgeiae, B. rochalimae* and *B. vinsonii*. However, 11 sequences amplified from *M. ovinus* and *R. sanguineus* sampled in sheeps and dogs presented 100% similarity with 2 unidentified *Bartonella* deposited in GenBank (accessions AF415209 and EU189218), while 1 sequence amplified from *P. irritans* found in guinea-pig presented 99.61% similarity with another undescribed *Bartonella* species (accession AF415210). Our nested specific PCR primers detected 4 known species and probably 2 new undescribed *Bartonella* species. Our research detected 29.5% of positive samples in contrast with other studies carried out by Parola 2002 and Nelder 2009, they detected less 10% and found these two unidentified Bartonella in sheeps and gray squirrel ectoparasites, respectively. We cannot discard the fact that some clinical manifestations could be associated with transmission of these still uncharacterized and uncultured *Bartonella* species. We suggest complete the research with methodologies like MLST or metagenomic sequencing. This study demonstrates the circulation of undescribed Bartonella species in Peru highlights the necessity of carry out new and more complex studies in order to understand present and future bartonellosis outbreaks

127

PROFILING OF MALARIA INFECTION IN ASYMPTOMATIC POPULATION IN KISUMU COUNTY, WESTERN KENYA

Benjamin Humphrey Opot, Hosea Akala, Raphael Okoth, Gladys Chemwor, Charles Okello, Redeptah Yeda, Edwin Mwakio, Jackline Juma, Agnes Cheruiyot, Dennis Juma, Ben Andagalu, Jim Ray Managbanag

United States Army Medical Research Directorate - Kenya, Nairobi, Kenya

Countries in malaria-endemic zones aim to enter pre-elimination phase. There is scanty information on the burden of asymptomatic malaria and its contribution in sustaining transmission in malaria holoendemic regions. This study aims to determine the burden of malaria parasite among asymptomatic cases. 480 individuals from Kisumu County were grouped into 29 clusters. Each cluster containing 4 households was followed up monthly between July 2015 and June 2016 and was tested for malaria by real-time reverse transcription PCR (rt RT-PCR). Malaria positive cases were treated with artemether-lumefantrine and further screened for *Plasmodium falciparum* 16 (Pf16) early, 25 (Pf25) late gametocytes stages and *Plasmodium* species. Prevalence of malaria was established at baseline diagnosis and incidence per house hold and per cluster across the study period. Fifty-six percent (2375/4214) of the tested participants were positive for malaria at multiple follow-up time-points. A case study of one of the clusters showed subsequent positive malaria detection of 72.2±21% infected during visit 5 to visit 9. Of these malaria positive samples, 68% harboured gametocytes comprising 48% both Pf16 and Pf25 stages, 19% Pf16 only and 1% Pf25 only. 70% were positive for *P. falciparum* only, 6.7% had mixed-infections of *P. falciparum* and *P. malariae*, 10% had *P. falciparum*, *P. malariae* and *P. ovale* while 1 was *P. falciparum* and *P. ovale mixed* infection. The Pf16 positive samples comprised 11 *P. falciparum* mono infections and 1 *P. falciparum* and *P. ovale.* Only 15% of samples that had no gametocytes were positive for *P. falciparum* single species infections. Gametocyte prevalence remained comparable despite artemisinin-based combination therapy (ACT) administration upon positive diagnosis suggesting that asymptomatic cases are involved in transmission of malaria. High rate of gametocytemia among mixed species infections than those comprising *P. falciparum* single species infections suggest that other species are involved in modulating *Pf* transmission. Analyses are underway to determine if recurrent gametocytemia is due to recrudescence or new infections.

128

SPATIAL DISTRIBUTION AND ALLELE FREQUENCIES OF THIOESTER CONTAINING PROTEIN 1 (TEP1) GENE, A KEY IMMUNE GENE AGAINST *PLASMODIUM* INFECTION IN *ANOPHELES GAMBIAE* MOSQUITOES IN KENYA

Shirley Akinyi Onyango[1], Andrew K. Githeko[2], Yaw A. Afrane[3], Kevin O. Ochwedo[4], Harrysone Atieli[5], James W. Kazura[6], Guiyan Yan[7]

[1]*Kenyatta University, Nairobi, Kenya,* [2]*Kenya Medical Research Institute, Kisumu, Kenya,* [3]*University of Ghana, Ghana, Ghana,* [4]*International Center of Excellence for Malaria Research, Homa bay, Kenya,* [5]*International Center of Excellence for Malaria Research, Homa Bay, Kenya,* [6]*Case Western Reserve University, Cleaveland, OH, United States,* [7]*University of Carlifonia, Irvine, Irvine, CA, United States*

Anopheles gambiae mosquitoes are efficient vectors for malaria in sub-Saharan Africa. Implemented control interventions, climate change, and environmental modifications enhance the local mosquito densities promoting selection of efficient malaria vectors either resistant or susceptible to *Plasmodium* and insecticides. In *An. gambiae*, the thioester-containing protein 1 (TEP1) is a highly polymorphic gene crucial in the mosquito's immune system and exhibits defenses against *Plasmodium* parasites. The TEP1 displays allelic variations associated with distinct genotypes in its resistance to malaria infections. Interactions between *Anopheles* and *Plasmodium* parasites are a potential target for blocking transmission. Therefore, genotyping local populations is critical for monitoring changes in mosquito densities that may explain variations in malaria prevalence within different settings. Female *An. gambiae* s.l. Mosquitoes were collected from Homabay, Vihiga, and Kakamega in western Kenya, and further identified to species using PCR. PCR-RFLP method was used to determine the TEP1 allelic classes. Mosquitoes collected from Homa Bay were all *An. arabiensis,* and they exhibited R1 (11%), S1 (68%), S2 (20%) and R2 (1%) alleles whereas Vihiga had R1 (22%), S1 (50%), S2 (6%) and R2 (22%). Kakamega had R1 (25%), S1 (56%), and S2 (19%), but no R2 allele was detected. The frequencies of TEP1 allele classes in *Anopheles* species varied significantly among locations, suggesting spatial heterogeneity in vector competence to malaria parasites.

129

MASSIVE BEHAVIORAL AND GENOMIC VARIATION IN *AEDES AEGYPTI* ACROSS SUB-SAHARAN AFRICA

Noah H. Rose[1], Massamba Sylla[2], Diego Ayala[3], Joel Lutomiah[4], Athanase Badolo[5], Jewelna Akorli[6], Ogechukwu Aribodor[7], Nnenna Ibe[1], John-Paul Mutebi[8], Rosemary Sang[4], Jacob E. Crawford[9], Bradley J. White[9], Carolyn S. McBride[1]

[1]*Princeton University, Princeton, NJ, United States,* [2]*Université Cheikh Anta Diop, Dakar, Senegal,* [3]*Centre International de Recherches Médicales de Franceville, Franceville, Gabon,* [4]*Kenya Medical Research Institute, Nairobi, Kenya,* [5]*University of Ouagadougou, Ouagadougou, Burkina Faso,* [6]*Noguchi Memorial Institute for Medical Research, Accra, Ghana,* [7]*Nnamdi Azikiwe University, Awka, Nigeria,* [8]*Centers for Disease Control and Prevention, Fort Collins, CO, United States,* [9]*Verily, Mountain View, CA, United States*

The recent evolution of a strong preference for human hosts in the globally invasive form of *Aedes aegypti* promotes the transmission of the Zika, dengue, chikungunya, and yellow fever viruses. Recent evidence suggests that this form of *Ae. aegypti* may have originated in West Africa about 10,000 years ago, but the geographical distribution, ecological correlates, and genetic determinants of preference for human hosts in ancestral African populations are largely unknown. Although African populations are often thought to be primarily animal-biting or opportunistic, they occupy diverse habitats ranging from forests where they encounter few human hosts to highly urbanized cities where humans are by far the most common potential host. We characterized behavioral and genomic variation in 26 forest, rural, and urban populations from seven countries

across sub-Saharan Africa. Behavior varied more or less continuously across the continent, ranging from strong preference for animal odors to strong preference for human odor in our assay. Both climatic variables and human population densities predicted behavior, with preference for humans appearing in relatively densely populated areas with high seasonal variation in precipitation in a band across the southern Sahel region. One population in Northern Senegal showed nearly as great a preference for human hosts as a laboratory strains derived from the globally invasive human specialist form. We also use whole genome sequence data to identify genomic *loci* and evolutionary processes that contribute to behavioral divergence between populations.

130

COMPUTATIONAL KARYOTYPING OF POLYMORPHIC CHROMOSOMAL INVERSIONS IN THE MAJOR MALARIA VECTORS *ANOPHELES COLUZZII* AND *AN. GAMBIAE*

R. Rebecca Love[1], Seth Redmond[2], Marco Pombi[3], Beniamino Caputo[3], Vincenzo Petrarca[3], Alessandra della Torre[3], The Anopheles gambiae 1000 Genomes Consortium[4], Nora J. Besansky[1]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*Institute Vector Borne Disease, Monash University, Melbourne, Australia,* [3]*Dipartimento di Sanità Pubblica e Malattie Infettive, Laboratory affiliated to Istituto Pasteur Italia - Fondazione Cenci Bolognetti, Sapienza University of Rome, Rome, Italy*

Chromosomal inversions are a type of genomic structural variant that arises when a segment of DNA breaks, rotates 180 degrees, and reattaches. Because inversions can protect sets of alleles from being separated through recombination, they have wide-ranging and long-studied consequences. In the *Anopheles gambiae* complex, which includes the major malaria vectors *An. arabiensis*, *An. coluzzii*, and *An. gambiae*, paracentric chromosomal inversion polymorphism can complicate both genomic analysis and vector control; in these species, chromosomal inversions are associated with variation in traits as diverse as indoor-outdoor resting behavior, aridity tolerance, and *Plasmodium* infection rates. However, nearly all common chromosomal inversions in these species are currently identified cytogenetically, through the labor-intensive preparation and examination of slides of stained chromosomes. This process requires not only extensive expert knowledge, but also the ovaries of half-gravid female mosquitoes, severely limiting the contexts in which the roles of chromosomal inversions can be explored. By leveraging the genomic resources of the *Anopheles gambiae* 1000 Genomes Project (Ag1000G), as well as known cytogenetic karyotypes, we developed and validated an innovative computational method for accurately genotyping chromosomal inversions based on single nucleotide polymorphism (SNP) data. In *An. gambiae* and, where applicable, *An. coluzzii*, our methods can predict the genotype of inversions 2L*a*, 2R*j*, 2R*b*, 2R*c*, 2R*d*, and 2R*u* with accuracy well above 90%. Our results suggest this method is also capable of accurately genotyping the same chromosomal inversions in mosquitoes sequenced to lower coverage than is typical of the specimens included in Ag1000G.

131

METAGENOMIC PROFILING FROM *ANOPHELES GAMBIAE* INDIVIDUAL GENOME SHOTGUN SEQUENCING DATA IN AG1000G PROJECT

Jiannong Xu, Dong Pei, Jinjin Jiang, Yuxin Yan, Jiandong Wang, Ashmita Pandey

New Mexico State University, Las Cruces, NM, United States

Anopheles gambiae Ag1000G project aims to profile natural genetic variation using individual genome shotgun sequencing data from wild specimens in Africa. In the sequencing output, there are reads derived from non-mosquito sources, largely from associated microbiota and blood source. We developed a pipeline to profile metagenomic composition and genetic capacity. The reads were mapped against *An. gambiae* reference genome to extract non-mosquito reads. The non-mosquito reads were used for further characterization. Two approaches were used. (1) The non-mosquito reads were mapped against Microbial Reference Database to get a peek of possible taxa, and (2) the non-mosquito reads were assembled into contigs for taxonomic and functional annotation. Reference reads mapping revealed taxa of fungi, bacteria, viruses and protists, but only <2% reads have hits. Assembled contigs contain more sequence information for annotation. In some cases, the size of contigs is longer than 10kb. In individuals that had taken blood, sequences of human and *Plasmodium* were discovered. Enteric bacteria, *Acinetobacter* and *Elizabethkingia* were often found, but abundance was not high. Quite portion of identified fungal taxa belong to Ascomycota. Mosquito-associated viruses like Mononegavirus were found in some individuals. At nucleotide level, usually less than 20% contigs have homologues with >70% identity. In most cases, >50% contigs do not have good nucleotide hit to any entries in the database. Apparently these contigs were derived from unidentified taxa. In these novel taxa, some predicted protein sequences show a similarity to fungal taxa. The data indicate that bacteria may not be predominant in the microbiota, fungi are more abundant than what we thought. There are large number of novel taxa that are associated with wild *An. gambiae.* Based on annotated genes, metabolic pathways can be predicted. Chemical ecology may be similar in different microbial communities in which taxonomic composition may vary. The shotgun sequencing data are a valuable source to characterize mosquito microbiome comprehensively.

132

SEX-SPECIFIC TRANSCRIPTIONAL PROFILING IN THE MOSQUITO, *CULEX PIPIENS*

Patricia Kamanda, Cheolho Sim

Baylor University, Waco, TX, United States

The autoregulatory pathway controlling sex determination is highly variable and has been identified in only a few non-mammalian model species. Therefore, sex determination in mosquitoes is largely unknown. Previous research suggests that a dominant male-determining factor, depending on the mosquito species, is the primary signal that initiates controls sex determination and initiates male development. In this study, we identify sex-specific transcripts indicative of sex-determining function in the *Culex pipiens* complex mosquitoes that transmit many human pathogens such as West Nile virus and filarial nematodes. We investigated sex-specific transcripts in the mosquito, *Cx. pipiens*. We used Illumina RNA-Seq to simultaneously identify and quantify differences in transcript abundance between male and female in two developmental stages, pupae and adult. We found 76 genes with differences in transcript abundance between male and female in the pupal stage and 214 genes in the adult stage. In addition, we also uncovered the sex-specific morphological key in pupal stage of *Cx. pipiens*. A deeper understanding of the genetic basis of sex-specific traits may provide a novel method of control for these disease vectors including sterile insect technology.

133

OXIDOREDUCTIN-LIKE PROTEIN AND PDZ ENHANCE THE COLD TOLERANCE IN THE OVERWINTERING DIAPAUSE OF THE MOSQUITO *CULEX PIPIENS*

Bryan P. King

Baylor University, Waco, TX, United States

Stress tolerance and low temperature survival are a few key features of the diapause program for the mosquito *Culex pipiens* to have a successful overwintering period. Here, we suggest two enzymes; oxidoreductin-like protein and PDZ are involved with these diapausing characteristics for overwintering survival. The gene that encodes oxidoreductin-like protein was suppressed by RNAi, and the proportion of degenerating follicles were assessed. Consequently, suppression of the oxidoreductin-like protein with RNAi significantly increased the proportion of degenerating follicles in diapausing mosquitoes. Similarly, the gene that encodes PDZ

was also suppressed by RNAi, and F-actin polymerization was assessed in the midgut and ovaries of *Cx. pipiens.* Inhibition of oxidoreductin-like protein and PDZ significantly reduce the survivability of diapausing female mosquitos, which indicates that these enzymes play key roles in protecting multiple tissues during early diapause.

134

MOLECULAR KARYOTYPING OF CHROMOSOMAL INVERSION 2RB IN *ANOPHELES GAMBIAE AND AN. COLUZZII*

Raquel Montanez Gonzalez[1], R. Rebecca Love[1], Verena Pichler[2], Maria Calzetta[2], Marco Pombi[2], Beniamino Caputo[2], Alessandra Dellatorre[2], Nora J. Besansky[1]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*Sapienza University of Rome, Rome, Italy*

The Afrotropical mosquitoes *Anopheles gambiae* and *An. coluzzii* are the deadliest vectors of human malaria. Types of structural chromosomal mutations known as chromosomal inversions are very common in these species and they appear to play important roles in ecological adaptation, influencing mosquito behavior and physiology in ways relevant to malaria epidemiology and control. Inversion 2Rb is the only pan-African *An. gambiae* inversion lacking a cheap and reliable molecular genotyping assay. Current methods of microscopical karyotyping are time consuming, prone to human error, and feasible only for female mosquitoes at one particular developmental stage—and only if they are properly preserved. Failure to account for inversion status is a barrier to further knowledge of important vector traits (e.g. biting and resting behavior, seasonality, aridity tolerance and *Plasmodium* infection rates), which can be influenced by inversions. To overcome this limitation, we exploited genome sequences of cytogenetically karyotyped specimens to identify tag SNPs (Single Nucleotide Polymorphisms) highly predictive of inversion status. Using these SNPs, three low cost PCR-RFLP (Polymerase Chain Reaction-Restriction Fragment Length Polymorphism) diagnostic assays were developed and then validated on cytogenetically karyotyped population samples field collected from eight different African countries (Benin, Burkina Faso, Cameroon, The Gambia, Guinea Bissau, Mali, Senegal, Tanzania). One assay showed a high concordance rate of 95% between PCR-RFLP and cytogenetic approaches in both *An. gambiae* (N=437) and *An. coluzzii* (N=133), and the other two assays agreed well (93%-97%) on either one or the other species only. The combination of the two most specific assays provides a useful diagnostic for inversion 2Rb in *An. gambiae* and *An. coluzzii* with a concordance rate of >96% with the 'gold standard' cytogenetic karyotyping method and opens the way to extensive assessment of the adaptive role of this inversion.

135

CONSTRUCTING A MODEL OF GENE EXPRESSION REGULATION IN *ANOPHELES* SALIVARY GLANDS

Michael B. Wells, Deborah J. Andrew

Johns Hopkins University, Baltimore, MD, United States

Mosquito-borne diseases remain among the deadliest threats to human health. Despite substantial diversity among the pathogens that mosquitoes spread, one commonality among them is that viruses and microbes must invade the mosquito salivary glands (SGs) and enter the salivary duct to be transmitted to a new host, during probing prior to the next blood meal. SGs are a high-priority target for new interventions for blocking transmission. Mosquito SGs display remarkable sexual dimorphism and functional distinctions. Female SGs are composed of two lateral lobes (with proximal and distal portions) flanking a medial lobe. An open ended duct runs most of the length of the lateral lobes and a short distance into the medial lobe. Each region adds different protein components to the saliva, which is thought to contribute to both sugar and blood feeding. The male SG, which contributes to sugar feeding, is made up of a single lobe (most similar to the female proximal lateral lobe) with a closed salivary duct running nearly the entire length of the SG. We propose that at least three types of factors coordinately regulate mosquito SG gene expression. SG transcription factors, including Fork head, Sage, Senseless, and CrebA likely provide SG identity, developmental progression, homeostatic maintenance, and secretory cargo identity. Sex determination cues may guide male versus female developmental, structural, and secretory fates. Finally, ecdysone hormone signaling is likely to play a role in stage-specific gene expression during developmental transitions. We discovered that both female and male SGs contain male-biased characteristics in *Anopheles gambiae* and female-biased characteristics in *Anopheles stephensi*. We find that gene expression may be regulated differently between SG secretory cells and duct-associated cells just outside the secretory portion of the SG. Here, we present our model, preliminary findings, and plans to interrogate this phenomenon. We will genetically, or molecularly, reduce female SG function, imposing additional barriers to pathogen invasion and reducing production of saliva proteins critical for pathogen transmission.

136

DEVELOPMENT OF MOLECULAR KARYOTYPING ASSAYS FOR COMMON INVERSIONS IN *ANOPHEL FUNESTUS*

Martin Lukindu[1], Rachel R. Love[1], Scott T. Small[1], Guelbeogo M. Wamdaogo[2], N'Fale Sagnon[2], Nora J. Besansky[1]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso*

Anopheles funestus is a proficient malaria vector in sub-Saharan Africa with a wide distribution across heterogeneous ecological settings, but its population structure is less studied relative to that of *An. gambiae* with which it is broadly co-distributed. In a situation reminiscent of *An. gambiae* and its sister species *An. coluzzii*, sympatric but assortatively mating *An. funestus* populations from Burkina Faso, West Africa differ in seasonality, larval habitat, adult resting behavior, and chromosomal inversion frequencies. The Kiribina form is largely devoid of inversion polymorphism and carries mostly standard arrangements, while Folonzo is highly polymorphic for inversions 3Ra, 3Rb and 2Ra. Unfortunately, there are no known molecular markers to guide taxonomic identification of these otherwise morphologically indistinguishable units. Their identification depends upon classical cytotaxonomy. Because cytogenetic karyotyping procedures are laborious, time consuming and require extensive expertise, this approach is impractical for large-scale field studies. Exploiting the new chromosome-based genome assembly for *An. funestus* (AfunF3) and more than 170 fully sequenced and cytologically karyotyped Folonzo and Kiribina specimens, we have been developing and validating molecular karyotyping approaches based on computationally identified tag-SNPs with high SNP-karyotype concordance in these samples. Our results based on array hybridization and amplicon sequencing will be discussed.

137

COMMUNITY ACCEPTANCE OF YEAST INTERFERING RNA LARVICIDE TECHNOLOGY FOR CONTROL OF *AEDES* MOSQUITOES IN TRINIDAD

Akilah Stewart[1], Nikhella Winter[1], Azad Mohammed[1], Limb K. Hapairai[2], Jessica Igiede[3], David W. Severson[3], Molly Duman-Scheel[2]

[1]*The University of the West Indies at St. Augustine, St. Augustine, Trinidad and Tobago,* [2]*Indiana University School of Medicine, South Bend, IN, United States,* [3]*The University of Notre Dame, Notre Dame, IN, United States*

RNA interference (RNAi), a technique used to study gene function in mosquitoes and other insects, is attracting attention in agricultural pest control communities but is a largely unexplored new approach for mosquito control. We recently began to engineer *Saccharomyces cerevisiae* (baker's yeast) to produce interfering RNA that silences genes required for mosquito survival, but which does not match genes in humans or other non-target organisms. These larvicides, which facilitate cost-effective production and delivery of interfering RNA to larvae that

consume the yeast, effectively kill mosquito larvae in laboratory and semi-field trials. Prior to pursuing field evaluation of larvicides targeting *Aedes* species in Trinidad, a Caribbean island with endemic diseases resulting from pathogens transmitted by *Aedes* mosquitoes, we engaged adult residents living in prospective trial site communities of Tamana, St. Augustine and Caroni. Paper surveys and open community forums were used to assess the potential acceptability, sustainability, and societal desirability of yeast interfering RNA larvicides. Respondents have good working knowledge of mosquitoes and mosquito-borne diseases. A majority of respondents practice some means of larval mosquito control and agree that they would use a new larvicide if it were shown to be safe and effective. During community engagement forums, participants were educated about mosquito-borne illnesses and the new yeast larvicides. When invited to provide feedback, forum attendees voiced strong support for the new technology, raised very few concerns, and offered advice regarding optimal larvicide formulations and prices. The results of these activities suggest that participants are open to the potential use of yeast interfering RNA larvicides and that the communities assessed are viable field sites.

138

MOLECULAR BASIS OF DDT AND PERMETHRIN RESISTANCE IN AN *ANOPHELES FUNESTUS* FROM BENIN

Genevieve Tchigossou

University of Abomey-Calavi, Benin, Abomey-Calavi, Benin

Insecticide resistance in *Anopheles* mosquitoes is threatening the success of malaria control programmes. To implement suitable insecticides control strategies, we investigated the molecular basis of permethrin and DDT resistance in an *Anopheles funestus* population from Benin. *GSTe2* gene was the most upregulated detoxification gene in both DDT- [fold-change (FC: 16.0)] and permethrin-resistant (FC: 18.1) mosquitoes. *CYP6P9a* and *CYP6P9b* genes were also significantly overexpressed with FC 5.4 and 4.8, respectively, in a permethrin resistant population. The absence of the *L1014F* or *L1014S kdr* mutations in the voltage-gated sodium channel gene coupled with the lack of directional selection at the gene further supported that knockdown resistance plays little role in this resistance. In conclusion, the role played by metabolic resistance to pyrethroids in *An. funestus* population in Benin suggests that using novel control tools combining the synergist such as PBO-based bednets, could help manage the growing pyrethroid resistance in Benin.

139

INSIGHT INTO GENOMIC AND CHROMOSOMAL DIFFERENTIATION BETWEEN *CULEX PIPIENS PIPIENS* AND *CULEX PIPIENS MOLESTUS*

Reem A. Masri[1], Andrey A. Yurchenko[2], Jeremy Jenrette[1], Natalia V. Khrabrova[3], Anuarbek K. Sibataev[3], Megan L. Fritz[4], Maria V. Sharakhova[1]

[1]*Virginia Tech, Blacksburg, VA, United States,* [2]*Gustave Roussy Cancer Center, Paris, France,* [3]*Tomsk State University, Tomsk, Russian Federation,* [4]*University of Maryland, Maryland, MD, United States*

The members of the *Culex pipiens* complex are globally distributed and represent competent vectors of West Nile virus and Eastern equine encephalitis virus transmitted to both birds and mammals. Two members of the complex, *Cx. p. pipiens* and *Cx. p. molestus*, exhibit important behavioral and physiological differences. *Cx. p. pipiens* mates in open spaces, feeds on birds, and requires a blood meal for oviposition. *Cx. p. molestus*, in contrast, mates in confined spaces, feeds on mammals, can lay eggs without a blood meal and is well adapted to human environment. However, the taxonomic status of these two members of the *Cx. pipiens* complex is under debate. We used whole-genome resequencing analysis of two laboratory colonies derived from Chicago, USA and field collections from Eurasia (Belarus and Kyrgyzstan). A cytogenetic analysis was performed on the Chicago colonies. The whole-genome resequencing analysis revealed strikingly different levels of genomic diversity within the genomes of *Cx. p. pipiens* and *Cx. p. molestus*. The diversity was low in the *Cx. p. molestus* genome but was high and distributed along the chromosomes in the *Cx. p. pipiens* genome. The comparison between the two members revealed high level of genomic divergence between them (mean Fst ≈ 0.3) which was more or less uniformly distributed along the chromosomes. Phylogenomic and ADMIXTURE analyses clustered *Cx. p. pipiens* from North America and Eurasia together but clustered *Cx. p. molestus* from both continents into two separate clades. Furthermore, mitotic chromosome analyses revealed significant length difference for chromosome 3 and distinct banding patterns in Hoechst 33342 staining between *Cx. p. pipiens* and *Cx. p. molestus*. High level of the genomic divergence and chromosome differentiation between *Cx. p. molestus* and *Cx. p. pipiens* suggest a long history of genetic isolation between them and support the idea that they may represent two distinct species.

140

STRUCTURE AND FUNCTION OF THE Y-CHROMOSOME IN *ANOPHELES ALBIMANUS*

Austin Compton[1], Varvara Lukyanchikova[2], Zhijian (Jake) Tu[1], Victor Llaca[3], Stephane Deschamps[3], Chujia Chen[4], Chunhong Mao[5], Igor Sharakhov[2]

[1]*Department of Biochemistry, Virginia Tech; Fralin Life Sciences Institute of Virginia Tech, Blacksburg, VA, United States,* [2]*Department of Entomology, Virginia Tech, Blacksburg, VA, United States,* [3]*Corteva Agriscience™, Agriculture Division of DowDuPont™, Johnston, IA, United States,* [4]*Department of Biochemistry, Virginia Tech; Fralin Life Sciences Institute of Virginia Tech; and Interdisciplinary PhD Program in Genetics, Bioinformatics, and Computational Biology, Virginia Tech, Blacksburg, VA, United States,* [5]*Biocomplexity Institute and Initiative, University of Virginia, Charlottesville, VA, United States*

Female mosquitoes are responsible for the transmission of harmful human pathogens, while Y chromosome-bearing males are not. Yet much remains unknown regarding the elusive mosquito Y chromosome, both regarding its structure and function. To date, no Y chromosome has been assembled in mosquitoes. With a growing interest in Y chromosomes and its importance in male biology, it is crucial to make strides to better resolve this critical gap in knowledge. These efforts have the potential to reveal novel methods for mosquito control as the Y chromosomes harbor the male-determining factor and can regulate dosage compensation. For example, when the Y chromosome gene Guy1 is expressed in female *Anopheles stephensi*, it confers 100% female lethality, making it salient targets for genetic control strategies and for improving sex separation techniques. However, despite the apparent significance of Y chromosome genes, the molecular mechanisms underlying their biological function remains unknown. Here we report the assembly of the first mosquito Y chromosome and describe our efforts to determine the function and molecular mechanism of a novel candidate for a male-determining factor, *albimanus Y chromosome gene 1* (*albY1*) in the New World malaria mosquito *Anopheles albimanus*.

141

IMPROVED GENE EDITING EFFICIENCY OF RECEPTOR-MEDIATED OVARY TRANSDUCTION OF CARGO -REMOT CONTROL- IN *AEDES AEGYPTI*

Duverney D. Chaverra-Rodriguez[1], Chan C. Heu[1], Donghum Kim[1], Vanessa Macias[1], Jason L. Rasgon[2]

[1]*Pennsylvania State University, State College, PA, United States,* [2]*Pennsylvania State University, University Park, PA, United States*

Receptor-Mediated Ovary Transduction of Cargo (ReMOT Control) is a technology that uses a peptide ligand (P2C) to deliver Cas9 ribonucleoprotein (RNP) complex from the female hemolymph to the developing oocytes. Heritable gene editing of the injected female's offspring is achieved at efficiencies as high as 0.3 mutants per injected mosquito. Here, we discuss experiments testing factors that affect the efficiency of ReMOT Control in the mosquito *Ae. aegypti*. First, we tested

the effect of using the P2C-derived peptides P2C1, P2C2 and P2C3 on Cas9 RNP transduction and gene editing efficiency. Second, we tested several concentrations of ribonucleoprotein and endosomal escape reagents for gene editing. Results confirmed that smaller P2C derivatives transduced Cas9 into the ovaries and that efficiency of ReMOT control could be improved using conditions that facilitate the transduction/release of Cas9 RNP into the oocytes.

THE GENETIC BASIS FOR INCREASED OUTDOOR HOST-SEEKING IN *ANOPHELES COLUZZII* DURING THE BIOKO ISLAND MALARIA CONTROL PROJECT

Jacob I. Meyers[1], Godwin Fuseini[2], Guillermo Garcia[2], Abrahan Matias[2], Hans Overgaard[3], Christopher Schwabe[4], Jo Lines[5], Immo Kleinschmidt[5], Michel A. Slotman[1]

[1]*Texas A&M University, College Station, TX, United States,* [2]*Medical Care Development International, Malabo, Equatorial Guinea,* [3]*Norwegian University of Life Sciences, As, Norway,* [4]*Medical Care Development International, Silver Spring, MD, United States,* [5]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Malaria vector control programs largely rely on indoor application of insecticides to target host-seeking adult mosquitoes. However, the efficacy of these control tools is threatened by behavioral resistance. For example, mosquitoes can avoid insecticides applied indoors by increasing outdoor host-seeking. One location where increased outdoor host-seeking has been documented is Bioko Island, Equatorial Guinea, where the Bioko Island Malaria Control Project (BIMCP) has conducted indoor residual spraying since 2004. We examined the genetic basis of increased outdoor host seeking of *Anopheles coluzzii* on Bioko Island. Using a pool-seq approach with large sample sizes (34-268 mosquitoes/pool) and high sequence coverage (average 491-894x/pool), we screened the genomes of *An. coluzzii* collected in 2009, and 2013/2014 for genetic variation linked to indoor vs. outdoor host-seeking. We also compared pre-intervention *An. coluzzii* collected in 2004 to these post-intervention samples to identify *loci* under selection during the BIMCP. We simulated the sampling effects of pool size and coverage level on *FST* estimates to determine significant cut-offs. Additionally, we used the Cochran-Mantel-Haenszel test followed by a Benjamini & Hochberg correction (CMH+BH) to identify significantly differentiated SNPs. Thirty-five SNPs significantly differentiated indoor and outdoor pools from 2009 according to both methods, five of which are located within genes and are non-synonymous. In the 2013/2014 data, a 1MB region on 2R differentiates indoor from outdoor feeding mosquitoes. This Fst peak contains 10 genes with differentiated SNPs. In addition, several genomic regions are differentiated between samples collected over the course of the BIMCP. Two of these regions include SNPs associated with insecticide resistance (IR) including *kdr* and possibly ABC-transporters. In summary, we have identified sites and genes linked to outdoor host-seeking, although the function of these genes does not currently point to a specific mechanism.

143

SNP-BASED HERITABILITY ESTIMATION FOR HOST PREFERENCE IN *CULEX TARSALIS*

Bradley J. Main, Fatima Tuqan, Tara C. Thiemann, Christopher M. Barker

University of California Davis, Davis, CA, United States

In the western United States, *Culex tarsalis* is an important vector of arboviruses, including West Nile, western equine encephalomyelitis, and St. Louis encephalitis viruses. *Cx. tarsalis* feeds frequently on birds, although it is opportunistic and host selection among bird species is non-random with respect to host availability. There is also a well-characterized increase in the frequency of mammalian blood meals starting in July and peaking in September, which is attributed at least in part to changes in host availability due to fledging chicks. In this study, we considered the question: do opportunistic versus strictly ornithophilic subpopulations of *Cx. tarsalis* occur in sympatry, and if so, are opportunistic genotypes over-represented among mammal-fed individuals? To test this, we resequenced 13 mammal-fed and 23 bird-fed *Cx. tarsalis* from a single site with known host availability in Yolo county, California. Using 262K high quality SNPs, we estimated the "SNP heritability" of host choice to be $H^2 = 0.08$, SE=2.247, indicating that there is no evidence for a substantial genetic component underlying host preference among these samples. However, genetic analysis of another population(N=24) from a single site in Sutter County, California using AmpliconSeq revealed an association between specific genotypes at the *prophenoloxidase* gene and cattle-feeding. Thus, an improved assessment of population structure across geography and season is needed to properly characterize functional genetic variation in this system. Future studies will involve genotyping more *loci* from larger mosquito populations across CA. In addition, we will sequence *Cx. tarsalis* populations early and late in the season to assess whether distinct genotypes contribute to the increase in mammal-feeding behavior.

144

REVERSE GENETIC ANALYSIS OF *AEDES AEGYPTI* SALIVARY PROTEIN GENES USING CRISPR/CAS9

Bianca B. Kojin, Zachary N. Adelman

Texas A&M, College Station, TX, United States

Mosquito saliva is composed of a complex cocktail of proteins that provide anti-hemostatic, vasodilatory, imunomodulatory and sugar digestion functions. While the sialomes of major disease vector species have been characterized, the majority of proteins identified on those studies have no known function. With advances in genome engineering tools, particularly CRISPR/Cas9 tool, reverse genetic experiments have become tractable in disease vector mosquitoes. We used CRISPR/Cas9 to generate loss-of-function knock out strains for four different salivary gland proteins. Target proteins were selected based on expression levels in female salivary glands of the vector *Aedes aegypti,* including both prior proteomic and transcriptomic analyses. For each loss of function mutant, we analyzed mosquito probing time and duration of blood acquisition, as well as impact on fecundity and fertility.

VECTORBASE.ORG: NEW OMICS AND POPULATION BIOLOGY DATASETS FOR INVERTEBRATE VECTORS OF HUMAN PATHOGENS

Gloria I. Giraldo-Calderón[1], Daniel Lawson[2], Scott J. Emrich[3], Mary Ann McDowell[1], VectorBase consortium[4]

[1]*University of Notre Dame, Notre Dame, IN, United States,* [2]*Imperial College London, London, United Kingdom,* [3]*University of Tennessee, Knoxville, TN, United States,* [4]*EMBL-EBI, Hinxton, United Kingdom*

VectorBase.org is a free online resource to all users, that started 15 years ago with the genome of *Anopheles gambiae* PEST. Currently, it hosts 40 genomes including vector mosquitoes, kissing bugs, tsetse flies, ticks, sand flies, body lice, non-vector species, and a snail intermediate host. A summary of our data sets, including major changes since April 2018 is provided here. The new *Aedes aegypti* Liverpool AGWG genome (AaegL5) is now available. Transcriptomes and proteomes, under different experimental conditions, are available for 37 and 2 species, respectively. Variation data sets, with >50 million SNP calls for *A. gambiae* (mostly from the Ag1000g), and between 0.29 to 12.9 million SNP calls, in other 15 species are available via the new Search (tool) capabilities. The population biology (PopBio) data comes from ~400 species of mostly field origin, and is divided in different map views including >20k and >13k insecticide resistance phenotypes and genotypes assays, respectively, >28 million population abundance mosquitoes records, >48k pathogen infection status assays. The most recent addition is >49k blood meal source assays. New Map views are also in development, including one for 'barcodes'. One of the largest to date (April 2019) PopBio datasets, is the one from Iowa (USA), for which we display more than 40 years of population abundance data going back to 1969. The PopBio map is used

for visualization, search, analysis and also for raw data download. For all data submitted to VectorBase the user will obtain the proper identifier, a project ID for PopBio data, VBPxxxxxxx or similar for other data types. For all data hosted by VectorBase, the source including scientific papers or, DOI numbers for unpublished datasets are provided. This latter case is more common for PopBio population abundance records, that mostly come from mosquito and vector control districts, and not from research projects. Interested users can request private or public webinars.

146

ADDITIONAL BLOOD-FEEDING REVEALS DIFFERENCES IN OOCYST SURVIVAL AND GROWTH BETWEEN *PLASMODIUM* SPECIES IN *ANOPHELES GAMBIAE*

Hyeogsun Kwon[1], **Rebekah Reynolds**[1], Maria L. Simões[2], George Dimopoulos[2], Ryan Smith[1]

[1]*Iowa State University, Ames, IA, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Blood-feeding is an integral determinant of mosquito-borne disease transmission in which the mosquito must take at least two blood meals during its lifespan to acquire, as well as transmit the pathogen. The vast majority of studies assessing mosquito vector competence simply examine pathogen infection as a single endpoint, without consideration of the influence of additional blood meals during the extrinsic incubation period (EIP) on the pathogen once initially acquired. To determine the role of an additional blood meal on malaria parasite development in *Anopheles gambiae*, we examined rodent and human malaria parasites with and without an additional non-infected blood meal. Blood-feeding has no effect on mature oocysts that have begun sporogony, yet significantly influence immature oocyst development revealing important differences in between *Plasmodium berghei* and *P. falciparum* adaptation to their mosquito host. An additional blood meal following an infection with the laboratory model *P. berghei* resulted in a significant reduction in immature oocyst numbers. A similar phenotype resulted when mosquitoes were fed on an artificial protein meal, suggesting that this reduction in parasite numbers is not due to physiological effects of blood feeding, but instead due to the distension of the mosquito midgut enabling complement recognition of immature oocysts. In contrast, an additional blood meal did not reduce *P. falciparum* oocyst survival, suggesting that these parasites evolved a mechanism of complement immune evasion. Moreover, *P. falciparum* parasites were significantly larger following a second blood or protein meal, a phenotype not seen with *P. berghei*. This argues that human malaria parasites developed mechanisms to evade immune recognition as well as benefit from the additional nutrients provided with a second mosquito feeding. Together, these data demonstrate additional mechanisms that determine mosquito vector competence and provide support that human malaria parasites utilize nutrients provided by a second blood meal to enhance oocyst growth and potentially decrease the EIP required for malaria parasite transmission.

147

AEDES SPECIES COMPOSITION AND ABUNDANCE IN NORTHEASTERN STATE OF ADAMAWA, NIGERIA

Iliya Shehu Ndams, Ibrahim Isa, Maryam Aminu, Thaddeus T. Gbem, Gloria Chetchet

Ahmadu Bello University Zaria, Zaria, Nigeria

The study focused on the occurrence, distribution and abundance of Aedes species in communities displaced by lingering upheaval in the north-eastern region of Nigeria. *Aedes* species were sampled from three locations namely; Mubi, Yola and Numan towns from July to October, 2017. They were collected using human bait methods and identified to species level using microscopy and coloured morphological identification keys of Rueda. The abundance of each species of *Aedes* identified was expressed in percentages while diversity was revealed using Shannon-Wiener diversity index. A total of 768 mosquitoes were examined, higher abundance of *Ae. aegypti* species were observed in Numan (53.3%;176/330), while lower species occurrence was recorded in Mubi (12.7%; 42/330). The abundance of *Ae. africanus* was highest and lowest in Yola (66.4%;146/220) and Numan (12:7%; 28/220) respectively. *Aedes hensili* showed higher abundance in Yola (43.1%; 88/204) while lower number (16.7%; 34/204) was recorded in Mubi. Also, higher occurrence of *Ae. triseriatus* (77.8%:7/9) was seeing in Numan whereas it was absent in Mubi. There was higher occurrence of *Ae. albopictus* (40%:2/5) in Mubi and Yola, whereas lower species abundance was recorded in Numan (20%:1/5). However, Shannon index showed higher diversity and evenness (H′= 0.06; e^H/S = 0.96) of *Ae. albopictus*, followed by *Ae. hensili* (H′=1.03; e^H/S=0.93) and Ae. aegypti (H′=0.96; e^H/S=0.87) while lower abundance of *Ae. triseriatus* (H′= 0.53) was observed in the three locations. This study indicates that *Ae. aegypti, Ae. africanus Ae. hensili, Ae. triseriatus* and *Ae. albopictus* are abundant and well diverse. The large distribution and evenness of *Ae. albopictus* observed may result from the increase in international travel and urbanization. This posed a potential danger of spreading infections like dengue, yellow fever, chikungunya and zika viruses

148

QUANTIFYING THE RISK OF CHIKUNGUNYA TRANSMISSION IN AUSTRALIA UNDER CLIMATE CHANGE

B.M.C. Randika Wimalasiri-Yapa[1], Liesel Stassen[1], Xiaodong Huang[1], Gregor J. Devine[2], Francesca D. Frentiu[1]

[1]*Queensland University of Technology, Brisbane, Australia,* [2]*Queensland Institute of Medical Research, Brisbane, Australia*

The recent worldwide epidemics of Chikungunya virus (CHIKV) represent a global public health threat. The geographical expansion of this mosquito-borne virus in Southeast Asia and the Pacific region necessitates the accurate forecasting and prediction of transmission risk in Australia. The vector competence of *Aedes* (*Ae.*) *aegypti*, the primary vector of CHIKV, is shaped by the interaction of vector and virus genotype with environmental temperature. Here, we investigate the vector competence of local *Ae. aegypti* for CHIKV strains from Asian and East/Central/South Africa (ECSA) lineage. Specifically, we evaluate the impact of environmental temperature and virus genotype on CHIKV transmission and the extrinsic incubation period. *Ae. aegypti* mosquitoes were orally challenged with a CHIKV strain from either Asian or ECSA lineage (10^7 pfu/ml), and maintained at a constant temperature of either 18°C, 28°C or 32°C. At 3, 5- and 7-days post-infection (dpi), CHIKV RNA copies were quantified in mosquito bodies, and wings and legs using qRT-PCR, while virus in saliva was amplified in cell culture and cytopathic effect observed in Vero cells. Overall, *Ae. aegypti* displayed high susceptibility and rapid viral dissemination of both CHIKV genotypes across all three temperatures. However, viral transmission was temperature and strain-dependent, with higher temperatures (28ºC and 32ºC) generally translating into more infectious mosquitoes and a shorter extrinsic incubation period (EIP) for both genotypes. There were significant treatment effects of temperature, genotype, and the interaction of temperature by day post-infection (dpi) on body and disseminated viral titres. Our results suggest a high risk of local transmission of the Asian genotype of CHIKV if introduced into North Queensland where *Ae. aegypti* are present. Based on our empirical data, we present models of transmission probabilities for this virus under different climate change scenarios and geographic areas in Australia.

Madagascar, Antananarivo, Madagascar, [4]The Foundation for Innovative New Diagnostics, Geneva, Switzerland, [5]Cleveland Museum of Natural History, Cleveland, OH, United States

Modeling serves as a tool for disease elimination by helping us to understand the complicated processes that dictate vector-borne disease transmission. Malaria transmission models rely on several entomological parameters extrapolated from field-collected data. When data from the field is sparse or difficult to interpret, it is crucial to evaluate how model predictions rely on unknown quantities or uncertain assumptions. One of the classic entomological parameters for malaria transmission, the human feeding rate (*a*), is calculated as the product of the proportion of bites taken on a human (*Q*) and the number of bites a mosquito takes per gonotrophic cycle (*f*). However, *f* is ubiquitously taken to equal 1, meaning the number of bloodmeals taken by a mosquito is equivalent to the number of gonotrophic cycles it has undergone. Numerous field studies, including several entomological surveys we have recently conducted in Madagascar and Papua New Guinea, indicate a violation of this assumption. Altering this parameter can significantly change the conclusions derived from transmission models, leading to different recommendations for disease control. Our analysis highlights how violating this assumption, a phenomenon known as multiple blood feeding (MBF), impacts malaria transmission models. To assess the impact of MBF, we show the effect of raising the number of bites per gonotrophic cycle on several important metrics, including the entomological inoculation rate, the vectorial capacity, and the proportion of living, infectious vectors in a population. We consider the effects of MBF in low, moderate, or high transmission environments (by altering values for other parameters that determine overall transmission intensity). Our data suggeststhat MBF causes a substantial increase in infection risk and warrants further investigation to determine the significance of this behavior for malaria control.

IDENTIFYING THE MOST SUITABLE SPATIAL SCALE FOR MICROGEOGRAPHIC MALARIA VECTOR STUDIES

Edgar Manrique[1], Gabriel Carrasco-Escobar[2], Jorge Ruiz-Cabrejos[1], Joseph M. Vinetz[3], Dionicia Gamboa[4], Manuela Herrera-Varela[1], Jan E. Conn[5]

[1]*Laboratorio ICEMR-Amazonia, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Division of Infectious Diseases, Medicine School, University of California San Diego, San Diego, CA, United States, [3]Section of Infectious Diseases, Yale University School of Medicine, New Haven, CT, United States, [4]Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Wadsworth Center, New York State Department of Health, Albany, NY, United States*

Malaria transmission in the Peruvian Amazon has been characterized by high temporal and spatial heterogeneity, and associated with the presence of water bodies, deforested areas and other environmental variables that allow mosquito population to thrive. For this reason, remote sensing is widely used to detect landscape composition. Recently, the use of drones was explored as a tool to map malaria vector breeding habitats in a range of landscapes. While this presents many advantages compared with satellite data, including better spatial resolution, this does not necessarily translate into better spatiotemporal modeling. Here we aim to distinguish the most appropriate spatial resolution of drone imagery to analyze landscape characteristics with malaria vector abundance in the Peruvian Amazon. Data collection was conducted during June and July, 2018 in six villages in the Mazan district of Loreto, Peru. Anopheline mosquitoes were collected using human landing catch in 28 locations distributed across peri-domestic areas. Villages were mapped using a drone equipped with a multispectral camera. In order to determine the most suitable spatial resolution, first we calculated normalized difference vegetation and red edge index (NDVI and NDRE) from the imagery, and distances to water bodies and forest from manually digitized areas. The outputs were resampled from 0.5 m to 10 m, at 0.5 m intervals. We then extracted the average values of these parameters using a 50 m buffer from each mosquito collection point for each spatial resolution. A generalized linear model (GLM) was fitted with the mosquito abundance as the response variable. We found that images with 9 m spatial resolution provided the best fit to the model based on the Akaike information criteria. On average, the surroundings of the collection points (50 m buffer) at 9 m resolution had low values of NDVI (mean = 0.2, CI= 0.17-0.23) and NDRE (mean = 0.06, CI= 0.04-0.07), and a distance to water bodies of 39.23 m (CI= 28.58 - 49.88 m). This methodology will allow researchers to fine-tune regression and classification models to determine the relationship of the landscape and malaria vector abundance.

151

MALARIA IN VENEZUELA: ENTOMOLOGICAL SURVEILLANCE IN A CHALLENGING OPERATING ENVIRONMENT

Yasmin Rubio[1], Melfran Herrera[2], Jorge Moreno[3], Darjaniva Molina de Fernandez[4], Luisa Figueroa[4], Leopoldo Villegas[5]

[1]*Universidad de Carabobo, Maracay, Bolivarian Republic of Venezuela, [2]Fundasalud Sucre, Cumana, Bolivarian Republic of Venezuela, [3]Centro de Investigacion de Campo Dr. Francesco Vitanza, Tumeremo, Bolivarian Republic of Venezuela, [4]Instituto de Altos Estudios "Dr. Arnoldo Gabaldon", Maracay, Bolivarian Republic of Venezuela, [5]Asociacion Civil Impacto Social (ASOCIS), Tumeremo, Bolivarian Republic of Venezuela*

Malaria in Venezuela has increased exponentially in the past 10 years due to several technical, socioeconomic, and political reasons. Vector control activities have been reduced to sporadic and insufficient distribution of LLINs. Entomological surveillance (ES) at country level has been reduced to three teams with limited resources working in Bolivar and Sucre States, which reported 72% and 12% of the total malaria cases in the country in 2018. In Bolivar State (Sifontes Municipality) all night mosquito collections using mosquito magnet traps were conducted in 5 villages along the road that communicates Venezuela with Brazil (8 gold mining camps and 2 towns). The most abundant species were *Anopheles darlingi*, *An albitarsis* and *An nuneztovari* in villages along the road and in mining camps. These species are resistant to organophosphates insecticides but susceptible to carbamates and pyrethroids. *An darlingi* bites throughout the night, *An nuneztovari* has a biting peak between 1800 and 2200 hrs. More mosquitoes were caught outdoors. Unfed mosquitoes were collected indoors and outdoors, but no blood-fed mosquitoes were found. Larval habitats were identified and characterized. ES in remote Amerindian villages were conducted by local leaders in Sucre Municipality (Bolivar State). The most abundant species were *An darlingi*, *An nuneztovari*, and *An oswaldoi*; *An darlingi* showed a different biting pattern with a peak around midnight, *An nuneztovari* has a peak early in the evening and at sunrise and *An oswaldoi* has a peak between 1800 and 2200 hr. Larval habitats were identified and characterized. All night human landing catches indoors and outdoors were conducted in 23 villages of Sucre state. Only *An aquasalis* was collected, mainly outdoors; biting behavior varies locally but over 70% of biting occurs between 1800 and 1900 hrs. Parous rate fluctuated around 55%. In general malaria vectors in Venezuela bite mainly in the first 4 hours of the night outdoors, making the conventional vector control measures available IRS and LLINs less effective to reduce transmission. Integrated vector control strategies should be based on local entomological indicators.

152

AEDES POPULATION AND ENTOMOLOGICAL INDEX RISK OF ARBOVIRUS TRANSMISSION DURING A CHIKUNGUNYA OUTBREAK IN DR CONGO

Fabien Vulu Zimbombe[1], Gillon Ilombe[2], Placide Mbala[2], Pitshou Mampuya[1], Mitterrand Moyo[1], Veerle VanLeberghe[3], Seth Irish[4], Steve Ahuka[2], Thierry Bobanga[1]

[1]*University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [2]*National Institute of Biomedical Research, Kinshasa, Democratic Republic of the Congo,* [3]*Institute of Tropical Medicine, Antwerp, Belgium,* [4]*Center For Disease Control and Prevention (CDC), Atlanta, GA, United States*

Chikungunya fever is an expanding viral disease. Kinshasa (DR Congo) has faced chikungunya fever outbreaks for about twenty years. The on-going outbreak seems to be larger than previous outbreaks. Probable and confirmed chikungunya cases have been found in many health areas of Kinshasa and Kongo Central provinces. Since vector control activities are essential in chikungunya control, this study aimed to determine *Aedes* populations, their breeding sites and entomological risk index of arbovirus transmission. We conducted *Aedes* adult catches and larvae collections in many sites in Kinshasa and Kongo Central provinces from 6 to 28 February 2019. Larvae were reared into adult stage and with adult wild caught mosquitoes were identified to species following Highton morphological key. The entomological risk index were determined according WHO criteria. We collected 1,172 *Aedes* (359 wild adults and 813 adults reared from larvae) which belonged to 3 species; *Ae. aegypti* (15.4%), *Ae. albopictus* (84.3%), and *Ae. vittatus* (0.17%). In all sites *Ae. albopictus* (62 - 100%) was the predominated species. Water storage containers (27.4 - 51.1%), discarded tires (14.2 - 30.1%), and discarded plastic containers (16.6 - 23.8%) were predominant breeding sites. House index, container index, and Breteau index ranged from 24 to 59%, 18 to 67%, and 22 to 59 positives containers/100 houses. *Aedes* densities found were sufficient to promote chikungunya outbreak. This study is relevant since *Aedes* were collected during chikungunya outbreak. Risk index found can be used as reference for *Aedes* surveillance activities. It would be useful to test *Aedes* mosquitoes of different species to determine which species are involved in transmission of chikungunya and other arboviruses.

153

EFFECT OF MIXED CROP IRRIGATION SYSTEM ON MALARIA VECTOR POPULATION ON WESTERN KENYA

Benyl Ondeto[1], Guofa Zhou[2], Ming-Chieh Lee[2], Harrysone Atieli[3], Simon Muriu[4], David Odongo[1], Horace Ochanda[1], Andrew K. Githeko[5], Guiyun Yan[2]

[1]*University of Nairobi, Nairobi, Kenya,* [2]*University of California, Irvine, CA, United States,* [3]*Maseno University, Kisumu, Kenya,* [4]*Pwani University, Mombasa, Kenya,* [5]*Kenya Medical Research Institute, Kisumu, Kenya*

Environmental degradation exacerbated by climate change has necessitated adaptation programs such as irrigation, in order to increase food security. However, irrigation may increase the risk of malaria. This study was undertaken in a semi-arid area, Homa Bay County, Western Kenya where mixed crop irrigation in ongoing. Vector control using long-lasting insecticidal nets and indoor residual spraying is underway. The study was conducted from January to December 2018. Indoor resting anopheline mosquitoes were collected using pyrethrum spray catches in two sites, irrigated and non-irrigated zones. Mosquitoes were morphotyped and analyzed for spatiotemporal density variation. *Anopheles gambiae* sibling species were identified by polymerase chain reaction (PCR). Of the 449 vector *anopheles* mosquitoes collected 94.9% were from the mixed irrigated zone while 5.1% were from the non-irrigated zones; they comprised of *An. gambiae* s.l. (89.8%) and *An. funestus* s.l. (10.2%). In the mixed irrigated (n=426) zone *An. gambiae* s.l. comprised 90.4% and *An. funestus* s.l. 9.6%. In the non-irrigated zone *Anopheles gambiae* s.l. was also dominant 78.3% compared to *An. funestus* s.l. 21.7 %. PCR analysis (n=79) indicated that all the *An. gambiae* s.l. were *An. arabiensis*. There was no significant variation in *An. arabiensis* densities between wet and dry season in either irrigated areas (t_7 = 0.1, p>0.05) or in non-irrigated areas (t_7 = 0.4, p>0.05). The irrigation systems increased vector density and the risk of malaria transmission. The application of IRS may have suppressed vector density seasonality. Previous studies in a similar ecosystem in the region have indicted that *An. arabiensis* is significantly zoophilic.

154

RESTING BEHAVIOR OF MALARIA VECTORS IN A HIGHLAND AND LOWLAND AREA OF WESTERN KENYA

Maxwell G. Machani[1], Eric Ochomo[2], Fred Amimo[3], Stephen Munga[1], Andrew K. Githeko[1], Guiyun Yan[4], Yaw Afrane[5]

[1]*Kenya Medical Research Institute, Kisumu, Kenya,* [2]*Entomology Section, Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya,* [3]*School of Health Sciences, Jaramogi Oginga Odinga University, Kisumu, Kenya, Bondo, Kenya,* [4]*Program in Public Health, College of Health Sciences, University of California, Irvine, CA, United States,* [5]*Department of Medical Microbiology, College of Health Sciences, University of Ghana, Ghana, Ghana*

Major progress in malaria control has been achieved in sub-Saharan Africa in the last two decades. Despite demonstrated success in reducing human-mosquito interactions, continual transmission has been experienced posing a significant challenge to malaria elimination efforts. The aim of this study was to assess the resting behavior, host preference and infection with *Plasmodium falciparum* sporozoites by malaria vectors in the light of emerging insecticide resistance in western Kenya. Indoor and outdoor resting *Anopheline* mosquito were sampled during the dry and rainy seasons in Kisian (lowland site) and Bungoma (highland site), both in western Kenya. PCR was used for mosquito speciation, genotype for resistance mutations and for specific host blood meal origins.ELISA was used to determine sporozoite infections. *Anopheles gambiae* s.l was prevalent (74.7%) followed by *Anopheles funestus* s.l (25.3%.) Majority of *Anopheles funestus* (97 and 100%) and *Anopheles gambiae* s.l (85.8 and 58%) were resting indoors in Bungoma and Kisian respectively. *Anopheles gambiae s.s* was the dominant sibling species in Bungoma followed by *Anopheles arabiensis* 7.6%, whereas in Kisian, *An.arabiensis* was dominant 60.2% followed by *An. gambiae* s.s 38.9%. Vgsc-1014S was observed at high frequency in *An. gambiae s.s* than *An.arabiensis*. Vgsc-*1014F* and *Ace1 G119S* mutations were detected in *An. gambiae s.s* resting indoors in Bungoma but at very low frequencies (0.6 and 0.1% respectively). In Bungoma, human blood index (HBI) for *An. gambiae*, *An .arabiensis,* and *An. funestus* resting indoors were 64.7, 25 and 74% and (46.2, 37.5 and 75% respectively) for outdoor. For Kisian, the HBI for the three species resting indoors was 59.7, 7 and 82.4% respectively whilst outdoors was 100 and 6.25% for *An. gambiae* and *An. arabiensis* respectively. Overall, in Bungoma, the sporozoite rate for indoor resting mosquitoes was 8.6 and 4.2 for outdoors. In Kisian the sporozoite rate was 0.9% for indoor resting *An.gambiae.* The occurrence of *Vgsc-1014F* and *Ace1 G119S* mutation calls for further screening and monitoring of other resistance mutations in this population.

155

EVALUATION OF IVERMECTIN BASED ATTRACTIVE TOXIC SUGAR BAIT AGAINST *AEDES AEGYPTI* IN A CONTROLLED ENVIRONMENT

Frank S. Tenywa[1], Revocatus Musiba[2], Fredros Okumu[2], Marta Ferreira Maia[3]

[1]*Ifakara Health Institute, Bagamoyo, United Republic of Tanzania,* [2]*Ifakara Health Institute, Ifakara, United Republic of Tanzania,* [3]*Kemri Wellcome Trust Research Program, CGMRC, Kilifi, Kenya*

Use of insecticides for *Aedes* mosquitoes control has been a main focus for eliminating mosquito- borne diseases such as dengue fever. However, emergence of insecticide resistance in the recent years and economic constrains are limiting this approach. This study aimed at determining the dose of ivermectin (IVM) in sugar solution and time needed for knock

down (KD) of 90% of the *Ae. aegypti.* This study also assessed the sugar feeding behaviour of *Ae. aegypti* when a blood host is available; and evaluated the efficacy of an attractive toxic sugar bait against *Ae. aegypti* in a semi field environment. Dose response experiments to determine KD90 of IVM against *Ae. aegypti* were done in laboratory conditions through a serial dilution of IVM in 10% sugar solution in separate cages. Mosquito mortality was observed at 4, 8, 24 and 48 hours post introduction of the treatments. *Ae. aegypti* feeding preference between sugar and blood meal was determined by releasing female *Ae. aegypti* into a cage in which both rabbit and sugar bait were deployed. Mosquito feeding status was detected after 24 hours. Ivermectin was toxic against male and female *Ae. aegypti* at 4‰ IVM dose. Over 90% of male and female *Ae. aegypti* were knocked down 48 hours post sugar feeding on sugar solutions containing at least 4‰ IVM respectively. Sugar bait significantly reduced *Ae. aegypti* blood feeding preference (OR=0.06; 95%CI [0.023-0.134]) within 24 hours. An ivermectin dose (0.04%) is enough to be incorporated into attractive sugar baits (ATSB) to achieve 90% *Ae. aegypti* mortality and would be effective against both sexes of *Ae. aegypti*. The presence of sugar bait will significantly inhibit *Ae. aegypti* blood seeking behaviour compared to if there was no sugar bait. Semi field experiments are ongoing to determine the efficacy of the sugar bait against *Ae. aegypti* in a controlled environment.

156

WHERE DO THE MALARIA VECTORS ACTUALLY REST INSIDE HOUSES?

Betwel John Msugupakulya, Emmanuel Kaindoa, Halfan Ngowo, Fredros Okumu

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Countries have set ambitious goals towards malaria control, primarily by scaling up effective interventions such as long-lasting insecticide treated nets (LLINs), indoor residual spraying (IRS) and effective case management. LLINs and IRS particularly target indoor-biting and indoor-resting malaria transmitting mosquitoes. It is therefore important to understand resting behaviours of the major malaria vectors inside houses and how much they can be affected by indoor interventions. This would provide crucial information on where best to direct the interventions to effectively prevent malaria. We investigated the resting behaviors of mosquitoes inside common house types in rural south-eastern Tanzania to identify preferred resting surfaces for the two main malaria vectors, *Anopheles arabiensis* and *Anopheles funestus*. The study houses were selected based on the following inclusion criteria: i) thatched roofs and un-plastered mud walls, ii) thatched roofs and un-plastered brick walls, iii) corrugated iron roofs and un-plastered brick walls, and iv) corrugated iron roofs and plastered brick walls. In each of these houses, mosquitoes were collected from multiple surfaces (floors, walls, roof and ceilings, furniture and utensils, clothes and bed nets) using Prokopack aspirators. Preliminary findings suggest that the two vector species do not only rest on walls, where they could be targeted with IRS, but also on the underside of roofs and other surfaces, such as on bed nets, floors, furniture and utensils. We have detected differences between preferred resting sites between the two major vector species. Additionally, we have observed that different house designs influence the preferred resting surfaces for studied vector species. Particularly, *An. funestus.* are much more of generalists in terms of their resting surfaces compared to *An. arabiensis*, even though both species preferred thatched roofs over iron roofs. Besides, while *An. arabiensis* rest mostly on underside of roofs, *An. funestus* readily also rests on other surfaces as well, such as the walls and on bed nets.

157

MOSQUITO ABUNDANCES AND BEHAVIOR SUPPORT POTENTIAL TRANSMISSION OF RIFT VALLEY FEVER VIRUS IN COLORADO

Daniel A. Hartman, Justin DeMaria, Lauren M. Rice, Erin M. Borland, Nicholas A. Bergren, Anna C. Fagre, Lucy L. Robb, Colleen T. Webb, Rebekah C. Kading

Colorado State University, Fort Collins, CO, United States

Rift Valley Fever Virus (RVFV) poses a major threat of introduction to several continents, including North America. Such an introduction could cause significant losses to the livestock industry, in addition to substantial human morbidity and mortality. Because of the opportunistic blood host selection of *Cx. tarsalis* mosquitoes in this area, we hypothesized that this species could be a locally important bridge vector of RVFV in the event of an introduction. We investigated the mosquito diversity community composition at livestock feedlots and surrounding natural and residential areas to determine differences in mosquito relative abundance and blood feeding patterns attributed to cattle feeding operations. Blood meals from engorged mosquitoes were sequenced to determine blood source, and these data were used to model host-selection behaviors by habitat type. Multivariate regression analyses revealed differences between mosquito community assemblages at feedlots and non-feedlot sites, with this effect driven largely by differential abundances of *Ae. vexans*. Mosquito diversity was lower on feedlots than surrounding areas for 3 out of 4 feedlots. *Cx. tarsalis* was abundant at both feedlots and nearby sites. Diverse vertebrate blood meals were detected in *Cx. tarsalis* at non-feedlot sites, with a shift towards feeding on cattle at feedlots. These data support a potential for *Cx. tarsalis* to serve as a bridge vector of RVFV between livestock and humans in Colorado.

158

A RETROSPECTIVE SURVEILLANCE OF THE OCCURRENCE OF FLAVIVIRUSES IN *AEDES* MOSQUITOES IN PHETCHABUN PROVINCE RELATED TO ENVIRONMENTAL FACTORS

Pornsawan Leaungwutiwong

Faculty of Tropical Medicine, Bangkok, Thailand

Mosquito-borne diseases are related to the medically important viruses in the Family *Flaviviridae*. Zika virus (ZIKV) and Dengue virus (DENV) are transmitted to humans by the bite of the infected mosquitoes. The most important vector is *Aedes* mosquito. Environmental factors such as temperature, relative humidity, and biting rate affect dengue virus infection. In addition, surveillance of field-caught mosquitoes is imperative for determining the natural vector and can provide an early warning sign at risk of transmission in an area. In this study, *Ae. aegypti* mosquitoes were collected in Phetchabun Province, Thailand in 2004-2005. The mosquitoes were collected in the rainy and dry season both indoor and outdoor. During mosquito's collection, the data of environmental factors were observed and recorded. Mosquitoes were pooled according to genus/species, and sampling location. Pools consisted of 10 mosquitoes. Ninety-eight pools of 939 *Aedes* mosquitoes were screened with PCR assay for Pan-flavivirus, ZIKV and DENV, respectively. Two pools were detected as DENV positive and no ZIKV was detected from the mosquito. To confirm individual infection for determining true infection rate, the mosquitoes which gave positive DENV infection were tested for dengue virus by RT-PCR method. Four individual *Ae. aegypti* mosquitoes were detected as DENV serotype 4. The infection rate of DENV in this study was 0.43%. Moreover, the probability to detect dengue virus in mosquitoes at the neighbor's houses was 1.25 times, especially where distances between neighboring houses and patient's houses were less than 50 meters. The relative humidity in dengue-infected villages with dengue-infected mosquitoes was significantly higher than villages that free from dengue-infected mosquitoes. Indoor biting rate of *Aedes aegypti* were 14.87 times higher than outdoor, and biting times of 09.00-10.00, 10.00-11.00, 11.00-12.00 yielded 1.77, 1.46, 0.68mosquitoes/man-hour, respectively.

These finding confirm environmental factors were related to Dengue infection in Thailand. Data obtained from this study will be useful for prevention and control of the diseases.

159

AN EPIDEMIOLOGIC SURVEY AND RISK FACTORS ASSOCIATED WITH LYMPHATIC FILARIASIS IN THE MIDDLE BELT OF GHANA

Dorcas Atibilla[1], David K. Dosoo[1], Joseph Ana-aro[1], Yussif Tawfiq[1], Love Ankrah[1], Gabriel Jakpa[1], Kingsley Kayan[1], Seth Owusu-Agyei[2], Kwaku Poku Asante[1], Felix B. Oppong[1], Michael D. Wilson[3]

[1]*Kintampo Health Research Centre, Kintampo-Ghana, Ghana,* [2]*University of Health & Allied Sciences PMB* [31]*, Ho, Ghana,* [3]*Noguchi Memorial Institute for Medical Research, Accra-Ghana, Ghana*

Lymphatic filariasis has been shown to be endemic in rural areas of Ghana with regional variations in prevalence and disease manifestations. A community based survey was conducted using Binax Now Immuno-Chromatographic Test (ICT) cards for screening participants. Pyrethrum spray collections (PSC) method for mosquito collections, dissection of mosquitoes as well as microscopy was also done. To assess the prevalence, 1320 participants aged between 2 and 80 years in 21 communities were screened during the day time using (ICT) cards. Participants positive with ICT were followed up for night-time finger-prick blood sampling (10 pm and 12 midnights). From a total of 1101 Anopheles spp. collected,500 mosquitoes were dissected for filarial worm examination. No filarial worm was present in the dissected mosquitoes, and hence the absence of active transmission of lymphatic filarasis in the study area. From the screening, a total of 82 (6.2%) out of the 1320 were antigen positive with the day-time samples using the ICT cards. Surprisingly, microscopy results later confirmed the filarial present as Mansonella perstans with a prevalence rate of 39.0% (32/82). There is an indication of a possible cross reactivity of the Binax Now ICT cards with Mansonella perstans since the ICT cards are mostly used for screening Lymphatic filariasis. From the survey, low ITN use,poor housing structure, type of roof and the absence of netting on windows were also some of the associated risk factors.

160

EFFECTS OF NECTAR PHYTOCHEMICALS ON LIFE-HISTORY TRAITS OF THE INVASIVE ASIAN TIGER MOSQUITO, *AEDES ALBOPICTUS*

Teresia Njoroge[1], May Berenbaum[2], Chris Stone[3]

[1]*University of Illinois at Urbana-Champaign, Urbana, IL, United States,* [2]*University of Illinois at Urbana-Champaign, URBANA, IL, United States,* [3]*Illinois Natural History Survey, Champaign, IL, United States*

Plant nectar is an essential component of adult mosquito diets. During nectar-feeding, mosquitoes ingest various phytochemicals, including phenolics, terpenoids, and alkaloids. Compared to other nectar-feeders (e.g., bees), the ecological significance of nectar phytochemicals for mosquitoes has not been extensively explored. The aim of this study was to conduct laboratory-based assays to evaluate the effects of nectar phytochemicals on the longevity, fecundity and sugar-feeding behavior of adult female *Aedes albopictus*. Longevity was assessed by subjecting newly emerged females to 10% sucrose solution containing quercetin, *p*-coumaric acid and caffeine and recording daily mortality. For fecundity assays, the mosquitoes were subjected to the same dietary phytochemicals for seven days and eggs counted following a single blood meal. The cold-anthrone test was used to quantify the amount of sugar consumed by mosquitoes exposed to the dietary phytochemicals. Dietary quercetin and *p*-coumaric acid were associated with lifespan extension (mean longevity= 69 and 67 days, respectively, compared to control =54 days). Although caffeine ingestion resulted in low sugar consumption (33.84 μg/μl) compared to the control group (67.84 μg/μl), none of the three phytochemicals affected the fecundity of gravid females. Our results demonstrate that dietary phytochemicals can affect mosquito longevity and sugar-feeding behavior and thereby may influence their fitness and vectorial capacity. We are currently conducting an experiment using a whole transcriptome-based approach to identify mosquito-nectar phytochemical interactions at the genomic level.

161

CLIMATE EFFECTS RELATED TO OUTBREAKS OF ACUTE CASES OF CARRION DISEASE IN PERU, 2000 - 2016

Gabriela Ulloa U.[1], César Munayco[2], Andree Valle[1], Andrés Lescano[1]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Centro de Control y Prevención de Enfermedades del Perú (CDC Perú), Lima, Peru*

Introduction Carrion disease (CD), present in Peru, Ecuador and Colombia, is considered an emerging disease due to its expansion to new areas. This is related to the migration of asymptomatic carriers and climate change. It has been demonstrated that climatic factors are associated with the incidence of vector-borne diseases. However, there is little information on the relationship of climatic factors associated with possible outbreaks of CD. Therefore, we analyze the relationship between climatic events and the distribution of acute cases of CD in order to develop future prevention and control plans that anticipate future events. Methods: Cases recorded by the CD surveillance system of the Centers for Disease Control and Prevention of Peru during the period 2000 - 2016 were analyzed. Epidemiological weekly data on environmental temperature (ºC) and rainfall (mm/day), obtained from NASA satellites and atmospheric models, were used. Possible outbreaks at district level were selected from the cumulative sum of acute cases of CD. The climatic variables of the weeks before the possible outbreaks were selected. Multiple regression with Poisson distribution, Stepwise Forward method and likelihood ratio test (LRT) were applied to select the variables that entered the final model, Stata statistical package and RStudio program were used. Results: Five of 11 departments had the highest number of possible CD outbreaks (84.9%) in Peru. Precipitations four and five weeks before the start of an "outbreak" presented significant association with the number of acute cases accumulated at the start of a possible outbreak of CD ($p<0.01$). However, the minimum ambient temperature was not significantly associated. The association observed between the increase in the number of cases and climatic variables could be related to the population dynamics of the vector. That is to say, the increase of the population density and variations in the transmission capacity of the etiological agent. Future studies should include the population density of the vector as a variable for a better explanation of climatic factors in the epidemiology of CD.

162

MOSQUITO DYNAMICS AND MALARIA IN ALULU-NIKE COMMUNITY, ENUGU-EAST LOCAL GOVERNMENT AREA, ENUGU STATE, NIGERIA

Pauline U. Umeanaeto[1], Angus E. Onyido[1], Martin O. Ifeanyichukwu[2], Joseph U. Anumba[3]

[1]*Nnamdi Azikiwe University, Awka, Nigeria,* [2]*Department of Medical Laboratory Sciences, Faculty of Health Science and Technology, Nnamdi Azikiwe University, Nnewi, Nigeria,* [3]*National Arbovirus and Vectors Research Centre, Federal Ministry of Health, Enugu, Enugu, Nigeria*

Mosquito dynamics and malaria were studied in Alulu-Nike Community, Enugu-East Local Government Area, Enugu State, Nigeria for a period of 12 months. Malaria was diagnosed using microscopy method. Mosquito collection was done using pyrethroid knockdown collection, human bait and larval collection methods. Mosquito identification was done using morphological characteristics and PCR. A total of 1440 people were screened for malaria and 476(32.4%) were infected. The overall mean malaria intensity was 545 parasites per microlitre of blood (p/μl). Nnegbune village had the highest malaria prevalence 86 (41.5%) which was significant (P&lt0.05) and the highest mean malaria intensity 741 p/μl which was not significant (P&gt0.05). Age 0-10 years had the highest malaria prevalence 229(44.7) and mean intensity 991 p/μl which was

statistically significant (P&lt0.05). Malaria prevalence and intensity were not dependent on sex and occupation of the participants (P&gt0.05) but on educational status (P&lt0.05). PCR characterization of indoor biting and resting adult mosquitoes revealed *Anopheles gambiae ss*and *A. arabiensis* and *A. funestus* asmalaria vectors which constituted 764 (77.1%) of the total mosquitoes collected while the Culicines accounted for 226(22.8%) of the total indoor collection. *A. gambiae sl*7(1.0%) was the only malaria vector collected while other species of Culicine mosquitoes accounted for 687(98.99%) of the outdoor collections. *A. gambiae*yielded 45(3.9%) while Culicine mosquitoes yielded 1,117(96.1%) of the total larval sampling. Mosquitoes were more abundant in wet months than in dry months. The distribution of indoor and outdoor mosquitoes and larvae in different villages and in different months showed significant results (P&lt0.05). Entomological study of mosquitoes is important for planning and optimizing malaria control in both time and space.

163

DISTRIBUTION OF MOSQUITO SPECIES IN KADUNA METROPOLIS, KADUNA STATE NORTHERN NIGERIA

Hosea Chigari Yayock[1], Iliya S. Ndams[2], Ezekiel Kogi[2], Ado Baba Ahmed[1], Jonathan B. George[3]

[1]*Department of Biological Sciences, Kaduna State University, Kaduna, Nigeria,* [2]*Department of Zoology, Ahmadu Bello University Zaria, Zaria, Nigeria,* [3]*Department of Veterinary Parasitology and Entomology, Ahmadu Bello University, Zaria, Nigeria*

Entomological survey was conducted to determine the diversity and abundance of mosquito species in relation to their malaria implication in the fast growing city of Kaduna located in Northern Guinea Savannah vegetation belt of Nigeria. The metropolis was sectioned into old and new settlement areas. Larval samples were used to identify 15 species of mosquito morphologically from 15 randomly selected settlement areas in Kaduna metropolis. *Culex pipiens* complex comprise 80.42% of the total catch (6,991 specimens). *Anopheles* species (0.06%) rarely occurred within Kaduna metropolis. Government Reserved Area; one of the old settlements had the highest number (8) of individual mosquito species. There were 4 species, which exclusively occurred in the old settlement areas and 2 species exclusively occurred at the new settlement areas. The mosquito species diversity (H′) and the similarity between the old and new settlement areas (H′ = 3.079; 3.128 old and new settlement areas respectively and Sorenson's coefficient was calculated (CC) = 0.667). There was no significant difference in the total mosquito species sampled between the two settlement areas (t = 0.436). This research identified *Culex pipiens quinquefasciatus* as the most abundant mosquito species within Kaduna Metropolis; thus further research should examine the implication for filariasis in this area.

164

EMERGENT VIRUSES AND THEIR INTERACTIONS IN *AEDES AEGYPTI*: MAYARO AND ZIKA VIRUS COINFECTED MOSQUITOES CAN SUCCESSFULLY TRANSMIT BOTH PATHOGENS

Marco Brustolin, Sujit Pujhari, Cory Henderson, Jason Rasgon

The Pennsylvania State University, University Park, PA, United States

The emergence of arboviral outbreaks represents one of the most challenging issues for human and animal health and can be complicated by the simultaneous circulation of multiple arbovirus in affected regions. However, little is known about the vector-pathogen interactions during a co-circulation scenario. In this study we explored the effect of simultaneous intake of Mayaro virus (*Togaviridae*) and Zika virus (*Flaviviridae*) on *Ae. aegypti* vector competence. After exposing *Ae. aegypti* mosquitoes to an infectious blood meal containing either one or both pathogens, we analyzed viral titers in body, legs and saliva using a focus forming assay at day 7 and 14 post feeding. Results demonstrate that *Ae. aegypti* can support both viruses concurrently and that coinfected mosquitoes can efficiently transmit both viruses at the same time. The data also suggest that these pathogens can interact in complex ways during the co-infection process.

165

IMPACT OF HOUSEHOLD CHARACTERISTICS ON *AEDES AEGYPTI* ABUNDANCE IN RURAL ECUADOR

Rachel Sippy[1], Froilan Heras[2], Anna Stewart Ibarra[1], Sadie Ryan[3], Erin Mordecai[4]

[1]*SUNY-Upstate Medical University, Syracuse, NY, United States,* [2]*Salud Comunitaria, Machala, Ecuador,* [3]*University of Florida, Gainesville, FL, United States,* [4]*Stanford University, Stanford, CA, United States*

Aedes aegypti is the principal vector for dengue, chikungunya and Zika. Both human cases and mosquito abundance measures are linked to the built environment but the relationship at household level is unclear. Using surveys and entomological data captured across the dengue transmission season (pre: July—December 2016, peak: January—May 2017, post: April—August 2018) in two cities (Zaruma and Portovelo) in Ecuador, we compare the effect of household environment on *Ae. aegypti* abundance. Data were analyzed using Poisson generalized linear mixed models (houses within clusters as random effects). Across seasons, 65 houses from Portovelo and 73 houses from Zaruma participated. In Portovelo, home ownership, cane /wooden housing and standing water presence had protective effects on the risk of capturing *Ae. aegypti* (40—55% decrease). Gaps in flooring, patio cleanliness and living near abandoned property were associated with increased risk (13—70%). Compared to homes with no patio, those with a sunny patio had an 18% decrease, mixed shade had a 44% increase, and shady patio had a 5% decrease in risk. Compared to homes with no water storage, using cisterns had a 17% decrease; other storage had a 32% risk increase. In Zaruma, gaps in flooring were protective against risk of capturing *Ae. aegypti* (63% decrease). Housing material, trash collection frequency, presence of standing water, crowding, and dog ownership were associated with increased risk (47—1517%). Compared to homes with no patio, sunny patios were protective (61% decrease); mixed shade and shady patios had a risk increase (83—128%). Compared to homes with no patio, those with a moderately clean patio had a 191% increase and those with an extremely clean patio had an 85% risk decrease. Compared to homes with no water storage, using cisterns had a 3% increase; other storage had an 81% risk decrease. Across locations, housing factor importance differed with some opposing directions of effect. This work demonstrates that the impact of built environment on *Ae. aegypti* abundance may vary according to location, suggesting that public health communication and control efforts should be place-specific.

CHIKUNGUNYA INFECTION AMONG SUSPECTED DENGUE PATIENTS IN SELECTED COMPOSTELA VALLEY PROVINCIAL HOSPITALS

Nestor Salcedo Arce Jr

Faculty of Clinical Tropical Medicine, Bangkok, Thailand

Controlling infectious diseases remains to be a dilemma and problem despite advancements in research and therapeutics in the past decades. An important area in the field of infection are cases of re-emerging diseases that have escalated in numbers after few years of hibernation, such as the Chikungunya infection which is caused by the same mosquito that carries dengue and zika infection. In the Philippines, dengue infection has been the more common infection among the illnesses caused by the mosquito vector than the other two infections, and the rapid diagnostic tests prepared and procured are commonly for dengue infection only. However, there are cases of Chikungunya outbreaks in the Philippines since the first case recorded in the 1950s. Clinical manifestation of chikungunya, dengue, and zika are almost the same, but in the Philippines, there is a limited resource for diagnoses that can differentiate the three illnesses. This report will discuss an ongoing prospective observational study for all

suspected clinical case of dengue infection of patients with acute febrile illness for seven days, with the aim to (1) determine prevalence of the disease, (2) identify clinical features of Chikungunya infections among suspected dengue patients, (3) determine Chikungunya and dengue co-infections, (4) evaluate significant differences in the laboratory features of chikungunya and dengue infection, and (5) identify the phylogenetic genomic characteristic of the chikungunya virus. Understanding the re-emergence of Chikungunya among closely-related vector-borne diseases presents an epidemiologic challenge that could lead to greater understanding of tropical infectious diseases.

FIELD TEST OF MINIATURIZED AUTOMATED WHOLE BLOOD CELLULAR ANALYSIS SYSTEM TO ASSESS IMMUNITY TO ARBOVIRUSES IN MSAMBWENI, KENYA

Amy R. Krystosik[1], Matthew Hale[2], Francis Mutuku[3], Sangeeta Kowli[4], Jael Sagina[5], Saidi Lipi[5], Phillip K. Chebii[5], Priscillah W. Maina[5], Elysse N. Grossi-Soyster[1], Holden Maecker[4], A. Desiree LaBeaud[1]

[1]*Stanford University, School of Medicine, Department of Pediatrics, Division of Infectious Disease, Stanford, CA, United States,* [2]*Smart Tube Inc., Menlo Park, CA, United States,* [3]*Technical University of Mombasa, Environment and Health Sciences Department, Mombasa, Kenya,* [4]*Stanford University, School of Medicine, Human Immune Monitoring Center, Stanford, CA, United States,* [5]*Vector Borne Disease Control Unit, Msambweni Laboratory, Kwale County, Kenya*

Our study aimed to evaluate the use of a novel miniaturized automated Smart Tube system for whole blood processing, that spares specimens, allows for immune stimulation and detailed immune function evaluation in remote regions of the world. We field tested—in Msambweni, Kenya in a pediatric cohort (median age, 8 years) known to be exposed to chikungunya virus (CHIKV) and/or dengue virus (DENV) by ELISA and PCR. In March 2018, 133 whole blood samples were processed in Kenya using the Smart Tube system for three conditions: no stimulation, stimulation with CHIKV or DENV peptide pools. Frozen samples were shipped to Stanford, where 121/133 samples will be tested by mass cytometry (CyTOF). We have tested 36/121 participant samples. Intracellular cytokine backgrounds were very low (<0.02% of CD4+ or CD8+ T cells). No IFNg+ TNFa+ and IL-2+ responses to CD4+ T cells were observed. There were occasional phenotypic differences suggestive of activated cell populations. MF1690, DENV exposed, showed a prominent CD16+CD14+ monocyte population, as well as a CD27+CD38+ plasmablast population, that were both much less visible in other subjects. Four donors showed CD8+IFNg+ and CD8+TNFa+ low-level responses to CHIKV and/or DENV peptide stimulation. MF1896 and MF1945, CHIKV exposed, showed a small IFNg+ response (0.05% and 0.02% of CD8+ T cells, respectively) only with DENV stimulation. MF0598, DENV exposed, showed a small population of DENV (0.02%) and CHIKV (0.02%) IFNg+ cells. MF1910, CHIKV exposed, showed a small IFNg+ and TNFa+ (0.04%, each) response to CHIKV and DENV stimulation (0.02% and 0.04% respectively). We will re-sample participants that responded to CHIKV and/or DENV, and test response using manual stimulation that will include, unstimulated, CHIKV and DENV stimulation (lysates and peptide pools), PMA+ ionomycin, and lipopolysaccharide, to confirm responses observed via automatic stimulation. The system has applications including vaccine trial monitoring, infectious disease treatment studies, and pathogenesis studies, and will enable new knowledge on the role of the cellular immune response in disease in pediatric populations.

INVESTIGATING THE PHYLOGENY, PHYLOGEOGRAPHY AND MOLECULAR EVOLUTIONARY HISTORY OF ROSS RIVER VIRUS THROUGH WHOLE GENOME SEQUENCING TECHNIQUES

Alice Michie[1], Michael Lindsay[2], John Mackenzie[3], David Smith[3], Allison Imrie[1]

[1]*University of Western Australia, Perth, Australia,* [2]*Department of Health, Western Australia, Perth, Australia,* [3]*PathWest Laboratory Medicine WA, Perth, Australia*

Ross River virus (RRV) infection causes Ross River fever, the most common arboviral disease in Australia, with an average of 5000 clinical cases reported each year nation-wide. Surveillance of RRV in Australia is based on isolation and identification of virus from homogenates of trapped and pooled mosquitoes. In Western Australia, mosquito-based arbovirus surveillance has been conducted routinely in the densely-populated south, and annually in the tropical and remote north, since the mid-1980s. Isolated viruses were identified using fixed-cell ELISA and virus-specific monoclonal antibodies and more recently, RT-PCR. Until now, phylogenetic studies of RRV have been based on analysis of partial gene sequences, typically 250nt long. We conducted whole genome sequence analysis of historical and contemporary mosquito- and human-derived RRV viruses to better understand their movement and evolution. Isolates were selected to cover a wide spatio-temporal range within Western Australia, including the regions of the Kimberley, Pilbara, Gascoyne, Mid-West, Goldfields, Perth Metropolitan, Peel and the South-West, sampled 1977-2014. Viruses isolated from individuals infected during the 1979-1980 RRV epidemic of the South Pacific Island region, as well as 13 published whole genome RRV sequences from humans and mosquitoes, were included in the analyses. Two of the three previously classified genotypes of RRV (G2-3) were identified within Western Australia during the study period, as well as a newly described fourth genotype (G4), which appears to be the contemporary lineage in circulation. The tMRCA and nucleotide substitution rate of RRV appears older and slower than previously estimated based on partial E2 gene sequence analysis. The biological implications of this observed genetic diversity, in terms of pathogenesis and antigenicity, are currently being investigated.

ANOPHELES GAMBIAE DENSOVIRUS (AGDNV) INHIBITS MAYARO VIRUS IN CULTURED CELLS AND MOSQUITOES

Nadya Urakova, Marco Brustolin, Jason L. Rasgon

Pennsylvania State University, University Park, PA, United States

Recent studies demonstrate that insect-specific viruses can influence the ability of their mosquito hosts to become infected with and transmit arboviruses of medical and veterinary importance. The aim of this study was to evaluate the interactions between *Anopheles gambiae* densovirus (AgDNV) (Parvoviridae) and Mayaro virus (Togaviridae) in both insect cell culture and mosquitoes. AgDNV is a benign insect-specific virus that infects An. gambiae mosquitoes. Mayaro virus is an emerging human pathogen that can be transmitted by An. gambiae mosquitoes. Results demonstrate that Mayaro virus replication was reduced in An. gambiae cells infected by AgDNV. Similar results were observed in mosquitoes *in vivo*. These data suggest that insect-specific viruses can modulate transmission of epidemiologically important arboviruses, and that AgDNV has potential as an agent to suppress virus transmission in Anopheles mosquitoes.

171

SINGLE-DOSE ADMINISTRATION OF MV-CHIK INDUCES SUBSTANTIAL IGG3 RESPONSE AGAINST CHIKUNGUNYA VIRUS

Ruklanthi de Alwis[1], Lisa Henß[2], **Roland Tschismarov**[3], Barbara Schnierle[2], Raphael Zellweger[1], Erich Tauber[3], Katrin Ramsauer[3]

[1]*Duke-NUS Medical School, Singapore, Singapore,* [2]*Paul Ehrlich Institute, Langen, Germany,* [3]*Themis Bioscience GmbH, Vienna, Austria*

Chikungunya virus (CHIKV) is an emerging arbovirus, causing debilitating disease and posing an immense societal and financial burden in affected countries and throughout the world. Currently, no specific preventive measures or treatments are available against CHIKV infections. However, since effective immune responses against CHIKV largely depend on neutralizing antibodies and all CHIKV lineages appear to comprise a single serotype, vaccination remains a promising countermeasure. We have previously shown safety and immunogenicity of our Measles-vectored Chikungunya vaccine, MV-CHIK, in published phase 1 and 2 clinical trials. While a single immunization with the candidate vaccine induced substantial levels of neutralizing antibodies, a prime/boost regimen resulted in sustained high antibody levels. To better understand the nature of the immune response induced by MV-CHIK, we performed additional analyses on serum samples collected during phase 2 clinical studies. We examined potential cross-reactivity of these antibodies against other alphaviruses. We found that the antibodies raised by MV-CHIK cross-react with the closely related O'nyong-nyong Virus (ONNV), indicating that the candidate might also be protective against this tropical disease. In addition, we assessed the avidity and IgG subclass composition of the induced antibodies. Interestingly, we found that while prime/boost vaccination induced higher titers of neutralizing antibodies with increased avidity, the amount of IgG3 induced was only slightly higher than in participants receiving one immunization. Given the observation that IgG3 responses early during infection correlate with successful defense against Chikungunya, these data indicate that a single immunization with MV-CHIK might be suitable for a traveller's vaccine.

172

CLINICAL OUTCOMES OF 3-DAY COURSE OF ADJUNCTIVE ORAL IVERMECTIN FOR THE PATIENTS WITH CHIKUNGUNYA VIRAL INFECTION; A PRELIMINARY STUDY

Sarunyou Chusri[1], Pornapat Surasombatpattana[1], Thanaporn Hortiwakul[1], Boonsri Charernmak[1], Butsaya Thaisomboonsuk[2], Stefan Fernandez[2]

[1]*Prince of Songkla University, Hat yai , Songkhla, Thailand,* [2]*The Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand*

Chikungunya (CHIK) fever is characterized by abrupt onset of high grade fever, rash and debilitating joint pain. In recent 2018, this disease re-emerged in southern Thailand. Ivermectin has *in vitro* efficacy to inhibit replication of chikungunya virus (CHIKV), then clinical trial of this drug is needed. Forty patients with symptoms of CHIK fever with virological confirmation of CHIKV infection were enrolled and randomized (1:1) to receive 200 mcg/kg/day of oral ivermectin for 3 days as the adjunctive therapy to standard treatment. Daily physical examinations and blood tests including basic laboratories, polymerase chain reaction (PCR) for CHIKV, c-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were performed in first weeks and every week for 12 weeks. Of 40 patients with CHIKV infection, 20 patients receiving only standard supportive treatment and 20 patients receiving adjunctive ivermectin. Clinical characteristics and basic laboratories of these 2 groups was indifferent. Time to disappearance of fever and joint pain among the patients receiving adjunctive ivermectin were significantly shorter than those receiving only supportive treatment [1.3 days VS. 2.2 days, $P = 0.002$ and 1.9 days VS. 2.8 days, $P < 0.001$, respectively]. Pain score in first 7 days and among those receiving adjunctive ivermectin was significantly lower than those receiving only supportive treatment [$P < 0.001$]. Persistent joint pain was observed in 2 patients receiving adjunctive ivermectin and 9 patients receiving only supportive treatment accounting to relative risk of 0.22(0.05-0.90), $P = 0.04$. Time to disappearance of CHIKV among the patients receiving adjunctive ivermectin were significantly shorter than those receiving only supportive treatment [1.9 days VS. 5.1 days, $P < 0.001$]. The level of CRP and ESR in first 7 days among those receiving adjunctive ivermectin was significantly lower than those receiving only supportive treatment [$P < 0.001$]. Adverse drug reactions were not different between these 2 groups. Favorable outcomes of 3-day course of adjunctive oral ivermectin for the patients with CHIKV infection was demonstrated.

173

CHARACTERIZING EXPOSURE TO CHIKUNGUNYA VIRUS INFECTION IN COASTAL KENYA

Doris Kemunto Nyamwaya[1], Donwilliams Omuoyo[1], Henry Karanja[1], John Gitonga[1], Barnes Kitsao[1], Daniel Wright[2], Rosemary Sang[3], Thumbi Mwangi[4], Charles Nyaigoti[1], George M. Warimwe[5]

[1]*KEMRI-Wellcome Trust, Kilifi, Kenya,* [2]*The Jenner Institute, University of Oxford, Oxford, United Kingdom,* [3]*KEMRI- Center for Virus Research, Nairobi, Kenya,* [4]*Washington State University, Seattle, WA, United States,* [5]*Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom*

Chikungunya virus (CHIKV) is a mosquito-borne alphavirus first isolated in Tanzania in 1953 that has been a major cause of geographically widespread epidemics characterised by acute, often chronic, debilitating polyarthralgia and polyarthritis that can last for months or years. There is no licensed vaccine or specific treatment available. One of the largest chikungunya disease epidemics on record emerged in coastal Kenya in 2004 and spread along the coast to Mombasa and islands on the Indian Ocean, affecting hundreds of thousands of individuals, before spreading to India and subsequently to Southeast Asia and Europe. Descriptions of this and other more recent epidemics outside Africa have informed most of what we know about chikungunya disease. Very little is known regarding the burden, distribution and viral genetic diversity of CHIKV infections in the East Africa. To begin addressing these knowledge gaps we are characterising the epidemiology of CHIKV infections in coastal

Kenya, where recurrent chikungunya outbreaks have previously occurred. Specifically, we are utilising a unique biobank of samples from children and adults in coastal Kenya spanning 20 years (1998-2018) to estimate: 1) the annual prevalence, age profiles and incidence of seroconversion for antibodies to CHIKV, and 2) the burden of clinical CHIKV infections among acute inpatient and outpatient hospital visits within the same period. Results from these analyses will be presented at the meeting.

174

CHITIN SYNTHASE IS INVOLVED IN MAYARO VIRUS INFECTION IN *AEDES AEGYPTI*

Chan C. Heu[1], Scott Emrich[2], Jessica L. Gillmen[1], Jason L. Rasgon[1], Sujit K. Pujhari[1]

[1]*The Pennsylvania State University, State College, PA, United States,* [2]*The University of Tennessee Knoxville, Knoxville, TN, United States*

Mosquitoes transmit a variety of disease-causing agents. The vector competence of mosquitoes is affected by factors such as genetics, age, sex, pathogen titer, and pathogen species and strain. Chitin has been shown to promote the infection of some viruses in arthropods and may have a similar effect in virus infection of mosquitoes. In this study, we evaluated the effect of chitin synthase on Mayaro virus infection in *Ae. aegypti* using RNAi against *AaCHS1* and *AaCHS2*. Knockdown of chitin synthase genes resulted in significant reductions of viral titer and infection rate compared to GFP RNAi controls. These results show that chitin synthase is involved in viral infection phenotypes in *Ae. aegypti* and could be a target for novel disease control strategies.

175

EVALUATION OF EASTERN EQUINE ENCEPHALITIS VIRUS (EEEV) WINTER ACTIVITY IN FLORIDA

Kristi Miley[1], Joni Downs[1], Nathan Burkett-Cadena[2], Richard West[2], Brenda Hunt[3], Benjamin Brewer[4], Peter Brabant[4], George Deskins[5], Billy Kellner[5], Sandra Fisher-Grainger[6], Thomas R. Unnasch[1]

[1]*University of South Florida, Tampa, FL, United States,* [2]*Florida Medical Entomology Lab, Vero Beach, FL, United States,* [3]*North Walton Mosquito Control, Defuniak Springs, FL, United States,* [4]*South Walton Mosquito Control, Santa Rosa Beach, FL, United States,* [5]*Citrus County Mosquito Control District, Lecanto, FL, United States,* [6]*Hernando County Mosquito Control, Brooksville, FL, United States*

Eastern Equine Encephalitis virus (EEEV) is a highly pathogenic arbovirus endemic primarily in the Eastern United States. Recent evidence suggests that Florida may serve as a primary reservoirto reintroduce the virus in the northeast. Florida is also the only state in which EEEV transmission occurs year-round. A risk index mapping and spatial optimization model for EEEV wintertime transmission was developed using sentinel chickens and horse case data. Risk-based surveillance was performed in Walton, Citrus, and Hernando counties. Results indicated that EEEV vector abundance was greater at high risk sites, with the primary enzootic vector *Culiseta melanura*as most abundant species collected. Bloodmeal analysisfrom blood fed mosquitoes collected during the winter months indicated that 73% were from avian hosts, 16% were from mammalian hosts and 11% were from reptiles. Wildlife cameras were deployed to evaluate fauna frequenting high and low risk sites. High risk sites had a greater overall abundance of wildlife, with *Procyon lotor*(racoon) as the predominant species at high risk sites. Although EEEV activity was high in the winter months of 2018, mosquito collections were quite low, suggesting the potential for non-vector borne pathways of transmission may exist. The results of this study may assist mosquito control districts in optimizing placement of surveillance sites as well as suggest modalities for interrupting EEEV transmission during the winter months in Florida, thereby protecting Florida residents from EEEV during peak transmission months and reducing the movement of EEEV from Florida to the northeastern states.

176

MOTOR NEURON DISEASE, PARKINSONISM AND OTHER NEUROLOGIC DISORDERS ASSOCIATED TO CHIKUNGUNYA AND ZIKA VIRUS INFECTION: A CASE SERIES

Roque P. Almeida, Phillip Nicolau G. Almeida, Juliana C. Alves, Camilla N. Santos, Philippe J. Macedo, Amelia R. de Jesus

Federal University of Sergipe, Aracaju-Sergipe, Brazil

Chikungunya (CHIKV) and Zika (ZIKV) virus has since 2014 been an emergent arbovirus in Brazil, transmitted by Aedes mosquitoes. Initial presentation is characterized by fever, headache, rash and myalgia and articular involvement is the hallmark of this infection. Neurological complications are common in severe cases and include encephalitis, myelopathy, Guillain-Barré syndrome and cranial neuropathies. Prognosis is poor in these cases and early recognition and adequate treatment may positively impact clinical outcomes. Due to the lack of clinical data in this area, mainly for motor neuron disease and parkinsonism, we here describe a case series of CHIKV and ZIKV patients who developed neurological disorders including these novel presentations.

177

SEROPREVALENCE OF DENGUE AND CHIKUNGUNYA VIRUS INFECTIONS IN FEBRILE PATIENTS FROM THREE SITES IN UGANDA

Elizabeth Namirembe[1], Andrew Walakira[1], Brenda Nakimuli[2], Joaniter Nankabirwa[1], Emmanue Arinaitwe[3], Moses Kamya[1], Sarah Stanley[4], Philip J. Rosenthal[5], Eva Harris[4], **Sam L. Nsobya**[1]

[1]*Makerere University, Kampala, Uganda,* [2]*MSH -Uganda, Kampala, Uganda,* [3]*IDRC- Uanda, Kampala, Uganda,* [4]*University of California Berkeley, Berkeley, CA, United States,* [5]*University of California San Francisco, Kampala, CA, United States*

Dengue virus (DENV) and chikungunya virus (CHIKV) infections are public health threats in sub-Saharan Africa. These infectionspresent with non-specific symptoms that are similar tothose of malaria. Wecharacterized associations between infections with these arboviruses and febrile illness in patients presenting with malaria-like illness in3 regions with different malaria transmission intensities in Uganda. Study subjects were participants aged 6months to 74 yearsfollowed in cohorts in Tororo, Jinja, and Kanungu Districts in Uganda. We studied 919 samples from study subjects that were collected at the time of presentation with fever(within 7 daysof onset of fever) irrespective of whether they had been diagnosed with malaria from 2011-2014.Temperature on the day of enrolment was measured to be >37.5°C.Thesamples were tested for malarial infection by microscopy of thick and thin blood smears and for DENVand CHIKVinfections using commercial rapid diagnostic tests (RDTs) for IgM for CHIKV (SD Bioline) and IgG/IgM/NS1for DENV (SD Bioline). Theoverallseroprevalence of DENVinfection was 2% and of CHIKV infection was 14%. Seroprevalence at the three sites for DENV and CHIKV was 3% and 27% in Tororo District, 2% and 10% in Jinja District, and 0.3% and 3% in Kanungu District, respectively. The prevalenceof *Plasmodium falciparum* infection in the same samplesfrom Tororo, Jinja and Kanungu districts was 34%,16% and42%, respectively. Thus,arbovirus seroprevalence did not correlate with relative intensity of malaria transmission, but it is noteworthy that, before recent implementation of malaria control measures, malaria transmission intensity at the 3 sites also followed the pattern Tororo>Jinja>Kanungu. In summary, we found serological evidence for relatively high prevalence of CHIKV infection and low prevalence of DENV infection in Uganda, with marked differences in seroprevalence across the country.Additional studies of the prevalence of arboviral infection in Uganda are needed.

178

INVESTIGATING THE ROLE OF EXOSOMES IN FLAVIVIRUS INFECTION OF *AEDES* MOSQUITOES

Alexander S. Gold, Sultan Asad, Fabiana Feitosa-Suntheimer, Tonya M. Colpitts

Boston University, Boston, MA, United States

Exosomes are a subset of small extracellular vesicles manufactured by most cell types and ranging in size from 40-150 nM in diameter. Originating from mutlivesicular bodies, the first step in exosome formation is the budding of these bodies, followed by the development and release of intra-luminal vesicles into the extracellular space by exocytosis. These vesicles have been detected in various bodily fluids and shown to mediate intercellular communication through the transfer of macromolecules, proteins, and genetic material. Apart from these natural functions, Ramakrishnaiah et al. (2013) demonstrated that exosomes from Hepatitis C virus (HCV)-infected human liver cells contained viral RNA and were infectious. Similarly, Bukong et al. (2014) reported that exosomes isolated from the sera of HCV-infected patients were infectious and contained viral RNA in complex with the protein Ago2 and micro RNA 122, a complex known to enhance viral infection. Whereas these findings support that exosomes are involved in cell-to-cell spread of HCV, the role of exosomes in other flavivirus infections has not yet been well-characterized. Vora et al. (2018) showed that exosomes derived from Dengue virus (DENV)-infected *Aedes* mosquito cells contained viral RNA and were infectious to naïve *Aedes* and mammalian cells, indicating a function of exosomes in the transmission of DENV from mosquito vector to human host. While the results of this study support the ability of DENV to use exosomes to enhance infectious output during transmission from vector to host, there has yet to be any evidence that exosomes serve a function in the opposite process: the transmission of DENV from human host to mosquito vector. By isolating exosomes from the sera of DENV-infected patients, confirming the presence of viral RNA in these exosomes, and demonstrating the ability of these exosomes to infect *Aedes* and *Aedes* cells, we have shown that DENV uses exosomes to mediate transmission from host to vector, further elucidating the role of exosomes in the viral lifecycle of DENV, as well as suggesting at the involvement of exosomes in other mosquito-borne flavivirus infections.

179

ARBOVIRUS SURVEILLANCE NEAR THE MEXICO-U.S. BORDER: CO-CIRCULATION OF DENGUE VIRUS SEROTYPES 1, 2, AND 3, WEST NILE VIRUS AND CHIKUNGUNYA VIRUS IN TAMAULIPAS, NORTHERN MEXICO

S. Viridiana Laredo-Tiscareño[1], Javier A. Garza-Hernandez[2], Ma Isabel Salazar[3], Erick J. De Luna-Santillana[4], Gloria L. Doria-Cobos[5], Julian E. Garcia-Rejon[6], Carlos Machain-Williams[6], Bradley J. Blitvich[7], Mario A. Rodríguez Pérez[4]

[1]*Centro de Biotecnología Genómica del Instituto Politécnico Nacional, Reynosa, Mexico,* [2]*Universidad Autónoma de Ciudad Juárez, Juarez, Mexico,* [3]*Instituto Politécnico Nacional, Mexico City, Mexico,* [4]*Instituto Politécnico Nacional, Reynosa, Mexico,* [5]*Secretaria de Salud, Reynosa, Mexico,* [6]*Universidad Autónoma de Yucatán, Merida, Mexico,* [7]*Iowa State University, Ames, IA, United States*

A clinical, serological, and molecular investigation was performed to determine the presence of dengue virus (DENV) and other mosquito-transmitted viruses among residents of the city of Reynosa, Tamaulipas on the Mexico-U.S. border in 2014 to 2016. The sample population consisted of 2355 patients with suspected dengue, in addition to 346 asymptomatic individuals recruited during a household-based epidemiological investigation designed to identify flavivirus seroconversions. Sera were collected from patients with suspected dengue in the acute phase of illness and from asymptomatic individuals at enrollment and every 5 to 7 months for 19 months. Sera from suspected dengue patients were tested for DENV antigen by enzyme-linked immunosorbent assay (ELISA) and select antigen-positive sera were further tested using a serotype-specific, quantitative reserve transcription-polymerase chain reaction. Sera from a subset of patients was also tested for chikungunya virus (CHIKV) RNA. A total of 418 (17.7%) patients with suspected dengue had laboratory-confirmed DENV infections, including 82 patients positive for DENV RNA. Three serotypes were detected (DENV-1, DENV-2, and DENV-3). CHIKV RNA was detected in 13 of 34 (38.2%) patients, including five who also contained DENV antigen. Sera from the household cohort were tested for flavivirus-reactive antibodies by immunoglobulin (Ig) M and IgG ELISAs using DENV antigen. A total of 217 (62.7%) household participants had flavivirus-reactive antibodies at enrollment and nine flavivirus-naïve individuals seroconverted. Sera from a subset of participants, including all those who seroconverted, were further tested by plaque reduction neutralization test, resulting in the detection of antibodies to DENV-1 and West Nile virus. In summary, we provide evidence for the co-circulation of five medically important arboviruses in Reynosa, Tamaulipas on the Mexico-U.S. border.

180

DENGUE: AN EMERGING DISEASE OF PUBLIC HEALTH CONCERN IN NEPAL

Sagun Paudel

Universitas Gadjah Mada, Yogyakarta, Indonesia

Dengue is fast emerging pandemic-prone vector-borne disease transmitted by the bite of a mosquito infected with dengue virus serotypes. The *Aedes aegypti* mosquito is the primary vector of dengue in Nepal. The first case of dengue was detected in 2005 then sporadic cases & outbreak was reported frequently. This paper aims to review dengue situation and existing challenges of dengue in Nepal. Information was gathered by reviewing articles, reports & government publications. Aedes aegipti was identified in five districts of Nepal which reflects that there was local transmission of dengue. The entomological survey shows that all four sub-types of the dengue virus were scattered in Nepal. 42 out of 77 districts were affected by dengue, spread of infection resembles that the disease is now going in tarai plains from west to east. In fiscal year 2015/16, total no. of 1527 dengue cases were reported from 42 districts. Integrated vector management strategies were conducted by government. However, frequent dengue outbreaks in the past couple of years & geographical expansion of dengue vector approves that, these measures are not sufficient. Dengue virus is rapidly expanding its range throughout the country with frequent major outbreaks. So, Early diagnosis and treatment, BCC, larva search and destroy, screening at border & strengthening early warning and reporting is recommended for prevention and control of dengue in Nepal.

Dengue fever is the world's most prevalent mosquito-borne viral disease caused by the four serotypes of dengue viruses (DENV), which are widely spread throughout tropical and sub-tropical countries with 390 million infections and 40,500 deaths per year. Currently, the dengue vaccine, Dengvaxia® by Sanofi, has been approved in several countries for use in endemic areas, however recent analysis found that Dengvaxia® could cause more cases of severe disease for those who had never been infected by dengue virus. To date, no antiviral agents have been approved to treat dengue fever, therefore, there is an urgent need to develop effective and

safe antiviral therapeutics. We have identified tetrahydrothienopyridine derivatives from phenotypic screening as a first-in-class pan-serotype dengue virus inhibitor. Resistance analysis showed that mutations in the dengue viral NS4B sequence (nonenzymatic transmembrane protein and a component of the viral replication complex) conferred resistance to compound inhibition, suggesting that the NS4B protein is a molecular target of this scaffold. Extensive SAR studies of this scaffold led to the discovery of new analogs with improved potency in a nanomolar to submicromolar range against all four dengue serotypes. Optimization of physicochemical properties as well as oral *in vivo* pharmacokinetic profile led to a compound showing excellent oral efficacy in the DENV-2 infected AG129 mouse model with >one log viremia reduction when orally dosed at 30 mg/kg once daily for three days. Furthermore, this compound showed good selectivity against off-target safety and cytotoxicity panels. This presentation will discuss our dengue phenotypic screening campaign, medicinal chemistry strategy, SAR, *in vitro* and *in vivo* profile of the optimized compound.

182

DENGUE VIRUS INFECTION AND LEISHMANIASIS IN PATIENTS ATTENDING A MEDICAL HEALTH CENTER IN THE RURAL COMMUNITY OF ILARA-MOKIN, ONDO STATE, NIGERIA

Olayinka Osuolale, Tolulope Daramola, Olanike Alajo

Elizade University, Ilara-Mokin, Nigeria

Dengue and leishmaniasis are serious diseases that the World Health Organization (WHO) characterizes as lacking effective control measures. Transmitted by insect vectors and can result in epidemic outbreaks. Sustained control of the vectors are difficult for dengue and leishmaniasis because their high reproductive potential allows the vector populations to recover quickly after intervention wherever adequate breeding conditions exist. Because of their misdiagnosis or underdiagnosed, it is endemic in the tropical countries. Prevalence and epidemiology of these diseases is poorly understood and misdiagnosed in Nigeria, in most cases with malaria. Our study aims to investigate dengue virus and leishmaniasis co-infections in patients visiting a rural community medical center in Elizade University, Ilara Mokin, Ondo State. Blood samples were collected and analyzed for two months. SD Dengue Duo and Bio-rad IT Leish serological test kits was used for the samples analysis. This study examined 101 samples which were simultaneously tested for the target infections. In about 23.76% of the samples (24 samples) were positive for dengue infections. Gender wise, more males (79.17%) than females (20.83%) tested positive to the virus infection. 37.5% of the positive samples were primary infections, 91.6% were past or secondary infections and 33.3% of the samples show late primary infections and early secondary infections. Only 1 sample was positive for Leishmaniasis. The majority of the study population had no pre-knowledge of dengue infection and leishmaniasis as they are carriers of the diseases, providing new insights on both incidence and prevalence. It was discovered that those from villages especially the South-South of Nigeria tested positive the most as carriers of the diseases. Therefore, these areas need special attention for surveillance and treatment for preventive measures. In addition, this study recommends a concerted effort by all stakeholders to enlighten the people about dengue infection and leishmaniasis, and its prevention and eradication from such regions.

C-REACTIVE PROTEIN AS A POTENTIAL BIOMARKER FOR DISEASE PROGRESSION IN DENGUE: A MULTI-COUNTRY OBSERVATIONAL STUDY

Duyen Thi Le Huynh[1], Vuong Lam Nguyen[1], Lam Khanh Phung[1], Hoai Tam Thi Dong[2], Kinh Van Nguyen[3], Cameron Simmons[1], Ngoun Chanpheaktra[4], Lucy Lum See[5], Ernesto Pleités Sandoval[6], Kerstin Rosenberger[7], Vinh Chau Van Nguyen[8], Christine Halleux[9], Piero Olliaro[9], Thomas Janisch[7], Bridget Wills[1], Sophie Yacoub[1]

[1]*Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam,* [2]*University of Medicine and Pharmacy, Ho Chi Minh City, Vietnam,* [3]*National Hospital of Tropical Diseases, Ha Noi, Vietnam,* [4]*Angkor Hospital for Children, Siem Reap, Cambodia,* [5]*University of Malaya Medical Centre, Kuala Lumpur, Malaysia,* [6]*Hospital Nacional de Niños Benjamin Bloom, San Salvador, El Salvador,* [7]*Heidelberg University Hospital, Heidelberg, Germany,* [8]*Hospital of Tropical Diseases, Ho Chi Minh City, Vietnam,* [9]*TDR, WHO, Geneva, Switzerland*

Dengue infection can cause a wide spectrum of clinical outcomes. The severe clinical manifestations occur late in the disease course, during day 4-6 of illness, allowing a window of opportunity for risk stratification. Markers of inflammation may be useful biomarkers. We investigated the value of CRP measured early on illness days 1-3 to predict dengue disease outcome and the difference in CRP levels between dengue and other febrile illnesses (OFI). We performed a nested case-control study using the clinical data and samples collected from the IDAMS-consortium multi-country study. This was a prospective multi-center observational study that enrolled almost 8000 participants presenting with a dengue-like illness to outpatient facilities in 8 countries across Asia and Latin America. Predefined severity definitions of severe and intermediate dengue were used as the primary outcomes. 378 cases with severe/intermediate dengue were compared to 1134 uncomplicated dengue patients as controls (ratio 1:3), and also 400 patients with OFI. In patients with confirmed dengue, higher CRP levels in the first 3 days of illness were associated with a higher risk of severe outcome (OR 1.64, 95% CI 1.21-2.24), and longer fever clearance time (HR 0.87, 95% CI 0.77-0.99) but not with hospitalization. CRP levels showed a quadratic association between dengue and OFI diagnosis; with levels of approximately 30 mg/dL associated with the highest risk of having dengue. This risk decreased with lower and higher levels of CRPs, likely representing diagnoses with other viral infections with CRP levels <30mg/dL and bacterial infections >30 mg/dL. Antibiotics were given in 6.6% of dengue patients, and these patients had similar outcomes to those not given antibiotics, even those with CRP levels >40mg/dL. CRP had a positive correlation with total white cell count and neutrophils and negative correlation with lymphocytes, but did not correlate with liver transaminases, albumin, or platelet nadir. In summary, CRP measured in the first 3 days of illness is a useful biomarker for early dengue risk prediction and may assist differentiate dengue from other febrile illnesses.

184

MITIGATION AND PREVENTION OF DENGUE OUTBREAKS AND SUSTAINING LOW ENDEMICITY THROUGH A COMPREHENSIVE INTEGRATED APPROACH BASED ON BEST PRACTICES: SRI LANKA

Dompeyalage Shamali Anoja Fernando Dheerasinghe[1], Mizaya Cader[2], Prashila Samaraweera[1], Iroshini Abeysekara[1], W.m.i.p. Weerasinghe[1], O.b.w Rajapaksha[1], K.a.l.c Kodithuwakku[1], Nimalka Pannila Hetti[1], Hasitha Tissera[1]

[1]*National Dengue Control Unit, Ministry of Health, Colombo, Sri Lanka,* [2]*National Programme for Tuberculosis Control and Chest Diseases, Ministry of Health, Colombo, Sri Lanka*

Dengue is a leading public health problem in Sri Lanka where all ages are affected. The aims of the dengue control programme are to carry out proactive integrated vector management based on real-time Dengue surveillance (epidemiological & entomological) data and to strengthen human resource and infrastructure to improve clinical management of Dengue. There has been significant progress in epidemiological and entomological surveillance, clinical management, and active engagement of various ministries through the Presidential Task Force (PTF) on Dengue to enhance community participation. A guideline was developed for *Aedes* vector surveillance and control. Field health officers were trained on vector surveillance and vector control according to the guideline. Field Assistants Mosquito Control (1287) were recruited in a phased manner in 2017 to work at the community level to lead source reduction activities and other vector control and vector surveillance activities. Special Mosquito Control Campaigns (SMCCs) were conducted in 2017 and 2018 for source reduction, with the participation of stakeholders covering 2.7 million and

1.4 million premises respectively. The PTF was reactivated in 2017 and 24 PTF meetings have been conducted to date to assess the progress of control activities with the participation of relevant stakeholders. In-service training programmes were conducted (35 and 15 in 2017 and 2018 respectively) for medical doctors and other clinical staff by the local and foreign experts on clinical management. Moreover, the capacities of high dependency units were strengthened to manage Dengue patients efficiently. During SMCC's conducted in 2017 and 2018, health workers along with the Tri-Forces/Police found 20% and 21% potential breeding places and 1.98% and 2.29% positive breeding places in the respective years. Thus there was a reduction in the incidence of Dengue from 865.9 to 239.8 per 100,000 population (in 2017 and 2018 respectively) and case fatality rate has been halved from 0.24% to 0.11% from 2017 to 2018. An integrated approach is an effective method in sustaining low endemicity and curtailing Dengue outbreaks.

185

COMPARING THE COMPETENCE OF GHANAIAN AND VIETNAMESE *AEDES* MOSQUITOES AS VECTORS OF THE DENGUE VIRUS

Michael Amoa-Bosompem[1], Daisuke Kobayashi[2], Katsunori Murota[2], Astri Nur Faizah[3], Kentaro Itokawa[2], Mitsuko Ohashi[1], Samuel Dadzie[4], Kofi J. Bonney[4], Toshinori Sasaki[2], Haruhiko Isawa[2], Kyoko Sawabe[2], Shiroh Iwanaga[1]

Dengue fever is an arboviral infection of public health concern caused by at least 4 antigenically different serotypes of the dengue virus. It is transmitted by the *Aedes* mosquito, infecting 390 million people annually with 25,000 deaths. The distribution, frequency and intensity of outbreaks have varied quite significantly over the years. In 2016, the Americas and Asia reported cases in the millions and hundreds of thousands respectively while Africa reported cases in the thousands. Within Africa, Ghana, unlike her neighboring countries, is yet to report a single outbreak despite an abundance of the *Aedes* mosquito vector. Serological reports have however suggested possible exposure to the dengue virus or a closely related flavivirus. While many factors have been hypothesized as the reason for the differences, determining the effect of vector competence is of utmost importance. The aim of this study was therefore to compare the vector competence of *Aedes* mosquitoes from Ghana and dengue endemic Vietnam. In this study, Mosquito larvae were collected from various parts of Ghana and Vietnam and established in the lab. The virome of the laboratory colonies were determined after which adult female mosquitoes were infected with the dengue virus. The Saliva, thorax/abdomen and carcass of individual mosquitoes were harvested and screened at 7 and 14 days post infection. The infection rate, dissemination rate and transmission rate were determined by qPCR and Focus assay. Our results show Vietnamese *Aedes* mosquitoes to be significantly more susceptible to Dengue virus colonization. Furthermore the dissemination rate of the virus in the Vietnamese mosquitoes was double that of the Ghanaian mosquitoes. Last but not least while there was no significant difference in the time viruses were detected in the saliva of infected mosquitoes, the concentration in the Vietnamese mosquitoes were significantly higher. In conclusion, *Aedes* mosquitoes from Vietnam are more efficient vectors of the Dengue virus than *Aedes* mosquitoes from Ghana and the difference in vector competence may play a significant role in distribution and intensity of outbreaks.

186

CONGENTITAL DENGUE: CD133+ AND CD34+ HEMATOPOETIC STEM CELLS IN UMBILICAL CORD BLOOD ARE INFECTABLE BY DENGUE VIRUS CONFERRING VERTICAL TRANSMISSION

Amrita Vats

National Cheng Kung University, Tainan, Taiwan

Dengue affects more than 100 million people worldwide annually. Numerous routes of transmission for dengue virus (DENV) have been documented. The cases of dengue resulting from stem cell transplantations and mother-to-infant vertical transmission are escalating in recent years. Consequences of mother-to-fetal transmission have been shown to be associated with miscarriage and stillbirth. DENV proteins and genomic RNA have been detected in placenta, serum and cord blood of baby with a fever and subclinical infection upon delivery. Umbilical cord blood (UCB) is the essential bridge connecting placenta and infant and is abundant with stem cells. We, therefore, hypothesize that DENV after passing through placenta may amplify further in stem cells within UCB. In this study, freshly obtained UCBs were utilized and fluorescence-activated cell sorting (FACS) was performed to analyze the stem cells after DENV infection. Viral titers in supernatants of infected UCB were performed by plaque assay. Results showed that cells in UCB were highly permissive to DENV, enhanced proliferation of hematopoietic stem and progenitor cells (HSPC) was observed, balance of transcriptional factors (GATA-1,GATA-2,GATA-3) were disturbed, DENV nonstructural protein 1 (NS1) was mainly associated with CD34+ and/or CD133+ cells analyzed by FACS and immunofluorescence staining, sorted CD133+ or CD34+ cells were infectable by DENV, and infectious DENV could be recovered from infected CD34+ and CD133+ cells upon co-culture . Furthermore, viral RNA in specific organelle was found after 30 days of infection, suggesting the longevity of stem cells in DENV infected UCB. Our cumulative results submit that CD133+ and/or CD34+ cells in UCB are not only permissive to DENV infection but also might serve as a reservoir for dissemination of the virus. The findings may indicate the unique property of DENV in stem cells contributing to DENV transmission from mother-to-infant, resulting in the clinical significances in newborn babies, especially in dengue-endemic regions.

Argentina is located at the southern range of arboviral transmission by *Aedes aegypti* and has experienced a rapid increase in arbovirus transmission in recent years. The aim of this study was to present, for the first time, the methods and findings from a prospective long-term entomological surveillance study that began in 2009 in the city of Córdoba, following the first dengue virus (DENV) outbreak. We analyze the seasonal and interannual dynamics of DENV transmission in the city,

in relation to *Ae. aegypti* indices and local climate. Therefore, from 2009 to 2017, larval surveys were conducted monthly, from November to May, in 600 randomly selected households distributed across the city. From 2009 to 2013, ovitraps (n=177) were sampled weekly to monitor the oviposition activity of *Ae. aegypti*. Cross correlation analysis was used to identify significant lag periods between climate, entomologic and epidemiologic variables. Climate, entomologic and epidemiologic variables exhibited a strong seasonal pattern with a single peak within the year (climate, epidemiologic) or sampling period (entomologic). The largest correlation between autochthonous dengue and minimum temperature was at 9 weeks (positive), and there was a large positive correlation between autochthonous dengue and relative humidity (minimum, mean, maximum) at 4 weeks. There was a positive correlation with mean relative humidity at lag 4 in 2009, and a negative correlation between ovitrap positivity and minimum relative humidity at lag 2 in 2010. Ovitrap positivity was positively correlated with relative humidity (mean, maximum) and precipitation at a 5-week lag and negatively correlated with mean temperature in 2012. This prospective entomological surveillance study provides the first evidence that *Ae. aegypti* larval indices in this temperate region have increased over the last 9 years, a period when arboviral diseases have become epidemic for the first time. These findings suggest an increasing the risk of arbovirus emergence and sustained transmission at temperate southern latitudes, where these diseases were not previously reported.

188

UNCOVERING THE DENGUE-1 SPECIFIC MEMORY B CELL DERIVED ANTIBODY REPERTOIRE IN IMMUNE DONORS 1 TO 43 YEARS AFTER DENGUE INFECTION IN A NON-ENDEMIC COHORT

Zoe Lyski[1], Bettie Kareko[1], Brian Booty[2], Jana Mooster[1], William Messer[1]

[1]*Department of Molecular Microbiology and Immunology, Oregon Health and Science University, Portland, OR, United States,* [2]*Oregon Clinical and Translational Research Institute, Oregon Health and Science University, Portland, OR, United States*

Mosquito transmitted flaviviruses, including dengue virus (DENV) are among the most important vector-borne pathogens of humans worldwide, responsible for 100 million symptomatic cases and ~35,000 deaths *each* year. Upon DENV infection, DENV-specific host B-cells differentiate and proliferate. Some become long-lived antibody-secreting cells (long-lived plasma cells) while others become DENV-specific memory B cells (MBCs) that remain in circulation, poised to protect against future infections, forming a founder population that plays a critical role in establishing and maintaining long-term viral immunity. Despite this critical role, much remains incompletely described regarding lifespan, specificity, and the potency and breadth of MBCs and the antibodies they encode and secrete upon reinfection. This knowledge is vital for understanding long-term human immunity to flaviviruses as well as for rational vaccine design. Here we identify and quantify DENV-specific MBCs in humans with a single DENV infection. Using PBMCs from 15 primary DENV-1 donors with times since infection ranging from 1-43 years, we employed two complimentary experimental approaches to quantify DENV-specific MBCs. In our first approach, PBMCs were stimulated *in vitro* to become antibody-secreting cells and the resulting antibodies assessed for DENV-specificity by ELISA using whole DENV virus (DENV1-4) as well as non-structural protein NS1. The second method used flow cytometry to quantify human MBCs (CD3-CD14-CD19+CD27+IgD-) that bind fluorescently labeled DENV. Using these approaches, we were able to identify DENV-specific MBCs that remain in circulation decades after infection. MBC frequency was inversely correlated with time since infection. These experiments lay the foundation to functionally characterize DENV-specific MBCs and the antibodies they are programmed to secrete, including frequency of DENV-binding and neutralizing MBCs and the potency and breadth these antibodies have against antigenically diverse DENV. The results of this project will provide insight into the MBC founder population and the role it plays in broader DENV immunity.

189

CHARACTERIZING THE SPATIO-TEMPORAL DYNAMICS OF DENGUE IN BRAZIL

Saki Takahashi, Isabel Rodriguez-Barraquer

University of California San Francisco, San Francisco, CA, United States

Roughly half of the global population is at risk of dengue infection, predominantly in urban areas in Southeast Asia and Latin America. There are four main serotypes of dengue virus that co-exist, and infection confers long-term immunity against only the infecting serotype. Although dengue is classically considered a childhood disease, the age distribution of cases depends on local demography as well as how long serotypes have been present. In Brazil, where dengue was re-introduced in the 1980s and which now accounts for the majority of dengue cases reported in the Americas, the disease classically affected mainly adult populations. However, in 2007, the age distribution of cases drastically shifted towards younger age groups. Here, we investigate the causes and consequences of this punctuated drop in the age distribution of dengue cases, leveraging annual state-level counts of age-stratified, hospitalized dengue cases in Brazil between 1992 and 2017. We deploy a mathematical modeling framework to clarify spatio-temporal patterns of population-level susceptibility to dengue in Brazil, and explore the interplay between human demography, transmission epidemiology, and serotype-specific immunity on dengue burden more generally. With more countries prone to dengue transmission undergoing the demographic transition, the ability to project age-structured cases into the future will inform public health planning. Clarifying serotype-specific immunity and risk will also be important for countries considering introduction of childhood immunization with the dengue vaccine.

190

THE LABORATORY PROFILE OF DENGUE IN PATIENTS ADMITTED TO TEACHING HOSPITAL ANURADHAPURA

Shobha Sanjeeewani Gunathilaka[1], SAM Kularatne[2], Jayantha Rajapakse[3], Rohitha Muthugala[4]

[1]*Rajarata University of Sri Lanka, Faculty of Medicine and Allied Sciences, Anuradhapura, Sri Lanka,* [2]*Faculty of Medicine , University of Peradeniya., Peradeniya, Sri Lanka,* [3]*Faculty of Veterinary Medicine and Animal Sciences, Peradeniya, Sri Lanka,* [4]*Teaching Hospital Kandy, Kandy, Sri Lanka*

Dengue is an arthropod-borne viral disease caused by an RNA virus belonging to the genus Flaviviruses. Dengue has become a major public health problem in the world as well as in Sri Lanka. The clinical and laboratory profiles of dengue may vary depending on the age, immunity states and the involved serotype of the virus etc. Nevertheless, the differences of presentation, the timely diagnosis, triage, and proper monitoring plays a vital role in saving lives of dengue patients. For this, the knowledge on clinical presentations, the utility of the available national and international guidelines and the choice of ideal lab test/s for the confirmation, in the local context, should be available to the clinicians and other stakeholders. This study was aimed to assess the utility of specific laboratory tests for the correct diagnosis of dengue. The data on available investigation results and blood samples were collected from patients admitted to medical wards of Teaching Hospital Anuradhapura, with the probable diagnosis of dengue. The PCR testing was conducted in the PCR laboratory at the Department of Veterinary Pathobiology, University of Peradeniya, during one year starting from 1st December 2016. A total of 213 patients were recruited by convenient sampling. The mean age of the study group was 32.98 years (SD=13.1). Of them, the majority (81.7%) were males. Only 1.6 % of the patients have a maximum drop of more than 100 x 10^3 per mm^3 platelets per one day. RT PCR was positive only in 38 blood samples. The sensitivity and specificity of NS1 and/or Ig M dengue 44.7% and 65.7% respectively. The commonest serotype was DENV 2. The utility of serology, NS1 and, PCR and virus isolation tests in the diagnosis of the disease in the Sri Lankan context should be investigated further by researchers.

191

CHARACTERIZING EXPOSURE TO DENGUE VIRUS INFECTION IN COASTAL KENYA

Henry Kibe Karanja[1], John N. Gitonga[1], Doris Nyamwaya[1], Donwilliams Omwoyo[1], Everlyn Kamau[1], Barnes Kitsao[1], Rosemary Sang[2], Limbaso Konongoi[2], Daniel Wright[3], Charles Nyaigoti[1], George Warimwe[1]

[1]*KEMRI-Wellcome Trust, Kilifi, Kenya,* [2]*KEMRI-Centre for Virus Research, Nairobi, Kenya,* [3]*The Jenner Institute, University of Oxford, Oxford, United Kingdom*

Dengue virus (DENV) is the most widespread arbovirus globally, causing over 300 million infections every year. Typically, the disease occurs as outbreaks of a self-limiting febrile illness that can sometimes result in life-threatening complications including shock and bleeding diathesis. However, despite occurrence of dengue outbreaks in Africa, very little is known regarding the burden, distribution and viral genetic diversity of DENV infections in the continent. To begin addressing these knowledge gaps we are characterising the epidemiology of DENV infections in coastal Kenya, where recurrent dengue outbreaks have previously occurred. Specifically, we are utilising a unique biobank of samples from children and adults in coastal Kenya spanning 20 years (1998-2018) to estimate: 1) the annual prevalence, age profiles and incidence of seroconversion for antibodies to DENV, and 2) the burden of clinical DENV infections among acute inpatient and outpatient hospital visits within the same period. Results from these analyses will be presented at the meeting.

192

A NEW SET OF PRIMERS FOR IN-HOUSE LOOP-MEDIATED IS OTHERMAL AMPLIFICATION (LAMP) FOR DENGUE VIRUS DIFFERENTIAL DIAGNOSIS

Scarlett Barrientos Peña, Oscar Nolasco Cárdenas

Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru

Early detection of infection is a key step in the management of dengue cases; both in the clinical management and the control of the expansion of the disease. However, serological tests, which are the most used tools for diagnosis in first-level health centers, need at least five days (from the beginning of the infection) to be useful. Even so, these tests are subject to problems of specificity. Loop mediated isothermal amplification (LAMP) tests are fast, simple and therefore attractive for environments where implements necessary for more complex tests do not exist, like real-time PCR. In this work, we performed the in-house design of LAMP primers for the differential diagnosis of dengue virus serotypes. To this end, dengue virus sequences were downloaded from GenBank and aligned in MEGA v7. Subsequently PrimerExplorer V5 was used to generate sets of candidate LAMP primers from the most conserved regions, for each serotype. Each set of primers was evaluated for the formation of secondary structures and specificity using OligoAnalyzer v3.1 and Primer Blast, respectively. The best sets were evaluated to determine their amplification conditions, using neutral red dye for visual detection, which shows a color change from yellow to fuchsia when DNA synthesis occurs. The limit of detection for the sets designed, using plasmids, was 664,99 copies/μL for DENV-1; 3 035,75 copies/μL for DENV-2; 19 6476.80 copies/μL for DENV-3 and 207,65 copies/μL for DENV-4. The average incubation time was 1 hour ± 10 minutes. The analytical specificity determined was 100%. Additionally, LAMP primers were evaluated in a RT-LAMP format using AMV enzyme for reverse transcription and RNA extracted from 106 samples obtained by active collection in peri-urban areas from Iquitos. Four samples were positive by DENV-2 LAMP and the results were compared with those obtained by real time PCR. The amplification region sequencing confirmed the presence of serotype 2 dengue virus in the samples, with a 99% identity to strains found in Peru according to GenBank (isolate DENV-2/PE/NFI1159/2010). The four sets of designed primers are shown as a promising alternative for use in LAMP tests.

193

CIRCULATION OF MULTIPLE DENGUE VIRUS SEROTYPES IN IBADAN NIGERIA

Anyebe B. Onoja[1], Mamoudou Maiga[2], Adekunle J. Adeniji[1], Georgina N. Odaibo[1], Robert L. Murphy[3], Olufemi D. Olaleye[1]

[1]*University of Ibadan, Ibadan, Nigeria,* [2]*Center for Innovation in Global Health Technologies, Northwestern University, Evanston Campus, IL, United States,* [3]*Centre for Global Health, Feinberg School of Medicine, Northwestern University, Chicago, IL, United States*

Dengue is a rapidly spreading mosquito-borne illness in many parts of the world. In Africa, the first empirical evidence of dengue virus was from Ibadan Nigeria, where DENV-1 and -2 serotypes were identified during an epidemic between 1964 and 1968. In recent times, high rate of dengue has been reported in Ibadan as a result of increased breeding of *Aedes species*. However, specific strains responsible for dengue outbreaks after 1960s episodes has been unknown. We employed molecular techniques to identify currently circulating DENV strains among the general population across different parts of Ibadan Nigeria. A prospective study was carried out from July to August, 2018 involving 175 randomly selected febrile participants attending three big hospitals in Ibadan Nigeria. The participants tested negative for malaria parasite examination and typhoid fever. Viral RNA was extracted from plasma and prM/E junction of DENV was detected using conventional PCR. Heat-inactivated tissue culture-based DENV1-4 isolates used by the Global Dengue Laboratory Network were included as positive controls. Kruskal-Wallis test was used to compare positivity of each serotype with respect to participants' age, occupation, hospital, and clinical symptoms. The post hoc test was conducted using Mann-Whitney test to identify specific association. All tests were conducted at 0.05 level of statistical significance. A total of 40 (22.8%) participants were infected with at least one DENV serotype. Specific serotypes identified are DENV-1 2 (1.1%), DENV-2 19 (10.9%), DENV-3 11 (6.3%) and DENV-4 13 (7.4%). Five participants had dual infection with DENV-2 and other serotypes. Dual infectivity was not a function of age. A significant association was observed between symptoms of participants confirmed with DENV-3 (X^2 = 29.930, df = 17, p=0.027). In this study, DENV-3 and -4 serotypes were found, with very low incidence of DENV-1. Findings indicate a deviation from high DENV-1 and -2 activity previously reported in Ibadan. Phylogeny and evolutionary analysis is required to establish ancestry of these strains.

194

DIFFERENTIAL SUSCEPTIBILITIES AND IMMUNE RESPONSES OF *AEDES AEGYPTI* TO TWO DENGUE 4 VIRUS STRAINS

Caroline J. Stephenson, Seokyoung Kang, John A. Lednicky, Rhoel R. Dinglasan

University of Florida, Gainesville, FL, United States

Dengue virus (DENV) is responsible for the largest number of arbovirus infections among humans globally. There are four serotypes: DENV1, -2, -3 and -4. Little is known about how genetic differences between DENV serotypes and among strains can lead to differences in mosquito susceptibility. We compared mosquito susceptibilities and immune responses within the midgut and carcass of Orlando strain *Aedes aegypti* infected with two strains of DENV4 and one strain of DENV2. Mosquitoes were given infectious bloodmeals containing either DENV4 lab strain H241, a field isolate of DENV4 obtained from a child in Haiti in 2015, or DENV2 New Guinea C (NGC) strain. When *A. aegypti* ingest viremic blood, the blood passes into the midgut, and epithelial cells are a target for infection. If DENV passes the midgut barrier, it disseminates into the hemolymph and then throughout the body. In our work, mosquitoes were fed either naïve blood (no virus) or virus-spiked blood, then collected 7- or 10-days post-blood meal for plaque assay to quantify virus titer. The median virus titers were between 2-4 logs higher ($p<0.01$) within DENV4 Haiti- and DENV2 NGC-infected mosquito midgut and carcass samples than in DENV4 H241-infected samples. These results suggest that the DENV4 strains that were tested have different phenotypes. The mRNA

levels of transcription factor Rel 2 and its negative regulator, Caspar, of the Immune Deficiency (IMD) innate immune pathway of *A. aegypti* were measured via quantitative real-time RT-PCR, relative to an internal control gene transcript (RPS7). Rel 2 and Caspar were significantly different within DENV4- Haiti-infected mosquito pools from that of the naïve blood control group. No significant changes were noted between either DENV4 H241 or DENV2 NGC with the naïve blood control. These data further suggest that in addition to higher susceptibility of *A. aegypti* to DENV4 Haiti, there may be a concurrent negative effect on the immune response, but not for DENV4 H241 or for DENV2 NGC. Further research is needed to pinpoint the genetic difference(s) between the two DENV4 strains responsible for the different responses in Orlando *A. aegypti* after infection.

GENETIC DIVERSITY OF CIRCULATING DENGUE VIRUSES IN THE PHILIPPINES (2014 - 2017)

John Mark S. Velasco, Chonticha Klungthong, Ma. Theresa Valderama, Paula Corazon Diones, Piyawan Chinnawirotpisan, Wudtichai Manasatienkij, Yongyuth Poolpanichupatam, Khajohn Joonlasak, Damon Ellison, Stefan Fernandez, Louis Macareo

U.S. Army Medical Directorate-Armed Forces Institute of Medical Sciences, Bangkok, Thailand

The Philippines conducted a dengue vaccination campaign involving ≈ 830,000 population from Apr 2016 to Apr 2017. The Philippines is also part of the Phase 3 Takeda dengue vaccine clinical trial with the 1st and 2nd doses given from Sept 2016 to Jul 2017. Sieve analysis by Rabaa et al. (2017) on breakthrough dengue infections from the CYD14/15 trials showed absence of a direct relationship between vaccine efficacy and genetic similarity between Dengvaxia (CYD-TDV) strains and wild-type strains while Juraska et al. (2018) described this effect to be limited to DENV-4 and the 2-8 y.o. age group. To provide circulating DENV genetic diversity data during the mass vaccination, we obtained serum samples from dengue-diagnosed patients who were located in the general area where vaccinations occurred but who were not vaccinated with either Dengvaxia or the Takeda dengue vaccine candidate. DENV PCR-positive samples were inoculated onto C6/36 cell culture. We used Illumina MiSeq to sequence the complete genome of the DENV isolates. Quality control, de novo assembly, comparison to reference sequences, and mapping were done to generate consensus sequences. Per serotype genotypic analyses were performed by reconstructing rooted maximum likelihood trees from DENV, reference, and vaccine strain sequences (whole genome and envelope gene). 75 isolates were obtained from 100 DENV-PCR positive samples (15 DENV-1, 15 DENV-2, 35 DENV-3, and 10 DENV-4). Phylogenetic analyses of DENV sequences and Dengvaxia strains showed that wild-type (WT) DENV-1 isolates belonged to genotype IV, DENV-1 vaccine strain belonged to genotype I; WT DENV-2 isolates belonged to the cosmopolitan genotype, DENV-2 vaccine strain belonged to Asian I genotype; WT DENV-3 isolates belonged to genotype I, DENV-3 vaccine strain belonged to genotype II; WT DENV-4 isolates and DENV-4 Dengvaxia strain both belonged to genotype IIa. Analysis of the Takeda dengue vaccine candidate (TAK-003) strains and circulating dengue strains was also done. All WT dengue strains belonged to different genotypes versus the Takeda's dengue vaccine candidate strains.

EARLY GUILLAIN-BARRE' SYNDROME COMPLICATING DENGUE HEMORRHAGIC FEVER: TWO CASES FROM MYANMAR

Aye Mya Theingi Win[1], Khin Ko[1], Aye Win[1], May Zabe[1], Cho New[1], Mya Paing[1], Patricia F. Walker[2], Moe San[1]

[1]*University of Medicine ([1]), Yangon, Myanmar,* [2]*University of Minnesota, Minneapolis, MN, United States*

Dengue fever is a mosquito borne flavivirus which creates a heavy burden of clinical illness in tropical and subtropical countries, including Myanmar. Although it has very wide clinical presentations, neurological manifestations are quite rare. Here we report two cases of Guillain-Barre' syndrome complicating dengue hemorrhagic fever. In both cases Guillain-Barre' syndrome occurred in the first week of fever, which is unusual compared with other case reports and literature review. Case 1's motor weakness was severe and the patient had to undergo plasma exchange. Case 2 had mild motor weakness and needed only conservative treatment. Nerve conduction study of both cases revealed variant types of Guillain-Barre' syndrome which are more common in Asian countries, specifically acute motor axonal neuropathy (AMAN) and acute motor-sensory axonal neuropathy(AMSAN). Both cases ended with an excellent outcome. Awareness of early Guillain-Barre's syndrome in patients with dengue fever is important in order to potentially reduce morbidity and mortality from this serious complication.

Zika virus (ZIKV) infection remains a public health concern with the recent epidemic infecting millions of people in the Americas. This flavivirus is transmitted primarily through the bite of *Aedes spp*. mosquitoes, providing the perfect vehicle to affect previously endemic dengue virus (DENV) areas with ZIKV. ZIKV and DENV share a homology in amino acid sequence of at least 50%, and studies have claimed that pre-existing immunity to ZIKV may enhance DENV pathogenesis. To address the role of prior flavivirus exposure on ZIKV associated to disease severity we recently showed that a previous DENV infection (> 2 years) does not result in enhanced ZIKV pathogenesis. For this study, we aimed to determine if the length of time between DENV and ZIKV infections has an impact on ZIKV pathogenesis. The experimental design is based on the infection of 16 rhesus macaques with ZIKV. Cohorts 1 (n=6) and 2 (n=4) had been exposed to DENV-2 one year and three months earlier, respectively, before infection with ZIKV. A third flavivirus-naive cohort (n=6) was included as a control group. qRT-PCR for measurement of viremia in serum, plaque reduction neutralization assays, ELISA tests, and cell phenotyping via flow cytometry were performed. qRT-PCR results show that viremia in serum was shorter in macaques that were exposed to DENV twelve months earlier in comparison to naïve and the cohort exposed to DENV three months earlier. We identified limited but significant differences in the magnitude of the early humoral immune response associated to a period of twelve months but not three months of DENV convalescence. However, the role of antibodies limiting ZIKV replication is not conclusive. Additionally, animals belonging to DENV 12M group display higher levels of activation of memory subsets of cellular immune response. Our results strongly suggest that there is a degree of cross-protection between DENV and ZIKV that is time-dependent. A one year time-lapse between DENV and ZIKV infections could positively modulate the immune response to induce protection.

Dengue fever, a mosquito-borne disease, is caused by dengue virus (DENV) which includes four major serotypes (DENV-1, -2, -3, and -4). Some serotypes cause more severe diseases than the other; severe dengue is associated with secondary infections by a different serotype. Timely serotyping can provide early warning of dengue epidemics to improve management of patients and outbreaks. A mobile insulated isothermal PCR (iiPCR) system is available to allow molecular detection of pathogens near points of need. In this study, side-by-side comparison with the CDC DENV-1-4 Real Time RT-PCR (qRT-PCR) was performed to evaluate the performance of four singleplex DENV-1 - 4 serotyping reverse transcription-iiPCR (RT-iiPCR) reagents for DENV subtyping on the mobile PCR system. The four RT-iiPCRs did not react with Zika virus and chikungunya virus; tests with serial dilutions of the four DENV serotypes made in human serum showed they had detection endpoints comparable to those of the reference method, indicating great analytical sensitivity and specificity. Clinical performance of the RT-iiPCR reagents was evaluated by testing 40 serum samples each (around 20 target serotype-positive and 20 DENV-negative); all four reagents had high agreement (97.5 - 100%) with the reference qRT-PCR. Moreover, testing of mosquitoes separately infected experimentally with each serotype showed that the four reagents detected specifically their target DENV serotypes in mosquito. With analytical and clinical performance comparable to the reference qRT-PCR assay, the four index RT-iiPCR reagents on the field-deployable PCR system can serve as a useful tool for DENV detection near points of needs.

There is a large unmet medical need for dengue vaccines. A live-attenuated tetravalent vaccine (LATV) was developed by the National Institute of Allergy and Infectious Diseases, consisting of 4 viral components representing the 4 dengue serotypes (DENV1, DENV2, DENV3, and DENV4) and attenuated by deletion of 30 nucleotides in the 3' non-coding region of the genome (DENV3 has 2 deletions of 30 and 31 nucleotides). This Phase 1 study examined two LATV dengue vaccine admixtures of the 4 DENV serotypes (TV003 and TV005) and was conducted in the continental United States and Puerto Rico. TV005 is the same as TV003 except for a 10-fold higher DENV2 component. Two hundred participants (including flavivirus-naïve and -experienced) were randomized into the trial (2:2:1; TV003:TV005:Placebo) to receive a subcutaneous injection administered at Day 1 and Month 6. Vaccine safety (solicited and unsolicited adverse events (AEs); daily temperatures) was assessed using a Vaccination Report Card for 28 days following each vaccination. All participants were followed for serious AEs and deaths, from study entry through 1 year after last vaccination. Immunogenicity was assessed relative to vaccination using a Virus Reduction Neutralization Test at Day 1 (baseline); 28 days, 56 days, and 6 months Postdose 1; and 28 days Postdose 2. Since ~50% of participants were enrolled in dengue-endemic Puerto Rico, endpoints related to wild-type dengue infection were included. Participants were followed for dengue-related AEs (regardless of seriousness) including laboratory-confirmed dengue fever, dengue hemorrhagic fever, or dengue shock syndrome beginning at informed consent through 1 year after last vaccination. Virologically-confirmed dengue was defined as fever of ≥38.0°C (≥100.4°F) for ≥2 consecutive days with a positive qualitative and quantitative serotype-specific reverse transcription polymerase chain reaction assay. The results of the interim analysis at 28 days Postdose 1 demonstrate that the vaccine is generally well tolerated and immunogenic in these flavivirus-exposed and -unexposed participants. Data to 28 days Postdose 2 will be presented.

Infection with dengue virus (DENV) is widespread across tropical regions and can result in severe disease. Early diagnosis is important both for patient management and to differentiate infections that present with similar symptoms, such as malaria, chikungunya, and Zika. Rapid diagnostic tests (RDT) that are used currently for point-of-care detection of DENV antigens lack the sensitivity of molecular diagnostics that detect viral RNA. However, no molecular diagnostic test for DENV is available for use in field settings. We developed and validated a RT-PCR for the detection of DENV adapted for use in resource-limited settings. RT-PCR was performed directly from patient blood or plasma samples without RNA extraction. The assay detected all four serotypes of DENV spiked into blood or plasma. The test performed equally well in a conventional lab qPCR instrument (Bio-Rad CFX) and the Open qPCR Thermocycler (Chai Biotechnologies Inc), a small, low-cost portable instrument that can be used in a field setting. The lower limit of detection for the assay was 1 x 10^4 genome copy equivalents/ml in blood. Finally, we validated our test using 126 archived patient samples. The sensitivity of our RT-PCR was 76.7% (95% CI: 65.8% to 87.9%) on the conventional instrument, and 78.3% (95% CI: 65.8% to 87.9%) on the field instrument, when compared with a commercial pan-DENV RT-PCR kit. The specificity was high, 93.9% (95% CI: 85.2% to 98.3%) on the conventional instrument and 90.9% (95% CI: 81.3% to 96.6%) on the field instrument. This molecular test is user-friendly, low-cost, and can be used in regions with limited laboratory capabilities.

INCREASED SEVERITY OF ILLNESS IN THE 2019 DENGUE FEVER EPIDEMIC IN RIBEIRAO PRETO, BRAZIL WITH CONSEQUENT INCREASING NUMBER OF HOSPITAL ADMISSIONS

Silvia N. Fonseca, Lude B. Silveira, Maria L. Freitas, Ivana C. Lucca, Ronaldo D. Marani, Deise R. Ustulin, Gabrielly R. Sarria, Franceliana B. Sgobi, Andre L. Fioravante, Rafael D. Duarte, Alexandre V. Celia, Felicia D. Maia, Ernani M. Martins, Viviane F. Veiga, Woe T. Chan

Hospital Sao Francisco, Ribeirao Preto, Brazil

Dengue fever (DF) is the most important arbovirus infection in the world. Our hospital emergency room (ER) located in an endemic DF region in Brazil has been dealing with large DF outbreaks since 2011. We established an ER suspected DF (SDF) surveillance, based upon the international classification of diseases codes, for ER patient visits and hospital admissions (HA); one patient was counted as SDF in his/her every ER visit for this reason. Yearly we calculated the ratio between #of SDF HA/SDF ER visits. In January 2019 and on, we noticed an increased number of DF patients with severe DF, requiring HA, even though we had not detected a large # of SDF ER patients compared to previous years. We trained all health care workers and followed the Brazilian Health Ministry Guidelines for DF patient care; the focus was prompt detection of warning signs, vigorous intravenous hydration for high hematocrit and low platelet count, oral hydration for every patient at the ER and daily or every other day returns based upon the patient risk to develop severe DF. All severe DF or DF with warning signs patient was considered for HA. We used NS1 and/or serology (IgM) to confirm DF diagnosis; the study period went from January 2011 to April 2019. The rates between # DF HA/ SDF ER visits in 2011, 2013 and 2016 were 112/29,349 (.38%), 54/21,842 (.25%) and 101/29,841 (.33%) respectively but in 2019, there was a 10-fold increase: 57/1,502 (3.8%). Of the 57 SDF HA, 45 patients had confirmed DF (31NS1+,14 IgM+); the patient median age was 58 y, the median length of stay (LS) was 4 days; 7 patients were admitted to the intensive care unit (median LS=4 days) and there were no deaths .The main causes for HA were low platelet count, hypotension, abdominal pain and spontaneous bleeding. A convenience sample was used to find out the circulating serotype by RT-qPCR; DENV-2 was detected in every sample. If this high proportion of HA for SDF continues in the next years, we will be facing difficult times ahead for available hospital beds if more patients are affected. To avoid this catastrophic event, control measures, aiming at reduction of vector population, should start before the next DF season.

Dengue fever is a major public health concern throughout much of the world. With one vaccine on the market and others in clinical trials, policy makers in endemic regions are faced with the decision of whether to introduce a dengue vaccine in their countries. The WHO recommends that before considering the introduction of a new vaccine, countries conduct individualized assessments that evaluate the disease in question and the strength of that country's current vaccination program. This study seeks to aid in that decision-making in the Americas by examining the acceptability and feasibility of dengue vaccine introduction in Colombia and Venezuela. The chosen study sites were Barranquilla, Colombia and Merida, Venezuela. Surveys were administered between February and June of 2018 for three target groups - patients (n=351), health professionals (n=197) and government officials (n=26). In Barranquilla, most respondents reported dengue to be a moderate-severe problem and that a dengue vaccine would be useful in their communities. In regards to subjective feasibility, most reported faith that their current vaccination programs can handle the addition of a new vaccine. In Venezuela, respondents were less likely to view dengue as a major concern and listed multiple barriers to not just dengue vaccine introduction, but to providing current vaccines as well. Further work is needed in Colombia to more objectively assess the country's readiness as a whole for a future dengue vaccine. As Venezuela continues to struggle with on-going political and social unrest, however, future studies and programs should focus on trust and capacity building.

Dengue is a major disease in Vietnam. It is known that dengue has been persisting in the South and expanding to the North of the country since the 90s. Vietnam is an exciting study site as there is great variation geographically in meteorological variables that contribute to the difference in dengue incidence in each region. Dengue has multi-annual cycle in Vietnam. Therefore, one key question that the authorities ask us is how likely is it that a major epidemic will happen next year? The arrival of a trustworthy dengue forecasting system is of high demand in order to plan for hospital resources as well as for disease control. In this work, we study how changes in several climatic factors such as temperature, humidity and precipitation affect the dengue dynamics. In order to predict dengue cases across all provinces in Vietnam, we employ data over the period of 1994-2017 to train, test and validate prediction models using various techniques from simple regression to recent trend machine learning such as Gaussian Process. In addition, Vietnam has a rapidly-growing economy, and the land-use has been significantly altered over the last twenty years. We will explore the use of information from satellite images to investigate whether urbanisation has led to the recent rise of dengue cases, focusing first on the two major cities Hanoi and Ho Chi Minh city.

LABORATORY-ACQUIRED DENGUE IN A RESEARCHER WORKING WITH HIGH-TITER VIRUS, USA, 2018

Tyler M. Sharp[1], Teresa Fisher[2], Kristin Long[3], Garry Coulson[4], Freddy Medina[1], Carolyn Herzig[2], Mary B. Koza[4], Jorge L. Munoz-Jordan[1], Gabriela Paz-Bailey[1], Zachary Moore[2], Carl Williams[2]

[1]*Centers for Disease Control and Prevention, San Juan, PR, United States,* [2]*Division of Public Health, North Carolina Department of Health and Human Services, Raleigh, NC, United States,* [3]*State Laboratory of Public Health, North Carolina Department of Health and Human Services, Raleigh, NC, United States,* [4]*Environment, Health, and Safety, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Dengue is a common tropical illness caused by infection with any of four dengue viruses (DENV-1-4). Although the overwhelming majority of DENV infections result from the bite of an infected mosquito, other routes of transmission have been reported, including exposure while working with infectious DENV in the laboratory. In August 2018, the North Carolina

Department of Health and Human Services was notified of a dengue case in a laboratory researcher who had presented for care with a two-day history of fever, rash, body and eye pain, and lethargy. The patient tested positive for DENV infection by detection of NS1 antigen and anti-DENV IgM antibody, and also had a four-fold increase in anti-DENV IgG and neutralizing antibody titer. The case-patient was not hospitalized and recovered after a six-day illness. Interview of the case-patient confirmed absence of recent travel to an area with risk of DENV transmission. However, the case-patient did report having worked with large-scale preparation (~4 liters of supernatant from infected cells) and concentration (final viral titer of up to 10^{10} plaque-forming units per mL) of DENV-4 under biosafety level 2 conditions in the two weeks prior to illness onset. The case-patient reported that small splashes inside the biosafety cabinet were common while performing the virus purification protocol, and that gloves were only occasionally decontaminated while working in the biosafety cabinet and routinely changed when exiting the biosafety cabinet. Review of the case-patient's laboratory safety practices suggested improper technique for doffing of gloves. This in combination with a small open wound on the patient's finger may have resulted in cutaneous exposure. Nonetheless, we could not rule out other routes of exposure in the laboratory. This case demonstrates the importance of conducting ongoing risk assessments, which may warrant enhanced biosafety precautions while working with high-titer DENV. Current laboratory safety guidelines encourage use of enhanced personal protective equipment such as double gloving, especially if working with an open wound on the hand or finger.

205

AVIDITY AS ASSESSMENT OF ANTI-DENGUE VIRUS ANTIBODY RESPONSE ELICITED BY A LIVE ATTENUATED TETRAVALENT DENGUE VACCINE

Isamu Tsuji, David Dominguez, Christina DeMaso, Allan Parker, Sunil Palani, Nicole Messere, Melissa Zahralban-Steele, Sharma Mayuri, Ralph Braun, Hansi Dean, DEN 203 and 204 study groups

Vaccine Business Unit, Takeda Pharmaceutical Inc., Cambridge, MA, United States

The quantitative immune parameters commonly employed for functional measurement of immune responses to viral vaccines include antiviral antibodies and viral neutralization titers in post-vaccination serum. However, serum antibody avidity can be an important qualitative measure of the humoral response, and mechanism of protection. Takeda's live attenuated tetravalent dengue vaccine candidate (TAK-003) has structural proteins from each serotype on the dengue virus type 2 (DENV-2) genomic backbone. Here, we describe the development of an assay we used to measure the avidity of humoral responses to DENV-1, -2, -3 and -4 in eight dengue-naïve subjects, pre- (day 0), and up to one-year (day 360) post-vaccination with TAK-003. Microneutralization titers (MNT) were highest on day 28 post-vaccination and had declined by day 360. The strength of antibody binding increased post-vaccination: $k_{off,}$ the antibody dissociation rate, decreased over time. Therefore, the Avidity Index of the antibody response to all four serotypes increased at day 28 post-vaccination and was maintained until day 360, reflecting affinity maturation of the DENV-specific antibody responses. These data suggest that antibodies elicited by TAK-003 undergo affinity maturation and show a sustained increase in avidity for at least one-year post-vaccination. We are now working on combining measures of antibody avidity with anti-DENV antibody response and serotype-specific neutralization titers, to systematically characterize antibody responses to TAK-003 over time.

206

ESTIMATING FORCE OF INFECTION (FOI) OF ALL FOUR DENGUE SEROTYPES FROM SEROLOGICAL STUDIES IN TWO REGIONS OF VIETNAM

Huynh Thi Phuong[1], Nguyen Ha Thao Vy[1], Ha Minh Lam[1], Erwin de Bruin[2], Marion Koopmans[2], Maciej F. Boni[3], Nguyen Thi Le Thanh[1], Hannah E. Clapham[1]

[1]*Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam,* [2]*Department of Viroscience, Erasmus Medical Centre, Rotterdam, Netherlands,* [3]*Center for Infectious Disease Dynamics, Department of Biology, Pennsylvania State University, University Park, PA, United States*

Vietnam is endemic for dengue fever and it is a major public health concern. Studying the epidemiology of the disease bring about the benefit of improving quality of intervention and control. However, it is hard to estimate the true rate of dengue infection due to its high asymptomatic rate. All four serotypes of dengue (DENV 1-4) co-circulate year round in Vietnam and immune interactions between serotypes leads to complex transmission dynamics. Therefore, knowing about circulating serotypes plays a key role in understanding disease patterns and for carrying out effective vaccination campaigns. However, the Enzyme-linked immunoassay (ELISA) test, the most common use in cross-sectional sero-studies, cannot discriminate between DENV serotypes or infer how many times people have been infected. In this study, 958 population serum samples, 432 from Khanh Hoa (KH, central) and 526 from Ho Chi Minh (HCM, southern), in age groups 1-30 years old collected from 2013 to 2017 were tested using a flavivirus protein microarray assay. By applying a previously developed mathematical model to the antibody profiles generated from the assay, we are able to determine the proportions in the population that have been infected 0, 1 or more than 1 time, and infer the infecting serotypes in those infected once. With this data we are then able to use mathematical models to estimate time-varying and serotype-specific FoIs for all four DENV serotypes over the past 30 years to 2017 in KH and HCM Vietnam. We found that the annual FoI of DENV-1 had the most variation in both KH and HC and the FoI of all four serotypes was higher in KH than in HC. In the future, we try to understand whether the dominance of a serotype is a driver for an outbreak. Also, we will compare estimated FoIs to the cases from these regions over time to determine whether high FoI always means high case numbers, or if there are periods of "silent" transmission.

207

COMPREHENSIVE MUTAGENESIS OF DENGUE VIRUS ENVELOPE PROTEINS TO MAP ANTIBODY EPITOPES AND IDENTIFY RESIDES ESSENTIAL FOR FUNCTION

Edgar Davidson, Tabb Sullivan, Jen M. Pfaff, Srikar Reddy, Benjamin J. Doranz

Integral Molecular, Inc., Philadelphia, PA, United States

To characterize the immune response to dengue virus (DENV) infection, we have epitope mapped over 200 anti-DENV monoclonal antibodies (MAbs), using high-throughput, rapid screens of MAb binding to DENV prM/E comprehensive mutation libraries for all four DENV serotypes, 3,380 mutations in total. Each library of individual mutant expression plasmids was transfected into human cells to achieve native protein expression and folding, and immunoreactivity of MAbs to each individual prM/E variant was quantified by high-throughput flow cytometry. The epitopes obtained were both conformational (including quaternary) and non-conformational, were spread across prM and E domains I-III, and many have been correlated with their abilities to protect against DENV infection. A number of anti-DENV MAbs cross-reacted with ZIKV prM/E, predominantly within the fusion loop but also within Domain II of the E protein, identifying critical immunogenic residues shared by DENV and ZIKV. We have also produced DENV virions from all four DENV mutation libraries using a previously developed DENV reporter virus particle (RVP) system, allowing us to screen each individual DENV Env variant protein for DENV particle budding and infectivity. For DENV3, we identified residues whose mutation

eliminated virus infectivity but did not impact E protein expression, antigenicity, virion assembly, or particle budding. We identified variants that showed increased DENV virion budding, up to 5-fold above wild-type, indicating the ability to engineer highly expressed, non-infectious DENV variants for use in vaccine design. To identify uncharacterized DENV cellular receptors we assayed wild-type DENV RVP infectivity in non-permissive cells expressing our membrane proteome array (MPA) of 5,300 unique human membrane proteins. This has identified candidate membrane proteins that enable DENV infectivity. We have identified neutralizing epitopes in DENV prM/E and specific sites that are critical for DENV infectivity, providing new targets and opportunities for vaccine development.

INTERCURRENT FLAVIVIRAL VIREMIA IN ILL RETURNED TRAVELERS WITH *PLASMODIUM VIVAX* MALARIA

Katherine Faith Tan[1], Ruwandi Kariyawasam[2], Rachel Lau[3], Filip Ralevski[3], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [3]*Public Health Ontario, Toronto, ON, Canada*

Similar epidemiology and clinical presentations of arboviral infections and malaria coupled with the typically sequential approach to diagnostic testing, where malaria is confirmed or excluded urgently in febrile returned travelers, may mask the true epidemiology of co-infections. Flaviviruses are known to trigger relapsing forms of malaria, including *Plasmodium vivax*, long after primary malaria infection, and this may delay the diagnosis of malaria. We aim to understand the incidence of intercurrent flaviviral infection in confirmed *Plasmodium vivax* infection. DNA and RNA from biobanked isolates of *P. vivax* detected in whole blood at the Public Health Ontario Laboratory between 2006 and 2018 were extracted and screened for intercurrent flaviviral infections using previously validated real-time PCR (qPCR) assays targeting multiple flaviviruses (pan-FLAV) and, specifically, dengue virus types 1-4 (DEN1, DEN2, DEN3, DEN4). Five hundred and two unique isolates of *P. vivax* were identified, of which 90 have been tested to date. Males accounted for 65.6% (n=59/90) of *P. vivax* cases, while females accounted for 32.2% (n=29/90), and sex was unassigned in 2.2% (2/90). Median age of *P. vivax* cases was 33.2 years (range 3.7 years - 85.8 years; IQR 23.4 - 45.9 years). Median parasitemia was 0.2% (range < 0.01% - 1.1%). Fifty-nine (65.6%) *P. vivax* cases had documented travel history exclusively to South Asia, with India as the most common source country (22/90 [16.7%]). Pan-FLAV assay yielded a 1.1% (1/90) positivity rate. Pan-DEN assay will be performed next. Intercurrent flaviviral viremia was noted in at least 1.1%, which may suggest that primary flaviviral infection triggered a relapse of *P. vivax*. Alternatively, such co-occurrence may suggest primary infection with both organisms known to cause fever in returning travelers. Consideration of flaviviral co-infection should be given to the *P. vivax* patient with deep thrombocytopenia, lymphopenia, and high-yield arboviral symptomatology such as rash and retro-orbital headache.

DETECTION AND SEQUENCING OF ZIKA VIRUS IN NORMOCEPHALIC NEWBORNS WITH CONGENITAL ZIKA IN FECTION

Breno L. de Almeida[1], Marta Giovanetti[1], João V. Oliveira[1], Tereza C. Xavier[2], Eduardo M. Figueiredo[3], Jaqueline J. Goes[1], Luiz C. Alcantara[1], Isadora C. de Siqueira[1]

[1]*Fundação Oswaldo Cruz-Fiocruz, Salvador, Brazil,* [2]*Maternidade de Referencia Prof José Maria de Maglhães Neto, Salvador, Brazil,* [3]*Maternidade de Referencia Prof José Maria de Magalhães Neto, Salvador, Brazil*

In 2015, Brazil has experienced an unprecedented Zika virus (ZIKV) outbreak and later that year, an unexpected outbreak of newborns with microcephaly occurred in major cities in northeastern Brazil, associated with Congenital Zika Infection (CZI). Most descriptions and publications regarding CZI focus on the clinical presentation of newborns and infants with microcephaly. Scarce information is available concerning CZI without microcephaly. During hospital surveillance for CZI in a reference maternity hospital, we identified 14 normocephalic newborns with confirmed CZI. Eight (57%) of the newborns were female and the mean gestational age at birth was 38.46 ± 1.90 weeks. The mean of head circumference was 38.57 ± 1.40cm. The transfontanel ultrasonography was performed in 13 (92.9%), and no alterations were observed in any of the cases. All newborns had a positive RT-PCR confirming the diagnosis of CZI, mostly in urine samples (57%). In two of the cases, ZIKV were detected in 2 distinct samples. ZIKV-specific RT-PCR amplification products have been obtained and NS5 gene fragments (426-bp) were obtained using Sanger sequencing. The phylogenetic analysis showed that the isolate belongs to the Asian genotype and clusters closely with strong bootstrap support (>90%) with sequences isolated in Northeast and Northern regions of Brazil. With this, we infer that CZI could present in a broad spectrum of clinical manifestation, including the asymptomatic presentation at birth. It is necessary careful surveillance to identify cases with few or no symptoms at birth and a close follow-up for early detection of clinical manifestations of CZI and timely intervention.

ZIKA VIRUS DETECTION IN PREVIOUSLY UNDIAGNOSABLE SAMPLES: OPTIMIZATION OF A QUANTITATIVE RT-PCR ASSAY FOR SAMPLES OF LOW VIRAL CONCENTRATION

Alejandra Garcia Glaessner[1], Patricia Barrera[2], Amy C. Morrison[3], Thomas W. Scott[4], Mariana Leguia[1]

[1]*Genomics Laboratory, Pontificia Universidad Católica del Peru, Lima, Peru,* [2]*Asociación Benéfica Prisma, Lima, Peru,* [3]*Department of Pathology, Microbiology, and Immunology, School of Veterinary Medicine, University of California, Davis, CA, United States,* [4]*Department of Entomology and Nematology, University of California, Davis, CA, United States*

The Zika virus (ZIKV) outbreak of 2015 affected many countries in Latin America and highlighted a pressing need for sensitive molecular diagnostics to detect the presence of ZIKV in various sample types. At the time, only two RT-qPCR assays, developed by Faye et al. and Lanciotti et al., were available to diagnose human ZIKV infections. These assays used primer sets that target separate regions of the ZIKV genome with enough specificity to serve as diagnostic tools that could differentiate ZIKV from other related arboviruses, such as dengue and yellow fever. However, their sensitivity was low, resulting in false-negative diagnosis of many ZIKV cases, particularly when ZIKV was present at low levels (CT values around 30 or higher). We developed an improved RT-qPCR protocol that uses optimized primer sets and cycling conditions to detect the presence of ZIKV at levels previously considered undiagnosable (CT values up to 38). The parameters optimized include primer length, GC content and annealing temperature. We also created a positive control plasmid that includes both the NS5 and envelope regions of the genome, allowing for side-by-side comparisons of the amplification efficiency of old and new assays. Using this control plasmid, we estimated the limit of detection of our new assay at 31 copies of the viral genome. We used our assay to test a number of samples suspected of being false-negatives and found that about 10% of those re-tested were positive for ZIKV. Our results indicate that the improved ZIKV assay can help address the issue of false-negatives during ZIKV diagnosis and will be a useful tool for those interested in a fast, rapid, and sensitive diagnostic for ZIKV, particularly in samples of low viral concentration encountered during clinical evaluation or research.

211

SEROPREVALENCEOF ZIKA VIRUS (ZIKV) IN CEBU PROVINCE, PHILIPPINES

Cameron R. Adams[1], Ramesh Jadi[1], Michelle Ylade[2], Jedas Daag[2], Kristal An Agrupis[2], Jacqueline Deen[2], Aravinda de Silva[1], Premkumar Lakshmanane[1], Anna Lena Lopez[2]

[1]*University Of North Carolina, Chapel Hill, NC, United States,* [2]*Institute of Child Health and Human Development, University of the Philippines Manila, Manila, Philippines*

Zika virus (ZIKV) is an emerging mosquito-borne Flavivirus notable for severe teratogenic properties and Guillain-Barré syndrome seen during the 2015 epidemic in Latin America. While ZIKV infection is documented in different regions of Asia, the virus was not linked to large epidemics or severe clinical symptoms. Moreover, the incidence, prevalence and ecology of ZIKV in Asia is poorly understood. For monitoring ZIKV transmission at a regional/population level, serology is more useful than methods for detecting the transient viremia caused by ZIKV as ZIKV infection often presents with no overt clinical symptoms. ZIKV and dengue virus (DENV) co-circulate in the same populations. As DENV and ZIKV are closely related and share conserved epitopes, antibodies induced by DENV infections are cross-reactive with ZIKV antigens commonly used in diagnostic assays. Using recombinantly produced domain III of the ZIKV envelope protein (EDIII), we have developed an assay for specific detection of antibodies induced by ZIKV infection. In this study, we use the ZIKV-EDIII ELISA to determine the seroprevalence of ZIKV in children aged 9-14 in the Cebu province of the Philippines. In a sample of 64 children, 12 (18%) tested positive for ZIKV EDIII antibodies. By performing antibody depletions and neutralization assays with DENV1-4 and ZIKV, we have confirmed that 11/12 children testing positive in the ZIKV-EDIII assay have ZIKV type-specific neutralizing antibodies. We tested a cohort of 3,000 children with our ZIKV-EDIII assay and defined ZIKV seroprevalence of ZIKV type-specific antibodies.

PREGNANCY AND BIRTH OUTCOMES AMONG COLOMBIAN WOMEN WITH ZIKA VIRUS DISEASE IN THREE SURVEILLANCE SITES, PROYECTO VIGILANCIA DE EMBARAZADAS CON ZIKA

Van Tong[1], Marcela Mercado[2], Suzanne Gilboa[1], Diana Valencia[1], Marcela Daza[3], Romeo Galang[1], Christina Winfield[1], Shana Godfred-Cato[1], Monica Benavides[3], Julie Villanueva[1], Jonathan Daniels[1], Julu Bhatnaga[1], Jarad Schiffer[1], Sheryll Corchuelo[3], Sarah Tinker[1], Kayla Anderson[1], Johana Osorio[3], Veronica Burkel[4], Jacob Hojnacki[5], Maritza Gonzalez[2], Cynthia Moore[1], Margaret Honein[1], Martha Ospina[2]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*National Institute of Health, Bogota, Colombia,* [3]*Vysnova Partners, Bethesda, MD, United States,* [4]*Eagle Medical Services, LLC, San Antonio, TX, United States,* [5]*Oak Ridge Institutes for Science and Education, Oak Ridge, TN, United States*

Proyecto Vigilancia de Embarazadas con Zika (VEZ) was an intensified surveillance system built upon existing national surveillance of pregnant women with symptoms of Zika virus (ZIKV) disease and conducted in three Colombian cities with high prevalence of Zika. This analysis of data from VEZ estimates the risk of Zika-associated birth defects among pregnant women with symptoms of ZIKV disease, and among a subset with laboratory evidence of possible ZIKV infection during pregnancy. During April-November 2016, pregnant women were enrolled if they were reported to the surveillance system (Sivigila) or visited participating clinics with symptoms of ZIKV disease. Maternal and pediatric data were abstracted from prenatal care, ultrasound, and delivery records, as well as from pediatric or specialist visit records. Available maternal and infant specimens were tested for the presence of ZIKV RNA and/or anti-ZIKV immunoglobulin (IgM) antibodies. Of 1,223 women enrolled, 47.8% and 34.3% reported first or second trimester symptom onset, respectively. Of 381 pregnancies with maternal and/or infant specimens tested, 108 (29%) had laboratory evidence of possible ZIKV infection during pregnancy; half of these (53.3%) were positive for ZIKV RNA only, 37.4% for IgM antibodies only, and 9.3% for both. Of 1,190 of pregnancies with known outcome, 63 (5%) had Zika-associated brain or eye defects; among the subset with any laboratory evidence, 12 (11%) had Zika-associated brain or eye defects. The prevalence of Zika-associated brain or eye defects was 5.9% (35/593) and 4.5% (19/423) among pregnancies with symptom onset in the first and second trimester, respectively. Among pregnant women with symptoms of ZIKV disease enrolled during the height of the ZIKV epidemic in Colombia, prevalence of any Zika-associated brain or eye defect was 5%, with a higher prevalence among those with laboratory evidence of possible ZIKV infection. Rapid enhancements to Colombia's national surveillance enabled the estimation of the risk of birth defects associated with ZIKV disease in pregnancy.

213

PEDIATRIC ZIKA VARIES BY AGE AND IS OFTEN MISSED UNDER CURRENT CASE DEFINITIONS

Fausto A. Bustos Carrillo[1], Raquel Burger-Calderon[1], Lionel Gresh[2], Sergio Ojeda[2], Nery Sanchez[2], Miguel Plazaola[2], Leah Katzelnick[1], Brenda L. Mercado[2], Jairo C. Monterrey[2], Douglas Elizondo[2], Sonia Arguello[2], Andrea Nuñez[3], Aubree Gordon[4], Angel Balmaseda[3], Guillermina Kuan[5], Eva Harris[1]

[1]*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California Berkeley, Berkeley, CA, United States,* [2]*Sustainable Sciences Institute, Managua, Nicaragua,* [3]*Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua,* [4]*Department of Epidemiology, University of Michigan, Ann Arbor, MI, United States,* [5]*Centro de Salud Sócrates Flores Vivas, Ministerio de Salud, Managua, Nicaragua*

Pediatric Zika is an understudied aspect of the 2015-2016 Zika pandemic. The diagnostic performance of the World Health Organization (WHO) and Pan American Health Organization (PAHO) Zika case definitions have not been assessed in children. We prospectively followed a cohort of ~3,700 children aged 2-14 years old in Managua, Nicaragua, from January 2016 to February 2017. We tested participants with a broad set of clinical profiles using rRT-PCR and a machine learning algorithm based on 5 serological assays and analyzed acute clinical findings (signs, symptoms, and complete blood counts). We used generalized additive models to assess non-linear age trends in the prevalence of clinical findings and the sensitivity of the WHO and PAHO case definitions. Overall, 556 Zika and 548 non-Zika cases were analyzed. Rash and leukopenia were significantly more prevalent among Zika cases, whereas fever and monocytosis were more common among non-Zika cases. Among Zika cases, rash, fever, leukopenia, and headache were the most common clinical findings, which tended to peak within 3 days of illness onset. The most common presentation over the first week of illness included only two clinical findings, rash (79.1%) and leukopenia (48.0%). Only 31.7% and 19.6% of lab-confirmed Zika cases were captured by the WHO and PAHO case definitions, respectively. These sensitivity values increased with age, as the prevalence of most clinical findings (chiefly arthralgia) increased with age. Standard case definitions tended to capture cases that presented with a dengue-like clinical profile; the remaining two-thirds, characterized principally by undifferentiated fever or afebrile rash, were missed. Our results suggest that most pediatric Zika cases are undetected under the current case definitions and that Zika-related epidemiological findings, R_0 values for Zika, and transmission models may have been systematically biased in an age-dependent manner. Overall, our results and the literature suggest that Zika manifests more mildly in children than adults, presenting major challenges to diagnosis, surveillance, and efforts to control future Zika epidemics.

CLINICAL AND EPIDEMIOLOGICAL FEATURES OF THE ZIKA OUTBREAK IN NICARAGUA

Natalie M. Bowman[1], Filemon Bucardo[2], Matthew H. Collins[3], Yaoska Reyes[2], Edwing Centeno[2], Quique P. Guerra[1], Rebecca J. Rubinstein[1], Guei-Jiun Alice Liou[1], Aravinda de Silva[1], Becker-Dreps Sylvia[1]

[1]*University of North Carolina-Chapel Hill, Chapel Hill, NC, United States,* [2]*Universidad Nacional Autonoma de Nicaragua-Leon, Leon, Nicaragua,* [3]*Emory University, Atlanta, GA, United States*

We conducted an observational study in León, Nicaragua between January 2016 and February 2018. Patients seeking care at the public hospital and health centers for reported fever, rash, and/or non-suppurative conjunctivitis of ≤7 day's duration were offered study participation. At enrollment, blood, saliva, and urine were collected and surveys recorded demographic information, clinical symptoms, and potential risk factors for ZIKV infection. All subjects were asked to provide a convalescent serum sample 2-4 weeks later. All PCR-positive samples at baseline were repeated in triplicate; if all three replicates were positive (Ct<38), the sample was considered a true positive and these subjects were considered acute ZIKV cases. Because of the short window of viral shedding in many ZIKV cases, we also considered those with negative PCR but serology (combined acute and convalescent dengue and Zika IgG and IgM) consistent with acute or recent ZIKV infection to be cases. 297 subjects were recruited, but 5 subjects could not be categorized due to missing or ambiguous serological and PCR test results and were excluded from further analyses. Mean age was 27.6 years (range 1-81, SD 17.3), and 187 (64%) were female. 55 subjects (19%) had acute ZIKV infection by PCR and/or serology, with the last case in June 2017. There was no difference in odds of ZIKV infection by age or sex. Pregnant women had higher odds of ZIKV infection than non-pregnant women of childbearing age (OR 10.66; 95%CI 2.19, 66.81). Conjunctivitis (OR 3.52; 95%CI 1.75, 7.39), rash (OR 8.39; 95%CI 3.18, 27.79), and sore throat were associated with increased odds of ZIKV infection while reported fever was associated with lower odds (OR 0.20; 95%CI 0.08, 0.53). ZIKV-infected subjects had significantly lower white blood cell, absolute neutrophil, and platelet counts. Multivariable modeling demonstrated that the clinical features rash, conjunctivitis, sore throat, and lack of fever were associated with increased odds of acute ZIKV infection in this cohort. These findings may help clinicians distinguish ZIKV from other acute febrile illnesses even where laboratory testing is not readily available.

215

DOSE SELECTION OF A PURIFIED IN ACTIVATED ZIKA VIRUS VACCINE (PIZV) CANDIDATE FOR FURTHER CLINICAL DEVELOPMENT

Htay Htay Han[1], the ZKV-101 Study Group[2]

[1]*Takeda Vaccines Inc., Cambridge, MA, United States*

We evaluated immune responses to a two-dose purified inactivated Zika virus vaccine (PIZV) candidate administered at three dosage levels (2, 5 or 10 μg) in a two-stage phase 1 study, first in flavivirus (FV)-naïve and second in FV-primed healthy adults. We enrolled 271 FV-naïve and -primed adults, aged 18–49 years, randomized into four groups (1:1:1:1) to receive two doses of either placebo or one of the three PIZV dose levels with 28 days intervals. Volunteers recorded solicited adverse events (AEs) for 7 days and unsolicited AEs for 28 days after each dose, and serious adverse events (SAEs) throughout the study period. Neutralizing antibody titers were measured before vaccination and 28 days after each dose using a plaque reduction neutralization test (PRNT) and an exploratory reporter virus particle (RVP) assay. We report the results from an interim analysis of safety and immunogenicity data leading to the decision of dose selection. This was based on the safety data of both FV-naïve and primed participants and the magnitude of the immune response in FV-naïve subjects, as measured by the pairwise ratios of geometric mean titer (GMT) of Zika virus neutralizing anti-antibodies and differences in seroconversion rates between the dosing groups. The safety data set included 271 FV-naïve and -primed participants, the per-protocol set for immunogenicity included 113 FV-naïve participants. Overall demographic characteristics were similar across the four study arms. The duration of safety follow-up at the time of interim analysis was until at least 28 days post-dose 2 for FV-naïve subjects and until at least 28 days post-dose 1 for FV-primed subjects. The PIZV vaccine was well tolerated with an acceptable safety profile at all dosages. The dose response effect was observed in FV-naïve subjects with increasingly higher GMTs with higher PIZV dosages. A pairwise comparison of GMTs (PRNT) confirmed the significance of the dose-ranging effect: i.e., the 10 μg group was significantly greater than in the 2 μg ($p<0.001$) and the 5 μg ($p<0.05$) groups. The RVP results showed a similar dose-ranging effect. The 10 μg PIZV candidate was selected for further development.

216

TGF-β AND TNF-α CYTOKINE GENE POLYMORPHISMS MAY INFLUENCE PREGNANCY OUTCOMES OF ZIKA VIRUS INFECTED WOMEN

Benedito A. Fonseca, Mayara R. Agostinho, Danillo L. Esposito, Vitor G. Floriano, Marcio J. Siconelli

School of Medicine of Ribeirão Preto, Ribeirão Preto, S.P., Brazil

Zika virus (ZIKV) infection and its association with Congenital Zika Syndrome (CZS) have recently become a great concern worldwide and several studies are investigating the mechanisms involved on the pathogenesis of fetal disease. During virus infection many cytokines are produced to induce a protective immunity, but some gene polymorphisms could interfere with cytokine expression, compromising the quality of the immune response. Cytokine gene polymorphisms were investigated on ZIKV-infected pregnant women (n=26) and correlated with their pregnancy outcome. TNF-α, IL-6, IFN-γ and TGF-β gene polymorphisms were evaluated in 12 pregnant women who had miscarriages or newborn malformations (study group) and in 14 who had healthy newborns (control group). Differences in TGF-β (*p=0.013*) and IFN-γ (*p=0.0161*) polymorphisms frequencies were statistically significant between the two groups. TGF-β polymorphisms (*low 10C/C 25G/C*; *intermediate 10T/C 25G/C*; *intermediate 10C/C 25G/G*; *high 10T/C 25G/G*) in the control group were 64.3%, 14.3% 14,3% and 7.1%, respectively, while (*high 10T/C 25G/G*; *low 10C/C 25G/C*) in the study group were 83.3% and 16.7%, respectively. IFN-γ polymorphisms (*high +874 T/T*; *intermediate +874 T/A*; *low +874 A/A*) in the control group were 50%, 14.3% and 35.7%, respectively, while in the study group (*low +874 A/A*; *intermediate +874 T/A*) were 66.7% and 33.3%, respectively. TGF-β inhibits the proliferation of endothelial, epithelial and hematopoietic cells, regulates the mesenchymal, epithelial, neuronal, immune cell differentiation and modulates their apoptotic response. IFN-γ is primarily involved in immune regulation and proinflammatory responses. Our data suggest that the increased frequency of *low +874 A/A* IFN-γ polymorphism and lower frequency of *high 10 T/C 25 G/G* TGF-β polymorphism could act synergistically in the causation of CZS following ZIKV infection as the IFN-γ polymorphism would downregulate the immune response against ZIKV and the increased inhibitory cell proliferation by the TGF-β polymorphism would interfere with fetal development, leading to miscarriages and fetal malformations.

217

CHARACTERIZATION OF A POTENTIAL CORRELATE OF PROTECTION PROVIDED BY TAKEDA'S PURIFIED INACTIVATED ZIKA VACCINE IN INDIAN RHESUS MACAQUES

Ginger Young[1], Stephanie Sonnberg[1], Hui-Ling Chen[1], Srisowmya Sanisetty[1], Melissa Zahralban-Steele[1], Tim Powell[1], Joseph Lee[1], Michael Johnson[1], Greg Hather[2], Lovkesh Karwal[1], Kelly Bohning[1], Lydia Andserson[1], Hetal Patel[1], Hansi Dean[1]

[1]*Takeda Vaccines, Inc., Cambridge, MA, United States,* [2]*Takeda Pharmaceuticals, Inc., Cambridge, MA, United States*

A substantial unmet medical need exists for a Zika vaccine which will help mitigate the effects of any future Zika epidemics. In this study we evaluated neutralizing antibody responses to Takeda's purified inactivated Zika vaccine (PIZV) and the efficacy against challenge with the Puerto Rico Zika virus (ZIKV) strain PRVABC59 in naïve Indian rhesus macaques. Macaques received one of five dose levels (0.08, 0.016, 0.4, 2.0, and 10 μg) of PIZV administered intramuscularly 28 days apart. Six weeks after the second immunization (Day 71), macaques were challenged with $1x10^4$ focus forming units of ZIKV PRVABC59 administered subcutaneously. Sera were collected prior to and after ZIKV challenge and assessed by a Zika reporter virus particle (RVP) assay for neutralizing antibody titers. Zika viral RNA (vRNA) load in the serum was measured using a quantitative real-time PCR assay. PIZV induced a dose-dependent immune response that was boosted by a second immunization. Importantly, after two immunizations at dose levels above 0.4 μg, the neutralizing antibody responses were similar in magnitude to the immune responses following ZIKV infection observed in the control group. Zika vRNA was detected in the serum of the control group for 5 consecutive days post-challenge. Complete protection of macaques, defined as the absence of quantified Zika vRNA in serum post-challenge, was achieved with doses of 0.4 μg, 2 μg and 10 μg. Only partial protection was achieved with the lower PIZV doses. Based on these data, a neutralizing antibody response above 3.67 $Log_{10}EC50$ was determined as the preliminary correlate of protection. In summary, Takeda's PIZV elicited a dose-dependent neutralizing antibody immune response, which correlated with lack of quantified Zika vRNA after ZIKV challenge.

218

RESEARCH OF ANTI-VIRUS ANTIBODIES OF MEASLES, RUBELLA, MUMPS AND T*OXOPLASMA GONDII* IN SALIVA OF SCHOOLS AND COLLEGES OF THE CITY OF SÃO PAULO

Barbara F. Sampaio

Institute of Tropical Medicine Sao Paulo, Sao Paulo, Brazil

Vaccines is a well-established public health intervention, with a major impact on the decline in the prevalence of infectious diseases, but outbreaks are occurring frequently due to primary and secondary. Serological control of the vaccination status population is essential but is based on invasive blood sampling, problematic for children and teenagers. Saliva can be as acceptable alternative IgG for children and other protected groups. We detect the prevalence of specific IgG response for measles, mumps, rubella and *T. gondii* in saliva samples, for evaluate vaccine efficiency and toxoplasmosis. For sampling, we collect 249 saliva samples from 7 to 13 years old students from São Paulo, Brazil. We developed and validated an IgG capture assay, with revealing of IgG specificity by the use of biotinylated recombinant measles, rubella, mumps and *T.gondii*. The assays had reproducibility greater than 98% and sensitivity and specificity> 95%, using sera. Saliva and sera of 47 university students were tested for paired comparison, without discordance. We detected in the saliva from elementary students, a prevalence of 8.5% for anti T.gondii IgG of, anti-measles IgG of 96.8%, anti-rubella IgG of 59.1% and anti-mumps IgG of 57.5%. The prevalence of antibodies against mumps and rubella was lower than measles, as described in other reports, but this approach shows the feasibility of saliva for sustained follow-up of vaccine immune status in teenagers for devising more adequate re-immunization protocols. Our approach was efficient in all aspects, from the hygiene exhibition for sampling, the use of saliva and the development of reliable tests for the determination of the IgG protection in students and the prevention of toxoplasmosis, in declining incidence. This approach allows cheaper follow-up for IgG detection of several diseases, including vaccine control. Appropriate public health measures, such as revaccination, can be properly planned and developed for avoiding outbreaks and upsurge of controlled infectious diseases.

ZIKA VIRUS COMPLICATIONS BEYOND CONGENITAL ZIKA SYNDROME: A SYSTEMATIC REVIEW

Leyla A. Hernandez-Donoso[1], Estelle Meroc[2], Laurence De Moerlooze[1]

[1]*Takeda Pharmaceuticals, Zurich, Switzerland,* [2]*P95 Pharmacovigilance and Epidemiology, Leuven, Belgium*

Zika virus (ZIKV) was considered a mild disease for decades until the outbreaks in French Polynesia and the Americas showed a link with severe complications: Congenital Zika Syndrome and Guillain-Barre Syndrome. We conducted a systematic review of the literature to quantify and characterize the scope of complications associated with the disease, independently of transmission mode and geography. We searched for articles published in English, Spanish, French, Dutch and Portuguese until July 2018 primarily in MEDLINE, EMBASE, LILACS, BIOSIS and SCIELO; complemented with manual searching from: WHO/PAHO, reports from Ministers of Health, Zika research associations and grey literature from academic theses and congress abstracts. Three researchers independently screened publications by title and abstract, only those relevant to the research questions were eligible for full text review. The quality of primary studies was assessed using Newcastle-Ottawa Scale (NOS) and NIH tools. We included a third reviewer to control for selection bias. The review followed PRISMA and is registered in PROSPERO. We identified 1535 articles and selected 396 for full-text review. 64 were included in the main analysis: 20 surveillance reports, 14 case-control, 24 cohort, 3 cross-sectional and 3 systematic reviews. Case reports and case series were described in a separate analysis. Beyond pregnancy outcomes and neurological disorders, other rare complications like cardiovascular, rheumatic, ophthalmic and cognitive were described. We quantified each outcome and summarized by type of study, geographical and temporal distribution, Zika confirmation, possible confounders and quality scores. This systematic review of ZIKV associated complications reveals new features of the disease that can be important to identify before a new outbreak occurs.

PROSPECTIVE STUDY OF HEPATITIS E VIRUS INFECTION AMONG PREGNANT WOMEN IN NIGERIA

Adeola Fowotade

University of Ibadan, Ibadan, Nigeria

Hepatitis E virus (HEV) is an emerging infectious agent causing acute viral hepatitis worldwide. HEV infection has a poor prognosis among pregnant women from high endemic countries. HEV infection during third trimester and especially with genotype 1 is associated with fulminant hepatitis. Varied HEV-prevalence and incidence among pregnant women has been reported in low-income settings. This prospective study was conducted to assess HEV infection among pregnant women attending antenatal care at the University College Hospital, Ibadan, Nigeria. Serum samples of 230 pregnant women were screened for the presence anti-HEV IgG and anti-HEV IgM using commercially available ELISA kits (DIA.PRO, Milan, Italy). All anti-HEV IgM positive samples were tested for HEV RNA using two independent reverse transcriptase polymerase chain reactions (RT-PCR) assays, targeting ORF2 and ORF3 of HEV genome. In addition, the PCR-positive samples were subjected to DNA sequencing to determine the prevalent HEV genotype. Socio-demographic variables and risk factors associated with HEV in these women, were analyzed using logistic regression to estimate statistical significance ($p<0.05$) and odd ratio. Of the 230 asymptomatic pregnant women, with a mean age of 32.1± 4.8

years, 11(4.8%) women had anti-HEV IgM, while 39(17.0%) women had anti-HEV IgG. All anti-HEV IgG positive samples were found to be negative for HEV RNA while 3 (1.3%) of the anti-HEV IgM positive samples were positive for HEV RNA. Sequencing data of all (100%) the HEV RNA positive samples identified genotype 1 HEV. HEV infection among pregnant women was statistically associated with age (p=0.044), educational status (p=0.005) and eating of food purchased from vendors (p=0.025). The HEV IgM and RNA prevalence rate in this pregnant population is on the lower part of the scale, compared with other Sub-Saharan African countries. However, the HEV IgG data provide indirect evidence of past contact with this virus and our findings also confirm the HEV genotype 1 as the most prevalent in West African sub region.

221

HEPATITIS E VIRUS INFECTIONS AMONG PATIENTS WITH ACUTE FEBRILE JAUNDICE IN BURKINA FASO, 2013-2016

Sylvie Zida[1], Chloé Di Méglio[2], Dramane Kania[3], Judith Mbombi Mantono[4], Thérèse Kagoné[3], Souleymane Tassembedo[3], Amadou Dicko[3], Bachirou Tinto[3], Seydou Yaro[3], Hervé Hien[3], Jérémi Rouamba[3], Brice Bicaba[5], Isaïe Medah[5], Nicolas Meda[5], Omar Traoré[6], Edouard Tuaillon[7], Florence Abravanel[2], Jacques Izopet[2]

INSERM, University of Montpellier, Etablissement Français du Sang, Montpellier, France*

Hepatitis E virus (HEV) infection is a significant public health problem in many parts of the world including Africa. Understanding HEV epidemiology in Africa will facilitate the implementation of evidence-based control policies designed to prevent the spread of this infectious agent. In Burkina Faso (West Africa), little is known about the epidemiology and the genotype causing hepatitis E. HEV infection symptoms include jaundice and fever. We have investigated the contribution of HEV to the cases of acute febrile jaundice reported in the Yellow Fever (YF) surveillance in Burkina Faso and identified the HEV genotype involved. We tested serum samples taken between 2013 and 2016 from 900 patients presenting febrile icterus. All samples were tested for anti-HEV antibodies. Wantai HEV IgG and IgM EIA kits (Wantai Biologic Pharmacy Enterprise, Beijing, China) were used as set out in the manufacturer's instructions. HEV RNA viral load was detected using the Procleix HEV RNA assay (Grifols, Barcelona Spain). HEV genotyping was conducted by sequencing a fragment of the ORF2 genome and by phylogenetic analysis based on the reference sequences. Demographic factors associated with exposure to HEV were evaluated using a bivariate analysis. For the 900 patients' samples tested, 23/900 (2.6%) contained markers of acute HEV infection (anti-HEV IgM and/or HEV RNA positive). Genotyping indicated that all the strains were HEV genotype 2b. There was an overall HEV IgG seroprevalence of 18.2% (164/900). HEV exposure was also higher in patients living in the arid, mainly Northern area (26.3%) than in the semi-arid and tropical areas (11.3%); OR = 2.8 (95% CI: 1.58-4.97, p<0.01). Age was the only variable linked to a recent HEV infection (OR = 1.02 (95% CI: 1-1.05), p<0.01). Patients with symptomatic acute hepatitis E infection were older than the other patients. Acute febrile icterus cases in Burkina Faso may include HEV genotype 2b (circulating only in humans) infections. Better access to safe water and sanitation and improved personal hygiene should improve the control of HEV infection in this country.

222

SEROPREVALENCE OF VIRAL INFECTIONS IN BLOOD DONORS IN YAOUNDE, CAMEROON

Diderot Fopa[1], Claude Tayou Tagny[1], Dora Mbanya[1], Daniel Candotti[2], Camille Doux[2], Syria Laperche[2], Edward L Murphy[3]

[1]*Yaounde University Teaching Hospital, Yaoundé, Cameroon,* [2]*National Institute of Blood Transfusion/INTS, Department of Blood Borne Agents, National Reference Center for Infectious Risks in Blood Transfusion, Paris, France,* [3]*University of California San Francisco and Vitalant Research Institute, San Francisco, CA, United States*

The high prevalence of transfusion-transmissible infections (TTIs) is the most important challenge of safe blood supply in Cameroon. The seroprevalence of Hepatitis B virus (HBV), Hepatitis C virus (HCV), Human immunodeficiency virus (HIV) was determined among prospective blood donors at blood bank Yaoundé University Teaching Hospital (YUTH), Yaoundé, Cameroon. Blood donors were consecutively screened for HBV, HIV and HCV infections (Murex HBsAg Version 3, Murex HIV Ag/Ab Combination, and Murex HCV Ag/Ab Combination [DiaSorin]). Additional HBV testing including anti-HBc (Monolisa Anti-HBc PLUS; BIO-RAD) was performed. HIV and HCV serology were confirmed with HIV BLOT 2.2 (Genelabs Diagnostic) and INNO-LIA HCV (Fujirebio), respectively. In total, 1.166 were serially included in the study. Screening for transfusion transmissible infections showed that 91 (7.80%) of total samples donations were reactive for HBsAg+, 14 (1.2%) for HIV+, 11 (0.94%) for HCV+, and 1 (0.08%) for HBsAg+ and /HIV+. 1.162 were screened for total Anti-HBc IgG+IgM and 613 (52.75%) were reactive. All the 91 samples HBsAg positive were also positive for HBcAb. In 1071 HBsAg negative participants, the prevalence of HBcAb was 48.7% (n=522). In seronegative participants for HBsAg, HCV and HIV, the prevalence of HBcAb was 48.8% (n=511). Of 13 HIV and 9 HCV reactive samples, 4 and 3 were confirmed positive by western blot, respectively. This study clearly showed a high prevalence of viral infections among Cameroonian blood donors at the YUTH. Strategies to increase voluntary and regular donors should be intensified as such as medical selection of blood donors to reduce the frequency of TTIs in blood donors. The confirmatory results of HIV and HCV underline the need to re-evaluate viral infection prevalences in Camerronian blood donors.

223

SEROPREVALENCE OF MOSQUITO-BORNE VIRUSES AMONG RESIDENTS FROM DIFFERENT CITIES OF NIGERIA

Garja S. Suner[1], Elysse N. Grossi-Soyster[1], Pius S. Ekong[2], Mabel K. Aworh[3], Yiltawe S. Wungak[2], Nanven A. Maurice[2], Michael J. Ekong[4], Bonto Faburay[5], A. Desiree LaBeaud[1]

Agriculture and Rural Development, Abuja, Nigeria, [4]University College Hospital, Ibadan, Nigeria, [5]Kansas State University, Manhattan, KS, United States

Arthropod-borne viruses (arboviruses), such as alphaviruses, flaviviruses, and phleboviruses are an important public health issue in many regions of the world. Nigeria, a West African country, has seen an emergence of these arboviruses over the past several decades, leading to concerns of a widespread endemic. The aim of this study is to determine the seroprevalence of alphaviruses, such as chikungunya virus (CHIKV) and o'nyong'nyong virus (ONNV), and flaviviruses, such as dengue virus (DENV) and Zika virus (ZIKV), and phleboviruses, such as Rift Valley fever virus (RVFV), in three areas of Nigeria. Human serum samples were collected from a wide age range (ages = <[1]-[89] years) of residents in three cities: Abuja, Ibadan and Jos. A total of [701] serum samples were collected between August [2011] and March [2018]. Data pertaining to occupation, animal exposure, and febrile illness was also collected during each visit in order to determine potential risk factors related to exposure to arboviruses. Testing for prior exposure to alphaviruses, flaviviruses, and phleboviruses was performed using indirect IgG ELISAs against CHIKV, DENV and RVFV antigen. Serologic results from this study confirmed that [142] ([20.3]%) were seropositive for prior alphavirus exposure, [230] ([32.8]%) were seropositive for prior flavivirus exposure, and [14] ([1.99]%) had prior phlebovirus infections. Additionally, seropositivity across children (ages <[1]-[14] years, n = [90]) was much higher for DENV ([56.7]%) than CHIKV ([4.4]%), indicating a recent flavivirus exposure. The high seropositivity across all age groups suggests that arboviral infections are prevalent in Nigeria and implies that further surveillance is required in order to determine the true burden of these infections.

224

OUTBREAK OF ENVIRONMENTALLY ISOLATED TYPE 2 CIRCULATING VACCINE-DERIVED POLIOVIRUS IN METROPOLITAN KANO, NORTHWESTERN NIGERIA. 2018

Usman L. Shehu

AFENET/National Stop Transmission of Polio Program, Kano, Nigeria

Globally, Nigeria remains one of the endemic countries with polio cases. With eradication of WPV in sight, continued focus is needed to eliminate immunity gaps through high-quality SIAs and strong routine immunization programs. In May, 2016, globally synchronized switch from tOPV to bivalent OPV occurred in all OPV-using countries, including Nigeria and a single dose of inactivated polio vaccine (IPV) was also introduced into routine immunization to interrupt transmission of type 2 poliovirus. Despite that, Kano has recorded outbreaks of vaccine-derived polioviruses (VDPVs) and polio compatibles. The last confirmed wild poliovirus (WPV) case in Kano had paralysis onset in July 2014.In December 2018, report of a cVDPV2 nucleotide isolate (ENV-NIE-KNS-TRN-HGL-18-005) was received. A state of emergency was declared immediately and an outbreak investigation and response team formed to investigate the source of the outbreak. Retroactive case search was done in 26 health facilities and community ACS in 13 settlements surrounding the site. OPV and IPV antigens were used for routine and supplemental Immunization coverage survey using sample size of 150 households around the environmental sample in 6 wards of the LGA. The routine administrative data was also reviewed. Of the 150 children surveyed, 59% were fully immunized for age while 20% were partially immunized and 21% were not immunized for OPV. For IPV, 59% were fully immunized for age while 14% were partially immunized and 27% were not immunized. For the last SIA and last three SIAs, OPV coverages were 97% and 93% for the respectively. Two missed AFP cases were found in the health facilities records while no case was found from the 4723 households searched. Routine immunization strengthening and quality mOPV and IPV SIA campaigns are necessary to minimize risks of cVDPV transmission. The missed AFP cases also strongly suggest surveillance gaps and calls for more AFP surveillance strengthening.

SPATIOTEMPORAL RESOURCES FOR PREEMPTIVE PREPAREDNESS AGAINST RIFT VALLEY FEVER

Austin Hardcastle, Joshua Osborne, Rebecca Ramshaw, Erin Hulland, Julia Morgan, Julia Hon, Lucas Earl, Shreya Shirude, Simon Hay, David Pigott

University of Washington, Seattle, WA, United States

Rift Valley Fever (RVF) is an arbovirus which has caused thousands of human cases, hundreds of human fatalities, and over 100,000 livestock deaths over the last 15 years. RVF has been reported from heterogeneous climates throughout Africa and the Middle East, but cases frequently occur in areas that have recently experienced an extended period of above-normal rainfall. Efforts are being made to use known environmental patterns to forecast areas suitable for outbreaks in real-time, but assessments of historic, consistent suitability are also necessary. Here we show synoptic maps of RVF suitability over its entire range at 5km-by-5km resolution for every month of the year. These resources can aid decisions regarding strategic, preemptive pandemic preparedness activities as opposed to immediate but necessary reactions to short-term forecasted risk. We conducted a systematic literature review to identify all reported cases of RVF from 1995-2018 and combined this data with records of RVF occurrence from the FAO's EMPRES-i database. We used boosted regression trees to analyze patterns in these occurrences across environmental covariates including precipitation, vegetation indices, and distances to floodplains. RVF suitability was found in known RVF hotspots such as Kenya and South Africa in addition to countries that have never reported cases. Some regions were suitable for the virus most or all months out of the year, while others only for short seasons. These findings can help policy makers prevent outbreaks by providing information regarding when and where to focus resources for preparedness such as health infrastructure, personnel training, and vaccine supplies for humans if and when they become available. Specifically, we show how our maps can be used to prioritize where a country or region should focus increased infrastructural resources for the surveillance of Rift Valley Fever. The temporal component of our maps can also advise about when during the year people in these identified geographies should be trained and re-trained in Rift Valley Fever surveillance to increase their awareness and hopefully prevent outbreaks.

CHARACTERIZING THE GENOMIC DIVERSITY, EVOLUTION AND PHYLOGEOGRAPHY OF RESPIRATORY SYNCYTIAL VIRUS GENOTYPE ON1 IN KENYA

James Richard Otieno[1], Everlyn M. Kamau[1], John W. Oketch[1], Joyce M. Ngoi[1], Alexander M. Gichuki[1], Špela Binter[2], Grieven P. Otieno[1], Mwanajuma Ngama[1], Charles N. Agoti[1], Patricia A. Cane[3], Paul Kellam[4], Matthew Cotten[5], Philippe Lemey[6], D. J. Nokes[7]

[1]KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, [2]Kymab Ltd., Cambridge, United Kingdom, [3]Public Health England, Salisbury, United Kingdom, [4]Imperial College London, London, United Kingdom, [5]Erasmus Medical Center, Rotterdam, Netherlands, [6]KU Leuven - University of Leuven, Leuven, Belgium, [7]University of Warwick, Coventry, United Kingdom

In December 2010, a new genotype of respiratory syncytial virus (RSV) with a 72-nucleotide duplication within the attachment (G) gene was identified in Ontario, Canada, and named ON1. Using the ON1 as a unique tag, this study aimed to understand; (1) how new RSV variants are introduced, spread and persist in communities, (2) the genomic signatures that define the emergent RSV variants and whether such substitutions may be associated with potential fitness advantages, and (3) the patterns of RSV spread across geographically defined regions (local and global). Partial G gene (n=483) and whole genome (n=184) sequence datasets collected between 2010 and 2016 were analyzed using genetic diversity, phylogenetics and statistical methods to understand the molecular epidemiology of RSV in Kilifi County, Coastal Kenya. Further, Kenyan

(partial G gene; n=2526) and global (full G gene, n=2238; whole genome, n=1194) sequence datasets collected between 1977 to 2016 were analysed in a Bayesian framework for the inference of the phylogeographic history of local and global RSV spread, respectively. Following initial detection genotype ON1 in Kilifi in 2012, there was rapid replacement of the previously circulating RSV group A genotype GA2 by ON1 in subsequent epidemics. While this suggests elevated fitness of ON1 viruses, there was no clear evidence of altered pathogenicity of ON1 relative to GA2 in Kilifi. Signature amino acid substitutions were identified between surface proteins (G, F), polymerase (L) and matrix M2-1 proteins of Kilifi ON1 and GA2 viruses, suggesting co-evolution amongst antigenic and non-antigenic genes of RSV variants. Genetic and phylogenetic analyses reaffirmed previous conclusions that each RSV epidemic is characterized by the frequent introduction of multiple variants, few of which persist across epidemics. Finally, the phylogeographic analyses predicted the northern hemisphere to be the major source population of RSV viruses into the tropics and the southern hemisphere and virus spread between locations in close proximity to be important for virus persistence within a country.

227

MAPPING THE ENVIRONMENTAL SUITABILITY FOR MIDDLE EASTERN RESPIRATORY SYNDROME CORONAVIRUS

Joshua C. Osborne, Rebecca E. Ramshaw, Ian D. Letourneau, Shreya Shirude, Simon I. Hay, David M. Pigott

University of Washington, Seattle, WA, United States

Middle East Respiratory Syndrome Coronavirus (MERS-CoV) is a respiratory pathogen transmitted to humans from dromedary camels reported across the Arabian Peninsula with a case-fatality rate of 35% overall. Repeated infection in both the endemic and imported settings demonstrate the need for preemptive preparedness for detection and treatment of MERS-CoV. Serological detection of MERS-CoV antibodies in dromedary camels ranging beyond geographies with known occurrences of human infection suggests that broadscale mapping is warranted. To this end, we construct a Boosted Regression Tree model of the ecological niche suitable for MERS-CoV spillover into human populations. We use this model to show administrative level relative risk estimates that are weighted by human and camel populations. As a result, we define a much broader geography of spillover potential of MERS-CoV due to the environmental similarity of these regions. MERS-CoV is listed as a priority pathogen by the World Health Organization, and a primary candidate for vaccine development as identified by the Coalition for Epidemic Preparedness Innovations initiative. Moving forward, a geographically precise, broadscale understanding of MERS-CoV spillover potential will be vital to the formulation of active surveillance and investigation strategies and to inform the deployment and provisioning of future vaccines.

228

DEVELOPING ALTERNATIVE SURVEILLANCE METHODS, FROM THE NEAR INFRARED SPECTROSCOPY TO PREDICT ZIKA INFECTION ON *AEDES AEGYPTI*, TO METAGENOMICS TO DETECT THE INVASION OF NEW ARBOVIRUSES AND HAPLOTYPES

Marcio G. Pavan[1], Gabriela A. Garcia[1], Lilha M. Santos[1], Mariana R. David[1], Maggy T. Sikulu-Lord[2], Ademir J. Martins[1], Jeffrey R. Powell[3], Cristopher E. Mason[4], Rafael Maciel-de-Freitas[1]

[1]*FIOCRUZ, Rio de Janeiro, Brazil,* [2]*University of Queensland, St. Lucia, Australia,* [3]*Yale University, New Haven, CT, United States,* [4]*Weill Cornell Medicine, New York, NY, United States*

A significant expansion on the geographic distribution of arboviruses occurred in the last decades, making more than half of human population under risk of transmission. Global cities receive millions of tourists and goods from all over the world and thus it is likely that new mosquito genotypes can be introduced, as well as new viruses. Timely detection of emerging threats and outbreak depends on efficient risk assessment. In endemic regions, there is an urgent need to early diagnose DENV, CHIKV and ZIKV in native *Aedes aegypti* populations. In the other hand, mass gathering events raise the vulnerability of a global city to the introduction of new pathogens. Herein, we propose different surveillance methods - (i) for endemic areas, the use of Near Infrared Spectroscopy (NIRS) to detect arbovirus in *A. aegypti* for a rapid, cost-effective and accurate surveillance system; and (ii) for monitoring cities in mass gathering events, Next-Generation Sequencing methods to detect early introduction of new arboviruses/mosquito genotypes. We analyzed 400 *A. aegypti* mosquitoes for each group (infected with DENV, CHIKV or ZIKV) to develop calibration models for NIRS. Partial Least Square regression models were performed with leave-one-out cross validation. The ZIKV model had >95% specificity and 94.2-99.3% accuracy at 4 and 7dpi. Preliminary results of DENV at 7 and 14dpi showed 85% specificity and 76% accuracy. To accomplish the second aim, *A. aegypti* samples were collected 3-months before, 3-m after and 1-year after the Rio 2016 Olympics in 8 venues and also in a control area, where tourists were not expected (90 female mosquitoes/area). DNA was extracted individually and analyzed in SNP-chip containing ~30K SNPs of *A. aegypti*. These results will be compared to our SNP database of worldwide mosquito populations to identify its origin. Mosquito females also had the midgut dissected individually, and DNA and RNA extracted and prepared for metagenomics and RNA shotgun metagenomic sequencing (SMS) to determine if new arboviruses entered during the Olympics and if they recurrently infected mosquitoes after the games.

229

THE ARRESTING VERTICAL TRANSMISSION OF HEPATITIS B VIRUS (AVERT-HBV) STUDY IN THE DEMOCRATIC REPUBLIC OF THE CONGO: PRELIMINARY RESULTS

Peyton Thompson[1], Jonathan B. Parr[1], Kashamuka Mwandagalirwa[2], Noro L. Ravelomanana[2], Martine Tabala[2], Malongo Fathy[2], Patrick Ngimbi[2], Bienvenu Kawende[2], Charles Mbendi[2], Jérémie Muwonga[3], Ravi Jhaveri[4], Gavin Cloherty[5], Marcel Yotebieng[6], Steven R. Meshnick[7]

[1]*University of North Carolina-Chapel Hill, Chapel Hill, NC, United States,* [2]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo,* [3]*National AIDS Control Laboratory, Kinshasa, Democratic Republic of the Congo,* [4]*Lurie Children's Hospital, Chicago, IL, United States,* [5]*Abbott Laboratories, Abbott Park, IL, United States,* [6]*Ohio State University, Columbus, OH, United States,* [7]*Gillings School of Global Public Health, Chapel Hill, NC, United States*

Despite the widespread availability of effective vaccination against hepatitis B virus (HBV), it remains endemic throughout sub-Saharan Africa. Mother-to-child transmission (MTCT) of HBV is preventable through birth dose vaccination and identification/treatment of "high-risk" pregnant women (those with high viral loads and/or HBV e antigen [HBeAg] positivity). The purpose of this study is to show the feasibility of adding HBV testing and treatment of pregnant women, and birth-dose vaccination, to the existing infrastructure of an HIV prevention of MTCT (PMTCT) program in the Democratic Republic of the Congo (DRC). We are enrolling pregnant women at two maternity centers in Kinshasa, DRC that have ongoing HIV PMTCT programs. We are screening women using point-of-care HBV surface antigen (HBsAg) testing (Abbott Alere Determine™, Abbott Park, IL). Women with positive HBsAg testing who present at <24 weeks' gestation are eligible for enrollment. Enrolled women are being evaluated for high-risk disease using HBV viral load (Abbott RealTi*m*e) and HBeAg (Abbott ARCHITECT) and for baseline liver and kidney function abnormalities. Pregnant women with high-risk disease are offered tenofovir disoproxil prophylaxis between 28- and 32-weeks' gestation and continued through 12 weeks' post-partum. Exposed infants are given a birth dose of monovalent HBV vaccine within 24 hours of life. Of 4,016 women screened, 109 (2.7%) were HBsAg-positive and 91 women have been enrolled. Among the 71 who have undergone additional testing thus far, nine (12.7%) of the enrolled women have high-risk disease; none of these women have baseline liver or kidney function abnormalities. Of the 19 infants who have been born to date, 14 (73.7%) have received birth dose vaccine within 24 hours. This ongoing study demonstrates the feasibility of adding HBV screening and treatment of pregnant women,

and infant birth-dose vaccination, to the existing HIV PMTCT platform in Kinshasa. Challenges exist in administering timely birth dose vaccination to Congolese infants; these implementation issues must be addressed prior to roll-out of universal birth dose vaccination in Africa.

230

SPATIO-TEMPORAL DYNAMICS OF MEASLES IN THE PROVINCE OF WESTERN KASAI IN DEMOCRATIC REPUBLIC OF CONGO FROM 2000 TO 2014

Dilubenzi Suami Divine, Bigirinama Rosine, Didier Bompague

URF/University of Kinshasa/INRB, Kinshasa, Democratic Republic of the Congo

Background: Despite immunization efforts since 2000, measles remains a major public health problem in the DRC. The upsurge of outbreaks throughout the country in general and in the province of the western Kasaï especially motivated the realization of this study. Aim: To start understanding of recurrence of these outbreaks. Methods: Measles cases and deaths reported in Kasai Occidental between 2000 and 2014 were used to calculate the attack rate and develop thematic maps for possible spatial heterogeneities. The outbreaks occurred during the period were analyzed together with an assessment of measles surveillance system. Results: A total of 33,126 cases (3.82% deaths) have been reported on all that ZS (Luebo, Mweka and Benaleka) were more at risk. Children <5 years unvaccinated (65.8%) were more affected and no difference in sex. Conclusion: The identification of the epicenter formed of the 3 ZS opens a perspective to lead the studies to the scale of health areas in order to search for the factors explaining these heterogeneities

231

SEROPREVALENCE OF HEPATITIS A AND HEPATITIS E VIRUSES AMONG PREGNANT WOMEN IN HAITI

Alexandra Tejada-Strop[1], Rania Tohme[1], Jocelyne Andre-Alboth[2], Lana Childs[1], Xin Ji[1], Vivianne de Oliveira Landgraf de Castro[3], Jacques Boncy[2], Saleem Kamili[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*National Public Health Laboratory, Port-au-Prince, Haiti,* [3]*Federal University of Mato Grosso do Sul, Campo Grande, Brazil*

Hepatitis A virus (HAV) and hepatitis E virus (HEV) are mainly transmitted through contaminated food and water. HEV infection is associated with a high fatality rate among pregnant women, and gestational complications have been reported among pregnant women infected with HAV. Determine the seroprevalence of HAV and HEV infections among pregnant women in Haiti. We selected 1307 residual specimens from the 2012 Biannual Sentinel Serosurveys for HIV among Pregnant Women. We stratified the population into West (includes Metropolitan Port-au-Prince) and non-West regions (all other departments). Specimens were tested for total HAV antibody immunoglobulin (total anti-HAV), anti-HEV immunoglobulin M (Anti-HEV IgM), and anti-HEV immunoglobulin G (Anti-HEV IgG). We evaluated the overall prevalence and the prevalence in the West and non-West regions and the association between demographic and socioeconomic characteristics with HAV and HEV infections. Overall, 96.8% of tested pregnant women were positive for total anti-HAV, 10.3% for Anti-HEV IgG, and 0.3% for Anti-HEV IgM. The prevalence of Anti-HEV IgG in the non-West (12.3%) was significantly greater than in the West region (5.3%) ($p<0.0001$). Prevalence of total anti-HAV ($p=0.008$) and Anti-HEV IgG ($p\leq0.05$) was significantly associated with age. Total anti-HAV increased from 92% to 98%, and Anti-HEV IgG increased from 6% to 16% among women aged 15-19 years and those aged ≥35 years, respectively. The majority of pregnant women in Haiti had evidence of past exposure and immunity to HAV. HEV is circulating at a greater rate in the non-West region than the West region. Improvements in food and water safety such as the implementation of the Water, Sanitation, and Hygiene (WASH) program may help with prevention of these viral infections in Haiti.

232

ASSESSING SERUM ANTI-ROTAVIRUS IMMUNOGLOBULIN A AS A CORRELATE OF VACCINE-INDUCED PROTECTION AGAINST ROTAVIRUS GASTROENTERITIS IN HIGH AND LOW CHILD MORTALITY SETTINGS: ANALYSIS OF POOLED IN DIVIDUAL-LEVEL DATA FROM NINE CLINICAL TRIALS

Julia M. Baker[1], Jacqueline E. Tate[2], Juan Leon[1], Michael J. Haber[1], Benjamin A. Lopman[1]

[1]*Emory University, Atlanta, GA, United States,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

A correlate of protection would facilitate rapid and efficient assessment of modified rotavirus vaccine strategies and the next generation of rotavirus vaccines. We aimed to quantify a threshold of post-vaccine serum anti-rotavirus immunoglobulin A (IgA) antibody units that serves as an individual-level immune correlate of protection against rotavirus gastroenteritis among vaccinated infants across child mortality settings. Individual-level data on 5,074 infants enrolled in nine GlaxoSmithKline Rotarix phase II and III clinical trials from 16 countries were pooled. Cox proportional hazard models were fit to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) describing the relationship between a series of anti-rotavirus IgA thresholds and the occurrence of mild/moderate or severe rotavirus gastroenteritis up to 1 year of age. Seroconversion (serum anti-rotavirus IgA ≥20 U/mL) conferred substantial protection against mild/moderate and severe rotavirus gastroenteritis across settings. Among infants in low child mortality settings, seroconversion provided near perfect protection against severe rotavirus gastroenteritis (HR=0.04, 95% CI=0.01, 0.32). In high child mortality settings, seroconversion reduced the risk of severe rotavirus gastroenteritis by 52% (HR=0.48, 95% CI=0.26, 0.90). As anti-rotavirus IgA threshold increased, the HR comparing the rate of gastroenteritis among those above that threshold to seronegative infants generally decreased. A given anti-rotavirus IgA threshold typically provided higher protection in low child mortality settings compared to high child mortality settings and for more severe disease compared to mild/moderate disease. Serum anti-rotavirus IgA is a valuable, though imperfect, correlate of vaccine-induced protection against rotavirus gastroenteritis across settings. Serum anti-rotavirus IgA alone may be insufficient to accurately predict an infant's risk of rotavirus gastroenteritis, however, serum anti-rotavirus IgA seroconversion provides an informative threshold for assessing rotavirus vaccine performance.

233

MATERNAL SECRETOR STATUS AFFECTS ORAL ROTAVIRUS VACCINE RESPONSE IN BREASTFED INFANTS IN BANGLADESH

Frank B. Williams[1], Abdul Kader[2], Dorothy M. Dickson[1], Ross Colgate[1], Muhammad Muhammad Ikhtear[2], Salma Sharmin[2], Shaidul Islam[2], Taufiqur R. Bhuiyan[2], Masud Alam[2], Uma Nayak[3], Josyf C. Mychaleckyj[3], William A. Petri[3], Rashidul Haque[2], Firdausi Qadri[2], Beth D. Kirkpatrick[1], Benjamin Lee[1]

[1]*University of Vermont, Burlington, VT, United States,* [2]*International Center for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*University of Virginia, Charlottesville, VA, United States*

Rotavirus (RV) remains the leading global cause of infectious diarrhea among infants despite availability of live-attenuated oral vaccines, which underperform in low-income settings. Histoblood group antigen expression on mucosal surfaces and in exocrine secretions (i.e. Secretor status) has been associated with RV susceptibility, with non-Secretor infants protected against symptomatic RV infection. However, the contribution of maternal breast milk Secretor status on infant responses to oral RV vaccination remains unclear. We hypothesized that infant and breast milk Secretor-positive status would be associated with increased vaccine response. Therefore, we performed a sub-study within PROVIDE, a Rotarix vaccine efficacy trial conducted in Dhaka, Bangladesh, to determine if infant or maternal Secretor status was associated with infant post-vaccination RV-specific IgA seroconversion. Seroconversion

was defined as post-vaccination plasma RV-IgA ≥20 U/mL at 18 weeks of age following pre-vaccination concentration <20 U/mL. Infant and maternal Secretor status were determined by enzyme immunoassay of saliva and breast milk, respectively. Phenotype data were available for 246 maternal-infant dyads. Seventy-four mothers (30%) and 71 infants (29%) were non-Secretor. Seroconversion rates were significantly higher among infants born to maternal non-Secretors (37% vs 22%, P=0.01); this effect was strongest among infant Secretors (55% vs 24%, P<0.01). Maternal status was not associated with breast milk RV-IgA or infant pre-vaccination RV-IgG. In a model evaluating both maternal and infant status, maternal, but not infant, phenotype remained significantly associated with seroconversion (P<0.01). Maternal Secretor status significantly affected RV vaccine response in Bangladesh. One hypothesis for these findings suggests inhibition of vaccine response by Secretor-dependent antigens in breast milk, possibly by serving as decoy receptors or by modulating the infant microbiome. Further studies may yield insights into pathogenesis and host response, but breast feeding should not be withheld at vaccination.

234

ALLERGIES, OBESITY AND RISK OF HOSPITALIZATION FOR SUSPECTED ARBOVIRUS INFECTIONS

Anita Susana Hargrave[1], Rachel Sippy[2], Anna Stewart-Ibarra[3]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Institute for Global Health and Translational Science, SUNY Upstate Medical University, Syracuse, NY, United States,* [3]*Institute for Global Health and Translational Science, SUNY Upstate Medical University; Department of Medicine, Syracuse, NY, United States*

Dengue, chikungunya and Zika are mosquito-borne arboviruses that lead to over 390 million infections per year worldwide. They can manifest as a short flu-like illness or as life-threatening organ dysfunction. The risk factors for development of severe complications requiring hospitalization remain poorly understood. In the same communities afflicted by these diseases, there are growing rates of allergies and obesity. These conditions are linked to pro-inflammatory states and altered immunity. The objective of this study was to elucidate how allergies and obesity change the risk of hospitalization due to arboviruses in an endemic region in southern coastal Ecuador. From 2014 to 2018, subjects were enrolled after being clinically diagnosed with an arbovirus infection by a Ministry of Health physician in the city of Machala. Weight and height were measured to calculate Body Mass Index (BMI), and a survey of demographics, symptoms, and health history including self-report of allergies was conducted after enrollment. The relationships between hospitalization and three measures: (1) BMI, (2) history of allergies and (3) overweight/obese BMI or allergies, were analyzed using general liner models adjusting for potential confounders. Three hundred and thirty-seven adults were recruited with complete data; of these patients, 34 were hospitalized, 57 reported allergies and 203 patients had a BMI over 25, classifying them as overweight/obese. For every BMI unit above 25, there was a 9% decrease in odds of hospitalization (95% confidence interval, 0.83—0.99). Those with reported allergies had a 23% decrease in the odds of hospitalization (95% confidence interval, 0.25—1.99) compared to those without allergies. Patients with either a history of allergies or an overweight/obese BMI classification had a 44% decrease in the odds of hospitalization (95% confidence interval: 0.21—1.50). Having a BMI above normal or allergies exhibited protective effects against hospitalization among adults with clinically diagnosed arbovirus infection; additional research is necessary to better understand the mechanisms contributing to these associations.

LASSA FEVER IMMUNE RESPONSE CROSS REACTIVITY TO RECOMBINANT ANTIGEN BASED IMMUNOASSAYS

Megan Heinrich[1], Matthew Boisen[2], Luis Branco[1], Katherine Hastie[3], Diana Nelson[2], Duane Bush[2], Irina Aimukanova[2], Mambu Momoh[4], Francis Baimba[4], John Adeyemi[5], Testimony Olumade[6], Benevolence Ebo[5], Olusola Ogunsanya[7], MacDonald Onyechi[8], Johnson Etafo[8], Matthew Afam Eke[9], Philomena Eromon[6], Andrew Hoffmann[10], Brandon Beddingfield[10], Ikponmwosa Odia[5], Chinedu Ugwu[6], Onikepe Folarin[6], Augustine Goba[4], Pardis Sabeti[11], Christian Happi[6], Donald Grant[12], Erica Ollmann Saphire[3], John Schieffelin[10], Robert Garry[10]

[1]*Zalgen Labs LLC, Germantown, MD, United States,* [2]*Zalgen Labs LLC, Aurora, CO, United States,* [3]*La Jolla Institute for Immunology, La Jolla, CA, United States,* [4]*Kenema Government Hospital, Kenema, Sierra Leone,* [5]*Irrua Specialist Teaching Hospital, Irrua, Nigeria,* [6]*Redeemers University, Ede, Nigeria,* [7]*University of Ibadan, Ibadan, Nigeria,* [8]*FMC Owo, Owo, Nigeria,* [9]*FMC Abakaliki, Abakaliki, Nigeria,* [10]*Tulane University, New Orleans, LA, United States,* [11]*Broad Institute, Cambridge, MA, United States,* [12]*Ministry of Health and Sanitation, Freetown, Sierra Leone*

During the 2019 Nigerian Lassa fever outbreak, serologic studies were conducted at Redeemers University, Nigeria and Kenema Government Hospital, Sierra Leone to assess the level of Lassa-specific IgG and IgM cross-reactivity towards recombinant Lassa virus (LASV) antigens from the three most prevalent circulating strains: LASV lineages II and III (Nigeria) and Lineage IV (Sierra Leone, Liberia, Guinea). Long-term LF Survivor samples were screened using recombinant LASV antigen-based IgG/IgM ELISA kits for Lassa-specific reactivity to Nucleoprotein (NP), Glycoprotein (GP), and Z protein (ZP). Assay reagents included ELISA microwell plates that were coated with individual antigens or mixtures of all three lineages of a particular antigen (Pan-Lassa), stabilized and packaged for use in West Africa. For human sample screening a 1:100 dilution was used. Samples exhibiting Lassa-specific IgG or IgM reactivity were selected to be retested for antigen specific end-point titers. Correlation of NP and GP assay reactivity was low (R2 <0.5) highlighting a differential adaptive immune response to viral antigens in convalescence. Cross-reactivity of antibody response to multiple lineages was significant (R2 >0.850) for both NP and GP antigens however, ZP exhibited poor cross-reactivity (R2 <0.500) and specificity. Samples from both Nigeria and Sierra Leone demonstrated consistent cross-reactivity to all three lineages of NP and GP antigens. Endpoint dilution of NP and GP reactive samples further elucidated cross-reactivity with lineage specific endpoints within 4-fold dilutions. Median end-point dilution for NP antigen was 1:6400 (maximum 1:51,200) and GP antigen 1:1600 (maximum 1:12,800). For samples with anti-GP endpoint ≥1:400, positive agreement with the Lassa GP pseudovirus neutralization reference method was 97.4% (38/39; 95th% CI 86.5 - 99.9%). Detection of anti-NP and anti-GP antibodies are important biomarkers of Lassa fever humoral immune response. These results help will guide selection of recombinant LASV antigens used in LF surveillance and vaccine development.

EVALUATION OF THE PERFORMANCE OF ALERE Q FILOVIRUS DETECT TEST AND THE ALERE Q ANALYZER FOR DIAGNOSIS OF EBOLA COMPARED TO RT-PCR

Yanis Ben Amor[1], Zelda Moran[1], Maitreyi Oka[1], William Rodriguez[2], Cassandra Kelly[2], Mamdou A. Baldé[3], Moussa Moussa Condé[3], N'Faly Magassouba[3]

[1]*Columbia University, New York, NY, United States,* [2]*Foundation for Innovative New Diagnostics, Geneva, Switzerland,* [3]*Laboratoire des Fièvres Hémorragiques en Guinée, Conakry, Guinea*

Over the past five years, outbreaks of Ebolavirus have resulted in devastating morbidity and mortality in West and Central Africa and Ebola remains a significant public health threat in several countries. Access to molecular diagnostic testing is crucial for effective early outbreak

identification and response, but nucleic-acid based tests are primarily limited to large laboratories with advanced equipment and highly trained technicians. In 2017, we performed an analysis of the accuracy of the Alere q Filovirus Detect Test using whole blood samples collected in Guinea in 2014-15. We compared each test result from Alere q to its respective RT-PCR record from the time of collection. To account for uncertain sample transport and storage history between collection and investigative testing, whenever the Alere q test was discordant with the original result from 2014, a confirmatory RT-PCR was performed. Two separate statistical analyses were conducted, the first (primary) excluding any samples with differing RT-PCR results, and, to account for possible sample degradation, the second (secondary) including all samples but considering the 2017 RT-PCR as the true Ebola status. Sensitivity in primary analysis was 97.3% (95% CI: 90.7% - 99.7%), and 97.7% (95% CI: 91.85% - 99.7%) in secondary analysis. Specificity was lower, at 89.1% (95% CI: 81.4% to 94.4%) in both analyses. Limitations included uncertain sample transport and storage history of samples, including the transportation to the United States and treatment with gamma irradiation after testing by Alere q but prior to confirmatory RT-PCR testing. This may have impacted the accuracy of the 2017 RT-PCR test result. The Alere q Filovirus Detect Test demonstrated high sensitivity and moderate specificity when used on whole blood samples collected in Guinea during the 2014-15 Ebola outbreak. Significant challenges faced during this study are likely to apply in futures studies attempting to validate new diagnostics using banked samples, and should be considered during study design and results interpretation.

VIRAL HEMORRHAGIC FEVERS IN PREGNANCY: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ribka Amsalu

University of California San Francisco, San Francisco, CA, United States

Driven by globalization, urbanization, changing human feeding habits, and change in land use, the risk for infectious disease epidemics and pandemics has increased over the years. In the last three decades, several infectious diseases have emerged as diseases of concern with epidemic or pandemic potential including Severe Acute Respiratory Syndrome (SARs), Influenza, Coronavirus infection (MERS-CoV), and Ebola Virus Disease (EVD). While, there are evidence-based interventions to tackle most infectious diseases, the evidence-base on the effect of viral hemorrhage fevers in pregnancy is limited. Viral hemorrhagic fevers (VHFs), is a term usually applied to disease caused by *Arenaviridae* (Lassa fever), *Bunyaviridae* (Rift Valley Fever), *Filoviridae* (Ebola and Marburg) and *Flaviviridae* (Yellow fever, Dengue) viruses. Globally, VHFs have accounted for nearly three fifth of infectious disease epidemic events in the last decade. We conducted a systematic review and meta-analysis to summarize the current evidence to determine whether VHF epidemics are associated with adverse pregnancy outcomes. Adverse pregnancy outcomes were defined as miscarriage, stillbirth, preterm birth, low-birth weight, and early neonatal death. Electronic literature search were conducted in PubMed, Embase, Web of Science and Cochrane library. The search was limited to English language. Common VHFs- dengue, yellow fever, lassa fever, rift valley fever, and ebola were included in the search. Medical subject heading, keyword search and the bibliographies and reference list of selected articles identified 1543 studies. Title and abstract screening was done by two authors using predesigned selection criteria. The eligible articles were then exported to Systematic Review Data Repository for data extraction. Most of the studies identified were observational studies, cohort and case control, and quality was assessed by the Newcastle-Ottawa Scale. Effect sizes were estimated for each adverse outcome and as composite indicator by disease by using Risk Ratio with corresponding 95% confidence interval. Results and conclusion will be presented at conference.

"THE CAT THAT KILLS PEOPLE": COMMUNITY BELIEFS ABOUT EBOLA ORIGINS AND IMPLICATIONS FOR DISEASE CONTROL IN EASTERN DEMOCRATIC REPUBLIC OF THE CONGO

Michael Hawkes[1], Kasereka Masumbuko Claude[2]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Université Catholique du Graben, Butembo, Democratic Republic of the Congo*

The current Ebola epidemic in Eastern Democratic Republic of Congo (DRC) has surpassed 1,000 cases and 600 deaths. Social resistance is a major barrier to control efforts, and invites an exploration of community beliefs around Ebola and its origins. Mixed-methods study, using focus group discussions (FGDs) with key community informants and a 19-item survey questionnaire broadly sampling the outbreak zone. Between 4 to 17 August, 2018, we conducted 4 FGDs (20 participants) and surveyed 286 community members across Eastern DRC. FGDs revealed a widespread rumour early in the epidemic of two twins bewitched by their aunt after eating her cat, who developed bleeding symptoms and triggered the epidemic. However, this myth appeared to dissipate as the epidemic progressed and biomedical transmission became generally accepted (medical syncretism). In our survey, 6% of respondents endorsed supernatural origins of Ebola. This subgroup did not differ from other respondents in terms of knowledge of biomedical modes of transmission or resistant attitudes toward control measures, but was more likely to believe that traditional healers could cure Ebola. Wild animals were recognized as sources of Ebola by 53%. Our findings suggest that skepticism and/or denial of the biomedical discourse, coupled with and mistrust and fear of ETUs may fuel "underground" transmission of Ebola outside western-style medical facilities, as patients seek care from traditional healers, who are ill-equipped to deal with a highly contagious biohazard. A deeper understanding of beliefs around Ebola origins may illuminate strategies to engage communities in control efforts.

A REVIEW OF THE GENETIC AND ANTIGENIC PROFILE OF INFLUENZA VIRUSES CIRCULATING IN CEBU CITY, PHILIPPINES, 2009-2017

Maria Theresa Payumo Alera[1], Louis Macareo[2], Stefan Fernandez[2], In-Kyu Yoon[3], John Mark Velasco[2], Wudtichai Manasatienkij[2], Catherine Lago[1], Chonticha Klungthong[2]

[1]*Philippines-Armed Forces Institute of Medical Sciences Virology Research Unit, Cebu City, Philippines,* [2]*Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand,* [3]*International Vaccine Institute, Seoul, Republic of Korea*

Genetic changes of influenza viruses may occur and form novel subtypes resulting in pandemics. Influenza surveillance is critical to detect mutations to assess the potential effectiveness of seasonal influenza vaccines. The objective of the study was to identify the antigenic and molecular characteristics of circulating influenza viruses in Cebu City, Philippines. 2,491 nasal/throat swabs collected from volunteers aged 6 months old and above presenting with influenza-like illness in city health clinics from 2009 to 2017, were tested by influenza real-time RT-PCR. 627 of 2,491 (25%) samples with Ct value <27 were randomly selected for sequencing. Influenza A viruses accounted for 426 of the 627 (68%) and Influenza B viruses for 201 (32%). A breakdown of Influenza A subtype viruses were as follows: 236/426 (55%) Influenza A/H3 and 190/426 (45%) Influenza A(H1N1)pdm09. A phylogenetic analysis of influenza A/H3N2 using 41 gene sequences showed the following clades: 1 (2009), 3B (2011-2012), 3C.1 (2011), 3C.3 (2012-2015), and 3C.2a (2015 to 2017). Influenza A/H3 subtype showed close antigenic identity to Northern Hemisphere vaccine strain A/California/7/2004/ Vaccine and Southern Hemisphere vaccine strain A/Switzerland/8060/ 2017/Vaccine. A phylogenetic analysis using 23 Influenza A(H1N1)pdm09 gene sequences showed that the virus strain during the 2009 influenza season belonged to genetic clade 1. It was closely related to A/California /7/2009 vaccine strain. Clade 6 was

the dominant A(H1N1)pdm09 subtype virus circulating between 2013 and 2017. Phylogenetic analysis of influenza B using 44 gene sequences showed both B/Victoria and B/Yamagata lineages co-circulating between 2011 and 2014. Clades of Influenza B Victoria lineage belonged to 1A and 1B while Influenza B Yamagata lineage belonged to clade 3. The study emphasizes the importance of sustained epidemiologic and virologic influenza surveillance coupled with timely antigenic and genetic evolution analysis which can be used by health authorities to guide policy decision making.

DEVELOPMENT OF SUBSTITUTED GUANIDINO-OSELTAMIVIR AS POTENT AGAINST INFLUENZA VIRUS TARGETING NEURAMINIDASE ACTIVITY

Sumit Kumar[1], Sonu Kumar[2], Prem P. Sharma[2], Atul FNU[2], Prakasha Kempaiah[3], Brijesh Rathi[2], Poonam FNU[1]

[1]*Department of Chemistry, Miranda House, University of Delhi, New Delhi, India,* [2]*Laboratory for Translational Chemistry and Drug Discovery, Department of Chemistry, Hansraj College University Enclave, University of Delhi, New Delhi, India,* [3]*Department of Medicine, Loyola University Stritch School of Medicine, Chicago, IL, United States*

Influenza, is an inoculable viral infection, belongs to *orthomyxoviridae* family is caused by number of circulating influenza viruses classified as influenza A, B and C. The influenza strains, H1N1, H3N2, H2N2, H5N1 causes epidemic that influences the respiratory organs in human and animals. As per the WHO reports, influenza creates major threat for human population, killing > 2,50,000 - 5,00,000 people worldwide. Oseltamivir, orally approved drug inhibits the neuraminidase (transmembrane protein). Neuraminidase plays an important role in release of virus from infected cell by cleaving sialic acid present on the surface of cell membrane. Therefore, neuraminidase are considered as potential drug target for anti-influenza agents. The active form of oseltamivir, oseltamivir carboxylate (Tamiflu) formed by the action of endogenous esterase inside the cell membrane and targets the neuraminidase. The use of oseltamivir showed a substantial decrease in influenza related death over the time, however rapid mutations of the virus resulted in the resistance against oseltamivir and other antiviral agents. In view of the ongoing pandemic threat and the emergence of resistance to oseltamivir, the development of new effective therapeutics must be of high priority. Guanidino-oseltamivir (GO) is one of the pro-drugs of oseltamivir with high anti-influenza activity in culture, however its poor bioavailability needs to be improved. Therefore, we decided to develop new analogs of GO by implementing slight chemical modifications. The main objective of our investigation is to build N-alkyl amides substituted GO and O-alkyl ester substituted GO analogs as potent anti-influenza agent. Several new GO analogs were synthesized and assayed for biological testes. The initial screening results supported few of the compounds as highly potent with inhibitory concentration of ~20 nM in culture with minimal toxicity. All the interesting observation will be presented.

PREVALENCE OF HIGH-RISK HPV GENOTYPES RELATED TO CERVICAL CANCER IN WOMEN OF LIMA, PERU THROUGHOUT THE YEARS 2012 - 2017

Caddie Laberiano Fernández[1], Wilmer Silva-Caso[2], Javier Arias Stella[1], **Migue A. Aguilar-Luis**[3], Luis J. del Valle[4], Jorge Valverde-Ezeta[3], Denisse Champin[2], Graciela Risco de Dominguez[2], Juana del Valle-Mendoza[3]

[1]*Instituto de Patologia y Biología Molecular Arias Stella, Lima, Peru,* [2]*Facultad de Ciencias de la Salud - Universidad Tecnológica del Peru, Lima, Peru,* [3]*School of Medicine, Research and Innovation Centre of the Faculty of Health Sciences, Universidad Peruana de Ciencias Aplicadas, Lima, Peru,* [4]*Barcelona Research Center for Multiscale Science and Engineering, Department d' Enginyeria Quimica, EEBE, Universidad Politecnica de Catalunya (UPC), Barcelona, Spain*

Human Papilloma Virus (HPV) is the most important risk factor in the pathogenesis of cervical cancer and precancerous lesions of the cervix. Currently more than 170 types of HPV have been characterized and their distribution of genotypes varies geographically. In Peru, is reported that about 20.5% of cervical cells with normal morphology determined by Papanicolau test (PAP) were infected by HPV. However, data regarding HPV infection is still limited, therefore our study is of the utmost importance since we evaluated high-risk HPV frequencies over the span of 6 years (2012 - 2017) in women from Lima, Peru. A Retrospective study was conducted based on the statistical analysis performed on a database of a total of 6665 samples from asymptomatic women over 15 years of age from the Stella - Maris Clinic in Lima - Peru (2012 - 2017). All samples were subjected to the COBAS ® 4800 HPV test (PCR to amplification of and nucleic acid hybridization for the detection of 14 high-risk HPV types in a single analysis (HPV 16,18,31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68). We found that 27.7 % (n = 1849) were positive for high risk HPV genotypes 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68, while 9.8 % (n = 650) tested positive for the HPV16 genotype, lastly only 1.91% (n = 127) were positive only for the HPV genotype 18. The most frequent coinfection was between the HPV16 genotype and any of the other genotypes evaluated as high risk (HPV 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68) was seen in 4.29% (N = 286). In conclusion, our results demonstrate a significant percentage of positive infections by the HPV16 genotype, however the group that is considered as positive for the other high risk genotypes (HPV 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 66 and 68) except without characterizing them individually, represented a percentage of 27.74%, which indicates that in our study population the flow of viruses considered high risk is very heterogeneous.

242

THE ROLE OF *PLASMODIUM FALCIPARUM* DERIVED MICROVESICLES IN MALARIA RELATED ANEMIA

Florence Awamu[1], Kai Matuschewski[1], Faustin Kamena[2]

[1]*Humboldt University Berlin, Berlin, Germany,* [2]*Leipzig University, Leipzig, Germany*

Severe anemia represents one of the major complications in malaria and affects primarily young children. Red blood cell destruction by the causative agent of malaria, intra-erythrocytic *Plasmodium* parasites, is the main origin of anemia, but clinical data suggests that additional factors, including dyserythropoiesis and phagocytosis of erythrocytes, add to the pathology. The underlying mechanisms that explain the disproportional loss of erythrocytes when compared to the proportion of infected cells remain to be elucidated. One attractive hypothesis is coating and immune recognition leading to phagocytosis of non-infected erythrocytes with *Plasmodium* antigens, which are released into the blood stream during intra-erythrocytic replication through microvesicles. In this study, we investigated microvesicle-mediated transfer of parasitic material to uninfected erythrocytes and its contribution to phagocytic destruction. We purified microvesicles from *Plasmodium falciparum* cultures and characterized the protein content by mass spectrometry. We show that a signature microvesicle protein, ring-infected erythrocyte surface antigen (RESA), can be found on the surface of non-infected erythrocytes. Transwell co-culture experiments further substantiate our notion that coating of normal erythrocytes by parasite antigens occurs through microvesicle transfer. We finally tested whether this mechanism primes uninfected cells for phagocytosis *in vitro* by macrophages. Our findings show that microvesicles derived from *Plasmodium*-infected erythrocytes can deposit parasite antigens on uninfected red blood cells. Whether this mechanism contributes to the pathogenesis of malaria-related anemia can now be examined in clinical studies.

243

THE ASSOCIATION BETWEEN ABO BLOOD GROUPING AND MALARIA INFECTION WITHIN KENYAN ISOLATES

Redemptah Yeda

Kenya Medical Research Institute - Kenya, Kisumu, Kenya

The ABO blood groups consist of A, B and H carbohydrate antigens which can regulate protein activities. Investigations have been conducted to find out whether or not ABO blood groups antigens are associated with susceptibility of malaria infections in Kenyan. This study aims to assess the distribution of ABO blood groups and their relationship with malaria infection among Kenyan isolates. A total 138 positive, *Plasmodium species* whole blood samples were obtained from an ongoing malaria surveillance study microscopy was done on all samples. ABO blood group was determined by agglutination test using Anti ABD blood grouping, monoclonal antibodies. *Plasmodium* speciation was achieved using ssRNA real-time polymerase chain reaction. Data collected was analysed using R software version 3.4.2. Chi square was used to assess the difference between frequencies and ANOVA used to test the difference between parasitemia means. Out of a total of 140 samples collected, 130 (93%) were found to be infected with plasmodium parasites as determined by microscopy. All samples examined for malaria were also tested for ABO blood groups accordingly, 47.7%, 26.2%, 20.8% and 4.6% were found to be blood groups O, A, B and AB respectively. The highest proportion of individuals in all blood groups were infected with P.falciparum as compared with other species, 91(70%), 26(20%), 11(8%) and 2(2%) were positive for *Plasmodium falciparum*, *Plasmodium ovale wallikeri*, *Plasmodium malarae* and *Plasmodium ovale Curtis*. This study indicates that individuals of blood groups O, A and B are more susceptible to plasmodium falciparum infection compared to individuals with blood type AB.

244

PLASMODIUM FALCIPARUM GAMETOCYTE SEX RATIO IN AN ASYMPTOMATIC POPULATION: IMPACT ON MALARIA TRANSMISSION

Raphael O. Okoth[1], Benjamin Opot[1], Gladys Chemwor[1], Irene Onyango[1], Gladys Kerich[1], Dennis Juma[1], David Abuom[1], Hoseah Akala[1], Ben Andagalu[1], Edwin Kamau[2], Jessica Cowden[3], Jim Ray Managbanag[4]

[1]*US Army Medical Research Directorate - Africa (USAMRD-A, Kenya Medical Research Institute (KEMRI), Kisumu, Kenya,* [2]*U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [3]*Walter Reed Army Institute of Research, Silver Spring, MD, United States,* [4]*US Army Medical Research Directorate - Africa, Kisumu, Kenya*

The burden of asymptomatic and sub-microscopic malaria infections in endemic settings is playing a role in sustaining transmission. *Plasmodium* gametocyte stage that is infectious to mosquito is central to sustained transmission. This argues for innovative transmission-blocking strategies in order to meet global elimination goals. Mosquito infection is mainly determined by gametocyte density and its sex ratio is crucial in ensuring fertilization. Conventional means of sex ratio quantification - microcopy - is imperfect and quantification has been improved by the introduction of molecular detection tools that allow detection at lower densities. It has been shown that adequate numbers of male and female gametocytes need to be generated during infection for successful fertilization. However, the range of the sex ratio that would allow transmission is unclear. Here, we aim to estimate a range of gametocyte sex ratio that would allow transmission in an asymptomatic population in a malaria holoendemic region. A total of 4214 blood samples collected from 29 clusters in a malaria transmission dynamics study in Kisumu between July 2015 and June 2016 were used in this study. Ribonucleic acid extraction was carried out followed by a DNase digest on all the samples. *Plasmodium* and gametocyte detection was then carried out using a reverse transcription quantitative real time polymerase chain reaction (RT-qPCR). Subsequently, *Plasmodium* species composition of each positive sample was determined. Participants who had gametocytes underwent either a membrane or direct landing feeding assay and on day 8, all the fed mosquitoes were dissected and diagnosed for the presence of oocyst - suggestive of successful infection. Gametocyte sex ratio analysis is being carried out as described by Schneider *et al.* with few modifications - replacing *Pfs230p* with *Pf*MGET as the male gametocyte marker. The findings of this study will describe a range of sex ratio fit for successful mosquito mid-gut infection and further give clue to whether a robust sex-specific quantification could replace mosquito feeding assays. Preliminary findings of the study will be presented.

245

URINARY METABOLITE CHANGES IN VOLUNTEERS CHALLENGED WITH *PLASMODIUM FALCIPARUM* SPOROZOÏTES

Madeleine Eunice Betouke Ongwe[1], Isabelle Kohler[2], Aswin Verhoeven[2], Jacqueline J. Janse[2], Yoanne D. Mouwenda[2], Peter G. Kremsner[3], Stephen L. Hoffman[4], Bertrand Lell[5], Akim A. Adegnika[5], Oleg A. Mayboroda[2], Maria Yazdanbakhsh[2]

[1]*LUMC/CERMEL, Leiden, Netherlands,* [2]*Leiden University Medical Center, Leiden, Netherlands,* [3]*Eberhard Karls University Of Tuebingen, Tuebingen, Germany,* [4]*Sanaria, Inc., Rockville, MD, United States,* [5]*Centre De Recherches Medicales De Lambarene, Lambarene, Gabon*

Immunity against malaria infection is being studied extensively but the underlying mechanisms of protection are not fully understood. Metabolomics is a post-genomic technology enabling a minimally invasive monitoring of the physiological responses to external and internal stimuli. Here, we present a longitudinal study of the urinary metabolic profiles of healthy individuals before and after intravenous administration of *Plasmodium falciparum* sporozoïtes, aiming at deciphering the metabolic changes observed during the course of malaria infection. Twenty healthy malaria-exposed Gabonese and 5 malaria-naïve Europeans were voluntary challenged with live *P. falciparum* sporozoïtes and followed up until they developed symptoms (Gabonese) and became thick blood smear positive (Europeans). Urine samples was collected before and after challenge at several times points until treatment. Samples were analysed in an untargeted approach using hydrophilic interaction chromatography-mass spectrometry (HILIC-MS). A combination of the univariate and multivariate data analysis approaches was used for dissecting the metabolic effects of a host response to the infection. Data analysis showed a clear difference in metabolomic profile between malaria-naïve and malaria-exposed subjects at baseline. Overall, 8 most important metabolites discriminate before and after the challenge and between parasitemic and non-parasitemic malaria-exposed Gabonese. One particular metabolite, glutamine conjugate phenylacetylglutamine, significantly distinguished malaria-exposed individuals who controlled their parasitemia even before the challenge from those who did not. This metabolomics study highlighted the changes in the urinary metabolite profiles related to *P. falciparum* challenge and identified potential urinary biomarkers of parasitemia.

246

INVESTIGATING A *PLASMODIUM FALCIPARUM* ERYTHROCYTE INVASION PHENOTYPE SWITCH AT THE WHOLE TRANSCRIPTOME LEVEL

Prince B. Nyarko

University of Ghana, Accra, Ghana

The central role that erythrocyte invasion plays in *Plasmodium falciparum* survival and reproduction makes this process an attractive target for therapeutic or vaccine development. However, multiple invasion-related genes with complementary and overlapping functions afford the parasite the plasticity to vary ligands used for invasion, leading to phenotypic variation and immune evasion. Overcoming the challenge posed by redundant ligands requires a deeper understanding of conditions that select for variant phenotypes and the molecular mediators. While host

factors including receptor heterogeneity and acquired immune responses may drive parasite phenotypic variation, we have previously shown that host-independent changes in invasion phenotype can be achieved by continuous culturing of the W2mef and Dd2 *P. falciparum* strains in moving suspension as opposed to static conditions. Here, we have used a highly biologically replicated whole transcriptome sequencing approach to identify the molecular signatures of variation associated with the phenotype switch. The data show increased expression of particular invasion-related genes in switched parasites, as well as a large number of genes encoding proteins that are either exported or form part of the export machinery. The genes with most markedly increased expression included members of the erythrocyte binding antigens (*eba*), reticulocyte binding homologues (*rh)*, surface-associated interspersed protein (*surfin)* gene families, exported protein family 1 (*epf1*) and the *Plasmodium* Helical Interspersed Sub-Telomeric (*phist*) gene family. The data indicate changes in expression of a repertoire of genes not previously associated with erythrocyte invasion phenotypes, suggesting the possibility that moving suspension culture may also select for other traits.

ENDOTHELIAL ACTIVATION IS ASSOCIATED WITH DISEASE SEVERITY ACUTE KIDNEY INJURY AND COGNITIVE IMPAIRMENT IN PEDIATRIC SEVERE MALARIA

Benson J. Ouma[1], John M. Ssenkusu[2], Estela Shabani[3], Dibyadyuti Datta[4], Robert O. Opoka[5], Richard Idro[5], Paul Bangirana[6], Gregory Park[4], Moses L. Joloba[1], Kevin C. Kain[7], Chandy C. John[4], Andrea L. Conroy[4]

[1]*Department of Medical Microbiology, College of Health Sciences, Makerere University, Kampala, Uganda,* [2]*Department of Epidemiology and Biostatistics, Makerere University School of Public Health, Kampala, Uganda,* [3]*Department of Pediatrics, University of Minnesota, Minneapolis, MN, United States,* [4]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,* [5]*Department of Paediatrics and Child Health, Makerere University College of Health Sciences, Kampala, Uganda,* [6]*Department of Psychiatry, College of Health Sciences, Makerere University, Kampala, Uganda,* [7]*Department of Medicine, University of Toronto and University Health Network, Toronto, ON, Canada*

Endothelial activation is associated with disease severity in severe malaria (SM), but the relationship between endothelial activation and long-term cognitive outcomes in children surviving SM are unknown. Ugandan children with SM and community children (CC) were prospectively enrolled from 2008-2013 in Kampala, Uganda. Children underwent neurocognitive evaluation at enrollment (CC) or hospital discharge (SM) and at 6, 12, and 24 months follow-up using validated tools. Endothelial activation was measured on admission samples by ELISA (von Willebrand factor (VWF), angiopoietin (Angpt)-1 and-2) or Luminex (sICAM-1, sVCAM-1, sE-Selectin, P-Selectin). False discovery rate was used to adjust for multiple comparisons. SM was associated with widespread endothelial activation compared to CC (p&it0.0001 for all). Using multiple regression analyses to evaluate the relationship between severe malaria complications and endothelial activation, acute kidney injury (AKI) was an independent predictor of changes in VWF, sICAM-1, sE-Selectin, P-Selectin, Angpt-2 (p&it0.0001 for all). Using linear mixed effects modelling, increases in $\log_{10}$ levels of Angpt-2 were associated with worse cognition independent of disease severity (presence of coma, number of seizures, AKI), and sociodemographic factors (adjusted p&it0.05). Angpt-2 levels were associated with increases in sequestered parasite biomass, acidosis (lactate), markers of hemolysis (LDH, total bilirubin), inflammation (TNFα, IL-10), increased CSF-to-plasma albumin index, and markers of neuroinflammation/injury (TNFα, kynurenic acid, Tau) in children with CM (adjusted p&it0.05 for all). These data support Angpt-2 as an important mediator of disease severity in malaria that is a risk factor for long-term cognitive injury.

A *PLASMODIUM FALCIPARUM* NF54 REPORTER LINE EXPRESSING MCHERRY-LUCIFERASE IN GAMETOCYTES, SPOROZOITES AND LIVER-STAGES

Catherin Y. Marin-Mogollon[1], Ahmed M. Salman[2], Karin M. Koolen[3], Judith M. Bolscher[3], Fiona J. van Pul[1], Shinya Miyazaki[1], Takashi Imai[4], Ahmad Syibli Othman[5], Jai Ramesar[1], Geert-Jan van Gemert[6], Hans Kroeze[1], Severine Chevalley-Maurel[1], Blandine Franke-Fayard[1], Robert W. Sauerwein[6], Adrian V. Hill[2], Koen J. Dechering[3], Chris J. Janse[1], Shahid M. Khan[1]

[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*The Jenner Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom,* [3]*TropIQ Health Sciences, Nijmegen, Netherlands,* [4]*Department of Infectious Diseases and Host Defense, Gunma University Graduate School of Medicine, Gunma, Japan,* [5]*Faculty of Health Sciences, Universiti Sultan Zainal Abidin, Terengganu, Malaysia,* [6]*Department of Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands*

Transgenic malaria parasites expressing fluorescent and bioluminescent proteins are valuable tools to interrogate malaria-parasite biology and to evaluate drugs and vaccines. Using CRISPR/Cas9 methodology a transgenic *Plasmodium falciparum* (Pf) NF54 line was generated that expresses a fusion of *mCherry* and *luciferase* genes under the control of the *Pf etramp10*.3 gene promoter (line mCherry-luc@etramp10.3). *Pf etramp10*.3 is related to rodent *Plasmodium uis4* and the *uis4* promoter has been used to drive high transgene expression in rodent parasite sporozoites and liver-stages. We examined transgene expression throughout the complete life cycle and compared this expression to transgenic lines expressing mCherry-luciferase and GFP-luciferase under control of the constitutive *gapdh* and *eef1a* promoters. The *mCherry-luc@etramp10.3* parasites express mCherry in gametocytes, sporozoites and liver-stages. While no mCherry signal was detected in asexual blood-stage parasites above background levels, luciferase expression was detected in asexual blood-stages, as well as in gametocytes, sporozoites and liver-stages, with the highest levels of reporter expression detected in stage III-V gametocytes and in sporozoites. The expression of mCherry and luciferase in gametocytes and sporozoites makes this transgenic parasite line suitable to use in *in vitro* assays that examine the effect of transmission blocking inhibitors and to analyse gametocyte and sporozoite biology.

CIRCULATING EXOSOMAL MICRORNAS LET-7I-5P AND MIR-451A LEVELS ARE DIFFERENTIALLY EXPRESSED IN SICKLE CELL TRAIT (HBAS), ANEMIA (HBSS) AND HBAA INDIVIDUALS

Keri Harp[1], Felix Botchway[2], Michael Wilson[3], Yvonne Dei-Adomakoh[2], Jonathan K. Stiles[1], Adel Driss[1]

[1]*Morehouse School of Medicine, Atlanta, GA, United States,* [2]*Korle-bu Teaching Hospital, Accra, Ghana,* [3]*Noguchi Memorial Institute for Medical Research, Accra, Ghana*

Sickle-cell disease (SCD) is a common genetic disorder in about 300,000 newborns globally each year and 50-80% will not survive to adulthood. The hemoglobin (Hb) allele variant S or C (HbS or HbC) causes sickle cell anemia when both alleles are inherited (HbSS or HbSC). Sickle cell trait (SCT) individuals carry one of the hemoglobin variants (HbAS or HbAC) and have been reported to have a reduced risk of developing severe malaria compared to HbAA controls. In 2017, there were 200-300 million cases and 435,000 malaria associated deaths mostly in Africa. Previous *in-vitro* studies determined that endogenous microRNAs (miRNAs), such as let-7i-5p, are differentially expressed in SCD erythrocytes compared to HbAA and were associated with reduced parasite proliferation. In this study, we tested the hypothesis that Hb genotypes govern susceptibility of erythrocytes to *Plasmodium* infection via exosomal let-7i-5p. Blood samples, with different Hb genotypes (HbAA, HbAS, HbAC, HbSS, HbSC, HbCC), with (+) and without (-) malaria, were collected from volunteers

in Accra, Ghana as part of NIH research projects (1K01TW010282, 1R01NS0916161 and 1R25TW009340). Exosomal let-7i-5p (using RT-qPCR), Complete Blood Counts (CBC) and other clinical data were compared between Hb genotypes with (+) or without (-) malaria. Exosomal let-7i-5p was significantly elevated in HbSS (-) compared to HbAA (-) and HbAS (-) individuals as well as HbAS (+) versus HbAS (-). In SCT (-) we found a correlation between exosomal let-7i-5p expression levels and some clinical characteristics. These results indicate that elevated levels of exosomal let-7i-5p in SCD and malaria mediate susceptibility to malaria and could be used as a predictive biomarker for severe malaria risk.

CEREBRAL MALARIA ASSOCIATED EXPRESSION OF NRG-1 IN HUMAN BRAIN

Juan Cespedes, Jonathan Stiles, Mingli Liu

Morehouse School of Medicine, Athens, GA, United States

Plasmodium falciparum malaria is associated with 500,000 deaths a year. Cerebral malaria (HCM) is a neurological manifestation of infection by *P. falciparum* and accounts for the majority of malaria associated deaths. CM is associated with increased expression of adhesion molecules, vascular endothelial dysfunction, sequestration of infected red blood cells, cerebral edema and disruption of blood brain barrier (BBB) integrity. Neuregulin-1 (NRG-1), a neurotrophic growth factor has been shown to attenuate several brain injuries caused by neurotoxin exposure, acute ischemic stroke, and most recently HCM. NRG-1 is mainly expressed in neurons, Schwann cells of the nervous system in humans and mice, human cornea epithelial and stroma cells, and in human/mouse vascular endothelial cells and cardiomyocytes. Previous assessments of circulating NRG-1 in serum of survivors and non-survivors of cerebral malaria indicated a significant decline in NRG-1 concentration compared to that in mild malaria. It was unclear whether this decline was a result of HCM induced inhibition or sequestration of NRG-1 at injury sites in brain. In this study, we assessed distribution of NRG-1 expression in post-mortem human brain tissues of individuals who died of HCM and compared results with those who died of non-malaria causes. Our hypothesis is that in HCM, NRG-1 expression is significantly increased in injured brain areas matching severity and mortality while its receptor phosphorylated ErbB4 (pErbB4) is decreased. Previous post mortem studies conducted in Ghana, yielded archived paraffin-embedded sections of brain tissues from cortex, cerebellum and brain stem. These samples were analyzed quantitatively for immunoreactive signals of NRG-1 and perbB4 antibody. Results indicate that NRG-1 expression levels in neurons and blood vessels increased significantly in HCM postmortem tissues compared to patients who died of non-malaria causes ($p<0.05$) suggesting that the observed depletion of circulating serum NRG-1 in severe disease may be due to sequestration of NRG-1 brain parenchyma. pErbB4 expression levels significantly decreased in brainstem neuronal cells

251

CENTRAL NERVOUS SYSTEM VIRUS INFECTION IN AFRICAN CHILDREN WITH CEREBRAL MALARIA

Douglas G. Postels[1], Lawrence Osei-Tutu[2], Karl B. Seydel[3], Qian Xu[3], Chenxi Li[3], Terrie E. Taylor[3], Chandy C. John[4], Macpherson Mallewa[5], Tom Solomon[6], Robert Opoka[7], Tsiri Agbenyega[8], Daniel Ansong[2], Lillian M. Khan[9], Kristoffer E. Leon[9], Joseph DeRisi[9], Charles Langelier[9], Michael R. Wilson[9]

[1]*Children's National Medical Center, Washington, DC, United States,* [2]*Komfo Anokye Teaching Hospital, Kumasi, Ghana,* [3]*Michigan State University, East Lansing, MI, United States,* [4]*Indiana University, Indianapolis, IN, United States,* [5]*University of Malawi, Blantyre, Malawi,* [6]*University of Liverpool, Liverpool, United Kingdom,* [7]*Makerere University, Kampala, Uganda,* [8]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [9]*University of California, San Francisco, CA, United States*

Cerebral malaria (CM) is defined as an otherwise unexplained coma with malaria parasitemia. The condition predominantly affects African children and presents with coma, fever, and seizures. Two-thirds of African children with clinical CM have a malaria specific retinopathy. Based on autopsy studies, children with retinopathy-positive CM have a malaria infection exclusively responsible for their illness. Children dying of retinopathy-negative CM have non-malarial etiology of deaths. Children with retinopathy-negative CM were hypothesized to have a non-malarial etiology of acute illness coupled with asymptomatic malaria parasitemia, the latter reflecting residence in an area of high transmission intensity. As children with viral encephalitis have a similar phenotype to those with CM, our goal was to identify the contribution of central nervous system (CNS) viral infection to illness in children with retinopathy-negative CM. We collected cerebrospinal fluid (CSF) from 272 Ghanian, Ugandan, and Malawian children with CM, and selected CSF from 111 of these children (38 retinopathy-positive, 71 retinopathy-negative, 2 retinopathy-unknown) for analysis by metagenomic next-generation sequencing (mNGS). We found CSF viral co-infections in 7/38 (18.4%) retinopathy-positive children and in 18/71 (25.4%) retinopathy-negatives. Excluding HIV-1, human herpesviruses (HHV) represented 75% of viruses identified. CNS viral co-infection was equally likely in children who were retinopathy-positive and retinopathy-negative ($p= 0.1431$). Neither mortality nor neurological morbidity was associated with the presence of virus (OR=0.276, 95% CI: 0.056-1.363). Retinopathy-negative children with higher temperature, lower white blood cell count, or being dehydrated were more likely to have viral co-infection. Level of consciousness at admission was not associated with CNS viral co-infection in retinopathy-negative children. Viral CNS co-infection is unlikely to contribute to coma in children with CM. The herpesviruses other than HSV may represent incidental bystanders in CM, reactivating during acute malaria infection.

GLYCOSYLATION OF *PLASMODIUM FALCIPARUM* THROMBOSPONDIN REPEATS DRIVES MOSQUITO TRANSMISSION AND SPOROZOITE VIRULENCE

Sash Lopaticki[1], Charlie Jennison[1], Nichollas Scott[2], Alan John[1], Annie Yang[1], Matthew O'Neill[1], Norman Kneteman[3], Ethan Goddard-Borger[1], **Justin Boddey**[1]

[1]*Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia,* [2]*University of Melbourne, Melbourne, Australia,* [3]*University of Alberta, Edmonton, AB, Canada*

Apicomplexans are the only known unicellular organisms that express proteins bearing thrombospondin repeats (TSRs), ancient protein modules that are stabilized by O- and C-glycosylation in metazoans. However, other than the installation of GPI anchors, it was long believed that malaria parasites do not glycosylate their proteins. Recently, the presence of O- and C-glycosylation was identified on the TSRs of CSP and TRAP in *Plasmodium falciparum* and *P. vivax* sporozoites, which was a major advance for studying the glycobiology of malaria parasites and for vaccine design. We subsequently showed through genetic disruption of the O-glycosylation pathway in *P. falciparum* that this modification functionally stabilizes virulence proteins during infection of the mosquito midgut epithelium and human hepatocytes in humanized mice. However, the roles and glycosylation states of most parasite TSR proteins remain unknown, as does the function of C-glycosylation in the malaria lifecycle. Of the different types of protein glycosylation, C-glycosylation is unique because of the unusual C-C linkage formed between sugar (mannose) and target protein (tryptophan). Here, we identify new substrates that are O- and C-glycosylated in *P. falciparum* and demonstrate the functional importance of these modifications for sexual development, transmission to mosquitoes and virulence of sporozoites in humanized mice. By genetically disrupting the C-glycosylation pathway, we reveal hitherto unknown essential roles of tryptophan-mannosylation in the *P. falciparum* lifecycle. Our study shows that O- and C-glycosylation of TSR proteins comprises a protein quality control mechanism that has evolved to drive parasite-host interactions necessary for transmission and virulence of *P. falciparum*, the etiological agent of the most lethal malaria.

STUDY OF ANTI-MALARIAL DRUG RESISTANCE USING THE MUSE® RBC INVASION ASSAY

Kimvan Tran, **Kamala Tyagarajan**

Luminex Corporation, Hayward, CA, United States

The increasing resistance of malaria parasites to common anti-malarial drugs is a major concern for controlling the disease. The evolution of rapid, simple methods that can be used in diverse environments can help facilitate the discovery of new anti-malarial drugs. Current approaches include DNA-binding dyes and fluorometric approaches that result in loss of intact and parasitized cells. Flow cytometry can provide information on the percentage of parasitized cells; however, the cost and complexity of current instrumentation has been prohibitive for use in many environments. We have developed the research use only Muse® RBC Invasion Assay on the easy to use, low-cost Muse Cell Analyzer. The assay allows for the determination of the percentage of the RBCs invaded by *Plasmodium* parasites. The assay has been used for routine monitoring of RBCs infected by different *Plasmodium falciparum* strains, such as 3D7, D10, and Dd2 strains, as well as *in vitro* drug susceptibility studies. In this study, the *in vitro* impact of anti-malarial drugs on different *Plasmodium falciparum* strains was studied using the Muse RBC Invasion Assay. In particular, we looked at the dose response of chloroquinine and mefloquinine on 3D7 and Dd2 strains, and the impact on invaded RBC percentages. The IC50 for chloroquinine was 18.8 nM for 3D7 and 104 nM for Dd2 strains in this study, while mefloquine had IC50's in similar ranges for both strains. Our results demonstrate that the 3D7 strain showed susceptibility to chloroquine at low doses, while the Dd2 strain was resistant and only showed response at higher drug concentrations. Additional studies should help characterize the impact of more recent artemisinin drugs such as dihydroarteminisin on both strains. The studies performed demonstrate the importance of performing *in vitro* screening of antimalarial drugs on multiple strains, in order to truly characterize their action and utility. The Muse RBC Invasion Assay can be a useful and accessible method to characterize the *in vitro* impact of anti-malarial drugs, and can be a powerful drug discovery and development tool for malarial researchers.

ARTEMISININ RESISTANCE MARKER OF *PLASMODIUM FALCIPARUM* IN OSOGBO METROPOLIS, SOUTH WEST, NIGERIA

Sulaiman Adebayo Nassar

Ladoke Akintola University of Technology, Ogbomoso, Nigeria

Artemisinin derivatives constitute a key component of the present-day treatment for *plasmodiumfalciparum* malaria and rsesistance with artemisinins is generally associated with S769N point mutation in the sarco-endoplasmic reticulum-dependant ATPase6 (SERCA ATPase6) gene of *Plasmodium falciparum*. However, few studies have been carried on the current level baseline and level of mutation of this drug in Nigeria most especially in Osun State. The present study determined the distribution of *plasmodiumfalciparum* and resistance marker for artmisinins drugs from the blood smears of 60 randomly sampled patients attending LAUTECH Teaching Hospital , Osogbo ,Osun state after obtaining ethical clearance from the relevant authority.The entire study period was divided into Pre-Treatment ,drug administration and post -Treatment phases .Blood smears of 70 consented participants were assessed microscopically using Giemsa ststaining technique for parasite identification and parasitaemia.. Samples found to have parasitaemia after drug administration were amplified and assessed for distribution of the *Pf*ATPase6 S769N mutation using Polymerase Chain Reaction (PCR) . 28 out of 30 samples subjected to PCR had successful amplification. However, none of the amplified samples harboured the *Pf*ATPase6 S769N mutation, suggesting 100% sensitivity of P. Falciparum population examined at the study area. There is therefore need for continuous surveillance for earlier detection of resistance as the use of ACT isbeing scaled up in the country.

255

SELECTION OF *PLASMODIUM FALCIPARUM* DRUG RESISTANCE MARKERS POST-ACT INTRODUCTION AND A NEARLY COMPLETE REVERSION TO CHLOROQUINE SENSITIVITY

Kevin Wamae[1], Dorcas Okanda[1], Leonard Ndwiga[1], Victor Osoti[1], Kelvin Muteru[1], Abdirahman Abdi[2], Philip Bejon[3], Colin Sutherland[4], Lynette I. Ochola-Oyier[2]

[1]*KEMRI-Wellcome Trust Research Programme, CGMRC, Kilifi, Kenya,* [2]*KEMRI-Wellcome Trust Research Programme, CGMRC/Pwani University Bioscience Research Centre, Pwani University, Kilifi, Kenya,* [3]*KEMRI-Wellcome Trust Research Programme, CGMRC/Nuffield Department of Medicine, Centre for Clinical Vaccinology and Tropical Medicine, Churchill Hospital, University of Oxford, United Kingdom, Kilifi, Kenya,* [4]*Department of Immunology and Infection, Faculty of Infectious Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom/PHE Malaria Reference Laboratory, London School of Hygiene & Tropical Medicine, London, United Kingdom, Kilifi, Kenya*

The emergence and spread of artemisinin resistance in South East Asia are of great concern as drug resistance renders drugs ineffective in the fight against malaria. Additionally, resistance to previous first-line treatments, including chloroquine (CQ) and sulfadoxine-pyrimethamine (SP), was imported to Africa from South East Asia. Genetic markers of resistance are important molecular epidemiological tools used for early detection and monitoring of the spread of drug-resistant parasites. We carried out a temporal analysis of changes in allele frequencies of 8 drug resistance markers and 4 putative artemisinin resistance background markers over two decades of changing anti-malarial drug policy in Kenya. Using the *crt*-76 and *mdr1*-86 and *mdr1*-1246 molecular markers, we found that the withdrawal of CQ and SP as first-line treatment in Kenya shifted the parasite population from CQ resistant to a nearly fixed (99%) CQ sensitive population. On the other hand, *dhps* mutations associated with SP resistance (A437G and K540E) were maintained at a high frequency (greater than 75%). Something that may be attributable to the fact that SP is still readily available in Kenya, with a recent survey reporting a market share of 57% in the private sector. We did not detect any of the artemisinin resistance markers nor the background mutations that precede artemisinin resistance except mdr2 I492V mutation. However, we show a gradual decline in the novel *nfs* (K65 allele) marker, which potentially confers resistance to lumefantrine, from 38% to 20% with a significant allele frequency difference pre- and post-ACT introduction. In summary, the high frequency of CQ sensitive parasites circulating in the population supports the on-going debate on re-introduction of chloroquine for the treatment of malaria and the impact of the decreasing frequency of *nfs* (K65 allele) on the efficacy of Artemether-Lumefantrine combination warrants close monitoring.

256

INFLUENCE OF OXYGEN AND CARBON DIOXIDE ON *PLASMODIUM FALCIPARUM IN VITRO* RESISTANCE TO ARTEMISININ

Sandra Duffy, Vicky M. Avery

Griffith University, Brisbane, Australia

With the goal of malaria eradication firmly on the table, several aspects are undermining this, including the resurgence of malaria cases in some malaria endemic countries and artemisinin combination therapy (ACT) failure within the greater Mekong subregion of Asia. *Plasmodium falciparum* (*Pf*) ACT resistance presents as a slow parasite clearance time (> 5 hours) *in vivo* and *in vitro* greater than 1% survival of early ring stage parasites, 0-3 hours post red blood cell invasion, after a 6-hour dose of 700nM of artemisinin derivative (ART). Both these phenotypes are correlated to mutations within the *Pf*K13 propeller domain, but not exclusively as some genetic predisposition is proposed to pre-empt the K13 mutation acquisition. The *in vitro* acquisition of K13 mutations through escalating ART challenge has only resulted from one study where O_2 levels

throughout incubation were 21% in comparison to 1-5% in other studies. Routinely the *in vitro* culture of *Pf* utilizes a single gaseous environment that is constant and maintained at, for example, 5% O_2 and 5% CO_2. However, *in vivo* the gaseous microenvironment has a diverse range of concentrations and ratios of O_2 and CO_2 depending on the location within the circulatory system and the presence of certain pathologies. To study the impact of alterations in the gaseous environment on parasite susceptibility to ART, the ring stage survival assay (RSA) was performed on *Pf* parasites, designated resistant or sensitive (K13 mutant or WT), cultured under different O_2 and CO_2 concentrations. To advance knowledge on the effect changing gaseous environments has on ART sensitivity and resistance at different stages of *Pf* asexual lifecycle, the RSA was also performed at a range of O_2 and CO_2 concentrations at selected times post red blood cell invasion. The effects of gaseous environments on parasite *in vitro* resistance and susceptibility profiles, relationship to K13 mutations, and biological evaluation of the underlaying mechanisms behind the altered responses will be discussed.

257

PREVALENCE OF ANTIMALARIAL DRUG RESISTANT MARKERS IN KWARA, NORTH-CENTRAL, NIGERIA: A DECADE AFTER REPLACEMENT OF CHLOROQUINE AND ANTIFOLATES AS FIRST-LINE REGIMEN

Olugbenga Akinola[1], Daniel E. Egboro[2], Ese Iyenmoana[2], Bukola F. Abdulkadir[2], Yusuf O. Yakub[2], Abimbola A. Adeosun[2], Hidayah A. Olumo-Abdul[3], Chairat Utaipibull[1], Olusola G. Gbotosho[4]

[1]*National Center for Genetic Engineering and Biotechnology (BIOTEC), Khlong Luang, Pathum thani, Thailand,* [2]*Department of Pharmacology and Therapeutics, University of Ilorin, Ilorin, Kwara State, Nigeria,* [3]*Department of Pharmacology and Toxicology, University of Ilorin, Ilorin, Kwara State, Nigeria,* [4]*Department of Pharmacology and Toxicology, University of Ibadan, Ibadan, Oyo State, Nigeria*

The emergence of "super malaria" parasites, resistant to artemisinins based combinations (ACT), portend danger to malaria control efforts. While measures to curtail the spread must be addressed, preparedness, also becomes necessary. One premonition is to evaluate background status of parasites resistant to previously used drugs, especially as artemisinin resistance selects for sensitive alleles of chloroquine resistant markers. This study was designed to establish the current profile of *Plasmodium falciparum* resistant markers of chloroquine (*Pfcrt*), pyrimethamine (*Pfdhfr*) and *Pfmdr1* in field isolates. In a cross sectional survey, 305 participants were enrolled from four communities in Kwara state, Nigeria. Participants were randomly tested for malaria infections, using rapid diagnostic detection. Parasite densities were determined from thick blood smears by microscopy. Dried blood spots samples were collected on Whatman FTA cards, from which parasite genomic DNA was extracted. Polymerase chain reaction (PCR) and restriction fragment length polymorphism were conducted on genomic samples. The prevalence of *P. falciparum* infections by microscopy was 22.30% (68/305), with a PCR corrected value of 23.28% (71/305). *P. falciparum* chloroquine resistant transporter (*Pfcrt*) mutation (K76T) was predominantly significant ($p<0.05$) in all positive samples (100%), compared to 56% and 38%, for dihydrofolate reductase (*Pfdhfr*) primary point mutation (S108N) and the *P. falciparum* multidrug resistant gene (*Pfmdr1*) mutation (86Y), respectively. Background detection of *Pfcrt* wild-type K76 was recorded in 41% (29/71) of the positive samples. More than ten years after withdrawal of chloroquine (CQ) and PYR from first-line treatment of malaria in the region, there is still a strong presence of resistant markers to these drugs in *P. falciparum* isolates. However, the presence of CQ sensitive strains in mixed population with resistant cousins may suggest development of reversal processes by parasites probably due to fitness cost in the absence of chloroquine and/ or evolving mechanisms towards artemisinin resistance due to ACT pressure.

258

IDENTIFYING MOLECULAR MARKERS OF *PLASMODIUM FALCIPARUM* ARTEMISININ RESISTANCE USING THE CRISPR-CAS9 GENOME EDITING SYSTEM

Oheneba Charles Hagan

University of Ghana, Accra, Ghana

The emergence and spread of *P. falciparum* to artemisinin and the artemisinin combination therapy partner drugs threatens to upend the gains made by the control program in recent times especially in Africa. With hindsight from the devastation chloroquine and sulphadoxine-pyrimethamine resistance wreaked in Africa due to an unprepared public health system, real time monitoring of resistance has therefore been recommended in other to forestall any similar occurrence. Monitoring of the molecular markers of resistance is less logistically and financially constraining compared with *in vivo* and *in vitro* monitoring especially in resource limited setting. However, the kelch 13 molecular markers for monitoring artemisinin resistance have arisen independently, with multiple mutations either conferring resistance or otherwise. Gene-editing system has previously been utilised to validate some of these mutations, we therefore undertook to use the CRISPR-Cas9 genome editing system validate kelch 13 mutations detected from recrudescing parasites sampled from the monitoring sentinel sites in Ghana. We have successfully edited kelch 13 V568G and C580R previously detected in Ghana in addition to C580Y and R539T commonly found in Southeast Asia and C580C (silent mutation) into Dd2 *P. falciparum* strain. We utilised a single plasmid system carrying a chimeric short-guide RNA, a codon-optimised Cas9 sequence and a donor DNA.Cloning by limiting dilution method has been used to clone out isogenic parasites, which would be utilised to perform ring stage survival assay to validate these mutations. In addition, conventional SYBR green drug assays of commonly used antimalarial, fitness and growth assays.

259

THERAPEUTIC RESPONSE OF SINGLE *PLASMODIUM FALCIPARUM* SPECIES VERSUS MIXED SPECIES INFECTIONS TO ARTEMETHER-LUMEFANTRINE AS COMPARED TO OTHER ARTEMISININ COMBINATION THERAPIES IN KISUMU COUNTY, WESTERN KENYA

Gladys C. Chemwor[1], Hoseah M. Akala[1], Benjamin H. Opot[1], Raphael O. Okoth[1], Redemptah M. Yedah[1], Agnes C. Cheruiyot[1], Irene Onyango[1], Dennis W. Juma[1], Ben Andagalu[1], Jim R. Managbanag[2]

[1]*Department of Emerging Infectious Diseases (DEID), United States Army Medical Research Directorate-Kenya (USAMRD-K), Kenya Medical Research Institute (KEMRI), Kisumu, Kenya,* [2]*United States Army Medical Research Directorate-Kenya, Kisumu, Kenya*

Information on treatment outcomes of infections comprising non-*falciparum* species is scanty despite it being reported to be responsible for around 25% of imported malaria from Africa. The recommended first line treatment in Africa is artemether-lumefantrine (AL) with dihyroartemisinin-piperaquine (DHAPPQ) as second line whereas in Asia, artesunate-mefloquine (ASMQ) is the preferred choice of treatment. The aim of this study was to compare the treatment outcomes of mixed *Plasmodium* species versus pure *falciparum* species infections during dosing with AL, DHAPPQ & ASMQ. Samples collected at hours 0, 4, 8, 24 and 30 from individuals enrolled in an ACT efficacy study in Kisumu County, Western Kenya, between 2013 and 2015 were analyzed for species composition using real time polymerase chain reaction (rt-PCR). The assay targeted detection of *Plasmodium falciparum* (*Pf*), *Plasmodium malariae* (*Pm*), *Plasmodium ovale curtisi* (*Poc*) and *Plasmodium ovale wallikeri* (*Pow*). Therapeutic response was evaluated using parasite clearance parameters as well using the World Health Organization criteria and compared with species composition of each infection. Recurrent parasitemia for the subsequent time points specifically hours 24 and 30 was also characterized to rule out re-infection. There was a steady decline in parasites for

infections comprising *Pf* species alone following administration of AL and ASMQ as opposed to those comprising *Pf* and other species. *Pow* frequency persisted in the subjects treated with AL in all the time points with an increase at hour 8 whereas for ASMQ, it appeared at hour four and eight then cleared completely. *Pm* seems to have been cleared early at hours 4 and 8 for AL and ASMQ respectively. Data analysis for DHAPPQ is in progress. Obtaining more information and continued monitoring of non-*falciparum* malaria during implementation of ACTs is therefore warranted to advise clinical intervention and align them to solving challenges of increasing traveler malaria.

260

SELECTIVE IMPACT OF ARTESUNATE-AMODIAQUINE AND ARTEMETHER-LUMEFANTRINE THERAPIES ON THE POLYMORPHISM OF *PFCRT* K76T, *K13 PROPELLER* AND *PFMDR1* (CODONS 86 AND 184) GENES IN THREE MALARIA SENTINEL SITES IN CÔTE D'IVOIRE

Abibatou Konate, Paterne Akpa Gnagne, Valerie A. Bedia, Herve Menan, William Yavo

Felix Houphouet boigny University, Abidjan, Côte D'Ivoire

Plasmodium falciparum resistance to most of antimalarial drugs including the more recent is a concern to malaria elimination. Despite their adoption for the treatment of uncomplicated malaria in Côte d'Ivoire, there is few information regarding the selective impact of *artemisinin-based combination therapies* (ACTs) on *Plasmodium falciparum* strains circulating in the country. The present study aimed to assess *pfcrt* K76T, *K13 propeller* and *Pfmdr1* (codons 86 and 184) mutations before and after treatment with artesunate-amodiaquine (ASAQ) or artemether-lumefantrine (AL) in three sentinel site for malaria monitoring in Côte d'Ivoire. *P. falciparum* infected samples were collected in 2013,2014 in Abidjan and 2016 in Abengourou and San Pedro through routine monitoring of antimalarial drug's efficacy. Only patients with treatment response were included in this study. Samples collection concerned Day 0 before treatment and the day of recurrent parasitaemia during the 42-day follow-up. The single nucleotide polymorphism in the *pfcrt* (codon 76) gene was analyzed PCR-RFLP after *Plasmodium* DNA extraction while *K13 propeller* and *Pfmdr1* genes were analyzed by sequencing. Overall 340 samples were genotyped i.e. 322 from D0 and 18 at follow-up day. No recrudescence was observed in ASAQ arm. For *Pfcrt* K76T, a selection of mutant strains by both therapies was found. The analysis of *Pfmdr1* gene showed a selection of mutant strains *Pfmdr1* 86Y (11.1%) and *Pfmdr1* 184F (66.7%) in case of new infestation after ASAQ treatment. After treatment with AL, in case of recrudescence, the wild-type strains of *Pfmdr1* N86 (100%) and Y184 (42.9%) were selected. This trend was the same in case of new infestation. As regards the *K13 propeller* gene, no mutation was found after treatment by ASAQ as well as AL. This study shows an antagonism in the selection of strains by ASAQ and AL associations. This demonstrates the benefit of the use of several antimalarial drugs as first-line treatments which could lead to the delay the apparition of chemoresistance.

261

EVALUATING THE ANTIMALARIAL ACTIVITY OF GOSSYPOL, A NATURAL PRODUCT AGAINST *PLASMODIUM FALCIPARUM*

Jersley Didewurah Chirawurah, Yaw Aniweh, Gordon A. Awandare

West African Center for Cell Biology of Infectious Pathogens and Department of Biochemistry, Cell and Molecular Biology, University of Ghana, Legon, Accra, Ghana

Gossypol is a natural product from cotton seeds that has been shown to have good antimalarial activities against both chloroquine resistant and susceptible *Plasmodium falciparum* parasite strains. However, the target and mechanisms of action of this compound have not been clearly demonstrated. This study first evaluated the potency of gossypol using laboratory strains and clinical isolates of *Plasmodium falciparum* parasites. This was followed by the selection of resistant parasites against gossypol for studying the mechanisms of resistance to this compound. The gossypol resistant parasites (*P. falciparum* Dd2 background) were subsequently screened against Chloroquine, Dihydroartemisinin (DHA) and three Malaria Box compounds (MMV006087, MMV085203 and MMV008956). A total of six (6) laboratory strains and eight (8) clinical isolates of *P. falciparum* were screened against gossypol using optimized growth inhibitory assays. Additionally, gossypol resistant Dd2 strains were selected (using media containing 3.5 μM gossypol) and screened against Chloroquine, DHA and the three Malaria Box compounds.The results from this study suggest gossypol was more efficacious against the clinical isolates (IC_{50} value of 5.108 μM) compared to the laboratory strains (IC_{50} value of 6.1135 μM). Interestingly, the gossypol resistant Dd2 parasites were observed to be more sensitive after three months (IC_{50} value changed from 5.049 μM to 2.599 μM) and then resistant after six months (IC_{50} value changed from 2.599 μM to 14.94 μM). The gossypol resistant Dd2 parasites were also observed to be more sensitive to chloroquine, DHA and the three Malaria Box compounds compared to their parental strains.The results from this study suggest gossypol might possess an interesting mechanism of action and potentially new targets. Further experiments are currently underway to determine the mechanisms modulating the sensitivity in the gossypol resistant Dd2 strains. This work will be instrumental in identifying novel targets in *P. falciparum* parasites, which is critical for the discovery of novel antimalarial compounds against drug resistant malaria parasites.

262

GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* PARASITES IN PREGNANT AND NON-PREGNANT WOMEN AND POTENTIAL RESISTANCE TO ANTIMALARIAL DRUGS IN KENYA

Brenda Makena Mugambi

US Army Medical Research Directorate Africa-Kenya, Kisumu, Kenya

Malaria infection during pregnancy has detrimental effects owing to decreased immunity to malaria. In high transmission regions most individuals are presumed malaria-immune; non-pregnant women have been shown to have faster parasite clearance compared to pregnant ones. This suggests non-immune environment in pregnant women may select for parasite populations associated with resistance to artemisinin. This study will determine genetic variations in *Plasmodium falciparum* parasites in pregnant versus non-pregnant women. Blood samples were collected at hours 0, 8, 24 and days 7 and 28 from 75 malaria positive women; 25 pregnant in second trimester (arm1), 25 pregnant in third trimester (arm2) and 25 non-pregnant (arm3); enrolled in an artemisinin combination therapy efficacy study in Ahero, Kenya. All samples were diagnosed for malaria using 18s rRNA rtPCR. Genotyping for both merozoite surface proteins 1 and 2 was done to determine recrudescence and reinfection. Single nucleotide polymorphisms (SNP) genotyping for K13, *Pfmdr1, Pfdhfr, Pfdhps* and *Pfcrt* genes was done to determine mutations in parasites with varying clearance using Sanger sequencing and MassARRAY. Additionally, microsatellite genotyping using 12 markers was performed to determine genetic variations in parasites between the two populations. Of the 75 women; 45 consisting n=15 arm 1, n=12 arm 2 and n=18 arm 3 had samples at all study time points merited to be included in the analysis. The 45 individuals comprised: Hr 0=100.0%; Hr 8=84.4%; Hr 24=26.7%; Day 7=24.4% and Day 28=4.4% samples positive for *Plasmodium*. *P. falciparum* species were observed in: Hr 0=44.4%; Hr 8=44.7%; Hr 24=8.3%; Day 7=0% and Day 28=0% samples. Samples positive for *Plasmodium* on days 7 and 28 were confirmed as reinfections based on MSP genotyping. A total of 225 samples including all subsequent positives have proceeded to MassARRAY, Sanger sequencing and microsatellites genotyping. Findings of this study will present genotypic properties of malaria parasites in pregnant and non-pregnant women and advise on expression of genes associated with resistance to artemisinin among the three arms.

DRUG USE IN THE MANAGEMENT OF SEVERE MALARIA IN PUBLIC HEALTH FACILITIES IN DEMOCRATIC REPUBLIC OF CONGO

Aline Biongo Engo, Nsengi Ntamabyaliro, Didier Bomene Nzolo, Yves Ntamba Lula, Gaston Lutete Tona

Clinical Pharmacology Unit, Kinshasa, Democratic Republic of the Congo

Democratic Republic of the Congo (DRC) is the second most affected country by malaria deaths. National Policy recommends the usage of Injectable artesunate or quinine for the management of severe malaria. These drugs, especially injectable artesunate have shown to be effective and safe. The increased number of deaths in DRC may be due to many factors, including irrational use of drugs. The study was conducted in all previous eleven provinces of DRC in 2014. One Referral hospital one Urban Health Centre and one Rural Health Centers were selected in each of the Provinces. In each of the Health Facilities, 100 randomly selected medical files containing the prescription of an antimalarial drug from January to December 2013 were reviewed. For each file, the following variables were recorded: age of patient, diagnosis of malaria (clinical and parasitological), treatment and issues of treatment. Descriptive analysis were performed. Out of the 3254 files collected, 531(16, 2%) concerned complicated malaria. Children under five year of age represented 52.7% of patients affected by severe malaria. Parasitological confirmation of diagnosis have been made by thick smear in 228 patients (43%) and Rapid diagnostic tests (RDTs) in 126(24 %). Treatment of positive parasitology in 51, 4%, treatment despite negative parasitology in 12, 2%. Quinine was used in 465 patients (87, 6 %) but was never associated with Doxycycline or Clindamycin as recommended by National Malaria Program. Apart from antimalarials, patients received an average of 3.9 other drugs among which antibiotics (73.2%), antalgics (48.6%), anemia drugs (22.8%) and corticosteroids (16.8%). Seventy-four patient (14%) patients received blood transfusion. After treatment, 168(3, 6%) patient were cured and 3, 4% died; the issue was not known for 63, 8%. Deaths rates seems to be higher in patient concomitantly treated with corticosteroids (9, 4%) (p=0, 000815) Treatment of malaria is not complete in almost all cases. Numerous concomitant medications are added. There are significantly more deaths in patients treated by corticosteroids. Determinants of this irrational use need to be assessed.

264

PATIENTS' ADHERENCE TO MALARIA TREATMENT IN DEMOCRATIC REPUBLIC OF THE CONGO

Pierre-Michel Nsengi Ntamabyaliro[1], Didier B. Nzolo[1], Aline B. Engo[1], Yves N. Lula[1], Samuel M. Mampunza[1], Eric S. Mukomena[2], Gaston Lutete Tona[1]

[1]*Clinical Pharmacology Unit, Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [2]*National Malaria Program, Kinshasa, Democratic Republic of the Congo*

Irrational use of antimalarials in Health facilities is probably hampering the fight against malaria in the Democratic Republic of the Congo (DRC) as shown by a survey conducted in 2014. However, the use of these drugs by the community the adherence of patients to treatment need to be assessed as well in order to have a better picture of the use of antimalarials in DRC. A survey was conducted in December 2017 in all the 11 previous provinces of DRC. In each of them the catchment area of one Rural and one Urban health center were selected. In the selected area, all the household which had had a case of malaria in the 15 days before the survey were selected and the patient or the caring person were interviewed. For all antimalarial that had been prescribed the adherence (considered as non-interruption of treatment before its end) and reasons for treatment interruption were recorded. A total of 1987 households were interviewed. Patients received an average of 3.1 drugs among which the drugs recommended by the National Malaria Control program, Artesunate/amodiaquine (ASAQ), artemether/Lumefantrine (AL) and Quinine were the most cited. Treatment with Quinine was interrupted in 33% of cases (259/790), ASAQ in 16.1% (106/658) and AL in 5.9% (15/255). Reasons for interruption of quinine and ASAQ were most of the time adverse events (51.9% and 60.0% respectively). Adherence to Quinine and ASAQ are low. Adverse events are the major cause of interruption of treatment for the drugs used in the management of malaria especially Quinine and ASAQ. The impact of this in this need to be monitored. Management of adverse events need to be considered at the initiation of antimalarial treatment.

INCREASED GLUTATHIONE PRODUCTION CONTRIBUTES TO THE MECHANISM OF ARTEMISININ RESISTANCE IN *KELCH13*-MUTANT *PLASMODIUM FALCIPARUM*

Darren J. Creek, Amanda De Paoli, Ghizal Siddiqui

Monash University, Parkville, Melbourne, Australia

Artemisinin and its derivatives (ARTs) underpin the most effective treatments for uncomplicated *Plasmodium falciparum* malaria. However, resistance to ARTs is becoming increasingly prevalent and the cellular mechanism of resistance requires further elucidation. Untargeted metabolomics and peptidomics analysis of *PfKelch13*-mutant *P. falciparum* revealed a down-regulation of haemoglobin digestion, and an increased abundance of key antioxidant molecules such as glutathione (GSH) and its precursor gamma-glutamyl cysteine in ART-resistant parasites. We propose that these differences enhance the ability of ART-resistant parasites to ameliorate ART-induced free radical damage, as glutathione conjugation has been shown to function as a detoxification mechanism for many drugs that act via the generation of reactive intermediates. This study further investigated the role of glutathione in *PfKelch13*-mediated ART resistance in *P. falciparum* parasites using metabolomics, and tested whether inhibition of this detoxification system can be a strategy for modulation of resistance to ART. ART-resistant isolates were incubated with buthionine sulphoximine (a gamma-glutamylcysteine synthetase inhibitor) and sulfasalazine (a cysteine transport inhibitor) in order to inhibit glutathione production. Pre-incubation with these compounds increased ART ring-stage activity in the ART-resistant parasites (40% survival decreased to 18%, $p < 0.05$) to a level of activity comparable to sensitive isolates. On the contrary, pre-incubation of ART-sensitive parasites with the glutathione precursor, N-acetylcysteine, was sufficient to reduce ART ring-stage activity to a level comparable to the resistant parasites. This confirmed that anti-oxidant capacity plays a key role in the cellular mechanism of ART resistance. In conclusion, we have identified altered glutathione metabolism as a major contributing factor to the mechanism of *PfKelch13*-mediated ART resistance. Furthermore, the *in vitro* ART resistance phenotype can be reversed by inhibiting this detoxification system.

Ababa, Ethiopia, [6]Ethiopian Federal Ministry of Health, Addis Ababa, Ethiopia, [7]Malaria Branch, US Centers for Disease Control and Prevention, Atlanta, GA, United States

Artemisinin-based combination therapy has been used for the treatment of uncomplicated malaria in Ethiopia since 2004. The national malaria diagnosis and treatment guidelines employ a species-specific approach for malaria treatment. Artemether-lumefantrine (AL) and Chloroquine (CQ) are the first line treatments for *Plasmodium falciparum* (Pf) and *P. vivax* (Pv), respectively. In this study, we report the clinical and parasitological efficacy of AL and dihydroartemisinin-piperaquine (DP) against uncomplicated Pf, and of CQ and DP against uncomplicated Pv infections. The WHO guideline for monitoring antimalarial drug efficacy was followed for 42 days. The study was conducted from October 2017-February 2018 in two sentinel sites in Ethiopia. A total of 379 patients were enrolled in four arms (n = 106, AL/Pf; n = 75, DP/Pf; n = 142, CQ/Pv; n = 56, DP/Pv). Only patients above 18 years were enrolled for the DP arms. High cure rate was observed at 28 days (PCR uncorrected): 98% in AL/Pf (95% CI: 93-100); 98% in CQ/Pv (95% CI: 94-100). Efficacy at 42 days was 94% in AL/Pf (95% CI: 87-97), and 82% in CQ/Pv (95% CI: 75-88). There was 100% adequate clinical and parasitological efficacy in the DP/Pf and DP/Pv arms up to 42 days. For secondary endpoints, 98% (95% CI: 93-100) of AL/Pf patients cleared parasites and 99% were afebrile by day three. For all other arms, 100% of patients cleared parasites and were afebrile by day three. Early treatment failure was not detected in any arm. No severe adverse event was observed with a slight hematological recovery in all arms. Despite pending PCR corrected failure rates which will be available shortly, the results support the efficacy of the current anti-malaria drugs used by the malaria control program in Ethiopia. In addition, DP appears to be a good alternative for the treatment of both species. The high recurrence rate observed for Pv with CQ after 28 days is concerning, and highlights the importance of providing anti-relapse therapy.

Highly efficacious treatment is required to reduce adverse effects for the mother and fetus from *Plasmodium falciparum* infection in pregnancy. The current WHO guidelines recommend quinine- and artemisinin-based combination therapy (ACT) for first and second/third trimester women, respectively. There is now a significant body of evidence on the safety of ACTs in pregnancy, including in the first trimester. However, the current guidelines are supported by limited evidence on efficacy because pregnant women have usually been excluded from antimalarial studies. In addition, there is no fixed guideline for antimalarial efficacy studies in pregnant women: most study designs have been variably extrapolated from guidelines for non-pregnant populations; which complicates aggregated data meta-analysis on efficacy. In an effort to assemble the available evidence on antimalarial efficacy in pregnancy in a uniform way with data standardisation for statistical analysis, we conducted a systematic review and an individual patient data (IPD) meta-analysis of antimalarial efficacy studies on uncomplicated falciparum malaria in pregnancy. A one-stage IPD meta-analysis was conducted to identify the factors associated with PCR-corrected treatment efficacy. IPD of 4968 pregnant women (93% of the total targeted IPD) from 19 studies (10 in Asia and 9 in Africa) were analysed. Studied drugs included artemether-lumefantrine (AL, n=1278), artesunate-mefloquine (n=1028), dihydroartemisinin-piperaquine (n=874), artesunate-amodiaquine (n=841), quinine monotherapy (n=244), artesunate monotherapy (n=230), artesunate-sulfadoxine-pyrimethamine (n=173), artesunate-clindamycin (AC, n=142), artesunate-atovaquone-proguanil (n=91) and quinine-clindamycin (n=67). Quinine monotherapy and higher baseline parasitaemia were associated with a higher risk of failure. Adverse abdominal symptoms and tinnitus were more frequently observed with quinine compared to AL. Considering the lower efficacy and lower tolerability, withdrawal of quinine monotherapy from the first-line treatment for pregnant women should be considered.

268

THERAPEUTIC EFFICACY OF ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN COLOMBIA, 2018-2019

Mario Javier Olivera[1], Angela Patricia Guerra[1], Liliana Jazmin Cortes[1], Roberta Horth[2], Jonathan Novoa[3], Maria de la Paz Ade[4], Naomi Lucchi[2], Dragan Ljolje[2], Wilmer Marquino[3], Martha Renteria[5], Wilman Yurgaky[6], Alexandre Macedo de Oliveira[2]

[1]*Instituto Nacional de Salud, Bogota, Colombia,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Pan American Health Organization, Bogota, Colombia,* [4]*Pan American Health Organization, Washington, DC, United States,* [5]*Laboratorio de Salud Publica de Choco, Choco, Colombia,* [6]*Hospital Local Ismael Roldan Valencia, Choco, Colombia*

Artemether-lumefantrine (AL) has been the first-line antimalarial treatment for uncomplicated *Plasmodium falciparum* malaria in Colombia since 2010. The World Health Organization (WHO) recommends evaluating antimalarial treatment regimens every three years in low-endemic countries to confirm efficacy. To assess the therapeutic efficacy of AL in uncomplicated *P. falciparum*-infected patients in Quibdo, Colombia, we conducted a 28-day trial following WHO and Pan-American Health Organization guidance for antimalarial efficacy surveillance. From July

2018 to February 2019, febrile patients ≥5 years old with microscopically confirmed *P. falciparum* monoinfection and asexual parasitemia 250-100,000 parasites/μL were enrolled and treated with a supervised 3-day course of AL. The primary endpoint was adequate clinical and parasitological response (ACPR) on Day 28. We used neutral microsatellites to differentiate reinfection and recrudescence during the follow-up. Out of 259 patients offered participation, 86 consented and were ultimately enrolled, two of those were lost to follow-up, and 84 (97.7%) reached a valid endpoint: treatment failure or ACPR. One patient had recurrent infection with low-level parasitemia (12 parasites/μL) on Day 28. The parasite responsible for this infection was not isolated on molecular testing; therefore, this patient was excluded from the microsatellite-corrected analysis. The uncorrected and microsatellite-corrected ACPR rates were 98.8 % (83/84) (95% confidence interval [CI]: 93.5-100%) and 100% (83/83) (95% CI: 95.7-100%), respectively. In addition, no patient remained positive on Day 3, which would signal delayed parasite clearance, commonly associated with artemisinin resistance. AL remains efficacious for falciparum malaria in Quibdo, Colombia. Due to the time and effort, 8 months in our study, required to conduct efficacy trials in low-endemic settings, routine use of molecular markers for antimalarial resistance could greatly expand the coverage of antimalarial drug efficacy monitoring.

269

EFFICACY OF THREE REGIMENS OF CHLOROQUINE AND PRIMAQUINE FOR THE TREATMENT OF *PLASMODIUM VIVAX* MALARIA IN CRUZEIRO DO SUL, ACRE STATE, BRAZIL, 2018-2019

Sarah-Blythe Ballard[1], Suiane Negreiros[2], Samela Farias[2], Giselle Maria R. Viana[3], Stella Chenet[4], Paola Marchesini[5], Cassio Peterka[5], Marinete Marins Povoa[3], Alexandre Macedo de Oliveira[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Acre State Health Secretariat, Cruzeiro do Sul, Brazil,* [3]*Instituto Evandro Chagas, Belem, Brazil,* [4]*Instituto de Salud Publica, Santiago, Chile,* [5]*Brazil Ministry of Health, Brasilia, Brazil*

Treatment of *Plasmodium vivax* malaria infections requires the administration of chloroquine (CQ) and an aminoquinoline, such as primaquine (PQ), to eradicate hypnozoites, dormant liver forms that can lead to relapses. The World Health Organization (WHO) recommends a total PQ dose of either 3.5 mg/kg or 7.0 mg/kg depending on the expected relapse rates for each region of the world. After reports of frequent malaria recurrent infections, likely relapses and not new infections, with the low PQ dose, we evaluated the efficacy of three regimens of CQ and PQ for the treatment of uncomplicated *P. vivax* malaria in Brazil. This was a randomized 3-arm study among patients presenting to malaria diagnostic posts in Cruzeiro do Sul from April 2018 to February 2019. We enrolled patients ≥5 years of age with microscopy-confirmed *P. vivax* monoinfection and no evidence of severe disease. Patients received CQ under direct observation for 3 days (total dose: 25 mg/kg). After confirmation of normal glucose-6-phosphate dehydrogenase activity levels, we randomly assigned patients to receive a total PQ dose of 3.5 mg/kg divided over seven days in group 1 (non-observed therapy) and group 2 (observed), or a total dose of 7.0 mg/kg over 14 days in group 3 (observed). We monitored patients clinically and parasitologically on days 1, 2, 3, 7, 14, 21, 28, and every 4 weeks until day 168. We enrolled 257 patients: 63 in group 1, 98 in group 2, and 96 in group 3. The median asexual parasitemia at admission was 3,988 parasites/μL. By day 28, one patient in group 1, two patients in group 2, and no patient in group 3 presented with *P. vivax* infection; while 21, 33, and 11 presented with *P. vivax* parasitemia by day 168 in groups 1, 2, and 3, respectively. Adequate clinical and parasitological response was estimated at 59.6% (95% confidence interval [CI], 46.3-73.0%), 57.1% (95% CI, 46.1-68.2%), and 85.9% (95% CI, 78.2-93.6%), for groups 1, 2, and 3, respectively. While all regimens were efficacious for treatment of the acute infection, the higher WHO-recommended PQ dose was associated with superior efficacy in preventing recurrent infections within 168 days post treatment.

270

UNRAVELING NEW ANTIMALARIAL TARGETS

Sonia Moliner Cubel[1], Frank Schwach[2], Marcus Lee[2], Julian C. Rayner[2], Esther Fernandez Velando[1], Francisco Javier Gamo[1], Maria de Gracia Gomez Lorenzo[1]

Resistance to all known antimalarial drugs has been reported, highlighting the urgent need to discover new chemical entities with novel modes of action. Target based screening is an excellent approach to identify novel chemical diversity to enable development of new antimalarial drugs. However, in malaria this approach is restricted due to the limited number of validated drug targets. One method that has been used extensively in malaria parasites for target discovery and chemical validation is *in vitro* resistance evolution and whole genome sequencing (WGS). In many cases, new mutations are found in genes that are predicted to encode the target. Our aim was to follow this strategy with whole cell antimalarial inhibitors with unknown mode of action to unravel new targets for future target-based screenings. Antimalarial compounds with good parasitological profile from several MedChem programs were selected and progress through a battery of functional and cross-resistance assays to discard those with already known modes of action. After this triage, *in vitro* resistance selection studies under constant drug pressure were performed for 9 compounds. Resistance selection attempts were succssesful with 3 of them. Degree of resistance was confirmed in IC50 assays. Experiments were repeated in triplicate to obtain a wider diversity of genotypes and 3 different clones from the 3 independent flasks were isolated from the resistant pools. Results from WGS of those clones as well as hints toward the mode of action of the compounds will be presented. The human biological samples were sourced ethically and their research use was in accord with the terms of the informed consents under an IRB/EC approved protocol.

271

EFFICACY OF ARTESUNATE-AMODIAQUINE AND ARTEMETHER-LUMEFANTRINE FOR UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA IN MADAGASCAR

Antsa Rakotondrandriana[1], Arinomenjanahary Rakotoarisoa[1], Tovonahary Angelo Rakotomanga[1], Marie Ange Rason[1], Catherine M. Dentinger[2], Laura Claire Steinhardt[3], Samaly Souza[3], Naomi Lucchi[3], Venkatachalam Udhayakumar[3], Eric Halsey[4], Arsène Ratsimbasoa[1]

[1]*National Malaria Control Program, Antananarivo, Madagascar,* [2]*Malaria Branch, Centers for Disease Control and Prevention, US President's Malaria Initiative, Antananarivo, Madagascar,* [3]*Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Malaria Branch, Centers for Disease Control and Prevention, US President's Malaria Initiative, Atlanta, GA, United States*

Since 2006, artemisinin-based combination therapy has been recommended to treat uncomplicated malaria in Madagascar. Artesunate-amodiaquine (ASAQ) and artemether-lumefantrine (AL) are the first- and second-line treatments, respectively. To understand whether ASAQ and AL remain efficacious, a therapeutic efficacy study was conducted. Patients between 6 months and 15 years with uncomplicated *Plasmodium falciparum* malaria (1,000-100,000 parasites/μl) were assessed from May—September 2018 in a 28-day *in vivo* efficacy trial in two sites: Ankazomborona (tropical, north) and Matanga (equatorial, southeast). The 2009 World Health Organization (WHO) protocol for monitoring antimalarial efficacy was followed. Polymerase chain reaction (PCR) was used to distinguish recrudescence from reinfection, which allows determination of the PCR-corrected day 28 efficacy. Assays for molecular markers of resistance, including *K13*, *Pfcrt,* and *Pfmdr1*, were carried out. A total of 344 patients were enrolled; 163/170 (96%) in the ASAQ arm and 166/174 (95%) in the AL arm reached day 28. The day 28 uncorrected efficacy was 98.2% (95% CI 94.5-100%) for ASAQ and 93.4% (95%

CI 89.7-97.1%) for AL. PCR-corrected analyses are being finalized. Sequencing was attempted in 85 pre-treatment samples for the *K13, Pfcrt,* and *Pfmdr1* genes. Of the 83 successfully sequenced samples for the *K13* gene, no mutations associated with artemisinin resistance were observed. Of the 82 successfully sequenced samples for the *Pfcrt* gene, all were wild type for codons 72-76. Of the 74 successfully sequenced samples for the *Pfmdr1* gene, a majority carried the NFD (30 single and 7 mixed infections) and NYD (23 single and 7 mixed infections) haplotypes corresponding to codons 86, 184, and 1246. Prior to PCR correction, which will eliminate reinfections from the analysis and reveal an even higher efficacy, this study indicates that both ASAQ and AL have therapeutic efficacies above the 90% WHO acceptable cut-off. Periodic monitoring of therapeutic efficacy should continue routinely to ensure these treatments remain efficacious.

272

MUTATIONS IN *PLASMODIUM FALCIPARUM* PRO-DRUG ACTIVATION AND RESISTANCE ESTERASE MEDIATES RESISTANCE TO A SUB-CLASS OF SESQUITERPENE DIMER ANTIMALARIAL NATURAL PRODUCTS

Joshua H. Butler[1], Emilio F. Merino[1], Rodrigo P. Baptista[1], Judith I. Okoro[2], Ryan M. Scales[3], Philip J. Rosenthal[4], Roland A. Cooper[5], Jessica C. Kissinger[1], Jian-Min Yue[6], Bin Zhou[6], Maria B. Cassera[1]

[1]*University of Georgia, Athens, GA, United States,* [2]*University of California Berkeley, Berkeley, CA, United States,* [3]*University of North Carolina, Charlotte, Charlotte, NC, United States,* [4]*University of California San Francisco, San Francisco, CA, United States,* [5]*Dominican University of California, San Rafael, CA, United States,* [6]*State Key Laboratory of Drug Research, Shanghai Institute of Materia Medica, Chinese Academy of Sciences, Shanghai, and University of Chinese Academy of Sciences, Beijing, China*

Plasmodium falciparum is the deadliest of the *Plasmodium* species that cause human malaria, and the emergence of drug resistant parasites is a constant threat. Many parasitic mechanisms of drug resistance to antimalarials have been both observed in nature as well as demonstrated *in vitro*. Recently, *P. falciparum* Prodrug Activation and Resistance Esterase (PARE) was identified and its deactivation implicated in conferring *P. falciparum in vitro* resistance to antimicrobial pepstatin esters as well as the benzodiazepine, MMV011438. Our work, suggests *Pf*PARE deactivation is also a resistance mechanism to the potent antimalarial ester-containing sesquiterpene dimers: Fortunilide A, Fortunilide E and Chlorajaponilide C. In addition, we screened the open source compound libraries called the "Malaria box" and "Pathogen box" using our mutant resistant cell line. Among these libraries, MMV011438 and MMV011576 presented reduced efficacy in parasites resistant to the sesquiterpene dimers. Using a combination of *in vitro* cell-based assays with parasites harboring mutations in *Pf*PARE gene, recombinant *Pf*PARE enzymatic assays and whole genome sequencing and analysis, we provide evidence that mutations in *Pf*PARE confer resistance to the sesquiterpene dimers. *Ex-vivo* efficacy studies performed suggest this parasitic mechanism of resistance to several different classes of small molecules is not currently found in field isolates. Analysis of structure-resistance relationships of 11 lindenane type sesquiterpene dimers provides insights for possible future development of these compounds as an antimalarial therapy aimed at preserving low nanomolar efficacy, high selectivity and circumvent possible *Pf*PARE mediated resistance.

273

LONG-TERM EFFECT OF SEASONAL MALARIA CHEMOPREVENTION WITH AMODIAQUINE PLUS SULFADOXINE-PYRIMETHAMINE ON MOLECULAR MARKERS OF RESISTANCE IN OUELESSEBOUGOU, MALI

Almahamoudou Mahamar[1], Kelsey Sumner[2], Brandt Levitt[2], Betsy Freedman[2], Aliou Traore[1], Amadou Barry[1], Djibrilla Issaka[1], Adame B. Dembele[1], Moussa B. Kanoute[1], Oumar Attaher[1], Issaka Sagara[1], Abdoulaye Djimde[1], Patrick Duffy[3], Michal Fried[3], Steve Taylor[2], Alassane Dicko[1]

[1]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali,* [2]*Division of Infectious Diseases, Duke University Medical Center, Durham, NC, United States,* [3]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States*

Seasonal malaria chemoprevention (SMC) was recommended as policy for malaria control by the World Health Organization (WHO) in Sahel and sub-Sahel in 2012 along with monitoring of drug resistance. To assess the long term impact of SMC on *Plasmodium falciparum* resistance to Sulfadoxine-Pyrimethamine (SP) and Amodiaquine (AQ), blood smears and blood spots on filter papers were obtained from children aged 0-5 years, randomly selected each year during two cross-sectional surveys before and after SMC rounds in areas of Ouelessebougou where SMC had been implemented for 0, 1, 2 and 3 years. Frequencies of molecular markers of resistance to SP and AQ were assessed by PCR and genotyping. None of the molecular markers of resistance significantly increased in frequency over the period of study (2014-2016). At the beginning of the transmission season, the frequency of the *pfdhfr*59R was 93.9% at baseline and 98.2% after two years of SMC implementation (p = 0.12). The frequencies of *Pfdhps*540E, *Pfmdr1*-86Y and *Pfcrt*K76T mutation were also similar at baseline and after two years of SMC implementation 4.0% vs. 3.5%, p = 0.87; 5.6% vs. 9.8, p = 0.35 and 71.3% vs 80.7%, p = 0.20 respectively. At the end of transmission season after SMC drug administration, the frequencies of *Pfdhfr*59R, *Pfdhps*540E, *Pfmdr1*-86Y and *PfcrtK*76T mutation were also similar in areas where SMC was implemented for one or three years 97.0% vs. 100%, p = 0.21; 0.8% vs. 1.4%, p = 0.64, 10.8 % vs. 18.6%, p = 0.14 and 85.1% vs. 67.4% p = 0.01, respectively. The results of genotyping are consistent with those by PCR for the mutations tested by PCR, but also indicate for the first time the presence of the *dhps*581G mutation at low frequency, varying between 0-6.2% between areas and years, and only associated with the additional *dhps*431V mutation. In conclusion, two and three years of SMC implementation were not associated with a significant increase in the frequencies of the molecular markers of SP and AQ resistance. The detection of the *dhps* haplotype bearing the I431V and A581G mutations for the first time in Mali even at low frequency warrants further long-term surveillance.

274

EVALUATION OF AUTOMATED MALARIA DIAGNOSIS USING HEMATOLOGY ANALYZER WITH FINGER PRICK BLOOD FOR DETECTION OF *PLASMODIUM FALCIPARUM* PARASITEMIA IN RURAL AFRICA

Daisuke Usuda[1], Mamadou Ousmane Ndiath[2], Nuredin Ibrahim Mohammed[2], Haddy Nyang[2], Jane Achan[2], Grant Mackenzie[2], Yasuhiro Kawai[3], Yoshitsugu Iinuma[3], Kento Takeshima[1], Kinya Uchihashi[4], Abdoulie Jammeh[5], Ignatius Baldeh[6], Davis Nwakanma[2], Koya Ariyoshi[7], Umberto D'Alessandro[2]

[1]*Kanazawa Medical University Himi Municipal Hospital, Himi, Japan,* [2]*Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Fajara, Gambia,* [3]*Kanazawa Medical University, Uchinada, Japan,* [4]*Sysmex Corporation, Kobe, Japan,* [5]*Basse*

District Hospital, Basse, Gambia, [6]National Public Health Laboratories, Ministry of Health and Social Welfare, Banjul, Gambia, [7]Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

Light microscopy (LM) remains the gold standard for malaria diagnosis. Sysmex Corporation has recently developed an automated hematology analyzer, XN-30 equipped with a new violet laser that was able to count both malaria-infected red blood cells and white blood cells. The good performance of XN-30 in clinical setting has been demonstrated with venous blood (Pillay et al., Malar J 2019), but it has not been evaluated using finger-prick blood in a rural African setting. The study was done in The Gambia during the 2018 malaria transmission season (August-December). Malaria suspected patients were recruited at Basse district hospital. In addition, a malariometric survey was carried out in 6 villages near Basse, Upper River Region. A finger prick blood sample (250 μL) was collected for XN-30 measurement, high sensitive rapid diagnostic test (RDT; the Alere™ Malaria Ag P.f test), thick blood film, and molecular analysis (dry blood spots on filter paper). One hundred forty two suspected malaria patients and 404 randomly selected healthy individuals were recruited. Malaria prevalence was 31% (44/142) by molecular methods, 15% (22/142) by XN-30, 23% (33/142) by RDT, and 16% (23/142) by LM in suspected malaria patients and 15% (60/404) by molecular methods, 6% (24/403) by XN-30, 17% (67/404) by RDT, 5% (20/404) by LM in 404 randomly selected individuals. A scattergram pattern was judged suboptimal for the XN-30 analysis in 43% (61/142) malaria suspected patients and 73% (293/404) healthy individuals. When those suboptimal results were excluded, the sensitivity and the specificity of XN-30 in the community to compare with molecular methods were 70% and 94% respectively. To compare with LM or RDT, the sensitivity/ the specificity of XN-30 in the hospital were 90.9%/96.6%, 84%/98.2%, respectively. XN-30 has a potential role in malaria elimination program as it demonstrated similar performance to current standard diagnostic methods in rural Africa. However it requires substantial improvement to reduce the proportion of suboptimal results when a finger prick blood sample was applied.

275

EXTERNAL ASSESSMENT OF PROFICIENCY OF MALARIA MICROSCOPISTS AND LABORATORY CAPACITY IN DISTRICTS STRATIFIED FOR MALARIA ELIMINATION IN ETHIOPIA

Desalegn Nega Wada, Abnet Abebe, Adugna Abera, Bekuretsion Gidey, Ababa Gebretsadik, Sindew Mekasha, Eyasu Tigabu, Geremew Tasew, Adugna Woyessa

Ethiopian Public Health Institute (EPHI), Addis Ababa, Ethiopia

Successful Malaria Elimination Relies on Accurate Case Detection and Prompt Treatment by Qualified Professionals and Well Equipped Laboratories. Light Microscopy is an Easily Accessible and Routine Diagnostic Tool for Malaria in Ethiopia. Hence, This Study Assessed the Competency of Malaria Microscopists and Laboratory Capacity in Terms of Reagents and Equipments in the 6 Regional States Targeted for Malaria Elimination in Ethiopia, February to March 2018. A Total of 106 Facilities: 17 District Hospitals, 71 Health Centers (hcs) and 18 Private Clinics (pcs) Were Assessed. Of the Total Facilities, 91.5%(97) Was Using Light Microscopy While the Others Were Using Microscopy and Rapid Diagnostic Tests to Diagnose Malaria. Availability and Appropriate Storage of Giemsa Was Reported by 58.8%(10/17) Hospitals, 81.7%(58/71) hcs and 72.2%(13/18) pcs. In 84.6%(11) Hospitals, 35.7%(25) hcs and 26.7%(4) pcs, Malaria Laboratories Comply with the National Quality Assurance Guidelines. Technical Manuals and Laboratory Bench Aids Were Observed in 56.2%(9) Hospitals, 57.1%(40) hcs and 35.3%(6) pcs. Only 55.6%(10) pcs Had License of Registration. Of the 1896 Malaria Positive and 474 Negative PCR-Corrected Slides Administered to 237 Study Participants, 318 Slides Were Reported Falsely Negative (Rate: 42.7%) and 47 Slides Were Reported Falsely Positive (Rate: 2.9%). The Participants Skill Was Graded Good (Agreement: 84.6%, Kappa: 0.6) on Parasite Detection and Poor (A: 43.8%; K: 0.11) on Species Identification. Agreement Was Even Very Slight for Differentiation of *P. Falciparum* from Other Species (A: 28.41%; Kappa:0.29). Above 95% of Participants Didn't Count Parasitemia or Reported Plus System of Estimation That is Unacceptable Per Who Guideline. Therefore, the Low Competency of Malaria Microscopists Together with Poor Laboratories in the Current Study Implies the Further Need of Comprehensive Laboratory Supervisions and *In-Service* Trainings of Professionals by the Ministry of Health and Relevant Partners, Not to Miss-Diagnose the Low Number but Highly Significant Malaria Cases in Elimination Settings.

276

PREVALENCE OF MALARIA PARASITEMIA AMONG UNDER-FIVE CHILDREN LIVING WITH HIV ATTENDING SELECTED HEALTH FACILITIES IN JOS, NORTH CENTRAL NIGERIA 2017

Kayode Abraham Olawuyi[1], Adebola Olayinka[2], Saad Ahmed[3], Patrick Nguku[2]

[1]*National Veterinary Research Institute, Vom Nigeria/Nigeria Field Epidemiology and Laboratory Training Program, Abuja, Nigeria, [2]Nigeria Field Epidemiology and Laboratory Training Program, Abuja, Nigeria, [3]Ahmadu Bello University Teaching Hospital, Zaria, Nigeria*

Malaria and HIV contributes to the burden of diseases among children less than five years globally. In Africa an estimated 86% of death due to malaria occurs among children under 5 years of age. The Nigeria National Malaria Elimination Program reported that 30% Under 5 (U5) mortality is due to malaria infection. Children living with HIV are more vulnerable to malaria infection because of their immune status. It is diagnosed by the presence of parasitaemia in the peripheral blood. We conducted this study to determine the prevalence and factors associated with malaria parasitaemia in children 6-59 months living with HIV in Jos, North Central Nigeria. A cross sectional study was conducted among children aged 6-59 months living with HIV. Blood specimen was collected from 264 U5 children and tested for the presence of parasitaemia by microscopy. Malarial parasitaemia was defined as the presence of at least one asexual parasite in the blood film. Haemoglobin estimation was carried out and CD4% determined. Structured, interviewer administered questionnaire was used to obtain demographic information and potential risk factors from caregivers. The mean age in months (± Standard deviation) was 40.6 (± 13.7) among children 6-59 months living with HIV. The Prevalence of parasitaemia was 16%. Mild anaemia was significantly associated with malaria parasitaemia among children living with HIV (aOR, 2; 95% Confidence interval (CI), 1.7-3.3). No association was found between CD4% and presence of malaria parasitaemia among children living with HIV. However, the presence of stagnant water and grasses surrounding the vicinity where these children resides were significant associated with parasitaemia (aOR 3; 95% CI, 1.2-11). Therefore we conclude that the prevalence of parasitaemia was relatively high among children 6-59 months living with HIV. Parents/caregivers of these children were educated on the need to intensify efforts in ensuring clean environment devoid of stagnant water and grasses as this will reduce the breeding site for mosquitoes.

277

ANGIOGENIC AND ANGIOSTATIC FACTORS IN THE SALIVA OF MALARIA PATIENTS

Cecilia Elorm Lekpor[1], Kwadwo Asamoah Kusi[2], Andrew Anthony Adjei[1], Nana Otu Wilson[3], Jonathan Stiles[3]

[1]*University of Ghana/korleBu Teaching Hospital, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana, [3]Morehouse School of Medicine, Atlanta, GA, United States*

Malaria death is associated with deregulation of host immune responses to inflammatory factors such as C-X-C motif chemokine 10 (CXCL10) and host angiogenic factors such as angiopoietin 1 (Ang-1) and angiopoietin 2 (Ang-2). Current diagnosis of malaria relies on microscopic detection of the parasites in the blood film. This approach is invasive, increases accidental infections and uncomfortable for some patients. The aim of this study was to investigate biomarkers -CXCL10, Ang-1 and Ang-2 levels in the saliva of malaria patients and compare with plasma levels with regard

to their potential use as biomarkers in malaria. This may be useful for further development of highly efficient non-invasive malaria detection methods using saliva. This was a case control study involving a total of 213 (119 malaria subjects and 94 non malaria subjects) aged 1 -16 years. Plasma and saliva levels of CXCL10, Angiopoietin (Ang)-1 and Ang-2 were measured among the study participants using Quantikine Elisa kit. The data was analyzed at 450 nm wavelength using a Spectra Max 190 fluorescence micro plate reader. Data was presented as mean ± standard error or median and interquartile range (IQR). Pearson's rank test was used to determine if there was any association between the biomarkers and malaria infection. A p-value < 0.001 was considered statistically significant. There was decreased plasma levels of Ang-1 ($p<0.009$) and increased plasma levels of CXCL10 ($p<0.001$) and Ang-2 ($p<0.001$) in individuals with malaria compared to those without malaria. Similar trends were observed in the saliva samples from study participants. Saliva biomarkers CXCL10, Ang-1 and Ang-2 levels correlated significantly with plasma levels of malaria patients. Finally, Ang-2 was informative when combined with CXCL10 to predict the risk of malaria and could be useful in clinical decision-making. These results provide insight into the use of saliva as a non-invasive diagnostic method and demonstrate that Ang-2 combined with CXCL10 is a promising predictive biomarker in malaria.

278

VALIDATION OF *PFHRP2/3* GENE DELETION ASSAYS USING CULTURED MALARIA PARASITES

Josphat N. Nyataya, George Awinda, John Waitumbi

Kenya Medical Research Institute/Medical Research Unit, Kisumu, Kenya

To encourage rational treatment of malaria based on confirmed diagnosis, WHO has spearheaded the development of antigen-based rapid diagnostic tests (RDT). These efforts could be eroded by the reported increase in *Plasmodium falciparum* that have deleted *pfhrp2/3* genes and therefore do not produce Histidine Rich Protein 2 and 3. To facilitate evaluation of these deletions in complex samples, we first validated the assay performance in *P. falciparum* strains grown in culture. Cultures of 3D7 and Dd2 strains were grown in RPMI 1640 medium at 5% hematocrit of 0+ human red blood cells supplemented with 10% heat inactivated human serum. At 3% parasitemia, the parasites were synchronization using Sorbitol to obtain 95% of rings stage parasites. The parasites were then diluted to a parasitemia of 7,500 parasites/μL allowed to grow for a 48-hr complete cycle to reach a parasitaemia of 15,000 parasites/μL. A 200 μL aliquot was removed and used for DNA extraction and subsequent amplification of exon 2 of *pfhrp2/3* genes and their respective flanking regions. Because detection of the deleted gene is based on absence of amplification, a quality control step included amplification of *msp1* and *msp2* genes. Another 200 μL aliquot of each culture was diluted serially in RPMI and 5 μL of each dilution read on RDTs. *msp1* (K1 in 3D7 and MAD20 in Dd2) and *msp2* (FC27 and IC3D7) genes were amplified in both strains. In 3D7, *pfhrp2* and *pfhrp3* genes and flanking regions were amplifiable, while for Dd2, only the *pfhpr3* gene and its flanking region were amplifiable. In agreements with these results, the limit of detection of HRP2 antigen in 3D7 was 300 parasites/μL and while for Dd2, the limit of detection was 2 log higher (30,000 parasites /μL). Our data validates the use of 3D7 and Dd2 parasites as appropriate quality control specimens for inclusion of *pfhrp2/3 gene* deletions assays. Future studies will need to include HB3 strain of *P. falciparum* that lacks the *pfhrp3* gene and the flanking regions.

279

A NOVEL HIGHLY SENSITIVE FLUORESCENCE BASED CARTRIDGE READER FOR RAPID DETECTION OF MALARIA PARASITES

Allan P. Lemtudo[1], Katie Todorof[2], Mike Lochhead[2], John N. Waitumbi[3]

[1]*United States Army Medical Research Directorate , Kenya, Kisumu, Kenya,* [2]*MBio Diagnostics, Inc., Boulder, CO, United States,* [3]*United states Army Medical Research Directorate , Kenya, Kisumu, Kenya*

The currently approved rapid diagnostic tests for malaria (mRDT) lack sufficient sensitivity, may not differentiate current and historical infections of *Plasmodium falciparum* and have false negatives due to deletions of histidine rich protein (HRP) genes. We describe the performance of a novel fluorescence based cartridge device that uses waveguide planar technology for detection of the pfHRP2 and pan-malaria pLDH. For this study, 326 frozen blood samples that had prior microscopy results were retested on the cartridge reader and a commonly used mRDT. Discordant samples between these two tests were resolved by qPCR. Of the 326 blood samples, 293 (89.6%) were HRP2 positive on the cartridge reader device and 289 (88.6%) on mRDT. The calculated HRP2 agreement was 98.2% (320/326). By qPCR, and in agreement with the cartridge reader, five of the discordant samples were positive by qPCR and one was negative. Significant discrepancy was observed on pLDH. By the cartridge reader, 302/326 (92.6%) were positive and only 220 (67.5%) by mRDT. The calculated pLDH agreement was 74.2% (242/326). For the 84 discordances, qPCR validated the cartridge reader's pLDH score in 83/84 samples. On speciation by qPCR, the 84 discordant samples comprised 35.7% (30/84) monoinfections of Pf with parasitemia of 46-1,376 Pf/μL, 64.3.2% (54/84) mixed infections of Pf/Pm and Pf/Po with parasitemia ranging between 46-9120 parasites/ μL. Taken together, our results indicate that, by HRP2, the performance of the novel cartridge reader is comparable to mRDT. The greatest improvement is in the performance of pLDH. The new pLDH assay will solve common false positives attributable to HRP2 persistence in blood long after parasite clearance and false negative results due to HRP2 gene deletions. Importantly, the test will improve detection of non-Pf infections and thereby allow better management of G6PD deficient patients who may have non-Pf infections.

280

THE ROLE OF MRDTS IN SCREENING OF ASYMPTOMATIC INDIVIDUALS TO BE ENROLLED IN CLINICAL TRIALS

Catherine Sumbi[1], Agneta Ogolo[1], Cornel Arima[1], Cephas Aguko[1], Michael Ayaya[1], Everlyne Omondi[1], Victor Otieno[1], Vincent Akolo[1], Rose Adeny[1], Hosea M. Akala[1], Bernhards Ogutu[2], Jim R. Managbanag[1]

[1]*US Medical Research Directorate-Africa/Kenya, Kisumu, Kenya,* [2]*US Medical Research Directorate-Africa/Kenya, Kenya Medical Research Institute, Kisumu, Kenya*

Malaria is one of the world's most prevalent parasitic diseases with the highest prevalence reported in Sub- Saharan Africa. The parasites that cause malaria are from the plasmodium genus. Clinical trials for effective treatments against malaria are reliant on microscopy and malaria rapid diagnostic kits (mRDTs) for determining treatment response. The antigen specific mRDTs are preferred for their ease of usability where microscopy may not be available. Recent studies showing genotype-based variability in response to mRDT marker proteins warrant assessment of performance of this method in clinical efficacy studies. 1451 participants were enrolled in Blood Collection Protocol 1 , a clinical efficacy study between 2007 and 2011 in Kombewa HDSS .They were tested for malaria using microscopy and Parascreen mRDTs as part of assessing eligibility for enrollment into the study. While mRDT indicated the presence or absence of malaria parasites in whole blood samples, microscopy was done to determine the presence or absence of malaria parasites, species and parasites enumeration. Data generated readouts from microscopy were compared with those from mRDT using descriptive statistics. Of the 1451, 1175

(81%) were positive while 272 (19%) were negative by mRDT. 940 (64%) were positive while 503 (35%) were negative by microscopy. this finding showing higher positive predictive rates for mRDTs than microscopy suggests the mRDTs usability alongside microscopy in efficacy study.

281

ASSESSING THE IMPACT OF MALARIA DIAGNOSTICS CENTRE COMPREHENSIVE MALARIA MICROSCOPY TRAINING COVERAGE IN KENYA AND BEYOND

Rose A. Adeny[1], Agneta Ogolo[1], Cornel Arima[1], Cephas Aguko[1], Catherine Sumbi[1], Michael Ayaya[1], Everlyne Omondi[1], Victor Otieno[1], Vincent Akolo[1], Hosea M. Akala[1], Bernhards Ogutu[2], Jim R. Managbanag[1]

[1]*U.S. Army Medical Research Directorate - Africa/Kenya, Kisumu, Kenya,* [2]*U.S. Army Medical Research Directorate - Africa/Kenya Medical Research Institute, Nairobi, Kenya, Kisumu, Kenya*

A survey of research institutions and hospital facilities globally revealed limited expertise in performance of microscopy for malaria diagnosis. Microscopy as a gold standard for malaria diagnosis is dependent on microscopists's expertise, periodic re-training and certification. The malaria Diagnostics Training Centre (MDC) was established in 2004 to enhance qualitative and quantative malaria diagnostic skills in laboratories globally. The aim of this study was to estimate training impact since its inception. Between 2004 and 2008, MDC implemented a 14 day training syllabus for individuals with no malaria microscopy training and a 5-day refresher for previous trainees. Prior to training commencement, a pre-test was conducted to gauge the knowledge of participants and a post test to gauge the skill sets acquired. Microscopy was alloted 50% of overall training time. Training comprised of theoretical and practical sessions. A total of 1843 laboratory trainees from 28 countries were trained between 2005 and 2018. Countries reached by regions were; East Africa 10, West 8, North 2, South4, Central 2 and Asia 2. The total number of countries trained in Africa 26(93%), outside Africa 2(27%). Number of Microscopy classes held was 126, within Kenya 109(87%), outside Kenya 17(13%). 1843 laboratory trainees comprised those from Kenya 1472(80%), outside Kenya 371(20%). MDC then established sister malaria diagnostic centers in three countries after 10 day mentorship program for facilitators. These results show that East and West Africa had the highest number of trained personnel compared to other regions with Africa at 93% compared to Asia at 7%. This findings show the need for establishment of malaria diagnostic centres across regions. This argues for dedicated funding for this framework as it would warrant an increase in coverage of trained malaria microscopists globally as a prerequisite for adopting pre-elimination phase.

282

MALARIA DIAGNOSTIC PRACTICES AND ACCURACY OF BLOOD SMEAR MICROSCOPY IN PRIVATE HEALTH FACILITIES OF ENTEBBE MUNICIPALITY, UGANDA

Tobius Mutabazi[1], Emmanuel Arinaitwe[2], Alex Ndyabakira[2], Simon P. Katongole[3], Pauline B. Kibwika[1], Moses R. Kamya[1], Joaniter I. Nankabirwa[1]

[1]*Makerere University College of Health Sciences, Kampala, Uganda,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*Faculty of Health Sciences, Uganda Martyrs University, Kampala, Uganda*

Malaria treatment policy in Uganda recommends that all suspected cases have a laboratory diagnosis prior to treatment. Studies have shown that almost half of the patients visiting public facilities are still presumptively treated despite availability of the diagnostics and personnel to do the testing. The practices in private facilities is still unknown despite most patients seeking care at these facilities.We evaluated the malaria diagnostic practices and the accuracy of the malaria blood smear test in private health facilities in Uganda. Between April and May 2018, we enrolled 700 patients suspected to have malaria at 26 private health facilities in Entebbe municipality. Patients records were reviewed following the clinical evaluation and all patients sent to the laboratory for a blood smear had a study smear collected in addition to clinical smear to evaluate for the accuracy of blood smear microscopy. Of the 700 participants enrolled, 695 (99.3%) had a malaria diagnostic test done before treatment. The sensitivity and specificity of the facility microscopy was 95.8% and 90.1 respectively. Factors associated with accurate facility microscopy included having five or more years experience of reading smears (OR=0.134, P<0.001), conducting 5 or more smear readings a day (OR= 0.040, P<0.001) and good laboratory illumination (OR= 5.685, P=0.015). Adherence to the malaria diagnostic guidelines in the private facilities located in this setting is higher than what is observed in the public facilities and accuracy of smear reading is high. The main factor associated with accuracy microscopy is the experience of the laboratory personnel either through conducting many smear readings or duration of reading smears. Private facilities in this setting should act as model facilities to improve the malaria diagnostic practices at public facilities in Uganda.

283

EVALUATING THE PREVALENCE OF *PLASMODIUM* PARASITES AMONG ASYMPTOMATIC INDIVIDUALS USING MICROSCOPY AND MALARIA RAPID DIAGNOSTIC TEST IN KOMBEWA HDSS AREA, WESTERN KENYA

Agneta Ogolo, Cornel Arima, Cephas Aguko, Catherine Sumbi, Michael Ayaya, Everlyne Omondi, Victor Otieno, Vincent Akolo, Rose Adeny, Hoseah M. Akala, Bernhards Ogutu, Jim Ray Managbanag

USAMRD-A Kenya, Kisumu, Kenya

Plasmodium parasite is the main cause of malaria infection in man. In *malaria* endemic areas, *people* tend to develop partial immunity, allowing occurrence of *asymptomatic* infections. The asymptomatic infections are an important reservoir for sustaining vector infections, and anchor the disease in eco-epidemiological settings. Though asymptomatic individuals significantly impacts transmission dynamics, they are often obscure to the health systems since they do not seek treatment. The aim of this study is to determine frequency of plasmodium infections in asymptomatic persons using Microscopy and malaria rapid diagnostic test (mRDT) diagnostic methods. 1451 individuals between 5 months to 65 yrs, from randomly selected households were enrolled between 2007 and 2011 within Kombewa HDSS. 250µl finger prick EDTA blood was collected from each individual. 2 thick and thin smears were made, complete blood count and RDT done using Parascreen®. Giemsa stained slides were read by expert microscopists to determine plasmodium species and parasitemia. Data was analyzed using descriptive statistics for frequency of positive infections per test methods used. Inferential statistics was used to describe variations in between diagnosis methods. Of the 1451, 940 (65%) samples were positive by microscopy and 1175 (81%) samples were positive by RDT. Of the 213 (23%) asymptomatic individuals by microscopy, the distribution of *Plasmodium spp* was; *Plasmodium falciparum* 197 (21%), *Plasmodium falciparum* with *Plasmodium malariae* 7(0.7%), *Plasmodium malariae* 3(0.3%), *Plasmodium ovale* 2(0.2%), *Plasmodium falciparum* with *Plasmodium ovale* 4 (0.4%). This findings shows high burden of asymptomatic infections using the most frequently used microscopy and RDT diagnostic method. Asymptomatic individual presents the risk of transmitting infections since they would not seek treatment. Strategy should be developed for diagnosis and treatment of asymptomatic individuals.

284

EVALUATING MICROSCOPY PERFORMANCE AMONG TRAINEES TRAINED IN MALARIA DIAGNOSTICS CENTER IN KISUMU.

Lack of metrics to uniformly ascertain effects of intervention such as drugs, vaccines impact and control hinders efforts to transition to pre-elimination phase. Malaria Diagnostics Center (MDC) was established in 2004 by United States Medical Research Directorate - Africa/Kenya, Kenya Medical Research Institute to standardize malaria diagnostics in the region. MDC designed a curriculum which is able to assess the competence of candidates at various proficiency levels. As part of entrenching this habit among malaria diagnosis professionals, it is essential to rate impact of the training on trainees. The aim of this study was to determine the uptake of diagnostic skill sets acquired before and after training among trainees who attended MDC's training in the year 2013. Ten-day malaria microscopy course was conducted for microscopists drawn from both private and public institutions. The course contained theoretical and practical sessions. The impact of training was evaluated by practical and theoretical pre- and post-training assessments on parasite detection (sensitivity and specificity), species identification and parasite quantification. A total of 61 participants completed the training which comprised of Ministry of health personnel at 48(79%) and other research organizations 13(21%). The knowledge of basic malariology (theory) at pre- and post-tests were 64% (95% CI 61-67%) and 93% (95% CI 91-94%), respectively (P<0.001). The mean parasite detection (sensitivity) were 57% (95% CI 50-64%), during the pre-test and 90% (95% CI 87-93%) for the post-test (P<0.001), improvement of 32% (95% CI 26-39%). However for specificity, there was negative reduction from a mean of 57% (95% CI 51-64%) in pre-test to 51% (95% CI 42-60%) post-test (P= 0.254), improvement -6%, (95% CI -12 to -0.7%). Conclusion: Overall improvement was observed in all areas tested except for specificity which had negative (-6) improvement. Findings show improvement in performance, if maintained would improve the quality of microscopic diagnosis of malaria.

285

COMPARING COINFECTION OF *PLASMODIUM OVALE* AND *P. MALARIAE* IN ASYMPTOMATIC INDIVIDUALS IN KOMBEWA HDSS AREA, WESTERN KENYA

Cephas Aguko Oyieke[1], Cornel Arima[1], Agneta Ogolo[1], Catherine Sumbi[1], Michael Ayaya[1], Everlyne Omondi[1], Victor Otieno[1], Vincent Akolo[1], Rose Adeny[1], Hoseah M. Akala[1], Bernhards Ogutu[2], Jim Ray Managbang[1]

[1]*MDC, Kisumu, Kenya,* [2]*KEMRI, Kisumu, Kenya*

The prevalence of malaria infection in Kombewa,Western Kenya still remains high despiteheightened interventions. Three *Plasmodium* species; *P. falciparum* (Pf), *P. ovale* (Po) and P. malariae (Pm), *P. falciparum* plus *P. malariae* (pfm), *P. falciparum, P. malariae* and *P. ovale* (pfmo) and *P. falciparum* and *P. ovale* (pfo) exist sympatrically. Bites from mosquitoes carrying different species of parasites often leads to co-infection in humans. Co-infection withdifferent species has been shown to modulate disease progression to either asymptomatic or symptomatic. As studies continue to highlight mortality among children less than 5 years, it isessential to understand variability in species carriage among the different age groups. The aim ofthis study was to estimate the role of species composition in malaria mortality in Kombewa,Western Kenya. 1451 samples were collected under the Blood Collection protocol between 2007and 2011. These samples from Kombewa HDSS randomly screened for malaria included both asymptomatic and symptomatic individuals. Each blood sample was tested for presence orabsence of *Plasmodium* parasites, species present determined by malaria rapid diagnostic test kit(mRDT) Parasreen® and confirmed by microscopy. Counts of positive Pf, Po, Pm, Pfm, Pfo,Pfmo were obtained and recorded. From asymptomatic individuals screened, a total of 41(3%)had pfm, 18(1%) pfo, 2(0.1%) pfmo, 322(22%) pf and 204(14%) were negative. As for childrenbetween 6-17 years, 37 (3%) had pfm, 5(0.3%) pfo, 1(0.1%) pfmo, 331(23%) pf and 121(8%)were negative. Adults above 18 years had 2(0.1%) pfm, 2(0.1%) pfo, 149(10%) pf 164(11%)were negative, no pfmo species were found in adult samples. The findings above show thatchildren <17 years were more vulnerable to *Plasmodium* infections compared to adults. Mortality could be as a result of poor health seeking behavior especially in the absence of fever and lack ofmechanisms to trace them within house holds

286

IMPLICATIONS OF *PLASMODIUM* PARASITES WITH HRP2 GENE DELETION ON THE PERFORMANCE OF HRP2 BASED RAPID DIAGNOSTIC TESTS IN MIDDLE GHANA OF AFRICA

Dennis Adu-Gyasi[1], Linda E. Amoah[2], Abagna Hamza Bukari[2], Prince Agyapong Darko[1], Felix B. Oppong[1], David Dosoo[1], Oscar Agyei[1], Seeba Amenga-Etego[1], Kwaku Poku Asante[1]

[1]*Kintampo Health Research Centre, Kintampo North, Ghana,* [2]*Noguchi Memorial Institute for Medical Research, Accra, Ghana*

From a previous study that evaluated HRP2 based RDTs to probe other causes aside low parasitaemia that might give false negative results, we sought to explore further using molecular techniques to assess the presence of *Plasmodium* parasites that lack *hrp2 genes* infecting human in the middle-belt of Ghana. The current study pooled together data of two cross sectional studies that evaluated malaria RDTs in the middle-belt of Ghana from 2014 to 2016. Blood samples were collected from participants and used to screen for malaria using microscopy and RDT. With the RDT results, false negative, false positive and samples with parasite densities below detectable limits were selected. DNA was extracted and used for speciation, multiplicity of infection identifying the presence of MSP2. Samples that were positive for MSP2 were further screened for HRP2 and HRP3 deletants. Performance of the malaria RDT was evaluated using the ROC and sensitivity with the specificity. The studies were approved by the Kintampo Health Research Centre Institutional Ethics Committee (FWA_ No.:00011103). The prevalence of *Plasmodium falciparum* infection based on microscopy in the studies pooled were 39.1% (281/754) and 28.1% (441/1569) respectively. The performance of the RDTs in the two studies had sensitivity (SE), specificity (SP) and ROC of 98.2% (95.9%, 99.4%), 66.3% (58.7%, 73.3%) and 0.82 (0.79, 0.86), and SE, SP and ROC of 92.1% (88%, 95.2%), 81.6% (79.2%, 83.8%) and 0.87 (0.85, 0.89) respectively. Of the selected samples screened with PCR, 53.2%(41/77) were speciation positive. Of these, 31.7% (13/41) were MSP2 positive. Screening among these 13 samples for HRP2 and HRP3 gene deletions, 30.8% (4/13) had pfhrp2 gene deletion in exon 1-2 segment. About 50.0% (2/4) of the pfhrp2 deleted parasites had pfhrp3 which did not compensate for pfhrp2 deletions. This study describes the prevalence of *pfhrp2/3 gene* deletions in the middle-belt of Ghana based on genotyping of *Plasmodium falciparum* positive samples from health facility and community levels, with 95% CIs for all point estimates. It is necessary to use standard guided protocol to assess the spread of HRP2 gene deletions.

Ababa, Ethiopia, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [5]Brown University, Providence, RI, United States, [6]World Health Organization, Geneva, Switzerland, [7]University of North Carolina, Chapel Hill, NC, United States

Plasmodium falciparum parasites with deletions of the *histidine-rich protein* 2 and 3 (*pfhrp2/3)* genes are not detected by commonly deployed malaria rapid diagnostic tests (RDTs) in Africa. Because RDTs account for the majority of diagnostic testing for suspected malaria in Ethiopia, increasing reports of these parasites has raised concerns that existing diagnostic strategies are threatened. High prevalence of *pfhrp2/3* deletions in neighboring Eritrea recently forced a shift away from PfHRP2-based RDTs to less sensitive, less heat stable alternatives. To determine the impact of these parasites in Ethiopia, we conducted the first study using the World Health Organization's (WHO's) protocol for *pfhrp2/3*-deleted parasite surveillance. 3,095 subjects with suspected malaria who presented to government health facilities in the West Armachiho district of the Amhara Region and the K/Humera and Atsede Tsimbila districts of the Tigray Region were enrolled and underwent testing with two distinct, WHO pre-qualified RDTs. Molecular and serological testing for parasites with *pfhrp2* and/or *pfhrp3* gene deletions is underway. Pilot testing of samples collected from 61 subjects with PfHRP2-negative but PfLDH-positive RDT results identified *pfhrp2/3*-deleted *P. falciparum* parasites in all three districts. Initial Luminex antigen testing confirmed the absence of PfHRP2 in 90% (55/61) of *P. falciparum* PCR-positive samples tested. Nested PCR with prolonged cycling failed to amplify *pfhrp2* in 34% (21/61) and *pfhrp3* in 74% (45/61). Deep sequencing of the *pfhrp2/3* genes and 29 flanking *loci* provided high resolution mapping of deletion regions. This work is being complemented by additional antigen profiling, PCR assays, and whole-genome sequencing. In summary, largescale surveillance near Ethiopia's northern border with Eritrea identified *pfhrp2/3*-deleted parasites in all surveyed districts. We are employing a multi-omics approach to characterize regionally specific deletion breakpoints, identify mutations associated with impaired PfHRP2 expression, and explore the evolutionary history of these parasites.

288

MALARIA IN SEMI-ISOLATED AMAZONIAN INDIGENOUS COMMUNITY: HETEROGENEITY OF TRANSMISSION AND PREDOMINANCE OF SUBMICROSCOPIC INFECTION

Daniela Rocha Robortella

Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

In Latin America, inequitable access to healthcare has a profound impact on the indigenous populations of the Amazon rain forest that typically suffer from an excess burden of infectious disease. Malaria official data are underestimated due to the difficulty of access to ethnic groups, such as the Yanomami, a traditionally semi-nomadic group living in widely dispersed communities in the Amazon border of Brazil and Venezuela. Here, we investigate malaria infection among 981 individuals (median age 14 years) from four Ianomâmis villages from Marari indigenous community (North of the Amazonas State). The methodological approach involved cross sectional surveys carried out during dry season (September/ November, 2014) and at the beginning of the rainy season (January, 2015). Different PCR protocols (ribosomal and non-ribossomal targets) were used to increase sensitivity in detection of submicroscopic malarial infection. Taken together, the results demonstrated that: (i) at the enrollment, malaria prevalence was 1.6% by conventional microscopy and 6% for PCR-based protocols, confirming the high frequency of submicroscopic malaria infections. Although the number of cases decreased during the second cross sectional, the submicroscopic infections remained relatively high (4% *vs.* 0.7%); (ii) *Plasmodium vivax* and *P. malariae* were responsible for the majority of malaria infections (35% and 32%, respectively); (iii) in the Yanomani area, malaria transmission was not homogeneous transmitted, with prevalence ranged from 1.5% to 12% between villages; (iv) while the frequency of malaria infection was similar between genders, there was a clear tendency in decreased malaria-positivity according to the increase in age, suggesting acquired immunity against malaria.

289

RETINOPATHY IN CEREBRAL MALARIA IN CHILDREN IN KINSHASA

Mireille Ngale Amba, Joseph M. Bodi, Joseph T. Kelekele, Dieudonné N. Mumba, Nsengi Ntamabyaliro, Celestin N. Nsibu

University of Kinshasa, Kinshasa, Democratic Republic of the Congo

Democratic Republic of the Congo (DRC) is the second most affected country by malaria worldwide, and cerebral malaria is the deadliest complication. However, its diagnosis difficult by the non-specificity of its signs and the lack of appropriate equipment in the context of DRC. Fundus is an accurate and early non-invasive means of observing pathognomonic ocular abnormalities and is very important for understanding pathophysiology, diagnosis and prognosis of cerebral malaria. This is an observational study conducted in the 4 districts of Kinshasa. One Health Facility was randomly selected in each of the districts, and all children admitted for cerebral malaria from 2012 to 2014 were included in the study after informed consent by parent or legal guardian. A fundus was performed with direct ophthalmoscopy within 24 hours of admission. Analyzes were performed on SPSS 20.0 and EXCELL. Pearsonian Chi- squared test was used to compare averages. Seventy-nine patients were included in our study. Median age of 5.8 ± 2.6 years. Children aged 3 to 5year accounted for 60.8%. More than three quarters of patients had retinal changes (77.2%). These changes consisted of hemorrhages (100%), bleaching (34.2 %), vascular discoloration (3.8 %) and papilledema (11.4 %). Patients also had seizures (60.7%), anemia (78.7%), thrombocytopenia (45.9%), acidosis (54.1%) and hypoglycemia (10%). A total of 22.8% did not have retinal changes. This may be due to genetic factors leading to cerebral malaria without retinal expression or incidental parasitemia in patient with other cause of coma. Fundus should be taken in account for rapid diagnosis and prompt treatment of severe malaria in Kinshasa. A training on the use of the ophthalmoscope to emergency department practitioners would be needed.

Malaria diagnosis in Nigeria was largely done based on clinical presentations until recently when the policy on parasitological confirmation of all suspected malaria cases before treatment was released by the government in 2011. One of the possible causes of over-diagnosis and over treatment of malaria in Nigeria is poor utilization of Malaria test results in health care delivery. This study demonstrates the influence of in-service training on malaria microscopy amongst medical laboratory scientists on the utilization of malaria microscopy results in a selected Government Health Facility in Nigeria. The base line study was conducted in 2014 while a follow up study where pre tested questionnaire on perception of Health care providers on malaria diagnostic results were administered to end users of laboratory results in selected secondary health facilities, Basic malaria microscopy training conducted for medical laboratory scientists working in these selected facilities in accordance with the World Health Organization (WHO) basic microscopy training manual. Level of improvement and confidence in malaria result utilization by health workers was assessed. To assess the performance after the training intervention, paired-test was used to determine if there was any significant difference between the performance scores before and after

the training and between the basic and refresher training. The study demonstrates a significant improvement in the mean written pre-and post-tests scores from 28.4% (95% CI 30.4-30.4%) to 75.2% (95% CI 73.6-78.2%) ($P < 0.001$). . Comparing the baseline and follow up study, there was significant difference when comparing the rate of utilization of malaria result from the Trained Med Lab Scientists. ($p < 0.001$)The increase in utilization of malaria microscopy result for effective case management of malaria in the study area was influenced by training outcome and competency of medical laboratory scientists.

291

THE LACK OF A STANDARD DEFINITION FOR SUSPECTED MALARIA CASE—HOW CAN WE DIAGNOSE WHAT WE DON'T FIRST SUSPECT? DIAGNOSE WHAT WE DON'T FIRST SUSPECT?

Julie I. Thwing[1], Jordan Burns[2], Erin Eckert[1], Erin Eckert[3], Kevin Griffith[2], Mateusz Plucinski[1], Peter Thomas[1], Eric Halsey[1], Meera Venkatesan[2]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*United States Agency for International Development, Washington, DC, United States,* [3]*United States Agency for International Development, Atlanta, GA, United States*

Since 2010, the World Health Organization has recommended parasitological confirmation by microscopy or rapid diagnostic test (RDT) for all patients with suspected malaria. Most sub-Saharan African countries have now widely scaled up RDTs for diagnosis; however, less than half of children seeking care for fever receive a diagnostic test. While there are multiple reasons for this poor coverage, malaria case management guidelines developed by national malaria control programs set the standard for provider behavior and are used to guide training and supervision of malaria case management. We reviewed 25 case management guidelines from malaria-endemic sub-Saharan African countries and assessed whether a suspected malaria case was defined, or if not defined, what guidance was given in regard to malaria diagnosis. Of the guidelines reviewed, 14 gave a definition of suspected malaria or guidance as to the population to test. Of these 14, all included fever and 12 included history of fever, though temperature cut-offs for fever and duration for history of fever varied. However, four of the 14 did not recommend testing if there were signs of another fever source, and two required at least one additional symptom of malaria. Of the remaining 11 guidelines, seven defined malaria as a febrile syndrome plus parasitologic confirmation without giving guidance as to whom to test and four gave only a general discussion of malaria symptoms. While all 25 guidelines discussed fever, seven did not include history of fever. If providers are not clearly directed to test all cases of febrile illness for malaria, they must use clinical judgment, which is notoriously inaccurate for malaria diagnosis, to decide if a febrile illness is suspected malaria and requires testing. Patients with malaria infection seeking care for fever who are not tested and therefore left untreated are missed opportunities to reduce morbidity and mortality as well as transmission in the community. Malaria case management guidelines for endemic zones should clearly define a suspected case of malaria as anyone with a fever or history of fever and require testing of all suspected malaria cases.

292

SENSITIVITY AND SPECIFICITY OF A NOVEL HIGHLY SENSITIVE RAPID DIAGNOSTIC TEST FOR DETECTING LOW DENSITY *PLASMODIUM FALCIPARUM* INFECTION DURING A CONTROLLED HUMAN MALARIA INFECTION STUDY IN EQUATORIAL GUINEA

[1]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [2]*Medical Care Development International, Malabo, Equatorial Guinea,* [3]*Ifakara Health Institute, Bagamoyo, United Republic of Tanzania,* [4]*Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea,* [5]*Medical Care Development International, Silver Spring, MD, United States,* [6]*Sanaria Inc., Rockville, MD, United States,* [7]*Marathon Oil Corporation, Malabo, Equatorial Guinea,* [8]*Ifakara Health Institute, Basel, Switzerland*

Plasmodium falciparum (*Pf*) malaria continues to pose a threat despite the range of extensive interventions currently implemented. The inability of conventional malaria rapid diagnostic tests (cRDTs) to routinely detect low-densityparasitemia that contributes to ongoing transmission is perhaps one reason why the 2018 World Malaria Report failed to show continued declines in the global burden of malaria. The relatively high limit of detection (>50 pf/μl) makes cRDTs insufficient to support malaria elimination efforts. The recently developed highly sensitive RDTs (hsRDTs) present an attractive improvement to cRDTs. However, information regarding which proportion of malaria infections are missed by hsRDTs during asymptomatic subpatent infections in the field are currently scarce. Additionally, data surrounding the point at which hsRDTs can be expected to give a positive result during an individual malaria infection are limited. Controlled human malaria infections (CHMI) provide a valuable platform to evaluate novel diagnostic tools and hence could be used to answer such questions. During our EGSPZV3 study (ClinicalTrials.gov ID: NCT03590340) a total of 98 healthy Equatoguinean adults, aged 18-35 years, underwent CHMI with non-attenuated 3.2 $x10^3$ live, cryopreserved sporozoites of *Pf* NF54 given intravenously (Sanaria® PfSPZ Challenge). Pf parasitemia was monitored by qPCR and thick blood smear (TBS) starting from day 8 post-CHMI until onset of TBS positivity which resulted in treatment of volunteers. Whole blood samples collected from all subjects during and after CHMI will be analysed in parallel by cRDT (Carestart Combo, Access Bio Inc) and hsRDT (Alere Malaria Ag P.f, Standard Diagnostic Inc). We will present data comparing results from cRDT, hsRDT, TBS and qPCR from identical samples collected during a CHMI study performed in malaria-pre-exposed population. This information will provide insight on which proportion of parasite infections may be missed by hsRDTs during asymptomatic, sub-patent *Pf* infections and help to establish when hsRDT start detecting parasites after infection and until when after malaria treatment.

293

SOLUBILITY OPTIMIZATION AND DOCKING STUDIES OF ANTIMALARIAL AMINOPYRAZINES

Peter Mubanga Cheuka[1], Kelly Chibale[2]

[1]*The University of Zambia, Lusaka, Zambia,* [2]*The University of Cape Town, Cape Town, South Africa*

Malaria was responsible for 219 million cases and 435,000 deaths in 2017. Once effective drugs like chloroquine have been rendered ineffective by wide-spread resistance. Eradication efforts are further jeopardized by rising resistance to current first line treatment options, the artemisinin-

combination therapies (ACTs). Thus, new antimalarial drugs are urgently needed. Recently, aminopyrazines, as a novel antimalarial chemotype, have been shown to demonstrate impressive *in vitro* activity and *in vivo* efficacy in animal models of malaria infection. Amongst these, one analogue has since progressed to an optimized late lead stage. Unfortunately, this compound has been beset by poor solubility, which can present challenges in clinical development if the compound were to progress to that stage. Thus, it became important to address such developability issues by improving solubility in follow-on compounds. In this study, we sought to generate other second-generation candidates with improved solubility by replacing the aryl rings in the parent molecules with saturated motifs. We hypothesized that such chemical modifications would potentially improve solubility by disrupting solubility-suppressing ϖ-ϖ stacking. The new analogues were tested for *in vitro* antiplasmodium activity and aqueous solubility. In order to help rationalize the *in vitro* antiplasmodium data, we retrospectively studied the binding of the new analogues in a homology model of *Pf*PI4K (*Plasmodium falciparum* phosphatidylinositol 4kinase), a known molecular target of this chemotype. Although the new analogues showed compromised antiplasmodium potency, with only one retaining sub-micromolar activity (IC_{50} = 0.51 μM), aqueous solubility was improved by 4 - > 20-fold compared to the initial lead. Our docking studies showed that the introduced molecular features resulted in the disruption of key binding interactions to the ATP binding pocket which corroborated the parasite-based SAR (structure-activity relationship).

294

DISCOVERY OF A NOVEL, FAST-ACTING ANTIMALARIAL COMPOUND THAT RETAINS POTENCY AGAINST A PANEL OF RESISTANT PARASITES

Stacie Canan

Celgene Global Health, San Diego, CA, United States

With examples of alternative data visualizations and decisions based on sufficient (minimum) data, this presentation will highlight how biopharma medicinal chemistry research efforts can contribute to our goal of discovering new, safe treatments for malaria. In collaboration with global partners, Celgene Global Health (CGH) has created a novel class of anti-malarial compounds. CGH identified this proprietary series from a phenotypic screen against *Plasmodium falciparum*, and simultaneously optimized potency, properties, and selectivity of the series. Lead compounds successfully achieved proof-of-concept *in vivo* efficacy and retained potency against resistant lab and field strains of *P. falciparum*, an early indication of a possible novel mechanism of action. Additional non-clinical studies toward progressing the late lead compound will be discussed.

295

EXPLOITING *IN VITRO* SYNERGISTIC INTERACTIONS BETWEEN THE CONSTITUENT PLANTS OF SOME ANTIMALARIAL POLYHERBALS TO IMPROVE THERAPEUTIC SELECTIVITY

Protus Arrey Tarkang[1], Regina Appiah-Opong[2], Michael F. Ofori[2], Lawrence S. Ayong[3], Alexander K. Nyarko[4]

[1]*Institute of Medical Research and Medicinal Plants Studies (IMPM), Yaounde, Cameroon,* [2]*Noguchi Memorial Institute for Medical Research, Accra, Ghana,* [3]*Centre Pasteur du Cameroun, Yaounde, Cameroon,* [4]*School of Pharmacy, University of Ghana, Accra, Ghana*

The low structural diversity of currently available anti-malarial drugs and the increasing ability of malaria parasites to quickly develop resistance to them underscores the need to explore new therapeutic strategies. Combination therapy improves efficacy by synergistic effects and slows down parasite resistance, as reported previously. Hence, the potential of combining plant extracts is a tool to be systematically explored. This study was ubdertaken to exploit *in vitro* synergistic interactions between the constituent plant extracts of selected polyherbals, to explore strategies of improving their therapeutic selectivity. A plant extract library was generated by accelerated solvent extraction (ASE). *In vitro* antiplasmodial activities of polyherbal constituents were previously evaluated on multidrug resistant *Plasmodium falciparum* strain, followed by cytotoxicity screening. Extract interactions were analyzed using an equipotency ratio drug combination approach. The 50% fractional inhibitory concentration (FIC_{50}) and combination indices (CI) were calculated from determined EC_{50} values. ASE yields: non-polar (1-5%); polar solvents (20-25%). 18/96 extracts exhibited good antiplasmodial activities (SI > 250). Exhibited fold increases in activity of polyherbal extracts (aqueous; ethanol): *Nefang* (5; 3), *PFC* (8; 0.8), *PFH* (6; 39), *PFA* (4; 0.3), *PFT* (1.3; 12.6), *PFS* (5.7; 0.2), indicating improved therapeutic selectivity, potential efficacy and safety for fold increases ≥ 4. Out of 120 paired extracts, 21 aqueous and 16 ethanol exhibited synergism (CI < 0.8). Observed synergism informed conditions for improving therapeutic selectivity. The outcomes are likely to substantially advance malaria phytotherapy.

296

METHYLENE BLUE ACTIVITY AGAINST HEPATIC STAGES OF *PLASMODIUM*

Henriette Bosson Vanga[1], Jean François Franeitich[2], Valérie Soulard[2], Steffen Borrmann[3], Olaf Müller[4], Olivier Sylvie[2], Dominique Mazier[2]

[1]*Félix Houphouët Boigny, Abidjan, Côte D'Ivoire,* [2]*Sorbonne Universités, UPMC Univ Paris* [06]*, INSERM, CNRS, Centre d'Immunologie et des Maladies Infectieuses, U*[1135]*, ERL*[8255]*, Paris, France,* [3]*German Center for Infection Research (DZIF), Tübingen, Germany,* [4]*Institute of Public Health, Medical School, Ruprecht-Karls-University, Heidelberg, Germany*

In the context of malaria elimination/eradication, drugs effective against the different developmental stages of the parasite are highly desirable. The oldest synthetic antimalarial drug, the thiazine dye Methylene blue (MB), is known for its activity against *Plasmodium* blood stages, including gametocytes. The aim of the present study was to investigate a possible effect of MB against malaria parasite liver stages. MB activity was investigated using both *in vitro* and *in vivo* models. *In vitro* assays consisted of testing MB activity on *P. falciparum*, *P. cynomolgi* and *P. yoelii* parasites in human, simian or murine primary hepatocytes, respectively. MB *in vivo* activity was evaluated using intravital imaging in BALB/c mice infected with a transgenic bioluminescent *P. yoelii* parasite line. MB shows no activity on *Plasmodium* liver stages, including hypnozoites, *in vitro* in primary hepatocytes. In BALB/c mice, MB has moderate effect on *P. yoelii* hepatic development but is highly effective against blood stage growth. In conclusion, while confirming activity of MB against both sexual and asexual blood stages, our results indicate that MB has only little activity on the development of the hepatic stages of malaria parasites.

297

AN EXTENSIVE COMPUTATIONAL APPROACH TO INHIBIT MEROZOITE SURFACE PROTEIN-1 OF *PLASMODIUM VIVAX* ELUCIDATES FURTHER HORIZON IN THE ESTABLISHMENT NEXT GENERATION THERAPEUTICS AGAINST MALARIA

Parag Palit[1], Md. Ohedul Islam[1], Jakaria Shawon[1], Md. Kamrul Hasan[2], Mustafa Mahfuz[1], Tahmeed Ahmed[1], Dinesh Mondal[1]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Department of Biochemistry and Molecular Biology, University of Dhaka, Dhaka, Bangladesh*

Malaria represents a life-threatening disease caused by the obligate intra-erythrocytic protozoa of the *Plasmodium* genus. It exerts a sinister global health burden and accounting for approximately 660,000 deaths annually. Additionally, 219 million new cases are reported each year, most of which result from the growing issue of artemisinin resistance shown by the *Plasmodium* parasite. Much of the research done for the purpose of development of therapeutics against malaria has traditionally been focused on *Plasmodium falciparum*, which is responsible for majority of the cases of mortality due to malaria. However, *Plasmodium vivax* is also known to contribute greatly towards the malaria relate morbidities

particularly in vivax endemic areas. In this study, we have used two different computational approaches aimed at establishing newer concepts towards the development of advanced therapeutics against vivax malaria by targeting the surface antigen, merozoite surface protein-1 (MSP-1). In-silico approach involving computational siRNA designing against MSP-1 resulted in a total of four candidate siRNAs being rationally validated following corroboration with a plethora of algorithms. Additionally, molecular docking analysis unraveled a total of three anti-parasitic peptides. These peptides namely: AP02283, AP02285 and AP00101 were found to exhibit considerable binding affinity with MSP-1 of *P. vivax,* thus providing an apparent indication of their anti-malarial property and affirming their potency to be used as novel molecules for development of next generation anti-malarials. However, irrespective of the prospective magnitude of these in-silico findings, the results require extensive validation by further rigorous laboratory experiments involving both in-vitro and in-vivo approaches.

298

INVESTIGATION OF *PLASMODIUM FALCIPARUM* CYTOADHERENCE AND EXPORTED PROTEINS INTERACTIONS WITH SULFATED POLYSACCHARIDES CONTAINING ANTI-MALARIAL PROPERTIES

Jennifer Mumbe Mutisya[1], Victor Mobegi[2], Johnson Kinyua[2], Hoseah Akala[1], Ben Andagalu[1], Dennis Juma[1], Marcel Nyabute[1], Martha Kivecu[1], Edwin Mwakio[1], Raphael Okoth[1], Benjamin Opot[1], Charles Okello[1], Brenda Makena[1], Gladys Chemwor[1], Redemptah Yeda[1], Agnes Cheruiyot[1], Jim Managbanag[1]

[1]*KEMRI-USAMRDIA, Kisumu, Kenya,* [2]*Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya*

Drugs are key interventions for malaria control. There are many diverse molecules in anti-malarial drugs and the parasite has developed resistance to most of the known available molecules. Diversity in merozoite proteins mediating pathogenesis is a challenge in development of drugs targeting intracellular parasites. Merozoite surface protein 2 (MSP2) with Duffy Binding-Like Domain (DBLMSP2) is a cytoadherence protein found in complex with MSP1 which mediates initial attachment of merozoite to erythrocytes. Poly-Helical Interspersed Subtelomeric domain b with RESA (Ring-infected Erythrocyte Antigen) Like Protein (PHISTb/RLP1) is an exported protein across the parasite parasitophorous vacuole to the erythrocytes and mediates remodelling and cytoadherence to microvascular of infected red blood cells. We explored inhibitors of these proteins in the sulfated polysaccharides compounds which contain anti-malarial properties and have pre-determined efficacy. *Plasmodium falciparum* 3D7 strain protein sequences were obtained from PlasmoDB and their structures predicted using I-TASSER. The chemical compounds were screened from PubChem. Interaction prediction was achieved through docking using autodock vina. Ten sulfated polysaccharides whose chemical properties fulfilled rules of a drug compound were obtained. The autodock vina results were visualized in pymol. The ligands bound closely to *Pf*DBLMSP2 binding sites inferring protein-ligand interaction. None of the ligands interacted with *Pf*PHISTb/RLP1. Further analysis on genetic variations within these proteins and how they affect interaction with the drug compounds is underway. These results support use of sulfated polysaccharides as lead compounds in development of antimalarials targeting merozoite-egress. In *Plasmodium falciparum*, the compounds block sialic independent pathway, which is used by the parasite to invade erythrocytes. Research on chemical inhibitors of exported proteins in *Plasmodium* parasites is further recommended given the sulfated polysaccharides failed to interact with PHISTb/RLP1 protein.

299

ANTIMALARIAL ACTIVITY OF TRADITIONAL MEDICINE COPTIS RHIZOME AND ITS MAJOR ACTIVE COMPOUNDS

Awet A. Teklemichael

Nagasaki University Institute of Tropical Medicine, Nagasaki City, Japan

Malaria has gained significant interest with various cases reporting high mortality and morbidity due to the emergence of resistance to first-line artemisinin-based combination therapy (ACT). To circumvent the threat posed by these, a new drug is needed. Kampo is originated from traditional Chinese medicine, mainly obtained from herbal plants which have been used for centuries to treat various aliment. Therefore, here we design a comprehensive screening to identify the antimalarial activity of Kampo extracts & their main active components using *in vitro* & *in vivo* assay. We designed a comprehensive screening to identify novel antimalarial drugs from a library of Kampo crude drug extracts (n = 120). The antimalarial activity was initially evaluated *in vitro* using chloroquine/mefloquine-sensitive (3D7) & -resistant (Dd2) strains of *Plasmodium falciparum*. The cytotoxicity was also evaluated using primary Adult Mouse Brain cells. Subsequently, major active components of Kampo crude drug extract showing high antimalarial activities and low cytotoxicity was further evaluated. Finally, the *in vivo* antimalarial activities of promising Kampo crude drug extract was investigated using a *P. yoelii* infected mouse model. Out of 120 extracts, Coptis Rhizome showed the highest antimalarial activity (IC_{50} 1.9 μg/mL of 3D7 & 4.85 μg/mL of Dd2) with a high selectivity index (SI) > 263 (3D7) & > 103 (Dd2). Three major components in Coptis Rhizome also showed antimalarial activities with IC_{50} ranging from 1.1 to 6.0 μM (against 3D7) & from 3.1 to 11.8 μM (against Dd2). Among them, coptisine chloride exhibited the highest antimalarial activity (IC_{50} 1.1 μM against 3D7 & 3.1 μM against Dd2) with SI of 37.8 & 13.2, respectively. Furthermore, Coptis Rhizome exhibited significant antimalarial activity in mice infected with *P. yoelii* 17X strain with respect to its activity on parasite suppression consistently throughout the entire test period ($P < 0.05$). In conclusion, Coptis Rhizome is a potential natural resource for antimalarials & it›s component coptisine chloride is a promising antimalarial lead compound.

A SINGLE ORAL DOSE OF DECOQUINATE FOR PREVENTING MALARIA INFECTION AND RELAPSING MALARIA

Hongxing Wang[1], Shuanghong Liang[1], Yinzhou Fan[1], Yucheng Liu[2], Xiaohui Ning[1], Sumei Zeng[1], Siting Zhao[3], Li Qin[2], Xiaoping Chen[3]

[1]*Bluelight Pharmatech. Co. LTD, Guangzhou, China,* [2]*CAS Lamvac Biotech Co., Guangzhou, China,* [3]*Guangzhou GIBH CAS, Guangzhou, China*

A liver stage antimalarial in man with no known drug resistance is in need of development for widespread use in resource-poor, disease-endemic areas. Lately, we have successfully created decoquinate (DQ) solid solutions (HME DSS) as an oral dosage form by using hot melt extrusion (HME) technology. In the optimized HME formulations after standing for 24 hours without mixing or vortex before taking samples for analysis, the amount of DQ in the aqueous phase determined by HPLC analysis is greater than 98%. No precipitation, no floating and no agglomeration of the drug particles appear. The consistency from batch to batch preparations was demonstrated by dissolution rate experiments. HME DSS suspended in aqueous solution (saline) had no change in both mean particle size (207 nm) and bioactivity for >12 months. The formation of the true solid solution of DQ was also evidenced by the analyses of thermogravimetry, differential scanning calorimetry and x-ray diffraction, indicating that DQ is thermodynamically stable during HME process and completely miscible with excipients over the whole composition range after HME. In vitro assays show that HME DSS has excellent antimalarial activity against both the liver stage (*Plasmodium berghei* in Hep G2 cells) compared to atovaquone and primaquine and the blood stage infection (*Plasmodium falciparum 3D7, Dd2* and *803* in human RBC) compared to chloroquine and artemisinin. In the efficacy study of causal prophylaxis

in mice, 1 mg/kg of DQ in HME DSS (a single dose of 3 consecutive days given by intragastric method) provided complete prophylaxis for most animals in the group whereas 3 mg/kg was totally effective in preventing *Plasmodium* infection (*P.b* 50,000 sporozoites (SP), IV) for all animals in the group. Intragastric dose of up to 2000 mg/kg of DQ of HME DSS to mice did not result in any signs of toxicity. The blood DQ concentration in Sprague Dawley rats was greater than 1000 ng/ml after intragastric dose of HME DSS (DQ 20mg/kg). We will further test in monkey model using inoculation of *P. cynomolgus* SP the effectiveness of our innovative HME DSS on preventing new malaria infection and malaria relapse.

301

INCORPORATION OF AN INTRAMOLECULAR HYDROGEN BONDING MOTIF IN THE SIDE CHAIN OF ANTIMALARIAL BENZIMIDAZOLES

Henrietta Dede Attram[1], Sergio Wittlin[2], Kelly Chibale[3]

[1]*University of Cape Town, Cape Town, South Africa,* [2]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [3]*South African Medical Research Council Drug Discovery and Development Research Unit, Cape Town, South Africa*

Malaria continues to cause significant morbidity and mortality globally, especially in sub-Saharan Africa where the disease is endemic. Recent reports of emerging resistance to Artemisinin-based combination therapies (ACTs), the current first-line antimalarial drugs, present an even grimmer picture regarding future control and eradication of malaria. Moreover, antimalarial medications in current clinical use are fraught with challenges of high cost, low availability and undesirable adverse effects associated with their use. These factors call for accelerated research efforts to identify novel, safe and efficacious agents for treatment of malaria. Benzimidazole is a heterocyclic aromatic organic compound. The benzimidazole motif is a recognized privileged scaffold in medicinal chemistry due to its capacity to interact with numerous biological systems, leading to a wide variety of biological activities, including antimalarial activity. Likewise, the incorporation of an intramolecular hydrogen bond (IMHB) into a molecule is gaining a great deal of interest in drug design due to its ability to significantly alter molecular properties because of the formation of various conformers that in turn influence solubility, permeability, pharmacokinetic and pharmacodynamic processes, as well as protein binding affinity. As part of the malaria eradication campaign, analogues of a novel class of benzimidazoles with an intramolecular hydrogen bonding motif were synthesized and evaluated *in vitro* for their antiplasmodium activity against chloroquine-sensitive (NF54) and multi-drug resistant (K1) strains of the human malaria parasite *Plasmodium falciparum*. Compounds were also screened for their cytotoxicity towards a mammalian Chinese Hamster Ovarian (CHO) cell line. Most of the compounds exhibited good antiplasmodium activity (*Pf*NF54 IC_{50} <1 μM) and were relatively noncytotoxic. Moreover, towards establishing the possible mode of action of these molecules, potential effect on the host haemoglobin degradation pathway was investigated. Single crystal X-ray data confirmed the existence of an intramolecular hydrogen bond.

DISCOVERY OF NEW INHIBITORS OF PLASMEPSINS TARGETING MULTIPLE LIFE STAGES OF THE MALARIA PARASITE

Neha Sharma[1], Prem P. Sharma[1], Poonam FNU[2], Prakasha Kempaiah[3], Agam P. Singh[4], Brijesh Rathi[1]

[1]*Laboratory for Translational Chemistry and Drug Discovery, Department of Chemistry, Hansraj College University Enclave, University of Delhi, Delhi, India,* [2]*Department of Chemistry, Miranda House, University of Delhi North Campus, Delhi, India,* [3]*Department of Medicine, Loyola University Stritch School of Medicine, Chicago, IL, United States,* [4]*Infectious Diseases Laboratory, National Institute of Immunology, Aruna Asaf Ali Marg, Delhi, India*

Malaria remains accountable for abundant lethal cases worldwide. New therapeutics with novel modes of actions are urgently needed to enlarge the extent of treatment and to conquer developing drug resistance. Hydroxyethylamines are high-valued chemical frameworks with various biological activities, particularly antimalarial. Encouraged with our recent observations, we developed a library of new chemical scaffolds based on hydroxyethylamine and heterocycles. The toxicity assays against HepG2 cells supported all the compounds as nontoxic up to 1300 μM concentrations. Firstly, all the compounds were tested for their inhibitory actions against malarial aspartyl proteases (Plasmepsins X) that indicated two hits with inhibitory concentrations of ~900 nM. Further, compounds were examined against *P. falciparum* (3D7) culture that afforded several hits with inhibitory concentrations of <1 μM. The compounds were additionally examined for their potency chloroquine-resistant strain, Dd2 and showed remarkable efficacy. The hit molecules showed significant inhibition in *P. berghei* infected mouse models. Besides, liver stage malarial infection of *P. berghei* in culture was examined for hits, which were further tested in mouse model. All the hits were evaluated against the gametocyte culture of *P. falciparum*. It was noticed that both heterocyclic scaffolds and hydroxyethylamine were essentially important for the activity. The interesting observations will be presented in the form of a poster.

303

SMALL MOLECULE ASPERACULANE B INHIBITS MALARIA INFECTION AND TRANSMISSION

Guodong Niu, Jun Li

Florida International University, Miami, FL, United States

Mosquito-transmitted *Plasmodium* parasites infect millions of people worldwide. Drug-resistant *Plasmodium* parasites and insecticide-resistant mosquitoes make this disease hard to control. A drug that inhibits malaria infection and transmission is desperately needed. We screened our Global Fungal Extract Library (GFEL) and obtained a candidate extract that completely inhibits *P. falciparum* infection in *Anopheles gambiae*. The candidate fungal isolate was determined as *Aspergillus aculeatus*. The bioactive compound was purified with a flash column and high-performance liquid chromatography (HPLC) and was identified to be Asperaculane B. The concentration of 50% inhibition on *P. falciparum* transmission (IC_{50}) is 7.89 μM. Moreover, Asperaculane B also inhibits the development of asexual *P. falciparum* with IC_{50} of 3 μM. Therefore, Asperaculane B can be used to develop a novel antimalarial drug to treat malaria as well as to block malaria transmission.

304

MULTISTAGE ANTIMALARIAL ACTIVITY OF NEW CHEMICAL LIBRARIES TARGETING MULTIPLE PROTEASES

Brijesh Rathi[1], Jiang He[2], Poonam FNU[1], Kailash C. Pandey[3], Daniel E. Goldberg[4], Agam P. Singh[5], Prakasha Kempaiah[6]

[1]*University of Delhi, Delhi, India,* [2]*Massachusetts Institute of Technology, Cambridge, MA, United States,* [3]*National Institute of Malaria Research, New Delhi, India,* [4]*Washington University, Washington, WA, United States,* [5]*National Institute of Immunology, New Delhi, India,* [6]*Loyola University Stritch School of Medicine Chicago, Chicago, IL, United States*

Despite the significant advances, malaria remains a major threat to human population in many parts of the tropical world including India. Complex life cycle of *Plasmodium* and the increasing drug resistance to the front-line treatments are the hard-hitting obstacles to achieve the eradication of malaria. The discovery of new chemical scaffolds with multistage antimalarial activity are urgently required to combat this lethal disease. As a part of our ongoing interest in this direction, we synthesized a library of hydroxyethylamine analogs and studied their antimalarial activity in *Plasmodium falciparum (Pf)* culture and in mouse models of the malaria.

Several of these compounds displayed a significant growth inhibition of blood stage drug-resistant parasites (*Pf*D6 and *Pf*Dd2) at sub-micromolar concentrations, with the best showing 50% inhibitory concentrations (IC_{50}) of 300 nM. The cytotoxicity of these compounds was tested in peripheral blood mononuclear cells, leukemic monocytic cell lines (U937), and HepG2 cells. I*n vitro* drug-drug interaction of potent compounds with dihydroartemisinin indicated synergistic effect against *Pf*Dd2. A significant decrease in blood parasite load was noted for the hits in chloroquine-resistant *P. berghei* and *P. berghei* ANKA infected mouse models. Of these, a notable activity was exhibited by few analogs against the gametocyte stage of *P. falciparum* and liver stage infection of *P. berghei* in culture with IC_{50} values of ~1 micromolar. Few potent compounds exerted strong and comparable efficacy against *P. berghei* liver-stage infection in mouse model. Further, few analogs showed significant activity against malarial aspartyl proteases and cysteine proteases with inhibitory concentrations at sub-micromolar range. We have also identified that these compounds act as a potent lead for optimization as an antimalarial drug as revealed good membrane permeability and long endurance in the bloodstream as supported by the preliminary pharmacokinetic experiments.

305

COMPLIANCE AMONG PATIENTS/CAREGIVERS AND SERVICE PROVIDERS IN LIBERIA USING FIRST LINE ANTIMALARIALS DRUG (ARTESUNATE+AMODIQUINE-ASAQ AND ARTEMETHER + LUMEFATHRINE-AL)

Victor S. Koko[1], Oliver J. Pratt[1], Paye K. Nyansaiye[1], Levi D. Hinneh[1], Joseph O. Alade[1], Moses Badio[2], Eric Diboulo[3]

[1]*Ministry of Health/National Malaria Control Program, Monrovia, Liberia,* [2]*Local consultant, Monrovia, Liberia,* [3]*Measure Evaluation, Monrovia, Liberia*

Liberia adapted the use of ACT as the first line treatment for uncomplicated malaria 2008. Efficacy studies have shown high parasite clearance of this drug. Its effectiveness depends on adherence to treatment by both service providers and patients but todate, NMCP has no current empirical data on adherence. In wake of the lack of current evidence on adherence to treatment by both patients/caregivers and service providers, NMCP conducted an adherence study to determine adherence/compliance among patients/caregivers and service providers. The study used cross sectional survey design in randomly selected 10 health facilities throughout the country. (Two from each of the five health regions). Study participants were followed-up to determine their compliance status. The study consisted of two major components; observations made at facilities on dispensers interaction with patients diagnosed and confirmed positive with uncomplicated malaria and given ACT and exit interview furthered by follow-up at patients' homes on day 4. Descriptive and analytical analysis conducted in finding association. On the overall, 50% patients/caregivers complied/adhered with treatment regardless of drug type. By drug type, ASAQ had the highest compliance/adherence 61% than AL 39%. Children under five years had the highest (33%) compared with 12-17 year reporting the lowest 7%. Regarding dispensers' interaction with patients/caregivers, over 94% of the patients/caregivers were told how to take the drugs, with 12% told the importance of completing the doses and 15% asked if they understood the instruction. The result poses threat to the alternative first line antimalarial (AL) as the drug is considered new in Liberia and irrational use may lead to early treatment failure. Service providers&patients/caregivers need to be advised on the importance of explaining and completing treatment as there is an increased chance of complying with treatment the more explanations a patient/caregiver receives.

MALARIA IN VENEZUELA: TRACKING THE WORST MALARIA EPIDEMIC IN THE AMERICAS REGION AND THE ROLE OF CIVIL SOCIETY IN THE MALARIA RESPONSE

Leonor Pocaterra[1], Luis F. Chavez[2], Maria M. Villegas[3], Jorge Moreno[4], Angela Martinez[5], Elsy Rojas[1], Maria E. Guevara[3], Jose Oletta[6], Gustavo Bretas[3], Aurora Hernan[1], Mary A. Torres[7], Michelle Gonnet[8], **Leopoldo Villegas**[9]

Venezuela is facing a complex humanitarian crisis, including the worst malaria epidemic in the continent. Since 1955, the Malaria Program consolidates weekly cases from all states with reporting rates ≈85%. Historically, the malaria information system (MIS) includes only "new cases"(NC), excluding relapses (R) and recrudescences (Rc) cases. In Bolivar State (where 75% of malaria occurs), weekly reporting of R/Rc was incorporated into the MIS from 2008 onwards. Although malaria information is being routinely collected, the Venezuelan government stopped publishing data since 2015. In response to this malaria situation, as part of the civil society, we aim.to describe and update the number of malaria cases in Venezuela (1995-2018), including data on relapses, recrudescences, self-medication and underreporting. Estimations of 2019-2020 cases are also presented. Nationwide, malaria NC rose 2.200% from 22501 cases in 1995 to 530414 cases in 2018. Similarly, annual incidence (per 1000 pop) increased from 1.27 in 1995 to 32 (2.4K%) in 2018. Over the study period, imported malaria increased 6.8 times and the median percentage of *Plasmodium vivax* infections (range) were 80.6% (64.8-91.2), and 18.15% (8.6-28.9) for *P. falciparum*. The percentage of mixed infections (Pf+Pv) increased from 0.01% in 1997 to 6.4% in 2018. The annual percentage of R and Rc shifted in 2013, coinciding with major contextual shifts in the country. Estimated malaria cases (range) for 2019 and 2020 were 2 M (1.1M-3.8M) and 3.9 M (1.9M-7.9M), respectively. All observations in this study are consistent with increased transmission over space and time. and we estimate that at least 1.4 M cases were not accounted for between 2008-2018. Venezuela has lost previous gains in malaria control and local transmission is occurring in areas that have been malaria-free since the 1960s. There is an urgent need for effective targeted interventions to reduce the burden of malaria in Venezuela and its regional spread. The organized civil society can play a key role in promoting accountability and transparency about the current malaria situation, and the implementation of targeted interventions.

307

BASELINE MALARIA PREVALENCE IN DISTRICTS TARGETED FOR MALARIA ELIMINATION IN ETHIOPIA

Adugna A. Hirpa[1], Desalegn Nega Wada[1], Sindew Mekasha Feleke[1], Bokretsion Gidey[1], Geremew Tasew Guma[1], Abnet Abebe[1], Honelegn Nahusenay[2], Semira Abdulmenen[2], Ayele Zewude[2], Dereje Dillu[3], Degu Mehari[3], Gudisa Aseffa[3], Gezahegn Tesfaye[3], Hiwot Teka[4], Mattew Murphy[4], Adugna Woyessa Gemeda[1]

[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia,* [2]*Addis Continental Institute of Public Health, Addis Ababa, Ethiopia,* [3]*Federal Ministry of Health Ethiopia, Addis Ababa, Ethiopia,* [4]*President Malaria Initiative-USAID Ethiopia, Addis Ababa, Ethiopia*

Baseline malaria prevalence in elimination targeted areas enables us to measure the impact of the intervention in malaria control program. The objective of this survey was to assess the baseline malaria prevalence at community level in elimination targeted districts of Ethiopia. Community based cross sectional survey was conducted from October to December 2017. Samples of malarious villages were randomly selected from 20 districts, among the 239 elimination targeted districts in Ethiopia. Open Data Kit programmed household questionnaires and laboratory formats were used to collect the data. Blood samples were examined with Care Start™ Malaria HRP-2/pLDH. Data analysis was done using STATA 14. The overall prevalence of malaria detected by RDTs in this survey was 1.17% (339/28983). High proportion of malaria infection was reported in some districts: Harari 4.7% (46/979), followed by 3.7% (87/2358) in Kersa, 2.7% (81/2999) in Misrak Badawacho, 1.7% (27/1597) in Kolla Tembien, 1.4% (32/2281) in Habru and 1.07% (22/2055) in Raya Kobo. Whereas, in half (50%) of the surveyed districts, the prevalence was less than 1%. Interestingly, four districts namely Berehet, Sire, Gemechis and Damboya reported zero prevalence. The total prevalence of fever was 9.2% (2766/29993). Symptomatic malaria was 75.2% (255/339) and symptomatic 24.8% (84/339) among malaria positives. In conclusion, the total malaria prevalence of 1.17% by RDT in the elimination setting is yet high which calls for further strong intervention measures. The presence of the considerable asymptomatic malaria prevalence indicated the presence of asymptomatic reservoirs for continuity of malaria transmission in the elimination settings. This residual malaria in low transmission sustains uninterrupted malaria transmission in the areas. Active case detection is highly suggested to break the transmission sources. The conventional diagnostic methods such as microscopy and RDT may not provide conclusive determination; therefore inclusion of sensitive methods such as PCR is highly necessary.

308

HOTSPOT BASED INTERVENTIONS: A SUCCESS IN REDUCTION OF MALARIA TRANSMISSION FROM HIGH ENDEMIC CHATTOGRAM HILL TRACT (CHT) DISTRICTS IN BANGLADESH

Shamsun Naher, Akramul Islam, Mohammad Moktadir Kabir, Abu Saeid

BRAC, Dhaka, Bangladesh

Malaria is endemic in 13 eastern and north-eastern border belt districts of Bangladesh with variable transmission potentials (high, moderate and low). A total of 13.25 million people are at risk of malaria inhabited in those areas. Three Chattogram Hill Tract (CHT) districts have the highest endemicity and mortality due to their socio-economic and geographical factors which cover about 11.78% (2.13 million) of the endemic population but contribute more than 90% malaria burden over the years nationally. BRAC has been performing malaria program since 1998 in close collaboration with the government of Bangladesh. BRAC applied its community-based approach in providing malaria diagnostic and preventive services to door-steps of the community. *Para* (the smallest administrative unit) wise micro-stratification data were collected since 2015 and hot-spot based intensified interventions were taking, such as distribution of community health workers, mobile campaign, Long Lasting Insecticidal Nets (LLINs) distribution, awareness activities etc. Here we analysed past two years (2017 and 2018) data in CHT in order to categorize the endemicity of the sub-districts and villages on basis of Annual Parasite Incidence (API). About 64 % reduction of malaria incidences in 2018 compare to the year 2017 in Bangladesh. In CHT which contributed 90.6 % in 2018 showed reduction of malaria cases to 65% percent in 2018 compare to the year 2017. Only 2 out of 7 deaths due to malaria were reported in CHT in 2018. Eight sub-districts out of 25 where population covered 28% of CHT reported 77.4% malaria cases in 2018. Among the community health workers 37.5% were deployed in those areas. Among 2180 villages, 318 (14.6%) villages reported malaria where API >50 per 1,000 population in the last year contributed 50% of malaria cases. In 2017, 582 villages showed API >50 per 1,000 which in 2018 reduced to 45.4 %. Our data suggest that intensive interventions and continuous surveillance targeting hot-spot area and high risk group, and sustaining political commitment and finance are essential to achieve the target of malaria free Bangladesh by 2030.

309

PREVALENCE AND DRIVERS OF *PLASMODIUM* INFECTION ACROSS VILLAGES IN SOUTHEASTERN TANZANIA

Elihaika G. Minja, Johnson Kyeba Swai, Emmanuel Mrimi, Halfan Ngowo, Fredros Okumu

Ifakara Health Institute, Ifakara, United Republic of Tanzania

Malaria prevalence has significantly declined over the past decade in Tanzania, due to scale-up of key interventions such as the long-lasting insecticidal nets (LLINS), indoor residual sprays (IRS) and improved diagnosis and treatment. In the south-eastern districts of Ulanga and Kilombero, detailed entomological surveys have been done to track the declining malaria transmission and its drivers, but there have been no survey of actual malaria prevalence in recent times. We therefore conducted a cross-sectional active-case detection to assess prevalence *Plasmodium* infections and associated factors in 12 wards of Ulanga and Kilombero districts, south-eastern Tanzania. Malaria infection was tested using rapid malaria diagnostic test (mRDT), and positive cases confirmed using microscopy and PCR. Structured interviews were done to identify households at risk. A total of 2,912 individuals were tested across all villages. Multivariate analyses showed no difference in malaria infections between males and females (OR: 1.25 [0.99-1.57], P=0.064), but living in urban or peri-urban areas was associated with 99.7% less malaria (OR: 0.02 [0.01-0.07], P<0.001). Village by village prevalence varied from as high as 52% (Tulizamoyo) and 43% (Igota) in the north, to 2% (Minepa) or 1% (Lipangalala) in the southernmost part of the study area. Three wards including Ifakara town and two of its surrounding wards had no positive malaria cases detected. Malaria prevalence was higher among under-fives than other age groups (OR: 1.25 [0.99-1.57], P<0.001). These findings highlight high levels of spatial variability in malaria transmission, and a major decline in prevalence in some of the villages previously experiencing hyper to holoendemic transmission. Specific underlying drivers are not yet known until final analysis is completed.

310

RISK FACTORS FOR PATENT AND SUB-PATENT GAMETOCYTE CARRIAGE OF *PLASMODIUM FALCIPARUM* (*PFS25*) AND *PLASMODIUM VIVAX* (*PVS25*) IN HYPO- TO MESO-ENDEMIC WEST TIMOR IN EASTERN INDONESIA

Ayleen A. Kosasih[1], Cristian Koepfli[2], Rintis Noviyanti[3], Dwi A. Pujianto[4], Decy Subekti[1], William A. Hawley[5], Frank H. Collins[2], J. Kevin Baird[6], Ivo Mueller[7], Neil F. Lobo[2], Inge Sutanto[8]

Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [7]Infection and Immunity Division, Walter & Eliza Hall Institute, Melbourne, Australia, [8]Department of Parasitology, Medical Faculty, Universitas Indonesia, Jakarta, Indonesia

Asymptomatic gametocyte carriage at low densities may often drive malaria transmission in low to moderate endemic settings. We examined risk factors for gametocyte carriage employing RT-qPCR diagnostics among residents of hypo- to meso-endemic West Timor in eastern Indonesia. Two mass blood surveys were conducted in June and September 2013. 1,551 blood samples were collected from 875 residents. Light microscopy identified 47 *Plasmodium falciparum*- and 74 *P. vivax*-positives. Later, qPCR was utilised to examine for malaria positivity, and a total of 91 *P. falciparum* and 315 *P. vivax* positives were identified. RNA for gametocyte assay was available from 85 and 227 *P. falciparum*- and *P.vivax* -positive subjects, respectively. Assay for gametocytemia employed *pfs25* and *pvs25* RNA markers. Participant age, sex, microscopic malaria status, plasmodial parasite density, fever, and fever history were examined as potential risk factors for gametocyte carriage using bivariate and multivariate analyses. Among microscopically patent subjects, 23/47 *P. falciparum* positives also had patent gametocytemia, whereas 16/74 *P. vivax* positives did so. Gametocyte carriage was detected in 52% (44/85) and 37% (86/227) *P. falciparum* and *P. vivax* infections. Bivariate analyses suggested younger age (<=17 yrs), microscopic positivity, estimated parasite density, and history of fever were positively associated with gametocyte carriage in both *P. falciparum* and *P. vivax* ($p<0.05$). Gametocytemia for either species did not appear to be impacted by sex or fever. Multivariate analyses suggested age and history of fever were associated with *P. falciparum* ($p=0.015$ and $p=0.006$) gametocytemia, whereas parasite density was the sole predictor for gametocyte carriage in *P. vivax* ($p<0.001$). Most parasitemias in this community occurred below the limit of detection by expert microscopy, as did almost all gametocyte carriage. This study demonstrates sub-patent gametocyte carriage and its apparently species-specific risk factors in a low transmission setting. Gametocytemia in *P. vivax* indeed appears to emerge independently of febrile illness.

311

ASSESSING RELATIONSHIP BETWEEN HUMAN SETTLEMENT PATTERNS AND MALARIA RISK IN A RESIDUAL TRANSMISSION SETTING IN SOUTHEASTERN TANZANIA

Emmanuel W. Kaindoa[1], Arnold S. Mmbando[1], Gustav Mkandawile[1], Maureen Coetzee[2], Sherif Amer[3], Fredros O. Okumu[1]

[1]*Ifakara Health Institute, Morogoro, United Republic of Tanzania, [2]Wits Research Institute for Malaria and Wits/MRC Collaborating Centre for Multidisciplinary Research on Malaria, School of Pathology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]Faculty of Geo-information Science and Earth Observation, University of Twente, Netherlands, Netherlands*

Spatial targeting of interventions is increasingly recognized as essential for malaria control, particularly in areas aiming for elimination. The associations between house characteristics and malaria transmission are known, but gaps remain on whether transmission is also influenced by factors such as distances between households or the degree to which houses are clustered. This study examined households densities and their distances influence malaria transmission in a set of rural Tanzanian communities. We performed indoor and outdoor mosquito collection from fixed as well as randomly selected households over 12 months period and assessed effects of spatial clustering of households on malaria transmission risks. The study found that high house densities increased *Anopheles* biting risk but mosquito density declined as distances between houses increased beyond 50m. Despite the recent scale-up of effective vector control interventions, such as LLINs, there are still major household and environmental characteristics contributing to persistent malaria transmission. Additional efforts such as house improvement programs targeted at village-level, could address the challenges by prioritizing high-risk household clusters. Such new efforts could be further improved by involving communities in the control strategies, and removing financial and access barriers associated with poor-housing.

312

PARADIGM SHIFT AND SEASONAL VARIATION IN MALARIA PREVALENCE AND ANAEMIA IN IJEDE, IKORODU LOCAL GOVERNMENT AREA, LAGOS STATE, NIGERIA

Oluwagbemiga Olanrewaju Aina[1], Adeola Yetunde Olukosi[1], Chimere Obiora Agomo[2], Bamidele Abiodun Bamidele Iwalokun[1], Olusola Ajibaye[1], Bassey A. Orok[1], Adeniyi K. Adeneye[1], Chinendum T. Oparaugo[1], Samuel K. Akindele[1], Olajumoke M. Akinyele[1], Samson T. Awolola[1]

[1]*Nigerian Institute of Medical Research, Lagos, Nigeria, [2]Department of Medical Laboratory Science, University of Lagos, Lagos, Nigeria*

Seasonal variation is the change that occurs as a result of climate change including rain fall, humidity and temperature. There are two main seasons in Nigeria wet season and dry season. The objective of this study is to compare the prevalence of malaria and anaemia in Ijede community in both the wet and dry seasons and to assess the malaria prevalence of children under-five and above five years old. This is a cross sectional study, the study participants were screened for malaria using mRDTs and microscopy. The anaemia status of the participants were defined using the WHO haematocrit cut-off for mild, moderate and severe anaemia based on age and sex. Participants with confirmed malaria parasite were treated with artemether-lumefantrine. Blood spots were made on filter paper for studies on antimalarial drug resistance. A total of 813 and 833 participants were screened in the dry and wet seasons respectively , majority of them were females 556 (68.4%) and 480 (57.6%) in both seasons, The mean age was 30.07 ± 20.5 years and 26.3 ± 20.6 years in dry and wet seasons respectively. Children under the age of 5 were 134 (16.5%) and 130 (15.6%) in dry and wet seasons respectively, while those above 5 years of age were 679 (83.5%) and 704 (84.4%) in dry and wet seasons respectively. The prevalence of aneamia was 100 (22.4%) and 206 (47.7%) in dry and wet seasons respectively. Malaria prevalence in Ijede community was 5.7% and 9.7% in dry and wet seasons respectively. Malaria prevalence was 122(3.2%) and 590 (6.2%) in Children under 5 years and above 5 years respectively in dry season while in wet season the malaria prevalence was 113 (13.1%) and 610 (13.4%) in Children under 5 years and above 5 years respectively. Malaria prevalence was higher in children above 5 years of age irrespective of methods of assessment ($P<0.05$) in both dry and wet seasons. There is a paradigm shift in high malaria prevalence from children under-fives to above five years in this study. Malaria control strategies should be also be targeted at Children above the age of 5 years mostly during the wet season.

313

A SYSTEMATIC REVIEW OF THE CHANGING MALARIA DISEASE BURDEN IN SUB-SAHARAN AFRICA SINCE 2000: COMPARING MODEL PREDICTIONS ANDEMPIRICAL OBSERVATION

Alice Kamau[1], Polycarp Mogeni[1], Emelda A. Okiro[1], Robert W. Snow[2], Philip Bejon[2]

[1]*KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya, [2]Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Oxford, United Kingdom*

The changing burden of malaria in Africa has been modelled using sparse data on parasite prevalence, environmental covariates and intervention coverage which are linked to historical estimates of clinical incidence. Uncertainty remains regarding the spatial consistency of these modelled declines. We undertook a systematic review (PROSPERO International Prospective Register of systematic reviews; ID= CRD42019116834) to identify empirical data on the temporal changes in clinical malaria in Africa since 2000, where reports covered at least 5 continuous years. These data were then compared with time-space matched estimates of the predicted

changes in clinical burden using data from the Malaria Atlas Project (MAP). The magnitude of relative change and correlation between changes in empirical clinical malaria and modelled estimates of clinical burden was assessed. Sixty-six articles met our inclusion criteria representing 120 sites surveyed between 5-15 consecutive years since 2000 from 23 African countries. Forty-one (34%) site-specific data showed evidence of an increase in malaria over the surveyed period, 79 (66%) showed a decline. Comparisons between changes in empirical clinical malaria and modelled estimates of clinical burden showed a mixed pattern of concordance, depending of data types, location and period of observation. Models provide a broad picture of changing global disease burden but cannot replace empirical data. The paucity of high quality, temporal clinical data in Africa must be redressed, to avoid a continued dependence on models or to help train future models.

314

HIGHLY DYNAMIC CHANGES IN IRON STATUS DURING PREGNANCY AND POSTPARTUM AND ASSOCIATIONS WITH ADVERSE MATERNAL OUTCOMES IN A MALARIA ENDEMIC REGION OF PAPUA NEW GUINEA: A COHORT STUDY

Eliza Davidson[1], Michelle Scoullar[1], Herbert Opi[1], Elizabeth Peach[1], Chris Morgan[1], Pele Melepia[2], Ruth Fidelis[2], Willie Pomat[3], Philippe Boeuf[1], Ricardo Ataide[1], Julie Simpson[4], James Beeson[1], Freya Fowkes[1]

[1]*Burnet, Melbourne, Australia,* [2]*Burnet, Kokopo, Papua New Guinea,* [3]*Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea,* [4]*Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia*

Iron deficiency is the most common nutrient deficiency worldwide and is the leading risk factor for anaemia; approximately half of all anaemia cases are attributed to iron deficiency. The highest prevalence of iron deficiency globally is observed in pregnant women, who are highly susceptible to both iron deficiency and anaemia; while postpartum susceptibility is less well known. However, iron is also an essential nutrient for a number of pathogens, and so a deficiency in host iron is hypothesized to reduce pathogen fitness and decrease infection susceptibility and/or severity. This interaction is of particular concern in malaria endemic countries. Here we determine temporal changes in iron deficiency during pregnancy and postpartum; and investigate associations with anaemia and *Plasmodium* species infection. This study utilized 700 samples and corresponding epidemiological data from women living in a malaria endemic region of Papua New Guinea, where the prevalence of iron deficiency and poor maternal outcomes are high. Iron deficiency, defined as ferritin<15μg/L, was highly prevalent at enrolment (80.6%) and delivery (84.9%); far less prevalent at 6 months (22.2%) and 12 months postpartum (28%). The prevalence of anaemia, defined as haemoglobin <11g/dL, was also very high at enrolment (82.3%) and delivery (57.6%), but less so at 6 (37.7%) and 12 (49.4%) months postpartum. Ferritin measures within women were highly dynamic over time, with huge fluctuations between enrolment and 12 months postpartum. Haemoglobin levels were more stable, gradually increasing from enrolment through to delivery and 6 months postpartum. Iron deficiency was significantly associated with lower haemoglobin levels at enrolment, delivery and 6 months postpartum ($p<0.05$), compared to iron replete women. Multivariate analyses quantified the relationship between *Plasmodium* species infection, iron status and anaemia. Findings highlight the high burden of deficiencies and disease in resource-poor settings and the complex interactions that exist between morbidities transitioning from pregnancy to postpartum.

315

COMPARISON OF *PLASMODIUM* INFECTION BETWEEN CHILDREN AND ADULTS IN KOMBEWA

Cornel Obonyo Arima, Jim Ray Managbanag, Cephas Aguko, Agneta Ogolo, Catherine Sumbi, Michael Ayaya, Everlyne Omondi, Victor Otieno, Vincent Akolo, Rose Adeny, Hoseah M. Akala, Bernhards Ogutu

[1]United States Medical Research Directorate - Africa/Kenya, [2]Kenya Medical Research Institute

Malaria remains one of the major causes of preventable illnesses and mortality in developing countries. In 2005, WHO estimated 214 million new malaria infected cases with 438,000 malaria associated mortalities. Malaria morbidity and mortality is higher in children under five years than adults. Studies have shown that recent up-scaled integrated vector control interventions have eased disease burden in Africa. Specifically, the world health organisation recommends that in endemic areas with intense malaria transmission, all infants at their first immunization and all pregnant women as early as possible in pregnancy should receive one long-lasting insecticidal net through immunization and antenatal care visits. As this guideline continues to be followed, it is essential to continue tracking the impact of these guidelines on disease burden across ages in the population. The aim of this study was to estimate the frequency of malaria in Kombewa by age group. A total of 1451 potential study subjects were screened in the blood collection protocol survey between 2007 and 2011 in Kombewa sub county, Kisumu. A total of 20μl of whole blood was drawn from each study subject. Each sample was tested by both RDT and confirmed by expert microscopy. Out of 1451, 940(64.8%) samples tested positive for *Plasmodium* species by microscopy. Of the 940 positive cases, children < 5 years were 400(43%), ages of 5-17years 385(26.6%) while adults above 18yrs were 150(10.5%) positive cases. Further, children ages <5 years had highest parasite counts than older children aged 7-17 years and adults based on expert microscopy confirmed read-outs ($P<0.005$). These findings show decreasing frequency of infection with increase in age suggesting sustained burden among children despite heightened intervention targeting this age group.

316

PARASITAEMIC PROFILES AND DISTRIBUTION OF HOST AND MATERNAL FACTORS AMONG INFANTS LIVING IN A HIGH MALARIA TRANSMISSION AREA OF GHANA

Akua Kyerewaa Botwe[1], Seth Owusu-Agyei[2], Ulf Hammar[3], Felix Boakye Oppong[1], Stephaney Gyaase[1], Gabriel Jakpa[1], George Adjei[4], Muhammad Asghar[5], Faith Osier[6], Anna Färnert[7], Kwaku Poku Asante[1]

Karolinska University Hospital, Stockholm, Sweden*

Insight into determinants of asymptomatic and symptomatic infections in infants can contribute to our understanding of malaria immunity and guide control interventions. The aim of study was to identify infants immune to malaria based on their temporal profile of episodes in the first year of life and identify pre-disposing factors to susceptibility. A birth cohort in Kintampo, Ghana (N = 1855) was followed with monthly blood sampling and passive surveillance of malaria between 2008 and 2011. Malaria parasites were detected by light microscopy. Host, maternal, parasite and hematological parameters were collected from infants and their mothers. Profiles of infections and distribution of host and maternal factors among infants through their first year of life were examined. Analyses were based on 1264 infants that had at least eight monthly visits in twelve months. Infants were either parasite negative in all samples

(36 %), or when parasites detected were always asymptomatic (7 %), always symptomatic (35 %) or alternated between asymptomatic and symptomatic episodes (22 %). Compared to infants who were parasite negative only, significantly higher proportion with symptomatic malaria only had low socioeconomic status (SES), were born in low transmission season, had mothers receiving one to three doses of intermittent preventive treatment during pregnancy (IPTp) and resided in rural areas. Compared to symptomatic malaria only, significantly lower proportions of infants with asymptomatic infections only had illnesses and fever before first infection, lower age at first infection, placental malaria, IPTp directly observed therapy and low SES. Birth weight, congenital abnormalities, age of mother, sickle cell status of mother or infant, insecticide treated bed-net use by mother and tetanus immunizations during pregnancy were not significantly different between the profiles. Although most infants experienced episodes of symptomatic malaria, some remained asymptomatically infected through the first year of life. Future studies will examine risk of asymptomatic infections and identify antibody correlates of protection for infants.

317

ABO BLOOD GROUP AND MORTALITY IN CHILDREN WITH SEVERE MALARIAL ANEMIA DUE TO *PLASMODIUM FALCIPARUM*

Jean-Bertin Kabuya[1], Luc Kamavu[2], Mike Chaponda[1], James S. Lupiya[1], Manuela Hauser[3], Jessica Schue[4], William J. Moss[4], Philip Thuma[5], Matthew Ippolito[4]

[1]*TDRC, Ndola, Zambia,* [2]*St Paul's Hospital, Nchelenge, Zambia,* [3]*University Children's Hospital, Zurich, Switzerland,* [4]*Johns Hopkins, Baltimore, MD, United States,* [5]*Macha Research Trust, Macha, Zambia*

Previous studies of ABO blood group and malaria describe a protective effect of blood group type O. To assess the possible relationship between blood group and survival in children with severe malarial anemia due to *P. falciparum* infection, we combined data from two observational studies of severe malaria conducted in two hospitals in Zambia. Study participants were children ≤12 y with falciparum malaria and severe anemia, defined as hemoglobin (Hb) concentration ≤5 g/dl. For comparison, we included children with severe anemia due to causes other than malaria. We examined associations between ABO blood group and mortality in unadjusted and adjusted logistic regression models. We identified 384 children with severe malarial anemia and 45 children with severe anemia due to another cause. Other causes included sickle cell, malnutrition, renal disease, and infections other than malaria. Among children with severe malarial anemia, blood group type O was the most prevalent (43%) followed by types A (28%), B (23%) and AB (5%). The median age was 23 m (IQR: 12-36) and 52% were girls. The median hemoglobin concentration was 3.8 g/dl (IQR: 3.1-4.3). Most (86%) received blood transfusion. The case fatality ratio was 13%. Children with other causes of severe anemia were similar across all characteristics. Adjusting for age, sex, Hb, and blood transfusion we found no statistically significant association between ABO blood group and mortality in children with severe malarial anemia, or in children with severe anemia due to other causes. Higher Hb and receipt of blood transfusion were associated with improved survival (OR 1.6, 95% CI: 1.1-2.3, p=0.02 per g/dl increase in Hb; OR 3.3, 95% CI: 1.5-7.4, p<0.01 for blood transfusion). Although previous studies demonstrated a relationship between ABO blood group and malaria-related outcomes, we did not find an association between blood type and mortality in Zambian children with severe malarial anemia, or severe anemia due to another cause. Further studies that assess the association between ABO blood group and malaria may lend insight into the pathophysiology of malaria caused by *P. falciparum*.

318

PREDICTORS OF MALARIA PARASITEMIA AMONG CHILDREN UNDER FIVE YEARS IN GHANA: A SUBNATIONAL COMPARATIVE ANALYSIS OF POPULATION SURVEY DATA, 2019

Samuel Kweku Oppong, Alexander Asamoah, Mildred Kommey

National Malaria Control Programme, Accra, Ghana

Ghana has 3 ecological zones(coastal, forest and savanna) with different malaria transmission patterns. With the current drive for elimination at subnational level, identifying predictors of malaria parasitemia to help inform appropriate area specific intervention mix is needed.Data was analyzed to assess factors contributing to malaria parasitemia across the ecological zones.Secondary data analysis on 2016 Malaria Indicator Survey was done.Variables included were age,sex,place of residence of child,wealthindex,IndoorResidualSpraying(IRS),mother's educational level,age,exposure to malaria messages,source of exposure,use of ITNandhousehold ownership of net.Odds Ratio(OR) was used to determine associations at 95% confidence interval(CI).Of the 2601 children data included in the analysis,39%(1014),38%(988)and23%(599) were from coastal, forest and savanna zones respectively. The odds of parasitaemia OR;CI was significantly associated with place of residence 2.64;1.47-4.76,Wealth index (middle 0.43;0.21-0.87,Richer0.29;0.13-0.63,Richest0.06;0.02-0.21,Mother's education (secondary1.33;0.13-0.84,Age of Child(24-35 months1.95;1.06-3.61,48-59 months1.95;1.06-3.61 in coastal zone; wealth index (middle0.34;0.16-0.71,Richer0.19;0.08-0.46,Richest0.03;0.00-0.17),Mother's education (secondary0.40;0.16-0.98, source of malaria message 0.49;0.25-0.97 in forest zone and wealth index (poorer0.25;0.09-0.70,middle0.24;0.07-0.82,Age of Child(36-47 months 2.63;1.35-5.13, 48-59 months2.67;1.48-4.83,IRS 0.53;0.30-0.93 in savanna zone. The odds of parasitemia reduces with increasing wealth index across all zones. Children 48-59 months are more likely to have malaria parasites in coastal and savannah zones whiles children of mothers with secondary or higher education are less likely to have malaria parasites in coastal and forest zones. IRS reduces the odds of malaria parasitaemia in the savannah zone. More data should be gathered on interventions implemented in specific areas of the country to assess their effect on parasitaemia to better inform program strategies.

319

HUMAN MOBILITY AND MALARIA HISTORY IN A PERIURBAN COMMUNITY OF THE PERUVIAN AMAZON

Andree Valle Campos[1], Jorge L. Maguiña[1], Gabriela Ulloa[1], Katty M. Arista[2], Viviana Pinedo-Cancino[2], Lastenia Ruíz-Mesia[2], Meddly Santolalla[1], Adam Bennett[3], Andres G. Lescano[1]

[1]*Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Universidad Nacional de la Amazonía Peruana, Iquitos, Peru,* [3]*Malaria Elimination Initiative, Global Health Group, University of California San Francisco (UCSF), San Francisco, CA, United States*

Human mobility is a main driver of *Plasmodium vivax* local transmission in rural communities of the Peruvian Amazon. However, this factor may not apply for a periurban Amazonian setting that develop different behavioral dynamics due to their proximity to roads and the city. Even more in populations that have a broad range of night activities due to their electricity access. We performed a cross-sectional household survey to adults (> 18 years old) in the periurban community of Zungarococha, 5km to the southwest of Iquitos city, during the dry season (July-August 2017). We applied a malaria history survey to assess past events diagnosed by a health worker by microscopy. Movement and travel patterns survey to assess the range of hours out of home and frequency of short (1 night - 1 month) and long (>1 month) travels. To identify associated variables to malaria history in the last year we performed a poisson-log multiple regression and reported adjusted prevalence ratio (PR) with 95% confidence intervals (95%CI). We surveyed 427 individuals within 247 households. Agriculture was the highest reported occupation (11.6%)

over fishing or logging. 26.9% of subjects reported being out of home between 18:00 and 05:59 hours and 20.5% had a malaria episode in the last year. Our model showed five associated factors: the sum of reported hours out of home between 18:00-05:59 h (PR 1.04 95%CI 1.00-1.08) and between 06:00-17:59 h (PR 1.04 95%CI 1.01-1.06), presence of long travels (PR 1.49 95%CI 1.00-2.22), and living in one village to the other three (PR 0.56 95%CI 0.34-0.91). We included outdoor work as confounder and walking transport as mediator. We did not identified difference in the prevalence of malaria history in the last year between hours spent out of home at night or day, although both were detected as associated factors. Additionally, its prevalence in subjects with travels greater than a month showed to be 49% higher than subject without long travel history. Lastly, urban village conditions decrease its prevalence in 44%. In conclusion, longer travels showed a different scenario for periurban settings with respect to malaria history, independent of occupation.

320

PREGNANT WOMEN MAY BE A SENTINEL GROUP FOR MALARIA SURVEILLANCE: PRELIMINARY RESULTS FROM A STUDY IN SOUTHERN MOZAMBIQUE

Alfredo Mayor[1], Gloria Matambisso[2], Gizela Bambo[2], Beatriz Galatas[1], Pau Cisteró[1], Sonia Maculuve[2], Caterina Guinovart[1], Francisco Saúte[2], Clara Menéndez[1], Pedro Aide[2], Eusébio Macete[2]

[1]*Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain,* [2]*Manhiça Health Research Center (CISM), Manhiça, Mozambique*

Antenatal care (ANC) clinics may provide accessible routine information of theoretically healthy women, which might serve as a proxy for several health indicators at the community level. Several studies have suggested that the prevalence of malaria among pregnant women attending the ANC may reliably reflect malaria patterns in their communities. However, evidence on the relationship between malaria parasite prevalence in the community and in pregnant women at first ANC visit is still lacking. To test this approach, pregnant women at first ANC visit were recruited between November 2016 and November 2019 at three ANC clinics located in two districts from southern Mozambique (Manhiça and Magude, in Maputo province). At this first visit, clinical and demographic information was collected, together with a dried blood spot for detection of *P. falciparum* (*Pf*) by real-time quantitative PCR (qPCR). In parallel, cross-sectional surveys conducted in May 2017-2019 estimated *Pf* infection prevalence by rapid diagnostic test (RDT) in an age-stratified simple random sample of the population of Manhiça and Magude districts. *Pf* prevalence by qPCR among pregnant women attending the first ANC clinic (PR_{ANC}) between November 2016 and 2018 was 7% in Manhiça, 33% in Ilha Josina and 5% in Magude. *Pf* infection prevalence by RDT (PfPR) in children 2-10 years old ranged from 30.9% (95% CI 14.7-53.5) in Ilha Josina 2017 to 1.6% (95% CI 1.1-2.3) in Magude 2018. Overall, *Pf* prevalence (determined by qPCR) was higher in pregnant women when compared with 2-10 year-old children (detected by RDTs). There was a good correlation between PR_{ANC} and $PfPR_{2-10}$, with a Pearson r of 0.9994 (p=0.0006). This preliminary analysis suggests a strong correlation between *P. falciparum* prevalence detected in May in children 2-10 years from the community and in pregnant women at their first ANC visit recruited between November and May. Further analysis should consider the impact of parity, HIV infection, gestational age and parasite densities on this correlation.

321

MONITORING MALARIA CASES IN THE STATE OF RORAIMA, BRAZIL

Rispah A. Abdallah[1], Jaime Louzada[2], Venkatachalam Udhayakumar[1], Joseli Oliveira-Ferreira[3], Naomi W. Lucchi[1]

[1]*Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Federal University of Roraima, Boa Vista, Brazil,* [3]*Institute Oswaldo Cruz- Fiocruz, Rio De Janeiro, Brazil*

In Brazil, Roraima State is considered moderate risk for malaria transmission. However, the state has recently seen an increase in the number of reported *P. falciparum* infections believed to be coming from residents travelling from Guyana and Venezuela. The objective of this study was to determine the prevalence of *Plasmodium* species among patients attending health clinics in Boa Vista (state capital), Pacaraima (a health post located in the Venezuelan border town) and Rorainopolis (211 Km south of the capital) in Roraima State and quantify the infections attributable to imported malaria. Information about residence, occupation and travel history was collected from all enrolled patients. Microscopic diagnosis was made during presentation at the clinic and a blood spot was collected to confirm diagnosis and for species identification using PET-PCR. For PCR, the samples were first screened for the presence of *Plasmodium spp; Plasmodium*-positive samples were then evaluated for the four human infecting species. A total of 751 patients were enrolled between 2016-2017 from the three sites: Boa Vista [340], Rorainopolis [57], and Pacaraima [354]. Field microscopy identified 489 positive samples: 283 (57.9%) *P. vivax* infections, 189 (38.6%) *P. falciparum* infections and 17 (3.5%) mixed *P. falciparum* and *P. vivax* infections. PET-PCR identified 541 positive samples: 257 (47.5%) *P. vivax*, 241 (44.5%) *P. falciparum*, 33 (6.1%) mixed infections (*P. falciparum* and *P. vivax*), 1 (0.2%) mixed infection (*P. falciparum* and *P. ovale*), 9 samples (1.7%) species could not be identified. Based on reported residence and travel history, 90% of the PCR-positive patients were likely to have acquired infection in Venezuela (76.0%) or Guyana (14.0%), which supports the hypothesis that imported malaria contributes to the bulk of malaria cases diagnosed in these health facilities. Given the high mobility of people between this state and the neighboring countries, these findings are not surprising and need to be considered when developing malaria control interventions in this region.

322

MOLECULAR SURVEILLANCE FOR ANTIMALARIAL DRUG RESISTANCE MARKERS IN *PLASMODIUM FALCIPARUM* CASES — RORAIMA, BRAZIL, 2016-2017

Christina M. Carlson[1], Julia N. Kelley[1], Rispah A. Abdallah[1], Dhruviben Patel[1], Jaime Louzada[2], Bryan C. Ezema[1], Venkatachalam Udhayakumar[1], Joseli Oliveira-Ferreira[3], Eldin Talundzic[1], Naomi W. Lucchi[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Federal University of Roraima, Boa Vista, Brazil,* [3]*Institute Oswald Cruz - Fiocruz, Rio De Janeiro, Brazil*

Artemisinin-based combination therapies (ACTs) are standard treatment for *Plasmodium falciparum* (*Pf*) malaria. ACT resistance in Southeast Asia has generated concern over the potential spread of these resistant parasites to other regions, threatening ongoing malaria elimination efforts and case management effectiveness. Molecular markers of resistance are a critical tool to monitor the emergence and spread of antimalarial resistance. Reports of the emergence of *Pf* parasites with the C580Y allele in the *k*13 gene (a marker of artemisinin resistance) in Guyana motivated a molecular surveillance study in the neighboring state of Roraima, Brazil to gather information about the prevalence of resistance alleles in this region and guide local antimalarial treatment policy. In 2016-2017, we collected dried blood spots from patients diagnosed with uncomplicated *Pf* malaria in three sites in Roraima State: Pacaraima, Boa Vista, and Rorainopolis. A next generation sequencing Malaria Resistance Surveillance (MaRS) method was used to generate single nucleotide polymorphisms

data for 6 drug resistance genes (*crt, cytb, dhfr, dhps, k*13*, mdr*1). Data were analyzed with the MaRS Next-generation Sequence-analysis Toolkit (NeST; https://github.com/CDCgov/MaRS). Of 204 samples, 194 were successfully sequenced. No *k*13 artemisinin resistant mutations were found. All samples exhibited known *crt* mutations associated with chloroquine resistance and mutations in *dhfr* and *dhps* genes associated with sulphadoxine-pyrimethamine resistance. Interestingly, the C350R mutation, associated with ACT partner drug piperaquine resistance and a reversal to chloroquine sensitivity, was found at an allele frequency of 18% in a pool of ten samples. We found no molecular markers associated with artemisinin resistance, supporting the use of the current ACT. However, molecular markers associated with chloroquine, sulphadoxine-pyrimethamine, and piperaquine resistance were observed. Given the high mobility of people in this region, continuous molecular surveillance and periodic assessment of the therapeutic efficacy of ACTs are necessary.

323

VERY LOW MALARIA TEST POSITIVITY RATES IN THE HIGHEST MALARIA BURDEN COUNTRY: A CASE FOR TESTING AND TREATING

Tobi Bamigbade[1], Ameh Akoji[1], **Nirmal Ravi**[2]

[1]*EHA Clinics, Kano, Nigeria,* [2]*Ehealth Africa, Kano, Nigeria*

Nigeria, a country of nearly 200 million people in Sub-Saharan Africa has the highest burden of malaria in the world. It accounts for 1 in every 4 cases and 1 in 5 deaths due to malaria globally. A previous population-based study found malaria prevalence as high as 60.6% in Kano, a city in Northern Nigeria. Clinicians and lay people frequently attribute clinical symptoms such as fever and malaise to malaria without any confirmatory laboratory test. This practice has lead to widespread misuse of anti-malarials. This retrospective study was done to determine malaria test positivity in 386 patients who reported clinical symptoms suggestive of malaria at a private primary care clinic in Kano, Nigeria. Clinical symptoms of malaria were defined as fever, malaise, headaches, bitter taste, nausea/vomiting and loss of appetite. The study period was from July 2018 to March 2019. *Plasmodium* spp testing was done using SD Bioline Malaria Ag P.f/Pan Rapid Diagnostic Test (RDT) kits and microscopy. Of the 386 patients tested, 84.5% were adults. Malaria RDT was positive in 34 (8.8%) of the 386 patients tested. Among the 85 patients who had fever with temperature greater than 37.5 Celsius, only 14% had positive malaria RDT. We tested a small subset of 75 samples among the 386 patients with both RDT and microscopy to determine concordance between the two test methods. Concordance between RDT and microscopy results among these 75 samples was 100%, indicating the reliability of the RDT in accurately diagnosing malaria. Malaria test positivity rate of 8.8% among our patient population is significantly lower than previously reported from Nigeria. This could be because most of our patients were from middle to high income households. Our study shows that prevalence of malaria can vary widely even within the same city in a high malaria burden country. Testing each presumptive malaria patient before treating with anti-malarials is imperative to avoid misdiagnosis and overuse of anti-malarials.

CHARACTERIZING THE HUMAN INFECTIOUS RESERVOIR FOR MALARIA IN TORORO, UGANDA: AN AREA UNDER EFFECTIVE MALARIA CONTROL

Chiara Andolina[1], John Rek[2], Joseph Okoth[2], Alex Musiime[2], Kjerstin Lanke[1], Melissa Conrad[3], Peter Olwoch[2], Lisette Meerstein-Kessel[1], Jessica Briggs[3], Emmanuel Arinaitwe[2], Joaniter Nankabirwa[2], Bryan Greenhouse[3], Moses Kamya[2], Chris Drakeley[4], Grant Dorsey[3], Sarah Staedke[5], Teun Bousema[1]

[1]*Department of Medical Microbiology, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*Department of Medicine, San Francisco General Hospital, University of California, San Francisco, CA, United States,* [4]*Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [5]*Department of Clinical Research, London School of Hygiene & Tropical Medicine, London, United Kingdom*

A better understanding of how malaria is transmitted from human hosts to mosquito vectors is needed to support malaria elimination efforts. Especially in low-endemic areas, our understanding of this human infectious reservoir is incomplete. In Tororo, an area in Uganda under intensive malaria control, we followed an all-age cohort (n=492) to characterize factors associated with gametocyte production and infectivity to mosquitoes. *P. falciparum* parasite density was determined by ultrasensitive varATS qPCR. All qPCR positive individuals were eligible for mosquito membrane feeding assays on their next visit, 4 weeks after parasite detection. Between November 2017-December 2018, 299 membrane feeding experiments were successfully conducted, including 10 on clinical malaria cases and 289 during asymptomatic infections; mosquitoes were dissected 9-10 days later for oocyst detection. Mosquito infections were observed in 10% (30/299) of these experiments; overall 1.8% (338/18,397) mosquitoes were infected with the proportion of mosquitoes per donor ranging from 1.1% to 81.4%. Only one clinical case infected mosquitoes (10.0% ; 1/10) whilst asymptomatic children aged 5-15 years comprised the majority of infectious individuals (80%, 24/30). The likelihood of being infectious and the proportion of infected mosquitoes increased with increasing varATS qPCR parasite density ($p<0.001$). Nevertheless, 13.9% (47/338) of all infected mosquitoes were infected by individuals with <100 parasites/μL. During the study period, parasite prevalence and parasite density declined in the cohort. In individuals with repeated membrane feeding assays, this decline in parasite burden was mirrored by a slowly declining likelihood of infecting mosquitoes. The unique longitudinal nature of our study allowed us to assess the human infectious reservoir for malaria during intensive malaria control. In this scenario, we find that asymptomatic infections in school aged children are responsible for the majority of onward transmission events and that the likelihood of infecting mosquitoes is strongly associated with parasite density.

325

ASYMPTOMATIC *PLASMODIUM FALCIPARUM* MALARIA INFECTION AMONG SCHOOL AGE CHILDREN IN KUMASI, GHANA

Natalie Olson[1], Santosh George[1], Sunil Parikh[1], Michael Kusi Addai[2], Lisa M. Harrison[1], Kweku Djan[1], Apongnwu Fopenawoh[3], Tsiri Agbenyega[4], Michael Cappello[1]

[1]*Yale University, New Haven, CT, United States,* [2]*HopeXchange Medical Centre, Kumasi, Ghana,* [3]*University of Maryland, College Park, MD, United States,* [4]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*

As the landscape of malaria in sub-Saharan African changes due to improved control efforts, there is increasing interest in elucidating the epidemiology of asymptomatic *P. falciparum* infection and its role in disease transmission, particularly in school age children. We conducted a cross-sectional survey in the summer of 2018 of children attending 4 primary/junior high schools within a 5 km radius of HopeXchange Medical Centre in Kumasi, Ghana, a city of 2.5 million inhabitants with year-round malaria transmission. Informed consent/assent and demographic information was obtained from 634 subjects (ages 5-17 years), after which measurements of height/weight/body temperature were recorded and a blood sample was obtained for evaluation by blood film microscopy, rapid diagnostic test (RDT) and nested polymerase chain reaction (PCR) for *P. falciparum*. Factors associated with malaria parasitemia were analyzed using a qualitative questionnaire covering socioeconomic factors, malaria prevention behaviors, and healthcare access. The overall prevalence of asymptomatic parasitemia varied by diagnostic test (microscopy: 5.5%; RDT: 11.8%; PCR: 23.4%). Agreement between methods was highest for samples with higher levels of parasitemia as measured by microscopy. Bivariate analysis showed that factors associated with a positive malaria test included school, lack of bed net usage and age. After controlling for

relevant factors, school of attendance was the single greatest predictor of a positive malaria test in the study population. Across the 4 schools, PCR (n=555) substantially increased the sensitivity for parasitemia detection when compared to microscopy (1.7 vs 7.6%; 2.8 vs 10.3%; 3.2 vs 28.4%; 12.2 vs 40.1%). These data are in agreement with previously described higher sensitivity of PCR for detection of asymptomatic parasitemia. More importantly, these results capture the significant heterogeneity in asymptomatic malaria risk in Kumasi, underscoring the importance of characterizing the epidemiology of asymptomatic malaria, even within small geographic areas.

326

BLACKWATER FEVER IN UGANDAN CHILDREN WITH SEVERE ANEMIA IS ASSOCIATED WITH POOR POST-DISCHARGE OUTCOMES. A PROSPECTIVE COHORT STUDY

Robert O. Opoka[1], Ali Waisswa[2], Harriet Nambuya[3], Ch C. John[4], James K. Tumwine[1], Charles Karamagi[5], Charles Karamagi[1]

[1]*Makerere University, Kampala, Uganda,* [2]*Global Health Uganda, Kampala, Uganda,* [3]*Jinja Regional Referral Hospital, Jinja, Uganda,* [4]*Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,* [5]

Blackwater fever (BWF), one of the complications of severe malaria, has recently re-emerged as a cause of severe anemia (SA) in African children. However, post-discharge morbidity in children with BWF has hitherto not been described. This was a descriptive cohort study in which children, aged 0-5 years, admitted to Jinja Regional Referral Hospital with acute episodes of SA (Hb ≤ 5.0 g/dl) were followed up for 6 months after hospitalization. Incidence of readmissions or deaths during the follow-up period was compared between SA children with BWF and those with no BWF. A total of 279 children with SA including those with BWF, n=92, and no BWF, n=187, were followed for the duration of the study. Overall 128 (45.9%) of the study participants were readmitted at least once while 22 (7.9%) died during the follow up period. After adjusting for age, sex, nutritional status and parasitemia SA children with BWF had higher risk of readmissions, HR 1.68 (95% CI, 1.1, 2.5), and a greater risk of death, HR 3.37 (95% CI, 1.3 to 8.5), compared to those with no BWF. Malaria and recurrence of SA were the most common reasons for readmissions. There is a high rate of readmissions and deaths in the immediate 6 months after initial hospitalization amongst SA children in Jinja hospital. SA children with BWF had increased risk of readmissions and deaths in the post discharge period. Post-discharge malaria chemoprophylaxis should be considered for SA children living in malaria endemic areas. Future studies should explore factors that predispose SA children with BWF to high post discharge morbidity.

327

CHARACTERIZING MALARIA BURDEN IN TURKANA REVEALS THE IMPACT OF DEVELOPMENT ON MAINTAINING TRANSMISSION

Hannah R. Meredith[1], Amy Wesolowski[1], Timothy M. Shields[1], James Maragia[2], Daniel Esimit[2], Samuel Lokemer[2], Joseph Kipkoech[3], Diana Menya[3], Andrew Obala[4], Wendy Prudhomme-O'meara[5]

[1]*Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Department of Health and Sanitation, Turkana County Government, Lodwar, Kenya,* [3]*School of Public Health, Moi University College of Health Sciences, Eldoret, Kenya,* [4]*School of Medicine, Moi University College of Health Sciences, Eldoret, Kenya,* [5]*Department of Medicine and Duke Global Health Institute, Duke University, Durham, NC, United States*

Malaria transmission has not been well characterized in the semi-arid areas of northern Africa, largely due to the assumption that the environment and people's pastoral lifestyles do not support stable malaria transmission. Brief, epidemic transmission could arise after unusually large rainfalls, but those are uncommon and isolated events. Here, we characterize malaria transmission in a prototypical example: Turkana, a vast county in northern Kenya with semi-arid conditions and semi-nomadic people. The discovery of oil in Turkana in 2012 has led to a rise in settlement and an increase in accessible water sources. While some studies suggest urbanization may decrease the risk of malaria, others predict that rapid, unplanned urbanization may increase it through the creation of open water surfaces where mosquitoes breed. Thus, we hypothesized that more settled areas in Turkana were more likely to support stable malaria transmission, despite rainfall patterns. We evaluated the impact of settlement and rainfall patterns on the malaria test positivity rate collected from routine surveillance reports of 36 health facilities from 2016-2018. These health facilities are located across Turkana and captured varied rainfall patterns and settlement levels. Satellite imagery was used to quantify rainfall and settlement in health facility catchment areas. Results revealed a range of malaria test positivity rates in both magnitude and duration that did not necessarily correspond with rainfall patterns. For instance, neighboring health facilities experiencing the same rainfall patterns reported malaria test positivity rates that were low and episodic in one and high and sustained in the other. Additionally, although 2017 lacked the long rain pattern observed in 2016 and 2018, its peak malaria test rates were similar to or greater than those recorded in the other years for many health facilities. These results highlight the role that dynamic populations play in creating environments suitable for malaria transmission. Consequently, malaria should be continuously monitored in areas assumed inapt for transmission.

328

SPATIAL AND TEMPORAL PATTERNS OF *PLASMODIUM FALCIPARUM* INFECTIONS IN BHUTAN, 2006-2014

Kinley Wangdi[1], Zhining Xu[1], Darren J. Gray[1], Kathryn Glass[1], Archie C. Clements[2]

[1]*Australian National University, Canberra, Australia,* [2]*Curtin University, Peth, Australia*

Malaria in Bhutan has dwindled in recent years and is aiming for malaria elimination in Bhutan. This study aims to identify *Plasmodium falciparum* clusters at a high geographical resolution and to determine the association between local environmental characteristics and the distribution and transmission of the disease. Notifications of *P. falciparum* cases from January 2006 to December 2014 were obtained from the Vector-borne Diseases Control Program under the Ministry of Health, Bhutan. The population of each sub-district (second-level administrative sub-division) was obtained from the Population and Housing Census 2007. Spatial autocorrelation in dengue incidence was explored using Moran's I statistic, Local Indicators of Spatial Association (LISA), and the Getis-Ord statistics. A multivariate, Zero-Inflated, Poisson regression model was developed with a conditional autoregressive (CAR) prior structure, and with posterior parameters estimated using Bayesian Markov chain Monte Carlo (MCMC) simulation with Gibbs sampling. There was a total of 2,062 *P. falciparum* cases during the study period. Malaria clusters were observed in the sub-districts in Sarpang district. Only rainfall lagged at one month was significant variable with *P. falciparum* cases increased by 6% (95% credible interval [CrI]: 3%, 9%) for a one mm increase in rainfall. There was no significant residual spatial clustering after accounting for climate and demographic variables. *P. falciparum* incidence had a positive association only with rainfall lagged at one month. This factor explained the observed spatial heterogeneity of infection.

329

FACTORS ASSOCIATED WITH ACCESS AND ADHERENCE TO ARTEMISININ-BASED COMBINATION THERAPY (ACTS) FOR TREATMENT OF FEVER IN CHILDREN UNDER FIVE: A SECONDARY ANALYSIS OF THE 2012 SIERRA LEONE MALARIA KNOWLEDGE, ATTITUDES, AND PRACTICES SURVEY

Kristin Banek[1], Emily L. Webb[1], Emily Bostick Doogue[2], Samuel Juana Smith[3], Daniel Chandramohan[1], Sarah G. Staedke[1]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Catholic Relief Services, Baltimore, MD, United States,* [3]*National Malaria Control Program, National Malaria Control Programme, Ministry of Health and Sanitation, Freetown, Sierra Leone*

To ensure effective malaria case management, patients must have access to artemisinin-based combination therapies (ACTs) and adhere to treatment guidelines. A secondary analysis of the 2012 Sierra Leone malaria Knowledge, Attitudes and Practices (mKAP) survey was conducted to investigate access and adherence to ACTs for treatment of fever in children under-five. The mKAP was a nationally representative, two-stage cluster-sample survey. The secondary analysis was restricted to children under-five with fever in the past two weeks. Factors associated with access and adherence were assessed using logistic regression. Of 5,169 enrolled households, 1,456 reported a child under-five with fever in the past two weeks, including a total of 1,641 children. Of these, 982 (59.8%) received malaria treatment and were analyzed for access; 467 (28.5%) received an ACT and were analyzed for adherence. Only 220 (13.4%) children with fever received an ACT and completed the recommended 3-day treatment. In a multivariable analysis, factors associated with ACT access included knowledge of ACTs (yes vs no; odds ratio [OR] 2.84, 95% CI: 2.07-3.89; p<0.001), knowledge of insecticide treated nets (ITNs) (yes vs no; OR 1.80, 95% CI: 1.25-2.58; p=0.001), source of care (public health facility vs other; OR 1.85, 95% CI: 1.27-2.71, p=0.002), geographic region (East vs West; OR 2.40, 95% CI: 1.26-4.55; p=0.018), and child age (24-59 vs 0-23 months; OR 1.46, 95% CI: 1.08-1.39; p=0.014). The only factor associated with ACT adherence was time to treatment; children treated within 24 hours were less likely to adhere (OR 0.58, 95% CI: 0.35-0.95; p=0.032). In 2012, access and adherence to ACTs remained low in Sierra Leone. Knowledge of ACTs and ITNs, and seeking care in the public sector, were most strongly associated with ACT access. Future national household surveys could expand the malaria treatment seeking section to capture indicators related to treatment adherence thereby providing critical information needed to realize optimal malaria treatment effectiveness.

330

RISK FACTORS FOR MALARIA, AND SPATIAL CLUSTERING OF CASES FROM A HOUSEHOLD SURVEY IN ARTIBONITE, HAITI

Karen E. Hamre[1], Nishant Kishore[2], Amber M. Dismer[1], Anyess R. Travers[3], Kathleen McGee[4], Baby Pierre[5], Kathleen Holmes[1], Eric Rogier[1], Jean Frantz Lemoine[5], Michelle A. Chang[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Harvard T.H. Chan School of Public Health, Cambridge, MA, United States,* [3]*University of Georgia, Athens, GA, United States,* [4]*Population Services International - Haiti, Peguy-Villy, Haiti,* [5]*Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti*

Malaria Zero Consortium partners are working together to accelerate malaria elimination in Haiti, where malaria distribution is heterogeneous. In such elimination settings, targeting interventions is essential to ensure efficient use of resources. Following a census in the study area, a cross-sectional household survey was conducted in the communes of La Chapelle and Verrettes, Artibonite, Haiti to identify and characterize spatial clustering of malaria cases. Of 8,818 sampled households, 79% participated; all consenting household members (N=21,566) were administered a questionnaire and tested for malaria. A case was defined as a person testing positive for *Plasmodium falciparum* by either conventional rapid diagnostic test (RDT) or a novel highly-sensitive RDT. Clusters were identified using SaTScan™ software, assuming a Poisson distribution. The associations between potential individual, household, and environmental risk factors for individual malaria risk and for risk of living in a spatial case cluster were evaluated using the *svy* estimation commands in Stata to account for the sampling weights and clustering at the household level. There were 161 malaria cases identified; median age was 15 years. Weighted malaria prevalence was low (0.56%, 95% CI: 0.45-0.71%), yet two predominant significant spatial case clusters were identified. Preliminary data from univariate logistic regression analyses suggest individuals who sleep under a bed net have lower risk of malaria as compared to those who do not (OR = 0.20, p &lt 0.01); as do shopkeepers when compared to farmers (OR = 0.41, p = 0.04). Individuals living in higher altitudes were at increased risk for having malaria and for living in a spatial cluster. Additional analysis and adjusted models will be presented. Haiti's National Malaria Control Program conducted a focus investigation, entomologic investigation, and vector control interventions. Identifying malaria clusters in low-transmission settings is an essential step for targeting interventions.

331

RAPID CHARACTERIZATION OF URBAN MALARIA TRANSMISSION — CONAKRY, GUINEA, 2018

Dean M. Sayre[1], Alioune Camara[2], Yaya Barry[2], Toure B. Deen[2], Denka Camara[2], Mohamed Dioubate[2], Ibrahima Camara[2], Kalil Keita[2], Nouman Diakite[2], Youssoufa Lo[2], Ibrahima Bah[3], Hadja F. Camara[4], Mohamed S. Conde[4], Aissata Fofana[4], Abdoulaye Sarr[5], Eugene K. Lama[2], Seth Irish[1], Mateusz Plucinski[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*National Malaria Control Program, Conakry, Guinea,* [3]*Catholic Relief Services, Conakry, Guinea,* [4]*Stop Palu+, Conakry, Guinea,* [5]*Centers for Disease Control and Prevention, Conakry, Guinea*

In 2018 the Guinean malaria control program requested assistance to rapidly estimate the extent of malaria transmission in Conakry to inform the planning for a national bednet distribution campaign. As is typical for urban settings, the reported malarial burden in Conakry was small compared to the remainder of the country, but the true risk of local disease acquisition was unknown because the proportion of cases resulting from importation was undefined. To inform decision-making on the need for bednet distribution in the city, we performed a combined entomological and epidemiological study to determine the risk of local acquisition of malaria in ten sites across Conakry. Mosquito populations were characterized by human landing catches, and cross-sectional surveys were used to measure household access to bednets and malaria infection prevalence (by rapid diagnostic test). Data regarding recent travel-related exposures from outpatients tested for malaria in 25 health centers were used to calculate risk ratios (RR) and population attributable fractions of risk (PAR) related to travel. *Anopheles* mosquitoes were found throughout Conakry, with an average of 7.1 (range: 0 - 21) females captured per night. Only 16.7% (170/1016) of sleeping spaces were protected by a hanging bednet. Prevalence of parasitemia among all ages was 5.2% (57/1102), with 75.4% (43/57) of those testing positive reporting no travel outside the city in the last 4 weeks, and 50.9% (29/57) not traveling in the last year. Among 4,678 outpatients, travel within 4 weeks of clinical presentation was a risk factor for malaria infection (RR: 2.2; 95% confidence interval: 2.0-2.4), though the PAR for travel was 8.7%. Malaria transmission in Conakry appeared heterogeneous, with the highest disease prevalence (10.7%) and most favorable conditions for transmission (21 female *Anopheles* captured per night, 7.5% of sleeping spaces with a bednet hanging) in Kaloum, the most urbanized portion of the city. Many malaria cases reported from Conakry appear to result from local transmission. Results of this assessment should inform decision-making on where to target future bednet distribution.

332

USING AMPLICON DEEP SEQUENCING TO CHARACTERIZE CLONAL EXPANSION OF A KELCH 13 R622I MUTANT IN GONDAR, ETHIOPIA

Daniel R. Castaneda-Mogollon[1], Abebe Genetu Bayih[2], Aberham Abere[2], Ranmalee Amarasekara[1], Habtie Tesfa[2], Dylan R. Pillai[1]

[1]*University of Calgary, Calgary, AB, Canada,* [2]*University of Gondar, Gondar, Ethiopia*

According to the WHO, almost two thirds of the Ethiopian population are at risk of contracting malaria, where infection with *Plasmodium falciparum* accounts for approximately 60% of cases today. The risk of artemisinin resistance spreading from SE Asia to Africa is a major concern. We conducted a 28-day *in vivo* efficacy trial of Artemether-Lumefantrine (Co-Artem) for treatment of uncomplicated malaria (n=97) in Gondar Region, NW Ethiopia in 2017-2018. Our data showed 100% adequate clinical and parasitological response (ACPR). Further analysis of day 0 samples showed the expansion of a kelch13 mutation R622I to 9.5% from 2.4% over a 3 year period. In order to better understand the emergence of this mutation and whether it is a sentinel of emerging resistance, we assessed the haplotypes and complexity of infection (COI) by employing PCR and amplicon deep sequencing of the genetic markers msp1, msp2 and the conserved *Plasmodium* membrane protein (cpmp) at day 0 and day 7. Sequences were subject to a bioinformatics pipelines (SRST2, PoolHap, DADA2) that could assess SNP and haplotype calling across each data point. The complete dataset is currently under analysis and will be presented at the meeting. Understanding the infection dynamics of *P. falciparum* in this region could provide a better insight of the geographic extension of emerging artemisinin-resistant clones and its implications in public health. Furthermore, clone dominancy variation over time may explain why some individuals have different clinical manifestations. Nevertheless, additional genotyping studies are required to assess the surveillance of artemisinin-resistant *Plasmodium* species across the region

333

GLOBAL SURVEILLANCE OF *PLASMODIUM FALCIPARUM* ANTIMALARIAL DRUG RESISTANCE AND DIAGNOSTIC TEST EVASION

Christiane Prosser[1], Rogan Lee[1], Wieland Meyer[2], John Ellis[3]

[1]*University of Sydney, Sydney, Australia,* [2]*Westmead Institute for Medical Research, University of Sydney, Sydney, Australia,* [3]*School of Life Sciences, University of Technology Sydney, Sydney, Australia*

Emerging drug resistance in *Plasmodium falciparum* imperils malaria control and elimination. Resistance to the frontline drug artemisinin, and partner drugs, is spreading throughout South East Asia. Deletion of *pfhrp2/3* genes (results in false negatives from HRP-based rapid diagnostic tests) has emerged and is thought to be under section globally. This project aimed to investigate imported malaria cases from travellers and refugees entering Australia, and field isolates from Southern Thailand. Malaria diagnostic samples from the NSW parasitology reference lab (n=205) and samples collected from health centres in 4 provinces of South Thailand (n=91) were screened for known markers of drug resistance including *pfK13* mutations underlying artemisinin resistance. The cohort was also screened for the presence of exons 1 and 2 for both *pfhrp2* and *pfhrp3*. This cohort captured many endemic regions with limited ongoing surveillance or no previous data on these markers - notably South Sudan, Sudan, Sierra Leone, and districts of Thailand bordering Malaysia. Epidemiologically relevant deidentified patient data associated with each case was analysed. Seven microsatellites were typed for the Sudanese and South Sudanese cohort (n=56) to identify phylogenetic clustering of HRP2/3 positive and negative parasites found. Propeller domain *pfK13* mutations were observed, including the C580Y mutation most strongly associated with artemisinin resistance. C580Y was found in an indigenous parasite originating from Papua New Guinea, where resistance *pfK13* mutations were previously unreported. C580Y mutations were additionally observed (n=31/91) in Southern districts of Thailand, including Yala, where resistance mutations were previously unreported. The findings demonstrate the utility of screening travellers as sentinels and the need for more comprehensive molecular surveillance of emerging malaria drug resistance and diagnostic test evasion.

334

FRAGMENTED POPULATION STRUCTURE OF *PLASMODIUM VIVAX* ASSOCIATED WITH THE DECLINE TRANSMISSION FACILITATE THE MALARIA SURVEILLANCE AND TARGET CONTROL IN THE GREATER MEKONG SUBREGION

Li Yuling[1], Cao Yaming[1], Wang Qinghui[1], Cui liwang[2]

[1]*China Medical University, Shenyang, China,* [2]*Department of Internal Medicine, South Florida, SC, United States*

The Asia Pacific Leaders in Malaria Alliance (APLMA) have committed to eliminate malaria from the region by 2030. Since the initiation of the WHO's Mekong Malaria Program a decade ago, malaria situation in the Greater Mekong Subregion (GMS) has greatly improved, but with the dramatically decline in annual malaria incidence and deaths, *Plasmodium vivax* has become the dominant malaria infection in some parts of this region. Therefore, to gain a better understanding of transmission dynamics and population structure of *P. vivax* in the GMS is imperative and beneficial to malaria control programme. We investigate genetic diversity and population structure in four geographically and ecologically distinct regions of The Greater Mekong Subregion. A total of 200 *P. vivax* isolates were from Yunnan, Anhui province of China, Thailand and China-Myanmar border regions (50 for each population) were analysed using 10 microsatellite markers. A wide range of genetic diversity was observed in the four populations reflecting a spectrum of transmission intensities across Greater Mekong Subregion. Fragmented population structure and genetic differentiation between regions was evident, suggest limited gene flow among these sites. a small panel of microsatellite markers was sufficient to assign the parasites to their geographic origins. In conclusion, with enhanced control efforts on malaria elimination, *P. vivax* population in the Greater Mekong Subregion has fragment into a limited number of clustered *foci*, but the presence of large *P. vivax* reservoirs still sustain transmission. The insights into *P. vivax* transmission dynamics and population structure will inform targeted strategies to *P. vivax* malaria surveillance and track parasites in this area.

335

SELECTIVE SWEEPS AND GENETIC LINEAGES OF *P. FALCIPARUM* CHLOROQUINE RESISTANCE GENE, *PLASMODIUM FALCIPARUM* DIHYDROPTEROATE SYNTHASE AND *P. FALCIPARUM* DIHYDROFOLATE REDUCTASE GENES IN KENYA

Marcel Nyabute[1], Dennis Juma[1], Penninah Muiruri[2], Benjamin Opot[1], Raphael Okoth[1], Martha Nginya[1], Jennifer Mutisya[1], Brenda Mugambi[1], Agnes Cheruiyot[1], Gladys Chemwor[1], Redemptah Yeda[1], Charles Okello[1], Hoseah Akala[1], Ben Andagalu[1], Jim Ray Managbanag[1], Edwin Kamau[3]

[1]*US Army Medical Research Directorate, Kenya, Kisumu, Kenya,* [2]*Department of Biochemistry; Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya,* [3]*U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Washington, MD, United States*

With the continued widespread use of antimalarial agents, molecular tools are valuable for determining evolutionary history and the prevalence of drug-resistant malaria parasites. These tools have helped to predict decreased sensitivity to antimalarials and fixation of multidrug resistance genotypes in some regions. Systematic studies of selective sweeps provides information on origin and evolution and have previously shown that chloroquine (CQ) and sulfadoxine-pyrimethamine (SP) resistance originated from Thailand - Cambodia border before eventually spreading to other Asian countries and sub-Saharan Africa. This trend has not been established for East Africa. This study investigated putative CQ and SP

drug resistance-associated gene mutations and genetic lineages for field isolates collected across Kenya to describe their origin and evolution. The *Pfcrt*, *Pfdhps,* and *Pfdhfr* mutations associated with CQ and SP resistance and the microsatellite *loci* flanking these genes were genotyped in 350 *Plasmodium falciparum* isolates from Kenya to give insights into the origin and spread of drug resistance *loci*. For *Pfcr*t, proportion of isolates carrying wild-type CVMNK was 90.1% while 9.5% had the mutant haplotype CVIET. 94.4% isolates had the *Pfdhfr* triple mutant haplotype CIRNI at positions 51, 59 and 108. For *Pfdhps*, 97.8% of the isolates had double mutant haplotype SGEAA at position 437 and 540. Initial analysis of genetic diversity and differentiation at microsatellite *loci* flanking all 3 genes appears to suggest that they have been under strong selection, because of CQ and SP use. The high SP resistance witnessed across Kenya was likely due to fixation of key mutations in the *Pfdhfr* and *Pfdhps* genes as well as drug pressure from other antifolate drugs being used to treat malaria and other infections. The sustained SP-resistant haplotypes, *Pfdhfr* 51I/59R/108N and *Pfdhps* 437G/540E despite withdrawal of SP as the first-line treatment in Kenya warrants continued evaluation of SP efficacy as long as IPTp-SP is in force. Wild-type *Pfcr*t 76 heralds possibility of re-introduction of CQ in combination with other malaria drugs.

336

EVALUATION OF *PLASMODIUM FALCIPARUM* HISTIDINE RICH PROTEIN 2 AND 3 (*PF*HRP2 *AND PF*HRP3) GENES POLYMORPHISMS IN KENYA

Martha N. Kivecu[1], Victor Mobegi[2], Brenda Makena[1], Raphael Okoth[1], Gladys Chemwor[1], Marcel Juma[1], Edwin Mwakio[1], Jackline Juma[1], Charles Okello[1], Redemptah Yedah[1], Agnes Cheryuiyot[1], Benjamin Opot[1], Dennis Juma[1], Hoseah Akala[1], Ben Andagalu[1], Jim R. Manangbanang[1]

[1]*Us Army Medical Research Directorate- Africa, Kenya (USAMRD-A), Kisumu, Kenya,* [2]*The University of Nairobi, Nairobi, Kenya*

Globally, 74% of malaria diagnoses are by malaria Rapid Diagnostic Test (RDT). The accuracy of *Pf*HRP2-based RDTs can be impaired by either deletion in *Pf*HRP2 gene or cross-reaction with *Pf*HRP3 antibodies. The World Health Organisation (WHO) criteria that require greater than 95% accuracy as the threshold for selection or withdrawal of RDTs argue for active mapping of *Pf*HRP2 deletions. As part of the on-going epedemiology of malaria drug resistance work, this study aims to determine the frequency and trends of *Pf*HRP2 and *Pf*HRP3 gene mutations and deletions in four of five malaria transmission regions in Kenya. 350 samples collected between 1998 and 2017 were diagnosed for malaria by microscopy, RDT and 18S rRNA PCR. All *P. falciparum* PCR positive samples were amplified then sequenced and multiple sequence alignment (MSA) done to detect *Pf*HRP2 and *Pf*HRP3 mutations. Additionally, twelve neutral microsatellites markers were amplified and parasites population structure determined. 255 samples of the 350 were collected between 2013 and 2017. 220 of 255 samples were *P. falciparum* positive by PCR, of these, 37(16.8%) were negative by *Pf*HRP2 based RDT. This appears to suggest possible *Pf*HRP2 and *Pf*HRP3 genes deletion. However, 29 of the 37 RDT negative samples were positive for both *Pf*HRP2 and *Pf*HRP3 amplification, 5 and 3 samples were positive for *Pf*HRP2 and*Pf*HRP3 respectively. 95 of the 350 samples were collected between 2003 and 2005, 89(93.7%) of these samples were positive for *P. falciparum* by PCR. RDT diagnosis was not carried out on these samples as only DNA samples were available. *Pf*HRP2 and *Pf*HRP3 genotyping did not clarify variability in RDT reactivity. Therefore, sequence analyses of these fragments are underway for additional clarification of polymorphisms within the *Pf*HRP2 and *Pf*HRP3 regions. Additionally, 12 microsatellites genotyping is underway to determine the population structure. Findings will guide policy decision on the relevance of continued deployment of *Pf*HRP2 based RDTs across Kenya. Temporal and population structure analysis will verify the role of evolution in the distribution of the *Pf*HRP2 and *Pf*HRP3 aberrant genotypes.

337

TEMPORAL CHANGE OF GENETIC DIVERSITY AND POPULATION STRUCTURE OF *PLASMODIUM VIVAX* IN THREE CONTRASTING SETTLEMENTS IN THE PERUVIAN AMAZON

Paulo C. Manrique Valverde[1], Roberson Ramírez Saavedra[1], Mitchel Guzman Guzman[1], Alejandro Llanos Cuentas[2], Joseph Vinetz[3], Ananias A. Escalante[4], Dionicia Gamboa Vilela[5]

[1]*Laboratorio ICEMR-Amazonia, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofa, Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Yale School of Medicine, Section of Infectious Diseases, Department of Internal Medicine, New Haven, CT, United States,* [4]*Institute for Genomics and Evolutionary Medicine (IGEM), Temple University, Philadelphia, PA, United States,* [5]*Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru*

Despite efforts made to eliminate malaria, *Plasmodium vivax* remains a challenge in Peru. The high heterogeneity of its transmission has limited the intervention measures based on global and generalized epidemiological information at medium and long term. Population genetic tools may provide information on the spatial heterogeneity of transmission by linking parasite genetic patterns with epidemiological information. In this study, the genetic diversity and population structures from three settlements located in the Peruvian Amazon, Cahuide (CAH), Lupuna (LUP) and Santa Emilia (STE) were measured on samples collected from September 2012 to March 2015. A total of 777 *P. vivax* mono-infections were genotyped. LUP showed the lowest proportion of polyclonal infections (0.197 CI95% 0.159 - 0.241) and genetic diversity (*Hexp* 0.544 ± 0.0012) in the whole study period. Moreover, in this study area results showed a significant increment of polyclonal infections and *Hexp* ($p < 0.005$), and the introduction and persistence of a new parasite population from March 2014 onward. STE showed the highest proportion of polyclonal infections (0.401 CI95% 0.323 - 0.485) and *Hexp* (0.596 ± 0.0028) among study areas, the presence of 4 genetic clusters without signals of clonal expansion and infections with lower parasite densities compared to the other two areas. Even though CAH showed the introduction of at least 4 parasite populations in 2012, a clear reduction of cases (from 213 to 61), a subtle reduction of polyclonal infections (from 0.286 to 0.18), and an unpredicted behavior of *Hexp* were seen since June 2014. These results suggest that LUP and mainly STE are two areas that maintain basal levels of transmission and that there are factors that allow the reintroduction of *P. vivax*. In contrast, malaria cases in CAH are circumstantial, thus, receptivity to malaria transmission and vulnerability to the importation of new parasite population vary drastically among the different study areas analyzed, and this information must be considered in the design of current control strategies.

PLASMODIUM VIVAX GENETIC POLYMORPHISM IN DIFFERENT BRAZILIAN ENDEMIC AREAS

Natália Ketrin Almeida de Oliveira[1], Rebecca Abreu Santos[1], Anielle Pina Costa[2], Patrícia Brazil[2], Cláudio Tadeu Daniel-Ribeiro[1], Maria de Fátima Ferreira da Cruz[1]

[1]*Oswaldo Cruz Institution, Rio de Janeiro, Brazil,* [2]*National Institute of Infectology/Fiocruz, Rio de Janeiro, Brazil*

Plasmodium vivax is the predominant species in Brazil, representing 87% of malaria cases. The country presents two malaria transmission autochthonous profiles: one in Amazon Basin (AB), where 99.7% of reported cases are occurred, and the other in non-endemic regions of Atlantic Forest (AF). The polymorphisms dynamic of circulating genotypes from different geographical areas provide insights into population structure generating inferences on gene flow patterns. Polymorphic genes encoding antigens, potential candidates to compose a malaria vaccine, have been useful to monitor changes in parasite genetic diversity. There are no data on evaluation of *P. vivax* antigen diversity in isolates

from endemic and non-endemic Brazilian regions. Thus, we investigated polymorphisms in MSP-1 and DBP-II genes in these two Brazilian malaria transmission scenarios. For this end, genomic DNA was isolated from 1 ml-whole blood using QIAamp columns and gene fragments were amplified by PCR using previously published primers. DNA sequencing was carried out after purification using the Wizard SV Gel and PCR Clean-Up System. Analysis of 248 isolates, 180 from AB and 68 from AF, showed that polymorphisms in MSP-1 (57 SNPs; 53 non-synonymous) was higher than those of DBP (27 SNPs; 26 non-) in all studied localities. Among MSP-1 mutations, 7 (12%) were specific of AF and 5 (9%) of AB localities. While in DBP, 5 (18%) mutations were specific of AF and 1 (4%) of AB. We concluded that these genes are continuous evolving under immune selective pressure and polymorphic sites are indicative of balancing positive selection on antigen molecules. In addition, these preliminary data suggest that the presence of 12 SNPs is indicative of *P.vivax* parasites from non-endemic Brazilian areas (AF).

339

POPULATION STRUCTURE OF *PLASMODIUM MALARIAE* USING MICROSATELLITES AND SELECTIVE WHOLE GENOME SEQUENCING

Eniyou C. Oriero[1], Deus S. Ishengoma[2], Lucas Amenga-Etego[3], Soulama Issiaka[4], Tobias Apinjoh[5], Umberto D'Alessandro[1], Abdoulaye Djimde[6], Martin Meremikwu[7], Alfred Amambua-Ngwa[1]

[1]*Medical Research Council Unit The Gambia at London School of Hygiene & Tropical Medicine, Fajara, Gambia,* [2]*National Institute for Medical Research, Tanga, United Republic of Tanzania,* [3]*University of Ghana, WACCBIP, Department of Biochemistry, Cell and Molecular Biology, Legon, Ghana,* [4]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso,* [5]*Faculty of Health Science, University of Buea, Buea, Cameroon,* [6]*Malaria Research and Training Center, University of Science, Techniques and Technology, Bamako, Mali,* [7]*Calabar Institute Of Tropical Disease Research & Prevention, University Of Calabar Teaching Hospital, Calabar, Nigeria*

Plasmodium malariae, one of five species that infect humans, is prevalent across sub-Saharan Africa. Recent completion of its reference genome paves way for new genomic studies aimed at understanding the biology of this parasite species. We characterized *P. malariae* samples from across sub-Saharan Africa using microsatellites and selective whole genome amplification (sWGA) techniques. Samples from Nigeria were obtained from rapid diagnostic test (RDT) positive individuals who attended health facilities in Cross River State, Nigeria, in October - November 2017, following community sensitization and consent. Additional samples were accessed from strategic collaborations (including DELGEME and PDNA) across sub-Saharan Africa, namely Tanzania, Burkina Faso, Mali, Ghana, Guinea and Cameroon. *Plasmodium* species were confirmed by real-time PCR (PrimerDesign®, UK). Five highly divergent microsatellites (Pm_02, Pm_09, Pm_11, Pm_34 and Pm_47) were used to genotype the *P. malariae* samples. Confirmatory real-time PCR revealed a total of 74 *P. malariae* samples (Nigeria - 18, Tanzania - 19, Burkina Faso - 17, Mali - 9, Ghana - 3, Guinea - 4 and Cameroon - 4). No population structure was detected with the five microsatellites. Towards population genome sequencing, dried blood spot (DBS) and leucocyte depleted (CF11 column filtration) *P. malariae* infected blood samples were subjected to sWGA using primers designed in-house. A combination of Illumina and Nanopore sequencing approaches are envisaged. Initial *P. malariae* genome sequence coverage remain patchy as most infections were mixed (*P. falciparum)*. Bioinformatics techniques for deconvolution of mixed genomes will be explored. Knowledge of population structure and diversity of *P. malariae* across endemic regions will help in monitoring local and regional transmission patterns. New sWGA approaches are needed to selectively improve *P. malariae* coverage in mixed species infections and to determine its contribution to the malaria burden.

EVALUATION OF A POOLED STRATEGY FOR TARGETED AMPLICON DEEP SEQUENCING OF *PLASMODIUM FALCIPARUM* DRUG RESISTANT ASSOCIATED GENES *DHFR* AND *MDR1*

Camelia Herman[1], Julia Kelley[1], Eldin Talundzic[2]

[1]*CDCF, Atlanta, GA, United States,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Sequencing large numbers of individual samples, which is often needed for countrywide surveillance-based studies, remains expensive despite the decreasing costs of next generation sequencing (NGS). Pooling several individual samples prior to gene enrichment, NGS library prep and sequencing is potentially an alternative cost and time effective method. Using 100 *P. falciparum* samples from a nationwide Haiti drug resistance surveillance study, we compared allele frequency (AF) calls for *dhfr* and *mdr1* drug resistance genes between individual and pooled deep sequenced samples. The individual sequenced samples were used to determine the expected allele frequency of the pooled samples. Samples with similar real-time PCR cycle threshold (CT) values (+/- 1.0 CT value) were combined into ten different pools, with 10 samples per pool. The CT value was used to estimate parasite DNA in each individual sample and ensure that similar parasite DNA volumes (5.0uL) were pooled. In *dhfr* only the S108N and in *mdr1* the Y184F drug resistant mutations were identified. The actual AF calls for the pooled samples were as follows, *dhfr* S108N: group 1 to 6: 45%, 12%, 47%, 51%, 86% and 60%, showing a difference of +/- 10.15% when compared to the expected AFs (e.g., sum of individual AFs /total number of pooled samples = expected pooled sample AF). In comparison, *mdr1* Y184F had an AF of 100% for all six groups and a difference of 1.67% when compared to the expected AFs. The remaining four pooled sample groups with a CT values ≥34.0 (e.g., <100 parasites per uL/blood) showed a difference of greater than 34% or more between the actual and expected AFs. This may have been due to low amounts of parasite DNA (indicated by a CT value ≥ 34.0), which can lead to variable PCR amplification efficiencies of the *dhfr* and *mdr1* genes. This method of grouping samples based on CT values prior to pooling can provide higher confidence that unbiased AFs are obtained in pooled deep sequencing experiments. With further validation, this method may be used as a screening approach to rapidly genotype large number of samples for drug resistant markers in population-based studies.

INSECTICIDE RESISTANCE GENE MUTATIONS IN *ANOPHELES STEPHENSI, AN. ARABIENSIS*, AND *CULEX PIPIENS S.L.* IN EASTERN ETHIOPIA

Tamar E. Carter[1], Lambodhar Damodaran[2], Shantoy Hansel[3], Callum Montgomery[3], Victoria Bonnell[4], Karen Lopez[3], Daniel Janies[3], Solomon Yared[5]

[1]*Baylor University, Waco, TX, United States,* [2]*University of Georgia, Athens, GA, United States,* [3]*University of North Carolina at Charlotte, Charlotte, NC, United States,* [4]*Pennsylvania State University, State College, PA, United States,* [5]*Jigjiga University, Jigjiga, Ethiopia*

The recent detection of the primarily South Asian malaria vector species *Anopheles stephensi* in the Horn of Africa emphasizes the importance of continued vector surveillance. Genetic analysis of insecticide resistance mutations across multiple species of Culicidae in the Horn of Africa provides an important ecological perspective on the potential impact of insecticides on *An. stephensi*. In this study, the voltage gated sodium channel (*vgsc*) and acetylcholinesterase (*ace-1*) genes were analyzed in *An. stephensi, An. arabiensis*, and *Culex pipiens s. l.* collected in east Ethiopia between 2016 and 2017. A portion of both genes that contain known insecticide resistance mutations (*vgsc* kdr L1014 and ace-1 G119) were amplified by polymerase chain reaction (PCR) and then sequenced with Sanger technology. Frequencies of resistance mutations were calculated, and nucleotide diversity was analyzed. *Vgsc* sequence analysis revealed no L1014 mutations in any *An. stephensi* (n=129) specimens, while 100% of

Cu. pipiens s.l. (n = 42) collected in the same location were homozygous for the L1014F mutation. Of the *An. arabiensis* (n=67), 71.6% carried the kdr L1014F mutation (heterozygous and homozygous). Analysis of the *vgsc* sequence including a downstream intron in all three species revealed nucleotide diversity only in *An. stephensi* (Pi= 0.001; haplotypes, h = 5; haplotype diversity; H_d = 0.135). The results of neutrality tests varied across species, with no evidence of non-neutral evolutionary processes for *An. stephensi* sequences. The *ace-1* G119 mutation was examined in *An. stephensi* and *An. arabiensis* and was absent in both species. Overall these results indicate that some Culicidae have been impacted by pyrethroid insecticides. The absence of the kdr mutation and lack of evidence for selection on the *vgsc* in the *An. stephensi* may be explained by one of the following: 1) *An. stephensi* is new to the region and not impacted by resistance like sympatric *Cu. pipiens* s. l. or 2) *An. stephensi* has other mechanisms of resistance. Further studies on additional sites will provide insight into the status of *An. stephensi* resistance in Ethiopia and its history in the region.

DISTINGUISHING AMONG *PLASMODIUM VIVAX* RELAPSES AND NEW INFECTIONS IN A LOW ENDEMIC AREA: A POPULATION GENETICS APPROACH

Christopher Delgado Ratto[1], Verónica E. Soto-Calle[2], Annette Erhart[3], Peter Van den Eede[4], Eliana Torres[2], Luis Sánchez-Martínez[2], Juan Contreras-Mancilla[5], Anna Rosanas-Urgell[4], Hugo Rodríguez Ferrucci[6], Alejandro Llanos-Cuentas[2], Umberto D'Alessandro[3], Jean-Pierre Van geertruyden[1], Dionicia Gamboa Vilela[2]

[1]*University of Antwerp, Antwerp, Belgium,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Medical Research Council Unit at the London School of Hygiene & Tropical Medicine, Fajara, Gambia,* [4]*Institute of Tropical Medicine, Antwerp, Belgium,* [5]*Universidad Peruana Cayetano Herediaerp, Lima, Peru,* [6]*Ministry of Health of Peru, Iquitos, Peru*

We used the population genetics information of the local parasite population retrieved from a 2-year follow up study carried in the Peruvian Amazon to provide an estimation of the origin of the 1st *P.vivax* recurrence experienced after the radical cure treatment, chloroquine (CQ) plus primaquine (PQ), was administered. A systematic blood sampling was performed weekly up to day 28 and later monthly after a direct observed treatment (3-day CQ+ 7-day PQ) until month 24. Recurrent parasites were detected by microscopy and PCR; and genotyped using 14 microsatellites. Population genetics analysis was performed. We compared D0 and 1st recurrence to classify recurrent parasites as homologous, highly related heterologous or heterologous parasites. Finally, the probability of reinfection with homologous or highly related heterologous parasites (*Pmatch)* was calculated to estimate the origin of the 1st recurrence. After treatment, 197 (65.2%) participants had at least one recurrence within the 2-year follow up and the median time to the 1st recurrence was 242 days. Up to month 6, recurrences carried predominately heterologous parasites (75%) and less homologous parasites (25%). Geographic population sub-structure and no significant temporal changes along the follow-up within areas were found. The likelihood of experiencing a 1st recurrence with relapsing homologous parasites varied according to the origin ($p<0.001$). Moreover, relapses with highly related heterologous parasites were also found. At 6-month post-treatment, the unadjusted relapse cumulative incidence (all homologous considered as relapses) was 10.7% (95%CI:7.4,15.3) whereas after adjustment decreased to 7.5% (*Pmatch*: homologous + highly related) and 5.1% (*Pmatch*: only homologous). The likelihood of experiencing a relapse with homologous or highly related parasites was affected by the genetic population structure of the local parasites. Unraveling of population genetics of local parasites can be used as additional tool to assess the efficacy of radical cure treatments.

RBTAP; A NOVEL REFERENCE BASED TOOL TO ASSEMBLE POLYMORPHIC GENES IN MALARIA

Saikou Y. Bah[1], Gordon A. Awandare[1], Thomas D. Otto[2]

[1]*West African Centre for Cellular Biology of Infectious Pathogens, Accra, Ghana,* [2]*Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom*

Thousands of malaria parasites have been sequenced and analysed often ignoring highly polymorphic genes which often hold significant genomic information. The sequencing reads do not map, or the amount of variation is too high to reliably detect polymorphisms by mapping based approaches. Therefore, alternative approaches are needed because de novo assembly requires high level bioinformatics skills and compute. Available reference genomes from long read sequencing, can be used as templates to obtain more information on these variable genes. Our primary objective is to develop a tool that allows laboratories with little computational power to access the sequencing data from large consortia to assess diversity of genes of interest. The tool needs the following inputs 1) The genome assemblies of the samples to be analysed, 2) The genomic reference of the *Plasmodium*, 3) Coordinates of the gene, and 4) Reference genes of interest from long reads. The multiplicity of infection (MOI) is estimated using the estMOI package. Reads mapping to genes of interests and unmapped reads are extracted from genomes and mapped to long reads gene alleles. If the MOI is 1 a consensus fasta is generated from the best mapping allele and gaps closed using iCORN2 and IMAGE. If MOI is greater than 1, consensus sequence is generated for the MOI with best coverage for phylogenetics. We applied the tool to the MSP gene family of 2500 P falciparum genomes in the Pf3k dataset from different regions. As reference set, we used 16 PacBio reference genomes. It took 15-20 minutes on laptop computer to run a sample to generate a consensus sequence with closed gaps for phylogenetic analysis. The tool accurately generates consensus sequences from highly polymorphic genes for phylogenetics and can be used in laboratories with limited computational and bioinformatic capacity for genomics comparisons. The tool will be made freely available on GitHub.

344

GENOMIC ANALYSIS OF *PLASMODIUM VIVAX* CLINICAL ISOLATES FROM THE CHINA-MYANMAR BORDER AND NEIGHBORING COUNTRIES IN SOUTHEAST ASIA PROVIDES INSIGHTS INTO GENETIC DIVERSITY AND PARASITE POPULATION STRUCTURE

Sonia Agrawal[1], Fang Huang[2], Biraj Shrestha[1], Matthew Adams[3], Sandra Ott[4], Lisa D. Sadzewicz[4], Hui Lui[5], David Serre[4], Myaing M. Nyunt[6], Joana C. Silva[4], Christopher V. Plowe[6]

[1]*Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*National Institute of Parasitic Diseases, Chinese Centre for Disease Control and Prevention, Shanghai, China,* [3]*University of Maryland School of Medicine, Baltimore, MD, United States,* [4]*Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States,* [5]*Yunnan Institute of Parasitic Diseases, Pu'er, China,* [6]*Duke Global Health Institute, Duke University, Durham, NC, United States*

Plasmodium vivax malaria has been refractory to malaria elimination efforts in Southeast Asia, especially in the border areas shared between the countries. Better understanding of the genomic epidemiology of *P. vivax* could inform these efforts by improving our understanding of parasite population structure, potentially leading to new tools for distinguishing between local and imported infections, and for identifying locations that serve as transmission sources and sinks. The objective of this study was to characterize and compare genetic diversity and population structure of circulating isolates of *P. vivax* in areas of low, intermediate and high *P. vivax* prevalence in South and Southeast Asia, using parasite whole genome sequences from clinical infections. Whole genome sequence data were generated from 73 leukocyte-depleted, RDT-positive, field samples with

low *P. vivax* genomic DNA collected from a refugee camp located adjacent to the border between Laiza Township in Myanmar's Kachin State and the town of Nabang in China's Yunnan Province. These new data were compared with publicly available sequences from 361 *P. vivax* clinical isolates from India, Sri Lanka, Myanmar, China, Thailand, Lao, Cambodia and Vietnam. Samples from the China-Myanmar border showed extensive population structure with 79% monoclonal infections and 46% genetically similar isolates. Furthermore, measures of population differentiation revealed relatively low between-country genome-wide differentiation ($0.006 < FST < 0.058$) but high differentiation between all Asian countries and this border population ($0.15 < FST < 0.26$). Taken together these results suggest the presence of an isolated *P. vivax* population in the China-Myanmar border. A modest decline in genetic diversity and proportion of polyclonal infections with decreasing transmission across Southeast Asia was also observed. The analyses showed that genomic surveillance could be used as a powerful tool for monitoring and tracking parasite populations using field-collected samples in these pre-elimination settings.

ROLE OF KILLER CELL IMMUNOGLOBULIN-LIKE RECEPTOR AND HUMAN LEUKOCYTE ANTIGEN-C GENETIC VARIANTS IN TRANSMISSION AND SEVERITY OF MALARIA IN UGANDA

Stephen Tukwasibwe[1], James Traherne[2], Olympe Chazara[2], Arthur Mpimbaza[1], Jyothi Jayaraman[2], John Trowsdale[2], Ashley Moffett[2], Francesco Colucci[2], Moses R Kamya[1], Joaniter I Nankabirwa[1], Grant Dorsey[3], Philip J Rosenthal[3], Stephen Cose[4], Annettee Nakimuli[1]

[1]*Makerere University, Kampala, Uganda,* [2]*University of Cambridge, Cambridge, United Kingdom,* [3]*University of California, San Francisco, CA, United States,* [4]*London School of Hygiene & Tropical Medicine/MRC, London, United Kingdom*

The ability of NK cells to produce inflammatory cytokines early in malaria infections and their role in direct cytotoxic killing of malaria infected red blood cells suggest a beneficial impact of NK cells in malaria. NK cell activity is modulated by interactions between Killer Cell Immunoglobulin-like Receptors (KIR) and Human Leucocyte Antigen (HLA). Several studies have shown certain KIR and HLA genes to be associated with decreased risk of severe malaria and to have varied prevalence in different populations. However, these studies have been limited by low resolution genotyping. Structural and copy number variation (CNV) in KIR and HLA genes have not been considered in malaria studies. We hypothesized that specific KIR and HLA-C genetic variants are associated with severe malaria among Ugandan children and that the prevalence of KIR and HLA-C variants differ in Ugandan populations with varied malaria transmission. We used high resolution multiplex qPCR to genotype for KIR and HLA-C structural and CNV in samples from two clinical studies in Uganda. First, we evaluated samples from 900 children, aged 6 months to 14 years enrolled in a case control study of children presenting with severe or uncomplicated malaria. Second, we evaluated samples from 1500 individuals residing in regions of Uganda with historically different malaria transmission. Preliminary results showed that the prevalence of KIR2DL1 was significantly higher in children with severe malaria compared to those with uncomplicated malaria (93% vs 76%; $p<0.0001$). There was no association seen between HLA-C variants and malaria severity. The prevalence of KIR2DL1 was significantly lower in Tororo, a historically high malaria transmission region compared to Jinja and Kanungu (84% vs 93%; $p=0.0014$ and, 84% vs 95%; $p<0.0001$). The prevalence of HLA-C2C2 was significantly higher in Kanungu compared to Tororo and Jinja (34% vs 27% vs 21%; $p=0.0039$). Malaria evolutionary pressure may have selected for KIR and HLA genetic variants that reduce transmission and susceptibility to severe malaria, but potentially increase risks of other diseases.

346

A SUICIDE-RESCUE-BASED CRISPR/CAS9 SYSTEM COMPETENT FOR LARGE DNA FRAGMENT KNOCK-IN AND SEQUENTIAL GENE EDITING IN *PLASMODIUM FALCIPARUM*

Ying Tong[1], Junnan Lu[2], Minghong Zhang[1], Rui Dong[1], Li Qin[1], Xiaoping Chen[3]

[1]*CAS-lamvac Biotech Company, Guangzhou, China,* [2]*Center for Synthetic Genomics, Institute of Synthetic Biology, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China,* [3]*Laboratory of Pathogen Biology, State Key Laboratory of Respiratory Disease, Center for Infection and Immunity, Guangzhou Regenerative Medicine and Health Guangdong Laboratory, Guangzhou Institutes of Biomedicine and Health (GIBH), Guangzhou, China*

CRISPR/Cas9 technology applied to *Plasmodium falciparum* offers the potential to greatly improve gene editing, but such expectations including large DNA fragment knock-ins and sequential gene editing, have remained unfulfilled. Here, we achieved an advance in addressing this challenge, especially for creating large DNA fragment knock-ins and sequential editing, by modifying our suicide-rescue-based system that has already been demonstrated to be highly efficient for conventional gene editing. This improved approach was confirmed to mediate efficient knock-ins of DNA fragments up to 6.3 kb, to produce "marker-free" genetically engineered parasites and to edit genes sequentially using the same select marker. This represents an important advancement in establishing platforms for large scale genome editing, which might gain a better understanding of gene function for the most lethal cause of malaria and contribute to adjusting synthetic biology strategies to live parasite malaria vaccine development.

347

MULTIPLICITY OF *PLASMODIUM FALCIPARUM* INFECTIONS IN ASYMPTOMATICALLY INFECTED CHILDREN IN UGANDA

Adnan Gopinadhan[1], Dibyadyuti Datta[1], Bob Opoka[2], Chandy John[1]

[1]*Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*Makerere University, Kampala, Uganda*

Prior studies have shown that Ugandan children with asymptomatic parasitemia are less likely to have subsequent uncomplicated or severe malaria episodes than children with severe malaria. It is unclear whether multiplicity or persistence of infection contributes to development of clinical immunity. To investigate this question, we assessed persistence of parasitemia over time and genetic diversity of parasitemia in 79 Ugandan children with asymptomatic parasitemia enrolled between 2008 and 2013. The presence of asymptomatic parasitemia was assessed by testing DNA from filter paper dried blood spots for *P. falciparum* by nested PCR at enrollment at 6 and 12 months after enrollment. Parasite genotype was assessed by PCR detection of variants in polymorphic region of merozoite surface protein-2 (*msp2*) with capillary electrophoresis. Prevalence of AP at baseline, 6 and 12 month collections was 73/73 (100%), 38/73, (52%), and 23/73 (31.5%), respectively. Children had similar number of parasite genotypes present (mean [SD]) at enrollment (2.98 [1.7]), 6 months (3.5 [1.6]) and at 12 months (3.2 [1.6]). Sixteen children tested positive for parasites at all 3 time points. MSP2 variants amplified from 13/16 enrollment samples all 6- and 15/16 12-month samples. 35, 46, and 39 unique *msp2* alleles were identified in enrollment, 6 month and 12 month samples, respectively. The number and frequency of infections with at least one identical genotype at two time points was: enrollment and 6 months, 4/13 (30.8%); 6 and 12 months, 2/16 (12.5%); enrollment and 12 months, 4/13 (30.8%). Only 1 of 16 children had one or more identical parasite genotypes at all three time-points. Ugandan children with asymptomatic *P. falciparum* parasitemia are often infected with multiple *P. falciparum* genotypes, and parasitemia at subsequent time points is usually due to new infections. Future studies will assess if infection with multiple or specific genotypes is associated with protection from subsequent episodes of clinical malaria

348

ANTIBODIES TO PFRH5-LIKE DOMAIN OF PFRH2B PROTEIN IS ASSOCIATED WITH INCREASE IN PARASITEMIA

Jonathan Suurbaar[1], Collins M. Morang'a[1], Prince B. Nyarko[1], Katherine Wright[2], Kwadwo A. Kusi[3], Felix Ansah[1], Eric Kyei-Baafour[3], Evelyn B. Quansah[1], Jessica Asante[3], Laty G. Thiam[1], Matthew Higgins[2], Gordon A. Awandare[1], Yaw Aniweh[1]

[1]*West African Centre for Cell Biology of Infectious Pathogens, Accra, Ghana,* [2]*Department of Biochemistry, University of Oxford, Oxford, United Kingdom,* [3]*Immunology Department, Noguchi Memorial Institute for Medical Research, Accra, Ghana*

Plasmodium falciparum virulence is characterized by the use of surface proteins as well as organelles such as the micronemes and the rhoptries to facilitate erythrocyte invasion aimed at proliferation. The multigene *P. falciparum* reticulocyte homolog (PfRh) family play a pivotal role in merozoites invasion. Structural polymorphism within the PfRh2b gene has been implicated in mechanisms to evade immune attack. More specifically, a 0.58 Kb deletion, at the C-terminus has been reported in high frequencies in Senegalese and Southeast Asian parasite populations. However, the outlook of this deletion mutation in parasite population across all malaria endemic locations has not been established. We therefore hypothesized that, the observed deletion in Rh2b is skewed towards hyper-endemic areas where humoral acquired immunity is normally predominant. Here, by analysing 1,674 *P. falciparum* isolates, we have successfully shown that this deletion is present within the parasite populations from Ghana (37.3%) and observed mainly in the Kintampo (holoendemic, 56.7%). Interestingly, some parasite isolates possessed mixed PfRh2b deletion status (7.4%), indicative of multiple clonal isolates. Globally, 4,032 parasites were analyzed, which showed varying deletion frequency with the west African sub-region as hotspot. The copy number evaluation indicated that the full-length gene could be duplicated in high endemic setting. although PfRh2b harbours a PfRh5-like domain, antibodies to the PfRh2b domain associated with increase parasitemia where as PfRh5 showed the inverse. In all, we have successfully characterized the Rh2b gene deletion polymorphism within parasite isolates globally. We have also indicated that, the deletion could have an important role to evade antibodies that will have effect on parasite survival whilst the duplication enhances the usage of the ligand. Antibodies to the PfRh5-like domain of PfRh2b is of diagnostic importance as antibodies persist in patients from one season to the other, though generally low.

EFFECT OF MALARIA PATHOLOGY ON CD4 AND IMMUNE CELLS

Emmanuel C. Amadi[1], Emmanuel Eze[2], Vincent Chigor[2]

[1]*Enugu State University of Science and Technology, GRA, Enugu, Nigeria,* [2]*University of Nigeria, Nsukka, Nigeria*

Knowledge of immunity in malariology is very essential to understanding the pathology, treatment and vaccine production. The effects of malaria disorder on CD4 and immune cells counts was carried out at a Teaching Hospital in Enugu, Eastern Nigeria between October-December 2018. Patients on doctor's provisional diagnosis of malaria were examined for *Plasmodium* infections and the degree of parasitaemia (0, +, ++, and +++). Positive samples and negative ones (0) were thereafter examined for their CD4 (Flow cytometry) and immune cells (Automated blood cell counter) counts. 45 patients were studied. All the *Plasmodium*-negative specimens were within reference ranges of CD4 cell count (464-1308); with mean value of 835. The (+) parasitaemia showed lower ranges of CD4 count (502-1282); mean = 678; with immune falls in one (427). The 12 (++) parasitaemia showed crash in 9 CD4 cells counts; range: 301-415; mean =399. All the 7 (+++) parasitaemia showed crashes in CD4 cell counts, range: 160-357; mean =225. The CD4 cells falls and crashes were detected only in *Plasmodium falciparum* parasitaemia infections. Depending on the CD4 cells count, also a reflex of parasitaemia, variances occur in the various immune cells' percent and numeric. Total WBC count fell in only 3 patients (1.99, 3.42 & 3.64) x 10^9cells/L, corresponding to (+++), (++) & (+) parasitaemia, respectively. Low CD4 counts do not always produce low lymphocyte numeric, probably because other CDs or killer cells compensate it. In conclusion, *Plasmodium falciparum* infection causes immuno-suppression in patients. Corollary, it means that malaria infection in the immunodeficients and AIDS patients will accelerate the complications as well as death, unlike prevailing reports.

350

VARIATION AND HOST GENETIC CONTROL OF MIRNAS IN RESPONSE TO *PLASMODIUM FALCIPARUM* INFECTION

Aissatou Diawara[1], Mame M. Dieng[1], Vinu Manikandan[1], Hala Tamin El Jarkass[1], Alfred B. Tiono[2], Sodiomon B. Sirima[2], Issiaka Soulama[2], Youssef Idaghdour[1]

[1]*NYU Abu Dhabi, Abu Dhabi, United Arab Emirates,* [2]*Centre National de Recherche et Formation sur le Paludisme, Ouagadougou, Burkina Faso*

Malaria is one of the greatest global public health problems and the host mechanisms responsible for protection against it remain poorly understood. Here, we report the landscape of human whole blood miRNA response to natural *Plasmodium falciparum* infection and its genetic control through genome-wide differential miRNA analysis, total RNASeq and whole genome sequencing of malarial children profiled before infection, during asymptomatic parasitemia, during symptomatic parasitemia and after treatment. The signature of miRNA expression differentiation associated with infection (127 out of 320 miRNAs, FDR 5%) and parasite load (72 miRNAs, FDR 5%) is striking and implicate core immune processes. In particular, we highlight several infection-responsive miRNAs affecting adaptive immune processes or erythrocyte function. Using miRNA *cis* eQTL analysis (111,367 cis SNPs and 274 miRNAs), we have identified 486 genetic variants associated with expression of 34 miRNAs (at permuted level 5%). We also show that host miRNA response to infection is predictable from allelic variation in the identified SNPs suggesting that the transcriptional mechanisms coping with controlling malaria infection are under host genetic control. Together, our findings highlight the role of miRNA and host genotype in modulating response to infection and advocate the use of integrative genomic approaches as companion to GWA mapping for linking molecular genetics to epidemiology in settings where profiling large cohorts is challenging.

INVESTIGATING THE IMMUNE PREDICTORS OF NATURALLY ACQUIRED IMMUNITY IN MALIAN CHILDREN USING SYSTEMS BIOLOGY APPROACHES

Jyoti Bhardwaj

Indiana University, Indianapolis, IN, United States

Parasite-specific IgG antibodies play a central role in naturally acquired immunity (NAI) to *Plasmodium falciparum (Pf)* malaria. However, the precise antigenic targets of these antibodies and the specific cellular correlates of immunity to malaria remain elusive. We sought to identify the immunological predictors of clinical or sterile immunity to *Pf* infection in a prospective cohort study of Malian children using systems biology approaches. We hypothesized that clinical outcomes can be predicted by global analyses of host immune factors at baseline which can influence the immune response during subsequent *Pf* exposures. Using whole blood, plasma, and peripheral blood mononuclear cells collected from children who were prospectively defined as clinically protected from febrile malaria or apparently protected from *Pf* infection, we assessed differences in gene expression, antibody responses, cytokines, and cellular profiles between classes. Whole-blood transcriptomics by RNA-seq revealed differential expression of blood transcription modules between protected and susceptible children for both clinical and apparently sterile immunity. We detected enhanced interferon (IFN) and dendritic cell (DC) module responses with increasing age in clinically immune children relative to clinically susceptible children. We observed upregulated enrichment of DC, monocyte, immune activation, toll-like receptor and inflammation and cell

cycle modules but decreased response of B-cell signatures with increasing age in infection-protected relative to infection-susceptible children. Taken together, our expression data suggests the possible role of DCs and monocyte subsets along with pro-inflammatory and interferon related cytokines in NAI to *Pf* infection. We will integrate the transcriptomic profiles with data obtained from *ex vivo* plasma cytokine analysis, cellular immunophenotyping, and IgM/IgG antibody profiles generated against a panel of 250 *Pf* liver and blood-stage antigens to identify features that are predictive of the clinical classes. Overall, this study may provide important insights into NAI to *Pf* infection.

CHARACTERIZATION OF MONOCYTES IN MALAWIAN CHILDREN PRESENTING WITH EITHER UNCOMPLICATED OR CEREBRAL MALARIA

Visopo Chizaso Harawa[1], Madi Njie[2], Iset Vera[3], Anne Kessler[4], Anthony Jaworowski[5], Terrie Taylor[1], Wilson Mandala[6], Karl Seydel[1], Kami Kim[3], Stephen Rogerson[2]

[1]*Blantyre Malaria Project, Blantyre, Malawi,* [2]*University of Melbourne, Melbourne, Australia,* [3]*University of South Florida, Tampa, FL, United States,* [4]*Albert Einstein College of Medicine, Bronx, NY, United States,* [5]*RMIT University, Melbourne, Australia,* [6]*Malawi University of Science and Technology, Thyolo, Malawi*

Monocytosis has been reported in malaria however their roles remain unclear. Intravascular influx of monocytes has been associated with placental malaria and fatal cerebral malaria (CM). Depletion of inflammatory monocytes abrogated experimental CM in mice. We hypothesised that monocytes could be driving local tissue inflammation through secretion and shedding of activation markers. We aimed to characterize monocyte numbers and their activation levels in children with uncomplicated malaria (UM) and those with CM. Children aged between 6 months and 12 years with malaria were recruited in Blantyre, Malawi. We quantified numbers and plasma monocyte activation markers soluble CD14 (sCD14) and soluble CD163 (sCD163) in 163 children [UM =87 and retinopathy positive (ret+) CM =76] using haematology analyser, ELISA and Luminex. *Mann Whitney* test was used to compare groups medians and a p value of ≤ 0.05 was considered statistically significant. Total monocyte counts were higher in ret+ CM than UM: ret+ CM 1000 median cells/μL IQR [615-1800] vs UM 630 cells/μL [430-900], p value <0.0001. Soluble CD14 was higher in ret+ CM than UM (ret+ CM median 2.56 x 10^6 pg/mL IQR [2.3 x 10^6 -3.15 x 10^6] vs UM 2.14 x 10^6 median pg/mL IQR [1.77 x 10^6 -2.42 x 10^6], p value <0.0001). Soluble CD163 concentration was similar between the two groups. Monocytes numbers and concentrations of sCD14 were higher in children with retinopathy-confirmed CM than matched children with UM. The expansion of monocytes in ret+ CM and elevated sCD14 could suggest a direct or indirect role in CM pathogenesis. . Further studies are needed to elucidate a role for monocytes in severe malaria.

FLOW CYTOMETRIC-BASED MULTIPLEX ASSAY TO ASSESS STRAIN TRANSCENDING ANTIBODIES TO *PLASMODIUM VIVAX* DBPII REVEAL AN EFFICIENT TOOL TO IDENTIFY BINDING-INHIBITORY ANTIBODIES (BIABS) RESPONDERS

Jéssica Rafaela Alves

René Rachou Institute, Belo Horizonte, Brazil

Malaria remains a major public health problem across the globe. In particular, *Plasmodium vivax* is the most prevalent species and its ability to cause relapses and subpatente infections challenge control and elimination strategies. Currently, leading *P.vivax* malaria vaccine target parasite ligands that are critical to reticulocyte invasion such as the Duffy binding protein II (DBPII). Naturally acquired Binding-Inhibitory antibodies (BIAbs) to DBPII is associated with reduced risk of clinical malaria. Due to the methodological issues to evaluate the functional proprieties of DBPII antibodies, so far, few studies have investigated DBPII BIAb responses in *P. vivax*-exposed population. Here, we hypothesized that the detection of high levels of DBPII strain-transcending antibodies is indicative of the presence of BIAbs response. For that, we standardized a sensitive multiplex flow cytometry-based serological assay to detect IgG antibodies against multiple DBPII variants, including an engineered DBPII, DEKnull-2, with conserved functional epitope targets of strain-transcending immune responses. The study design included long-term malaria exposed individuals (n=85) living in a well-characterized rural community of the Brazilian Amazon. Three cross-sectional surveys (baseline, 6 and 12 months) allowed us to characterize individuals as those with or without DBPII BIAbs response, as detected by standard COS7 cell assay. Taken together, the results demonstrate that the multiplex assay developed here increases the chance of identifying responders with BIAbs by at least 12 times. Of interest, around 80% of samples from BIAbs responders present high titers to DEKnull2 as detected by the multiplex assay. In conclusion the standardized multiplex assay confirms our hypothesis that DBPII-BIAbs activity is associated with high titers of strain-transcending antibodies. Futures studies involving different populations are required to confirm the multiplex assay as an alternative to screening individuals harboring DBPII inhibitory antibodies.

354

INFLUENCE OF EPSTEIN-BARR VIRUS INFECTION ON HUMAN MALARIA CAUSED BY *PLASMODIUM VIVAX*

Michelle Hallais Dias

René Rachou Institute, Belo Horizonte, Brazil

In highly endemic malaria areas of sub-Saharan Africa, it has been long recognized an association between *Plasmodium falciparum* malaria and the most common childhood lymphoma, the endemic Burkitt›s lymphoma (eBL) caused by the Epstein-Barr virus (EBV). Although eBL seem to be not associated with *Plasmodium vivax* malaria, it is not clear whether EBV may influence the morbidity and/or the development of a specific immune response against that parasite.Therefore we sought to investigate whether EBV infection may influence *P. vivax* morbidity. The study design include two groups of *P. vivax*-exposed individuals: (i) acute *P. vivax* infection (n=154); individuals sporadically exposed to malaria transmission who sought care at malaria reference centers in the Amazon area; and (ii) long-term malaria-exposed Amazonian individuals who present (n=38) or not (n=503) acute *P. vivax* infection at the time of enrollment; these individuals living in an agricultural community of the Amazon rain forest (Rio Pardo, Amazonas, Brazil) and their age basically correspond to their time of malaria exposure. Methodological approach included a real-time PCR amplification of BALF-5 gene from EBV (EBV-DNA) from peripheral blood from all volunteers. Taken together the results showed that (1) the frequency of EBV-DNA varied between the two groups studied, with virus been detected in 6% (9/154) of sporadically exposed individuals and in 23% (123/541) of long-term Amazonian residents, suggesting that continuous exposure to malaria transmission may have contributed for the difference (2) co-detection of *P.vivax* infection and EBV-DNA was associated with altered hematological parameters, including low levels of hemoglobin, hematocrit, and platelets; (3) a positive association between EBV-DNA and malaria-related clinical symptoms. In a prove-of-concept study, we demonstrated for the first time that EBV infection may influences on *P. vivax* morbidity and immunity. Future studies should include population of different endemic areas and individuals harboring different levels of *P. vivax* morbidity including severe disease.Financial support: CNPq, FAPEMIG, CAPES.

A PEPTIDE-BASED CHECKPOINT INHIBITOR THERAPEUTICALLY RESCUES MICE FROM LETHAL MALARIA AND ENHANCES PRIMING OF T CELLS FOLLOWING VACCINATION

Timothy W. Phares[1], Vinayaka Kotraiah[1], Deshapriya Karunarathne[2], Michelle Wykes[2], Jing Huang[3], Moriya Tsuji[3], Jim A. Pannucci[1], Gabe M. Gutierrez[1]

[1]*Explorations in Global Health / Leidos, Frederick, MD, United States,* [2]*QIMR Berghofer, Brisbane, Australia,* [3]*Aaron Diamond AIDS Research Center, New York, NY, United States*

Checkpoint receptors are highly expressed on T cells from chronically-infected individuals, arguing T cell exhaustion contributes to pathogenesis and lack of immunity. Targeting checkpoint receptors has shown to improve outcomes in models of chronic infections. In malaria, increasing evidence suggests that inhibitory receptors (e.g., PD1, LAG3), mediate immune suppression. Studies have shown that PD1-deficient mice rapidly clear chronic *Plasmodium chabaudi* and develop sterile immunity. Moreover, PD1 mediates loss of long-term protection against *P. chabaudi*. These data argue that blocking PD1 may rescue T cell exhaustion in malaria-infected individuals. While mAb-based checkpoint therapeutics are efficacious in oncology, they are not ideal for infectious diseases. We created a platform for discovering short peptides and evolving these peptide scaffolds by *in silico* design. Our lead checkpoint inhibitor, LD01, inhibits both the PD1 and CTLA4 receptors and has shown efficacy in oncology models. We evaluated the LD01 checkpoint inhibitor in therapeutic and prophylactic malaria vaccine mouse models. In the lethal *P. yoelii* model 100% mortality occurs 10 days post-infection. Treatment with LD01, as late as 3 days post-infection, decreased clinical severity and induced 50% protection. Further, all of the LD01 treated surviving mice were protected after re-challenge, indicating long-lived memory. Studies in the *P. yoelii* model to elucidate immunological mechanism of action are ongoing. In a recombinant replication defective AdPyCS vaccine model, a significant increase in splenic PyCS-specific, IFN-γ^+ CD8 T cells was detected in mice treated with LD01 compared to AdPyCS alone. Overall, LD01 appears to mediate release of immune suppression and acts as a T cell focused adjuvant when co-administered with a vaccine antigen, supporting further studies to understand its potential as a therapeutic peptide-based checkpoint inhibitor or as part of a prophylactic vaccine regimen.

An effective preventive malaria vaccine would add significantly to current malaria control methods, and would add significantly to the drive to malaria elimination. The goal of many vaccines is to generate long lasting and high affinity antibodies, which have been shown to be important mediators of naturally acquired anti-malaria immunity, but it is currently unclear how these responses are generated and maintained. We are analysing the immunoglobulin (Ig) repertoire, including key features such as clonal structure, rates of somatic hypermutation and Ig class-switching, in adults who present with different outcomes in controlled human malaria infection (CHMI) trials, and in children recovering from acute *Plasmodium falciparum* malaria. We determined the kinetics of memory B cells and plasmablasts in both populations using B cell ELISPot and flow cytometry assays. The proportions of plasmablasts increased during acute malaria infection in children, but decreased after treatment. By contrast, there was no synchronized peak in the proportions of plasmablasts in adults following CHMI, which could be indicative of suboptimal antigenic stimulation. Based on these results, we sorted plasmablasts (by flow cytometry) from children of different ages at various timepoints before, during and after acute malaria. These samples are currently being processed for B-cell receptor sequencing (BCRseq) to characterize the evolution of responding plasmablasts, and provide insights into whether there is a qualitative improvement of the response with time from diagnosis, and with increasing age and/or exposure. We have also sorted memory B cells from the "most highly immune" and the "least immune" adults, as determined by their ability to control parasite growth during CHMI, and will use BCRseq for the identification and comprehensive characterization of protective antibodies within these cohorts. This project will provide insight into characteristics of protective antibody responses, as well as the processes leading to them.

357

MALIAN CHILDREN WITH BOTH CEREBRAL MALARIA AND SEVERE MALARIAL ANEMIA HAVE A SEROLOGIC AND CYTOKINE PROFILE DISTINCT FROM THOSE WITH OTHER SEVERE MALARIA SUBTYPES

Abby R. Goron[1], Andrea A. Berry[1], Jason A. Bailey[1], Drissa Coulibaly[2], Matthew Adams[1], Abdoulaye K. Kone[2], Bourema Kouriba[2], J. Alexandra Rowe[3], Ogobara K. Doumbo[2], Marcelo B. Sztein[1], Philip Felgner[4], Christopher V. Plowe[1], Mahamadou A. Thera[2], Kirsten E. Lyke[1], Mark A. Travassos[1]

Children aged less than five years accounted for 66% of malaria deaths in sub-Saharan Africa in 2018. Pediatric severe malaria subtypes with the highest mortality include cerebral malaria (CM) and severe malarial anemia (SMA). We recently showed that Malian children with these severe malaria subtypes differed in serologic responses to particular *Plasmodium falciparum* variant surface antigens. A third group of children with both cerebral malaria and severe malarial anemia (CM+SMA) had serologic responses that differed from both of these groups. Unlike children with either severe malaria subtype, Malian children with CM+SMA had less parasite burden and higher overall mortality. Here, we aimed to further determine how children with CM+SMA differed from other severe malaria subtypes, by examining serologic responses to Apical membrane antigen-1 (AMA1), a merozoite surface antigen and surrogate for *P. falciparum* exposure, and cytokine profiles using cytometric bead array technology and flow cytometry. Using a protein microarray populated with 268 AMA1 field variants, we measured AMA1 reactivity of sera for 78 Malian children aged 4.7 to 79.4 months with severe malaria compared to that for age-, region- and ethnicity-matched controls with uncomplicated malaria. Serorecognition was defined as a fluorescence intensity at least two standard deviations above the mean for sera from malaria-naïve North American controls. Overall, sera from children with CM, SMA, or CM+SMA recognized similar numbers of AMA1 variants (87.8%, 92.1%, and 97.5%, respectively; NS). Unlike sera from children with CM or SMA, sera from children with CM+SMA responded more intensely to 50 AMA1 variants than matched controls. Serum cytokine level measurements showed that children with CM+SMA had lower levels of IL-1β and IL-12 than those with CM alone and higher levels of IL-6 and IL-10 than children with SMA alone. Children with both cerebral malaria and severe malarial anemia represent a distinct severe malaria subtype suggesting a unique parasite exposure pattern compared to other severe malaria subtypes and a distinct cytokine profile that merits further exploration.

358

MULTI-SITE COMPARISON OF CHANGES IN CYTOKINE AND CHEMOKINE EXPRESSION PROFILES OVER 1-YEAR IN CHILDREN <5 YEARS WITH ASYMPTOMATIC MALARIA

Katrina E. Co[1], Elizabeth C. Okafor[2], Dibyadyuti Datta[1], Elizabeth Fernander[1], Estela Shabani[3], Eliud O. Onyango[1], George Ayodo[4], Robert O. Opoka[5], Chandy C. John[1]

[1]*Indiana University School of Medicine, Indianapolis, IN, United States,* [2]*University of Minnesota School of Medicine, Minneapolis, MN, United States,* [3]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [4]*Kenya Medical Research Institute, Kisumu, Kenya,* [5]*Makerere University, Kampala, Uganda*

Understanding the cytokine and chemokine profiles over time in children with asymptomatic parasitemia (AP) may help explain the underlying immunity that keeps these children from developing symptomatic febrile malaria. To explore this question further, we studied children <5 years of age with AP in a region of low to moderate malaria transmission in Kampala, Uganda, and a region of high transmission in Ajigo, Kenya. Samples were collected at baseline and 6 and 12 months later (Uganda) and baseline and 12 months later (Kenya). *Plasmodium falciparum* was detected by nested PCR and cytokines, chemokines, angiogenic growth factors, and endothelial activation markers by cytometric bead assay. In the Ugandan cohort, AP was present at 34% (baseline), 22% (6 months), and 18% (12 months). At baseline, children with AP had lower levels of IL-1β, IL-8, IL12p70, IFN-γ, MIP-1α, RANTES, and IL-4 and higher levels of TNF-α, MIP-1β, IP-10, and IL-10 compared to children with no parasitemia (NP), showing a mixed anti- and pro-inflammatory picture. Levels of the angiogenic growth factors FGF-basic and G-CSF were lower and endothelial markers vWF, VCAM-1, and ICAM-1 higher in AP compared to NP. At 6-months, children with AP had a clear pro-inflammatory profile compared to NP, with higher levels of IL-6, IL-8, IL-17a, TNF-α, IFN-γ, MIP-1α, and MCP-1 than NP. FGF-basic and VCAM-1 levels were also higher in AP than NP (all $p<0.05$). In the Kenyan cohort, AP was present at 19% (baseline) and 36% (12 months). AP in this area had higher levels of pro-inflammatory cytokines/chemokines (TNF-α, MIP-1β, IP-10, MCP-1, and IL-1ra) and one anti-inflammatory cytokine (IL-10) compared to NP (all $p<0.05$). Testing of 12-month time point samples is ongoing. Children with AP in both sites generally showed increased levels of pro-inflammatory cytokines and endothelial activation markers compared to children with NP. However, the specific factors upregulated varied by time and area, possibly due to co-existing infectious or inflammatory stimuli.

359

DOES IT MATTER IF *PLASMODIUM* PREFERENTIALLY INVADES RETICULOCYTES OR NORMOCYTES?

Palmer Masumbe Netongo[1], Palmer Masumbe Netongo[2], Spencer Seely[2], Patrice Mimche[3], Aubree Earl[3], Nathan T. Jacobs[4], Tracey J. Lamb[3]

[1]*University of Yaounde I, Yaounde, Cameroon,* [2]*Department of Pathology, University of Utah, Salt Lake City, UT, United States,* [3]*Department of Pathology, University of Utah, Salt Lake City, UT, United States,* [4]*Population Biology, Ecology and Evolution Graduate Program, Laney Graduate School, Emory University, Atlanta, GA, United States*

Malaria is caused by infection with *Plasmodium* parasites that infect red blood cells to propagate infection. It is known that there is preference in some *Plasmodium* species for a particular age of red blood cells with *P. vivax* preferring to invade young reticulocytes (immature red blood cells). Infection of B cell deficient υMT mice turns a normally non-lethal *P. yoelii XNL* infection into a lethal one whereas υMT mice infected with *P. chabaudi-AS* all survive. One major difference between these two infections is that *P. yoelii XNL* infects primarily reticulocytes whereas *P. chabaudi-AS* infects normocytes. This implies that there could be a difference in the requirement for antibodies in the control of *Plasmodium*-infected red blood cells that are reticulocytes vs normocytes. Control of the primary peak of parasitemia in mice infected with the non-lethal reticulocyte-invading *P. yoelii XNL* requires antibody while mice infected with the more promiscuous-invading non-lethal *P. chabaudi-AS* does not. We investigated whether there were differential requirements for phagocytosis of *Plasmodium*-infected reticulocytes as opposed to more mature infected normocytes infected with *Plasmodium*. We also discuss results of the impact of altering the timing of infection on differences in requirement for parasitemia control by antibody-mediated vs non-antibody-mediated phagocytosis *during P. yoelii XNL* and *P. chabaudi-AS* infections.

PLASMA CYTOKINE AND CHEMOKINE SIGNATURES DURING ACUTE INFECTION BUT NOT CONVALESCENCE DISTINGUISH BETWEEN CHILDREN WITH DIFFERENT LEVELS OF PRIOR EXPOSURE TO MALARIA

Nancy K. Nyakoe[1], Jean Langhorne[2], Gordon A. Awandare[1], Kwaku P. Asante[3], Yaw Bediako[1]

[1]*West African Centre for Cell Biology of Infectious Pathogens, Accra, Ghana,* [2]*The Francis Crick Institute, London, United Kingdom,* [3]*Kintampo Health Research Centre, Kintampo, Ghana*

Regulation of cytokines plays an important role in malaria anti-disease immunity in naturally exposed individuals. Acquisition of natural immunity is influenced by variations in exposure due to differences in transmission intensity. This study aimed to investigate cytokine responses during acute and convalescent phases of *Plasmodium falciparum* infection in children exposed to different malaria transmission intensities. Children of ages 5-14 years were recruited from two regions in Ghana with distinct malaria transmission intensities: Accra (low transmission) and Kintampo (high transmission). Luminex magnetic 25-plex bead array was used to determine plasma levels of 25 cytokines and chemokines, including interleukins (IL), interferons (IFN), Tumor necrosis factor (TNF), IFN-γ-inducing protein 10 (IP-10), monocyte chemotactic protein-1 (MCP-1) and Monokine induced by (IFN-γ) (MIG), during infection (D0) and convalescent phases (D7 and D21). Cytokine levels were also compared between the 2 sites. *P. falciparum* infection induced a proinflammatory response driven by IL6, IFNγ, IFNα, MIG, MCP1 and IP10 cytokines, associated with an immunomodulatory profile mediated by IL10, IL-2R, and IL-1RA. These were significantly elevated during acute infection compared to convalescence with significantly higher levels in children from low transmission sites compared to those from high transmission sites. Only IFN-α, IL-6, IL-1RA and MCP-1 were significantly associated with parasitemia levels. Correlation network analysis identified a signature that distinguished individuals from the low transmission area. Interestingly, we identified a cytokine signature dominated by IL-10 and IL-1RA associated with asymptomatic parasitemia in a subset of children from the high transmission area with detectable parasitemia at D21. The study reveals significant differences in cytokine responses during active malaria infection in individuals with different levels of prior exposure. These differences are however transient and are not maintained during convalescence.

361

MALIAN ADULTS MAINTAIN SEROLOGIC RESPONSES TO NON-CD36-BINDING PFEMP1S AMID SEASONAL PATTERNS OF FLUCTUATION

Noah Thomas Ventimiglia[1], Emily M. Stucke[1], Andrea A. Berry[1], Drissa Coulibaly[2], Kirsten E. Lyke[1], Matthew B. Laurens[1], Jason A. Bailey[1], Matthew Adams[1], Amadou Niangaly[2], Abdoulaye K. Kone[2], Shannon Takala-Harrison[1], Bourema Kouriba[2], Ogobara K. Doumbo[2], Mahamadou A. Thera[2], Phillip L. Plasmodium falciparum erythrocyte membrane protein-1 (PfEMP1) antigens, a family of malaria parasite proteins expressed on the infected erythrocyte surface, play an important role in malaria pathogenesis, mediating infected erythrocyte adhesion to host vascular endothelium while evading immune recognition through genetic diversity. Antibody responses to PfEMP1s are likely essential to immunity to clinical malaria, with antibodies to non-CD36-binding PfEMP1s associated with protection against severe disease. Using a protein microarray, we aimed to determine how serologic responses to 166 3D7 strain PfEMP1 fragments changed during a dry season and subsequent malaria transmission season in 18 Malian adults. We defined antigen seroreco gnition using malaria-naive N. American adults as controls. We hypothesized that adults, given lifelong exposure to the *P. falciparum*, would recognize most PfEMP1 antigens and possess high levels of seroreactivity during the year of follow-up. We also expected that serologic responses would decrease during the dry season and increase during the malaria transmission season due to the intense, seasonal nature of parasite exposure in Mali. Considered as a group and by individual, Malian adult sera had significant serologic responses to PfEMP1s throughout the study year. While the group rarely gained or lost seroreco gnition, it had decreased seroreactivity to a subset of PfEMP1s during the dry season (22 fragments, $p < 0.05$) and increased seroreactivity to another subset during peak malaria transmission (18 fragments, $p < 0.05$) [Wilcoxon Signed-Rank test (WSR)]. Individual Malian adults generally followed these seasonal trends [McNemar's test (MT); WSR] and were more likely to experience a significant change in seroreco gnition of CD36-binding PfEMP1s than non-CD36-binding PfEMP1s (MT; Binomial test), which remained seroreco gnized throughout the year. If sustained seroreco gnition of non-CD36-binding fragments into adulthood amid seasonal patterns of fluctuation reflects underlying protective clinical immunity, future studies for potential vaccine development may be warranted.

362

MECHANISMS DRIVING ALTERED VΔ2+ ΓΔ T CELL FUNCTION DURING RECURRENT MALARIA INFECTION

Kathleen W. Dantzler[1], Sandy Klemm[1], Rafael Polidoro[2], Aditya Rao[1], Caroline Junquiera[3], Mai Dvorak[1], John Rek[4], Moses Kamya[5], Peggie Cheung[1], Alex Kuo[1], Grant Dorsey[6], Margaret Feeney[6], Judy Lieberman[2], Purvesh Khatri[1], William Greenleaf[1], Prasanna Jagannathan[1]

[1]*Stanford University, Palo Alto, CA, United States,* [2]*Harvard University, Boston, MA, United States,* [3]*Fiocruz Minas, Belo Horizonte, Brazil,* [4]*Infectious Disease Research Collaboration, Kampala, Uganda,* [5]*Makerere University, Kampala, Uganda,* [6]*University of California San Francisco, San Francisco, CA, United States*

Naturally acquired immunity to the most deadly human malaria parasite, *Plasmodium falciparum (Pf)*, provides some protection against symptomatic disease in older children and adults but is unable to eliminate parasite replication. Immune mediators, such as pro-inflammatory cytokines produced from innate-like γδ T cells, can reduce parasitemia but can also lead to chronic inflammation. Repeated malaria exposure among Ugandan children leads to attenuation of the pro-inflammatory response from the Vδ2+ γδ T cell subset, which associates with a reduced likelihood of symptoms upon subsequent *Pf* infection. Building on evidence that altered Vδ2+ T cell function is important in the development of antimalarial immunity, we are using epigenetic and transcriptional approaches to identify mechanisms driving this process. We used 2 parallel methods to examine epigenetic reprogramming: 1) EpiTOF, which uses CYTOF to interrogate specific histone modifications at the single cell level, and 2) Omni-ATAC, which reveals sites of open chromatin across a population of cells. Results indicate significant differences in chromatin accessibility and histone methylation between Vδ2+ T cells from children with varying malaria exposure (low *vs*. high transmission) or infection status (uninfected, asymptomatic *vs.* symptomatic infection), suggesting that epigenetic regulation may play a role in altering functional responses of these cells after repeated infection. We are further establishing *in vitro* systems both to quantify changes in various Vδ2+ T cell functions (cytotoxicity, growth inhibition, antibody-dependent cytotoxicity) and to replicate the phenotype of altered function following repeated *in vivo* infection. By deepening our understanding of the molecular mechanisms driving inefficient acquisition of antimalarial immunity in children, this work could enable novel therapeutic approaches that enhance parasite clearance and/or reduce disease severity.

STATISTICAL MODELLING OF SURVEILLANCE DATA TO IDENTIFY CORRELATES OF URBAN MALARIA RISK: A POPULATION-BASED STUDY IN THE AMAZON BASIN

Rodrigo Corder, Gilberto Paula, Anaclara Pincelli, Marcelo Ferreira

University of Sao Paulo, Sao Paulo, Brazil

Despite the dramatic decrease during the last decades in the malaria burden in the Americas, focal transmission persists across the Amazon Basin. Characterizing high-risk individuals and households is crucial for better targeting control interventions.Here we analyzed 5,480 laboratory-confirmed malaria episodes and combined with demographic and socioeconomic information to identify malaria risk factors in the main urban transmission hotspot of Brazil, themunicipality of Mâncio Lima, situated intheJuruá Valley, westernmost Brazil, close to the border with Peru. After determining the number of malaria episodes for each urban resident during 33 months of follow-up, overdispersed count data clustered into households were fitted with random-effects zero-inflated negative binomial (ZINB) regression models. Random-effect predictors and alpha-shapes were used to characterize the spatial heterogeneity in malaria risk. We found evidence for local and imported transmission. Poor housing and residence in the periphery of the town were key predictors of malaria risk, consistent with a substantial local transmission. On the other hand, adult males were identified as the population at greatest risk, likely due to increased occupational exposure away of the town. Around two thirds of the 8,878 urban residents remained uninfected after 23,975 person-years of follow-up and nearly 14% of them, mostly children and older adults living in the center of the town, were estimated as the excess of zeros and, therefore, free of malaria risk (unexposed, naturally unsusceptible, or immune to infection). Random-effects ZINB model of routinely collected malaria surveillance data can be explored to characterize drivers of transmission heterogeneity at the community level, thus providing evidence for the rational deployment of control interventions.

364

DEVELOPMENT OF A COMMUNITY-DELIVERED MALARIA ELIMINATION MODEL FOR MYANMAR

Win Han Oo[1], Lisa Gold[2], Elizabeth Hoban[2], Kyu Kyu Than[1], Aung Thi[3], Paul A. Agius[4], Freya J. Fowkes[4]

[1]*Burnet Institute, Yangon, Myanmar,* [2]*School of Health and Social Development, Faculty of Health, Deakin University, Melbourne, Australia,* [3]*Department of Public Health, Myanmar Ministry of Health and Sports, Nay Pyi Taw, Myanmar,* [4]*Burnet Institute, Melbourne, Australia*

The malaria program in Myanmar is currently transitioning from control to elimination phase in order to achieve its 2030 malaria elimination goal. As a consequence, malaria volunteers in Myanmar have been transforming into Integrated Community Malaria Volunteers (ICMVs) since 2017. This ICMV model was designed with no evidence base to include integrated services for malaria, lymphatic filariasis, dengue, tuberculosis (TB), HIV/AIDS and leprosy. To inform the evidence base, a series of studies aiming to develop an optimal and scientifically proven integrated community-delivered malaria elimination model for Myanmar was conducted. Firstly, a systematic review and meta-analysis of 28 studies investigating the impact of community-delivered models was undertaken to estimate the effectiveness of these community-delivered models. Secondly, inductive thematic analyses of qualitative data collected from focus group discussions (n=8), participatory workshops (n=2) and semi-structured interviews (n=19) were used to consolidate the perspectives of community leaders and members, and malaria stakeholders from Myanmar. In qualitative consultations, community leaders and members identified common health concerns in addition to malaria and included respiratory illness, childhood diarrhoea, skin infections and TB (in this order) and recommended incorporating preventive, and whenever possible curative, services for those diseases into the malaria volunteer model. Although stakeholders perceived that disease combination in ICMV model was optimal, community members perceived that more illnesses should be included. Stakeholders also suggested ways that volunteer recruitment, training, supervision and reporting in the current ICMV model could be optimized. Based on international evidence and recommendations from community consultations, a community-delivered malaria elimination model should consist of malaria, TB, dengue, respiratory illness and childhood diarrhoea. Providing a range of services together with malaria will ensure a positive advancement towards the malaria elimination goal.

TREATMENT ALGORITHMS WITH RADICAL CURE OF VIVAX MALARIA BASED ON SEX: A COST-EFFECTIVENESS ANALYSIS TO SUPPORT ROLL OUT STRATEGIES

Angela Devine[1], Sandra Incardona[2], Ric N. Price[1], Sabine Dittrich[2], Xavier Ding[2]

[1]*Menzies School of Health Research, Darwin, Australia,* [2]*FIND, Geneva, Switzerland*

The recent license of single-dose tafenoquine for radical cure of *Plasmodium vivax* has changed the landscape for malaria elimination. Tafenoquine will overcome the issue of poor adherence to a prolonged course of primaquine; however, its clinical use requires prior screening for glucose-6-phosphate-dehydrogenase (G6PD) deficiency to exclude patients at risk of drug-induced haemolysis. G6PD deficiency is a sex-linked disorder: whilst diagnosis at a 30% cut-off excludes hemizygous deficient males at risk of haemolysis, it will not accurately exclude heterozygous females with intermediate deficiency (30-70% activity). The diagnosis of intermediate deficiency requires a quantitative test, associated with increased logistical and infrastructure complexity as well as cost. To support a phased implementation and to bridge potential infrastructure gaps, we explored a treatment algorithm for tafenoquine stratified by sex. In this algorithm, after testing with the less costly qualitative test (which can diagnose G6PD deficiency at the 30% threshold), males who test normal will be prescribed tafenoquine. Females would be offered the choice of either primaquine or referral to a higher facility where quantitative testing (which can diagnose reliably at the 70% threshold) is available, enabling the use of tafenoquine after appropriate assessment of G6PD activity. The cost-effectiveness of this strategy was explored using a decision model for Afghanistan, Ethiopia, Indonesia and Vietnam. The model was parameterized for these countries using data on local costs, G6PD deficiency and hemoslysis from a large randomized controlled trial. In settings where quantitative testing is not readily available, this strategy would offer a cost-effective and easy to implement approach for enabling the safe and effective radical cure of vivax malaria, an essential step to achieving elimination.

366

REFINING GLOBAL MAPS OF G6PD DEFICIENCY: HARNESSING NEW DATA AND ANALYTICAL METHODS

Daniel A. Pfeffer[1], Timothy C. Lucas[2], Colin Johnston[2], Jia Wei[3], Jonas Sandbrink[2], Benedikt Ley[1], Archie Clements[4], Peter W. Gething[2], Ric N. Price[1], Rosalind E. Howes[2]

[1]*Menzies School of Health Research, Darwin, Australia,* [2]*University of Oxford, Oxford, United Kingdom,* [3]*Peking University, Beijing, China,* [4]*Curtin University, Perth, Australia*

Up to 2.5 billion people are at risk of *Plasmodium vivax* malaria. Clearance of dormant parasites in the liver ('radical cure') requires treatment with an 8-aminoquinoline, however this is associated with haemolysis in individuals with glucose-6-phosphate dehydrogenase deficiency (G6PDd). G6PDd is common, especially in malaria endemic regions. Understanding the spatial distribution of G6PDd, its prevalence, and local variants is essential to informing safe treatment policies. In order to refine global maps of G6PDd prevalence, we undertook a systematic literature review to update an existing global database of G6PDd prevalence surveys, identifying new studies published between 2010 and 2018. Surveys from the general population and among malaria patients were analysed separately. Surveys were georeferenced using published coordinates, information from authors or online mapping software (e.g. Google Maps). Global genomic datasets were explored to create a spatial covariate surface of broad-scale population relatedness. Final maps of G6PDd prevalence were produced via a Bayesian geostatistical model implemented using Integrated Nested Laplace Approximation (INLA). Of 7,447 papers screened, 813 were included. Population representative point prevalence data was extracted and added to the existing database of 1,734 spatially unique sites. Spatially continuous maps of G6PDd prevalence were produced at a resolution of approx. 5x5km, along with national estimates of the prevalence of G6PDd and number of affected individuals. Preliminary analysis demonstrated improved model performance and reduced uncertainty compared with previous research, particularly in areas where data coverage was previously poor. Improved input data, informative covariate data and computationally efficient methods have enhanced our ability to map G6PDd. The up-to-date maps of G6PDd synthesize our current knowledge on the local burden of G6PDd, while enabling informed inference where data are not yet available. These data will be critical for risk-benefit analysis of *P. vivax* radical cure and highlight priority areas for G6PD screening programs.

367

IN SILICO PREDICTION OF THE STRUCTURE OF *PLASMODIUM FALCIPARUM* GAMETOCYTE DEVELOPMENT PROTEIN 1 AND ITS EVALUATION AS A DRUG TARGET

Josephat K. Bungei[1], **Victor A. Mobegi**[2], Steven G. Nyanjom[1]

[1]*Jomo Kenyatta University of Agriculture and Technology, Juja, Kenya,* [2]*University of Nairobi, Nairobi, Kenya*

Malaria transmission is a critical point in the disease cycle but the current drugs and vaccines target pre-erythrocytic and erythrocytic stages of malaria parasites. Therefore, transmission blocking strategies should be designed to target the sexual stage of the parasite. The exploration of transmission mechanism of the malaria parasite, *Plasmodium falciparum,* reveals that gametocytogenesis is critical in human host to mosquito vector transmission. Molecular studies demonstrate that gametocyte

development protein 1 (*Pfgdv1*) is an upstream epigenetic activator of gametocytogenesis. Genetic characterization of *Pfgdv1* gene and prediction of its structure forms the basis of drug design and development to prevent the transmission of malaria. Prediction of protein structure, ligand-binding sites, and the nature of ligands provide critical information regarding functional sites and mechanism of action in gametocytogenesis as a molecular target. *Pfgdv1* amino acid sequence of *P. falciparum* 3D7 strain was retrieved from PlasmodDB and used in the prediction of protein structure and its ligand-binding sites. Sequence data obtained from clinical isolates was also used to ascertain the effect of Non-synonymous substitutions. Protparam tool at ExPASy, was used to predict physical and chemical properties of *Pfgdv1*. InterPro 71 was used to predict domains, family, and functional sites of *Pfgdv1*. Iterative threading assembly refinement (I-TASSER) was utilized to model the protein structure and visualized using Jmol. Protein-ligand docking was performed using both I-TASSER and COACH. Secondary structure prediction reveals that *Pfgdv1* constitutes 33% of α-helix, 16% of beta-sheet, and 49% of coil structures. The predicted 3D structure of *Pfgdv1* has three apparent domains, which cover 1-277, 278-437, and 438-599 segments of the amino acid sequences. Protein-ligand docking has identified some ligands of *Pfgdv1* protein which can be used as a basis for evaluation of this protein as a drug target.

368

VALIDATION OF PIPERAQUINE CONCENTRATIONS PROTECTIVE AGAINST *PLASMODIUM FALCIPARUM* INFECTION WHEN DIHYDROARTEMISININ-PIPERAQUINE IS GIVEN ASINTERMITTENT PREVENTIVE TREATMENT DURING PREGNANCY

Emma Hughes[1], Richard Kajubi[2], Erika Wallender[1], Liusheng Huang[1], Teddy Ochieng[2], Abel Kakuru[2], Prasanna Jagannathan[3], Miriam Nakalembe[4], Bishop Opira[2], John Ategeka[2], Patience Nayebare[2], Tamara D. Clark[1], Moses Kamya[5], Philip Rosenthal[1], Grant Dorsey[1], Francesca Aweeka[1], Rada Savic[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Infectious Disease Research Collaboration, Kampala, Uganda,* [3]*Stanford University, Palo Alto, CA, United States,* [4]*Department of Obstetric and Gynecology, Makerere University College of Health Sciences, Kampala, Uganda,* [5]*School of Medicine, Makerere University College of Health Sciences, Kampala, Uganda*

Dihydroartemisinin-piperaquine (DHA-PQ) is currently being tested for intermittent preventive treatment of malaria during pregnancy (IPTp). Accurate definition of the preventive PQ concentration is imperative to define dosing and regimen recommendations. Previously, using a prevention study in pregnant women residing in Tororo, Uganda, our group defined that a PQ concentration of 10.3 ng/mL or higher would protect 95% of pregnant women against *P. falciparum* parasitemia by loop mediated isothermal amplification, and reported that at least monthly dosing of standard 3-day DHA-PQ is required to achieve this concentration. The current study aims to validate established preventive targets and if monthly DHA-PQ dosing achieves those targets. The analysis was conducted using a pharmacokinetic/pharmacodynamic (PK/PD) model which described the relationship between PQ concentrations and risk of parasitemia. The validation trial was conducted in Busia, Uganda, a region with high transmission intensity. In total, 373 women received DHA-PQ every month during pregnancy with pre-dose trough blood samples collected for PQ quantitation and assessment of parasitemia using quantitative PCR (qPCR). In total, 1230 PQ samples and 1757 qPCR results were available for analysis. The observed PQ concentrations were higher than expected: the median PQ trough concentration in this trial was 12.8 ng/mL (2.8-41 ng/mL; 2.5-97.5% percentile) compared to 6.9 ng/mL (1.2-23 ng/mL; 2.5-97.5% percentile) from the previous study in Tororo. In the current study 63% of PQ concentrations were above 10.3 ng/mL compared to 27.6% in the previous study. Three women experienced symptomatic malaria, all with PQ concentrations <6 ng/mL at the time of diagnosis Poorer adherence to DHA-PQ in the Tororo study compared to the Busia study has been identified as one potential explanation for the observed PK differences. Further work will refine the estimate of preventive concentrations using quantitative qPCR as the PD marker. These findings confirm that monthly DHA-PQ dosing achieves PQ plasma concentrations which are sufficiently protective against symptomatic malaria.

369

INCREASED PATENT MALARIA IN THE DEMOCRATIC REPUBLIC OF THE CONGO (DRC): GEOGRAPHIC AND EPIDEMIOLOGICAL CHANGES FROM 2007 TO 2013

Molly Deutsch-Feldman[1], Jonathan Parr[2], Nicholas F. Brazeau[2], Kyaw Thwai[2], Melchior Kashamuka[3], Antoinette Tshefu[3], Jonathan J. Juliano[2], Robert Verity[4], Steven R. Meshnick[2]

[1]*University of North Carolina - Chapel Hill, Carrboro, NC, United States,* [2]*University of North Carolina - Chapel Hill, Chapel Hill, NC, United States,* [3]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo,* [4]*Imperial College, London, United Kingdom*

Malaria remains a significant public health problem in the Democratic Republic of the Congo (DRC), with 17 million confirmed cases in 2016, accounting for 11% of cases worldwide. To combat the spread of malaria, the DRC implemented several intervention programs over the past decade, including long lasting insecticide treated bed-nets (LLIN) distributions and increased intermittent preventive therapy for pregnant women (IPTp). However, the heterogeneous spatial epidemiology of malaria across the country complicates prevention efforts. This study explores changes in the spatial distribution of malaria infections in the DRC over the past decade and the impact of intervention programs on these changes. We performed quantitative PCR (qPCR) on 17,968 samples collected during the 2013-2014 DRC Demographic and Health Survey and leveraged previously generated qPCR data from the 2007 survey. Using data from these two national, cross-sectional surveys, we compared the prevalence and spatial distribution of patent *Plasmodium falciparum* infections (at least 100 parasites/uL of blood) amongst adults over time. We created risk maps to identify changes in province-level prevalence between 2007 and 2013. Additionally, we used geospatial Bayesian modeling to assess the causal effect of LLINs and IPTp on malaria prevalence. Among 26,965 subjects enrolled in the two studies, the overall prevalence of patent infections increased from 2.4% in 2007 to 7.5% in 2013. Province-level prevalence changes ranged from -1.0% to +12.8%, with a median change of +6.0%. Modeling results indicate heterogeneous effects for both interventions, from highly protective in certain provinces to no effect in others. The results of this study will aid the DRC in its efforts to reduce malaria transmission. Our findings demonstrate important differences in malaria transmission across the DRC and highlight variation of the effects of two interventions across the country. Understanding where malaria transmission increased and where recent interventions were least effective over the past decade is essential for the development of effective, targeted interventions.

370

THE ROLE OF LONG-LASTING SYSTEMIC INSECTICIDES IN ACCELERATING MALARIA CONTROL AND ELIMINATION: A MODELING STUDY OF THREE DIVERSE TRANSMISSION SETTINGS

Prashanth Selvaraj[1], Joshua Suresh[1], Edward Wenger[1], Caitlin Bever[1], **Jaline Gerardin**[2]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*Northwestern University, Chicago, IL, United States*

While bednets and insecticide spraying have had significant impact on malaria burden in many endemic regions, outdoor vector feeding and insecticide resistance may ultimately limit their contribution to elimination and control campaigns. Complementary vector control methods are therefore generating much interest. Here we explore the conditions under which systemic insecticides would have a substantial impact on transmission and burden. Hypothetical long-lasting systemic insecticides with effective durations ranging from 14 days to 90 days are simulated

using an individual-based mathematical model of malaria transmission. The impact of systemic insecticides when used to complement existing vector control and drug campaigns is evaluated in three settings - a highly seasonal high-transmission setting, a near-elimination setting with seasonal travel to a high-risk area, and a near-elimination setting in southern Africa. At 60% coverage, a single round of long-lasting systemic insecticide with effective duration of at least 60 days, distributed at the start of the season alongside a seasonal malaria chemoprevention campaign in a high-transmission setting, results in further burden reduction of 30-90% depending on the sub-populations targeted. In a near-elimination setting where transmission is sustained by seasonal travel to a high-risk area, targeting high-risk travelers with systemic insecticide with effective duration of at least 30 days can result in likely elimination even if intervention coverage is as low as 50%. In near-elimination settings with robust vector control, the addition of a 14-day systemic insecticide alongside an antimalarial in mass drug administration (MDA) campaigns can decrease the necessary MDA coverage from about 85% to the more easily achievable 65%. While further research into the safety profile of systemic insecticides is necessary before deployment, we find that long-lasting systemic insecticides can play a critical role in reducing burden or eliminating malaria in a range of contexts with different target populations, existing malaria control methods, and transmission intensities.

371

EVIDENCE-BASED TOOLS TO SUPPORT DECISION MAKING FOR MALARIA ELIMINATION

Sheetal Prakash Silal[1], Lisa White[2]

[1]*Modelling and Simulation Hub, Africa, Cape Town, South Africa,* [2]*Mathemical and Economic Modelling (MAEMOD), Mahidol Oxford Research Unit, Bangkok, Thailand*

With malaria elimination being high on the political and funding agenda globally, many countries are strengthening efforts towards this ambitious goal. There is no "one size fits all" intervention for malaria elimination due to the spectrum of available sub-optimal interventions acting at different stages of the parasite life-cycle and the heterogeneous transmission landscape. Every district of every country has its own unique challenges, conditions and solutions. Mathematical modelling is a leading approach for combining the many interacting factors that must be considered. A study has been conducted to create evidence-based tools to support decision making for malaria elimination. It involves the development of mathematical disease transmission models and costing tools to provide a platform to turn national surveillance data into strategic information to support the policy-makers in programme and funding decisions. User-friendly computer applications have be designed to allow policy-makers to run simple mathematical models and navigate the output of millions of simulations of more complex models with the aid of interactive graphs. These tools focus on implementation and translation of the modelling results allowing policy-makers to design an elimination/control strategy incrementally by combining candidate interventions to predict the desired impact and cost. Applications of the tool in several countries are highlighted.

372

AN INTEGRATED SOFTWARE PACKAGE FOR MODELLING CLINICAL TRIALS OF VECTOR CONTROL INTERVENTIONS FOR *PLASMODIUM FALCIPARUM* MALARIA REDUCTION

Keith J. Fraser, Lazaro Mwandigha, Azra Ghani

Imperial College London, London, United Kingdom

The public health benefit of vector control interventions including interior residual spraying (IRS), long-lasting insecticide-treated nets (LLINs) and attractive targeted sugar baits (ATSBs) can only be assessed in cluster randomized trials (cRCTs). Typically, such trials involve randomisation of the intervention at village level, with outcomes measured in a cohort formed of subsets of those residing in the villages. Standard statistical methods are available to estimate power for cRCTs given a single outcome metric. However, because typical outcomes including malaria prevalence and clinical incidence vary non-linearly by age and transmission intensity, mathematical models are often needed to estimate the expected effect size for a given location. To aid future trial design, we developed an integrated software package using an existing mathematical model of *Plasmodium Falciparum*. The software includes the effect of three vector-control interventions (LLINs, IRS and ATSBs, alone or in combination) on the vector population and on malaria transmission in the human population using a deterministic model for a range of transmission intensities (defined by EIR) and seasonality profiles. A linked stochastic individual-based model is incorporated that simulates a range of malaria outcomes (incidence of disease, incidence of infection, parasite prevalence by microscopy/RDT or PCR) in the trial cohort. The cohort model also captures censoring of observations due to treatment. Outputs include expected outcomes in the intervention and control villages by calendar time, and calculations of statistical power for a given set of design parameters (EIR, seasonality, number of clusters, number of individuals per cluster, coverage of interventions, outcome measure).

373

HAPLOTYPE FREQUENCY *VS.* PREVALENCE IN THE CONTEXT OF SEASONAL MALARIA

Kristan A. Schneider

University of Applied Sciences Mittweida, Mittweida, Germany

A plethora of empirical studies monitor prevalence of parasites, such as drug-resistance associated haplotypes or variants with deletions at the HRP2/3 *loci*. While prevalence of such haplotypes provides a proxy for the occurrence of treatment failure or false-negative RDT results, evolutionary processes drive the spread of such haplotypes. To correctly infer the evolutionary dynamics, haplotype frequencies need to be considered. Although the terms 'frequency' and 'prevalence' are often used synonymously, they actually refer to different concepts. A haplotypes' prevalence is the probability to observe it in an infection, and hence can be regarded a feature of infected patients. On the opposite, a haplotype's frequency is its relative frequency in the population of sporozoites within the mosquitoes' salivary glands ready to infect human hosts. Here, it is shown by a formal model that frequency and prevalence are linked by the process of infection. In particular, a haplotype's prevalence is a function of its frequency and multiplicity of infection (MOI). Importantly, higher MOI yields higher prevalence. This is especially relevant in the context of seasonal malaria, where MOI varies between seasons, leading to zigzag-like oscillations in prevalence, even if frequencies stay constant. Such oscillations also occur when estimating frequencies as relative haplotype prevalence. Notably, these estimates have an unpredictable bias depending on the overall frequency distribution and MOI and might severely underestimate the true frequency and prevalence of a common haplotype. Methods to correctly and accurately estimate frequency and prevalence alongside with MOI are presented and exemplified by various data applications.

374

WITS RESEARCH INSTITUTE FOR MALARIA (WRIM)

Miles B. Markus, Lizette L. Koekemoer, Robyn L. van Zyl

University of the Witwatersrand, Johannesburg, South Africa

The Wits Research Institute for Malaria (WRIM) in Johannesburg, South Africa, undertakes studies (especially work relevant to Africa) in collaboration with many national and international partners. There are opportunities for graduate and postdoctoral research by appropriately qualified individuals. Subject areas that are covered are diverse. Members of WRIM have expertise in regard to mosquitoes, and investigations are undertaken on insecticide resistance, systematics, population genetics, control of malaria-transmitting mosquitoes, and mosquito-parasite interactions. Novel drug discovery is also a focus of WRIM. This includes the design and evaluation of antimalarial and insecticidal activities of natural and synthetic compounds on various stages of the malaria parasite

within both hosts. Also, elucidation of the mechanisms of action and interaction of novel compounds with standard antimalarial agents, taking toxicity into account. All of this research falls within the broad fields of Molecular Parasitology, Pharmacology and Entomology. Clinical Medicine staff collaborate with Pharmacology and other experts to investigate the clinical incidence of malaria and treatment outcomes in tertiary hospitals, along with constant monitoring for drug resistance. A member of the Institute will, of course, be in attendance at the poster to answer any questions about WRIM.

375

MALARIA MANAGEMENT IN BÉNIN: FROM ETHNOBOTANICAL APPROACH TO AN EFFICIENT PHYTOTHERAPY

Gérard Hodévè Tiko[1], Rock Djehoue[1], Rafiou Adamou[1], Adandé Assogba Medjigbodo[2], Abdou Madjid O. Amoussa[1], Luc Salako Djogbenou[2], Latifou Lagnika[1]

[1]*Laboratoire de Biochimie et Substances Naturelles Bioactives/University of Abomey Calavi, Cotonou, Benin,* [2]*Institut Régional de Santé Publique (IRSP)/Université d'Abomey Calavi, Ouidah, Benin*

Benin is a malaria endemic country where more than 70% of the population uses a large number of medicinal plants for prophylaxis and malaria healing based on their cultural practices or ancestral knowledge. Unfortunately, there are no data that guarantee the efficiency, quality, and safety of these practices. Therefore, these plants need to be investigated assessing their properties. The goal of this study is to identify follows ethnobotanical approach efficient antimalarial plants for development of phytomedicine. A malaria-specific ethnobotanical survey was conducted by computer search and other supports to carry out antimalarial plants reported in Benin from 1989 to 2016. Comparative analysis of these survey followed by the bibliographical study have made it possible to identify the commonly used traditionally. Ethanolic and aqueous extracts of aerial part prepared was tested *in vitro* against CQ-sensible and field isolate of *Plasmodium falciparum* based on plasmodial lactate dehydrogenase detection. Hemolytic effect of extracts was also evaluated on human red blood measuring the absorbance of hemoglobin released by spectrophotometer and acute toxicity was performed on Wistar rats. 195 medicinal plants are listed in which 42 are commonly used. Both extracts of *Ampelocissus bombycina* and *Hibiscus surratensis* (IP> 60%) showed an interesting percentage of growth inhibition (IP) at 100 μg/ml whereas the same extracts of *Cola milenii* and *Costus afer* showed low activity (<40%). All extracts have hemolytic power less than 1% and no recorded mortality or difference between hematological and biochemical parameters at 5000 mg/kg of body weight. The results obtained in this study strengthen the use of *A. bombycina* and *H. surattensis* as antimalarial plants. They could be considered as a source of new anti-malarial drugs. A complementary study is ongoing on the capacity of these plants to block malaria transmission in order to develop an efficient phytomedicine

376

PROTECTING THE PERI-DOMESTIC ENVIRONMENT: THE CHALLENGE FOR ELIMINATING RESIDUAL MALARIA

Edgar J. Pollard, David MacLaren, Tanya L. Russell, Thomas R. Burkot

Australian Institute of Tropical Health & Medicine, Cairns, Australia

Malaria transmission that occurs after universal access and use of malaria preventive services is known as residual malaria transmission. The concurrent spatial-temporal distributions of people and biting mosquitoes in malaria endemic villages determines where and when residual malaria transmission occurs. This study tracked people movements in Solomon Island villages using structured questionnaires and daily movement diaries to identify where humans during peak biting by malaria vectors s. Although 84% of people sleep under an LLIN, only 7% of people are sleeping under an LLIN during the 18.00 to 21.00 hr peak biting period of the dominant vector, An. farauti when 76% of bites are delivered. During this critical exposure time to malaria vector bites, people are near but outside their houses, either in their kitchens or on the verandas of their primary residence. Novel vector control tools that protect individuals from mosquito bites in these peri-domestic areas have the potential to contribute significantly to ending residual malaria transmission.

377

PLASMODIUM OVALE AND *PLASMODIUM FALCIPARUM* CO-INFECTION AMONG SYMPTOMATIC AND ASYMPTOMATIC MALARIA ASSOCIATED WITH SYMPTOMS IN ENDEMIC REGIONS OF WESTERN KENYA

Jackline Juma, Hosea Akala, Dennis Juma, Benjamin Opot, Agnes Cheruiyot, Redemptah Yeda, Gladys Chemwor, Edwin Mwakio, Charles Okudo

Kenya Medical Research Institute-Walter Reed Project, Kisumu, Kenya

Plasmodium falciparum (*Pf*) infections occur sympatrically with *Plasmodium ovale curtisi (Poc), Plasmodium ovale wallikeri (Pow)* and *Plasmodium malariae (Pm).* Detection of these species has been conducted by semi-convenient sampling layouts that screen symptomatic rather than asymptomatic cases. Estimating the burden of species among symptomatic and asymptomatic cases is significant. This study assesses the composition of *Plasmodium* species among symptomatic and asymptomatic cases in Kisumu. Between 2013 and 2016, 435 symptomatic malaria individuals presenting at Kombewa Sub-County hospital were recruited for a malaria drug resistance surveillance study. Concurrently, 454 asymptomatic individuals within the same area were enrolled in a transmission dynamics study. About 2mL of blood drawn from participants, tested for presence of malaria parasites by 18s rRNA real-time PCR, typed for *Plasmodium* species composition using the genus specific small subunit ribosomal RNA gene (ssrRNA). Of 435 symptomatic cases, *Pf* had the highest prevalence at 96%, followed by *Pow*, Poc and *Pm* at 28%, 9% and 7% respectively. Co-infections between *Pf*/*Pow* were highest 21%, *Pf*/*Pm*, *Pf*/*Poc, Pf*/*Poc*/*Pow, Pow*,*Pf*/*Pm*/*Poc and Poc*/*Pow* at 6%, 5% 3%,0.5% and 0.2% respectively. In asymptomatic cases *Pf, Pm, Pow* and *Poc* prevalent at 90%, 15%, 11% and 10% respectively. *Pf*/*Poc* and Pf/*Pow* co-infections were observed at 5%, 2% while *Pf*/*Pm, Pf*/*Pm*/*Pow, Pm*/*Pow*,*Pf*/*Pm*/*Poc*,*Pm*/*Poc , Pf*/*Pm*/*Pow*/*Poc and Pm*/*Poc* were prevalent at 6%, 4%, 2%, 4%, 0.6% and 0.4% respectively. Comparison of overall species frequency between two infections showed stronger association between *Pow*/*Pf* co- infections with symptomatic malaria (OR of 10.4, 95% CI range [5.6 - 19.4 and *P< 0.0001*). Higher frequency of non-*falciparum* species especially *Pow*/*Pf* co-infections among symptomatic than asymptomatic malaria cases was observed. However higher *Pm* frequency was observed among asymptomatic than symptomatic cases suggesting low virulence. This argues for consideration of asymptomatic malaria matrices and simulation estimating malaria burden based on analyses of treatment seeking habits.

378

MOLECULAR DETECTION OF PARASITIC CO-INFECTION AND DETERMINATION OF INFECTION PREVALENCE IN PREGNANT WOMEN OF GHANA

Sarah Alhakimi[1], Abraham Anang[2], Nilanjan Lodh[1]

[1]*Marquette University, Milwaukee, WI, United States,* [2]*University of Ghana, Legon, Accra, Ghana*

In sub-Saharan Africa, a significant proportion of the population is exposed to malaria, schistosomiasis and soil transmitted helminths (STHs). Most importantly, about [40] million pregnant women are infected with STHs and Schistosome spp. along with malaria. The consequences include intrauterine growth retardation, low birth weight, pre-term delivery and neonatal mortality. When parasitic diseases overlap in distribution, high rates of co-infection occur and there is a shortage of data about co-infection prevalence in pregnant women in Ghana. We have detected single, dual and multiple infections (malaria, schistosomiasis, and Strongyloides) among pregnant women by amplifying cell-free repeat DNA (CFRD) fragments via polymerase chain reaction (PCR) from single

filtered urine samples collected from two districts (Adidome and Battor) of Ghana. In addition, sensitivity and specificity of PCR was evaluated against parasitological tests based on stool, urine and blood. Out of 163 samples, Schistosoma haematobium had the highest prevalence (47%) by PCR and then 37% for S. mansoni. The prevalence of malaria infection for Adidome district was 18% by rapid diagnostic test (RDT), whereas no infection was detected in Battor by RDT. Also, 10 positive infections for Strongyloides stercoralis were detected by PCR. We found malaria co-infection with schistosomes and with Strongyloides, when RDT and PCR were compared. Detection of CFRD by PCR from single urine sample is more cost-effective than individual parasitological tests and more sensitive. The study addressed the weaknesses in the current diagnostic techniques available for malaria, schistosomes and Strongyloides. Our approach and method can be optimized to the use in the clinical set up in endemic countries to determine multiple infection prevalence and for surveillance for this vulnerable group of population.

379

RISK FACTOR FOR CRITICAL CARE ADMISSION AMONG CHILDREN WITH MALARIA IN PUBLIC HOSPITALS OF THE PERUVIAN AMAZON

Nataly Atarama[1], Karen Arica[1], Amy C. Morrison[2], Raul Seminario[3], Stalin Vilcarromero[4]

[1]*Universidad Nacional de la Amazonia Peruana, Iquitos, Peru,* [2]*University of California Davis, Davis, CA, United States,* [3]*Hospital Regional de Loreto, Iquitos, Peru,* [4]*Stony Brook University, New York, NY, United States*

In Peru, malaria is a major public health problem affecting children and adults in endemic areas concentrated in the Amazon Region of the contry. Despite the high disease burden, there is a lack of clinical data on severe malaria especially in the pediatric population. To identify risk factors associated with admission to critical care units for severe malaria we conducted a retrospective clinical chart review of pediatric inpatients from two public hospitals located in Iquitos City where most of the severe malaria cases from this region are treated. Charts of pediatric inpatients (≤15 years old) with malaria (thick smear), and with at least one of the WHO severe malaria criteria during 2013-2017 were included. In total, 144 met the criteria. Of these, 58% (84/144) were male, 30.6% (44/144) were age 2-5 years, 73.6% (16/144) lived in rural or peri-urban settings, and 91% (131/144) reported travel to malaria endemic locations. Interestingly, 75.7%(109/144) of the cases were caused by *Plasmodium vivax.* Clinical characteristics included an average of 6.22 days between symptom onset and hospitalization, 59% (85/144) had parasitemia < 3+, 6.3% (9/144) presented complications at admission, 34.7% (50/144) had an acute comorbidity, only 43.3% (62/144) received intravenous antimalarial treatment, 33.3% (62/144) received an additional antibiotic, and 13.9% (20/144) had blood transfusions. The principal signs and symptoms were: fever (92.4%), vomiting (54.9%), headache (41.7%) and chills (40.3%). Only 21/144 (14.6%) were admitted to CCU. The most reported severity criteria were: coagulation disorders (44.4%), hyperparasitemia (36.8%), severe acute anemia (34%), hyperpyrexia (20.1%) and consciousness compromise (15.3%). Multiple logistic regression to identified severe anemia, hemoglobinuria, use of vasoactives drugs, need for blood transfusion, complications at admission, and parasitemia less than 3 crosses were significantly associated with admission to the CCU. Because anemia is common in children from this malaria endemic areas, programs to address anemia in the pediatric population should improve outcomes do to malaria infection.

380

EVOLUTION OF AVAILABILITY IN ACT, RDT AND SULFADOXIN/PYRIMETHAMIN AT THE LEVEL OF DIRECT CUSTOMERS OF COTE D'IVOIRE NEW PHARMACY OF THE PUBLIC HEALTH FROM JANUARY TO FEBRUARY 2019

Yepie Armande Eve Yapi

NMCP, Abidjan, Côte D'Ivoire

RCI has received two external funding in the fight against malaria since 2017 from Global fund and PMI. Its performance improves in the interventions against this scourge. We have analyzed specific reports relating to the availability of health products used against malaria and from eLMIS (electronic application) from January to February 2019. This analysis concerned the direct customers of the New Pharmacy of Public Health (Nouvelle PSP CI) regroups in: - health districts (DS) - and other Nouvelle PSP direct customers (CHU, CHR, general hospitals and FSU, CSU...) At the DS level, the results did not differ significantly, the percentage of DS with stock out in Artemether/Lumefantrin move from [1%-6%] to [2%-5%]. For DS in Overstock [22%-34%] to [14%-34%]. Finally, the well-stored DS percentage is going from [18%-51%] to [20%-45%]. Other direct customers show less satisfactory results. Thus, the percentage of these facilities with stock out in Artemether/Lumefantrin increase from [9%-17%] to [5%-16%]. For DS in Overstock, the percentage is going from [20%-46%] to [22%-51%]. Finally, the percentage of well-stored DS change from [22%-44%] to [20%-33%]. The DS, over the same period, have a decrease in RDT availability from 36% to 27% of DS well-stored, while other direct clients show a satisfactory evolution of 10% to 13%. However, the availability of RDT remains better at the DS level. DS and other direct clients have improved their availability of Sulfadoxin/Pyrimethamin (SP) over the period of [37%-41%] and [31%-43%] for well-stored sites and for sites with stock out [1%-1%] and [5%-2%]. An improvement in the availability of these facilities is observed in terms of the reduction of cases of SP and RDT stock out and the increase of well-stored facilities in SP. We note, a slight improvement in the availability of ACT, RDT and SP at the level of all Nouvelle PSP customers. However, some efforts are to be made to obtain at the end of each month no cases of stock out for all health product of malaria control in all facilities.

381

HEME SCAVENGER HEMOPEXIN, HAPTOGLOBIN AND HEMEOXEGENASE-1 LEVELS IN PREGNANT WOMEN WITH ASYMPTOMATIC MALARIA CORRELATE WITH ADVERSE BIRTH OUTCOMES

Annette Nti[1], Hassana Salifu[1], Felix Botchway[2], Nelly Yatich[3], Mingli Liu[1], Andrew Adjei[2], Pauline Jolly[3], Jonathan K. Stiles[1]

[1]*Morehouse School of Medicine, Atlanta, GA, United States,* [2]*Korle Bu Teaching Hospital, Accra, Ghana,* [3]*University of Alabama, Birmingham, AL, United States*

Malaria caused 435,000 deaths globally in 2017, with pregnant women and children at the highest risk. Malaria in pregnancy involves severe symptoms and outcomes including anemia, higher rates of miscarriage, premature delivery, low birth weight neonates, intrauterine, neonatal and maternal death. Current effective treatment for malaria targets parasite burden. Therefore, there is an urgent need to understand the causes of poor birth outcomes and to identify novel interventions as well as predictive biomarkers to determine at-risk individuals. However recent studies have shown that malaria pathogenesis is mediated by parasite -derived factors as well as host factors such as heme, a by-product of parasite-infected erythrocyte destruction. Our lab has previously determined that free serum heme levels and cytotoxicity in pregnant women were dependent on the robustness of their heme scavenging systems. We hypothesize that individuals with effective heme scavenging mediators will result in improved birth outcomes and that alternatively, those individuals with poor heme regulation will have poor birth outcomes. We assessed pregnant women in Ghana and identified *Plasmodium* infection by rapid diagnostic testing (RDT). Plasma samples

obtained from these women were assessed for heme, Heme Oxygenase-1, Haptoglobin, and Hemopexin levels to correlate results with birth outcomes. The results indicate that RDT *Plasmodium*-positive women had significantly different low HO-1: Hemopexin ratios that correlated with pre-term delivery.

382

EVALUATION OF A HOMEMADE SALIVA KIT FOR THE STABILIZATION OF *PLASMODIUM* DNA AT ROOM TEMPERATURE

Eric Berenger E. Tchoupe Kamoua

University of Yaounde [1], Yaounde, Cameroon

Malaria diagnostic require blood collection. Saliva from Malaria-infected individuals contains trace amounts of *Plasmodium* DNA, PCR showed great benefit using saliva; conserving parasite DNA in saliva is still problematic.. We designed this study to evaluate the effectiveness of a homemade kit to stabilize plasmodium DNA in saliva at room temperature. Blood and saliva samples were collected from 33 patients. Saliva samples were collected in two separate kits: OMNIGENE•DISCOVER kit as the standard kit and a newly formulated kit as the test kit. Samples were stored at room temperature for 12 months. Blood samples were analyzed using microscopy to detect Parasites. *Plasmodium* DNA was extracted from saliva by Chelex method and molecular detection of the parasite DNA was based on nested PCR amplification of the multicopy 18s rRNA gene. Products were separated on 2.0 % agarose gel and visualized under UV light. The frequency of malaria in this study was 78 % using microscopy. Saliva PCR-f1 detected 21 positive samples, saliva PCR-so detected 18 positive sample. When microscopy was used as gold standard, the sensitivities of PCR-so and PCR-f1 were all recorded at 100%; however the specificities were at 80%, and 85%, respectively. PCR-f1 had a "very good" agreement (kappa 0.81) compared to PCR-so (kappa 0.64).

383

TRACKING SPENDING ON MALARIA BY SOURCE IN 106 COUNTRIES, 2000-2016: AN ECONOMIC MODELLING STUDY

Annie Haakenstad[1], Anton C. Harle[2], Golsum Tsakalos[2], Angela E. Micah[2], Tianchan Tao[2], Joseph L. Dieleman[2]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Institute for Health Metrics and Evaluation, Seattle, WA, United States*

The Global Technical Strategy for Malaria, 2016-2030, articulates an ambitious agenda to make progress toward malaria elimination, including reducing case incidence and mortality rates by 40% by 2020. An estimated $6.6 billion in investments annually is required to meet these targets. We estimated malaria expenditure by source over 2000-2016 in 106 countries. We collected 36,038 data points reporting government, out-of-pocket (OOP), and prepaid private malaria spending, as well as malaria treatment-seeking, costs of patient care, and drug prices. We estimated government spending on patient care for malaria, which was added to government spending by National Malaria Control Programs. For OOP malaria spending, we used data reported in National Health Accounts and estimated OOP spending on treatment. Spatiotemporal Gaussian process regression was used to ensure estimates were complete and comparable across time and to generate uncertainty. In 2016, $4·3 billion (95% uncertainty interval 4·2–4·4) was spent on malaria worldwide, with 8·5% (8·1-8·9) in annual increases occurring since 2000, but still more than $2 billion short of the global goal. OOP spending amounted to $556 million (487-634) or 13·0% (11·6 -14·5) of all malaria spending in 2016. Governments spent $1·2 billion (1·1 -1·3) or 28·2% (27·1 -29·3) of all malaria spending in 2016. The source of malaria spending varied depending on whether countries were in the malaria control or elimination stage. Because most countries with a high burden of malaria are low- or lower-middle income, mobilizing additional government resources to meet the $6.6 billion target may be challenging. Furthermore, the major share of malaria expenditure sourced from DAH and OOP makes the fight against malaria vulnerable. The high dependence on DAH makes malaria endemic countries vulnerable to drops in contributions from development assistance partners. The high reliance on OOP spending may deter treatment-seeking and prevent countries from realizing malaria reduction aims.

NEURODEVELOPMENTAL PERFORMANCE IN PRESCHOOLERS AFTER SEVERE ANEMIA AT LIRA REGIONAL REFERRAL HOSPITAL, UGANDA

Andrew Sentoogo Ssemata[1], Robert O. Opoka[1], Noeline Nakasujja[1], Chandy C. John[2], Paul Bangirana[3]

[1]*Makerere University, Kampala, Uganda,* [2]*Indiana University, Indianapolis, IN, United States,* [3]*Makerere University, Kampala, Uganda*

Severe anemia (SA) is a global public health challenge commonly associated with morbidity and mortality among children <5 years of age in Sub-Saharan Africa. In this study, we investigated neurodevelopmental performance in preschool children (<5 years) diagnosed with severe anemia (SA) in Northern Uganda. We conducted a hospital based cross-sectional study among children < 5 years of age with SA (Hb≤5.0 g/dl; n=171) presenting to Lira Regional Referral Hospital, Uganda. Neurodevelopmental outcomes (cognitive, language [receptive communication and expressive communication] and motor [fine motor and gross motor]) were assessed 14 days post discharge using the Bayley Scales of Infant and Toddler Development, 3rd edition. Age-adjusted z-scores for each domain were calculated using scores from controls of healthy community children (n=88) from the same environment for each age category. Multiple linear regression was used to compare z-scores in the cognitive, language and motor scales between the two groups after adjusting for weight-for-age z score, social economic status, mother's education, father's education and father's employment on all the scales. Significant differences were observed between the severe anemia group and control group for cognitive adjusted mean score (SE), [-0.20, (0.64) vs. 0.01, (0.06), P=0.02]; receptive communication [-0.16, (0.05) vs. 0.01, (0.06), P=0.05]; expressive communication [-0.32, (0.05) vs. 0.01, (0.07), P<0.01]; overall language [-0.25, (0.04) vs. 0.00, (0.06), P<0.01]; Gross motor [-0.25, (0.06) vs. 0.00, (0.09), P<0.01]; Overall motor [-0.18, (0.05) vs. 0.00, (0.07), P=0.05]; but not for the fine motor scale [0.08, (0.07) vs. 0.00, (0.09), P=0.46]. In children <5 years of age, severe anemia was associated with worse cognitive ability, language and motor skills scores in the immediate period post clinical recovery. Neurodevelopmental assessment, especially in areas with high SA prevalence, could identify at risk children for early interventions.

ANALYSIS OF UNITED STATES PRESIDENT'S MALARIA INITIATIVE-SUPPORTED OPERATIONAL RESEARCH STUDIES, 2006-2018

Robin Miller[1], Michael Elhardt[1], Meera Venkatesan[1], Carrie Nielsen[2], Richard Steketee[3], Martin Alilio[1], **Achuyt Bhattarai**[2]

[1]*United States President's Malaria Initiative, United States Agency for International Development, Washington, DC, United States,* [2]*United States President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*United States President's Malaria Initiative, Washington, DC, United States*

The U.S. President's Malaria Initiative (PMI) has supported operational research (OR) studies to help overcome malaria control implementation challenges, test promising new tools, identify methods to scale-up malaria control interventions, find local solutions to optimize intervention effectiveness, and identify the most cost-effective mix of proven interventions under varying malaria transmission settings in PMI focus countries. We analyzed PMI-supported OR studies conducted during 2006-2018 with the aims to 1) examine completed and ongoing studies by technical areas, countries, and other descriptive metrics and 2) perform a pilot assessment to ascertain the dissemination, use, and influence of findings from a sample of PMI-supported OR studies. From 2006 to

2018, one hundred PMI-funded studies were implemented in twenty countries across eight technical areas. Vector control (n=41) and malaria case management (n=31) and were the most common technical areas funded. These studies mainly aimed to answer country-specific operational concerns (n=70) while other studies (n=30) addressed larger initiative-wide questions. The pilot assessment of a purposively selected sample (n=15) of studies completed during 2012-2016 demonstrated that the study results were often published in peer-reviewed journals (n=11), presented at scientific conferences (n=11), and communicated to broader audiences (n=9) through national or regional meetings and various media sources. The assessment also showed that PMI-supported OR studies have included training of research investigators (n=12) and involved National Malaria Control Programs staff (n=14) and in-country institutions (n=14) in the design, execution, analysis, and/or dissemination of study results. The findings of the pilot assessment indicate that it may useful to systematically document the impact and influence of PMI-supported OR studies, and prospectively collect data related to dissemination, use, and influence of ongoing and future OR studies.

386

SEVERE MALARIA WITH REPEATED MALARIA ATTACKS AND ACADEMIC ACHIEVEMENT IN UGANDAN CHILDREN

Ann J. Nakitende[1], John Ssenkusu[1], Richard Idro[1], Noeline Nakasujja[1], Chandy C. John[2], Margaret Semrud-Clikeman[3], Paul Bangirana[1]

[1]*Makerere University, Kampala, Uganda,* [2]*Indiana University, Indianapolis, IN, United States,* [3]*University of Minnesota, Minneapolis, MN, United States*

Children with a history of severe malaria are at higher risk of hospitalization for subsequent episodes of malaria. While severe malaria(SM) has been associated with poorer neurocognitive functioning, the additive effect of subsequent malaria attacks (RMA) has not been studied. This study compared academic achievement in children with a history of SM and RMA to those without RMA and to healthy community children. This study was nested in a prospective study of cognitive functioning after SM conducted at Mulago Hospital, Kampala, Uganda from January 2015 to August 2017. Children aged 5 to 12 years with SM and community children (CC) were assessed for academic achievement in word reading, sentence comprehension, spelling and arithmetic calculations using the Wide Range Achievement Test Fourth Edition. Age adjusted z- scores for academic achievement outcomes were calculated using scores of the CC children. Multiple regression was used to compare scores between the groups with caregiver employment and income entered into the regression model. 232 participants (CM=75, SMA =58 and CC=99) were enrolled in the study with a mean age of 9.6 (SD=2.6) years. Children with SM and RMA had statistically significant lower z- scores than SM without RMA for math (95% CI,-0.50- -0.05, p=0.016), reading (95% CI,-0.66 to -0.17, p=0.001) and spelling (95% CI -0.61 to -0.10, p=0.007). There was no difference in z-scores for sentence comprehension between the two groups. Children with a history of SM and RMA have poor academic performance compared to those with a history of SM without RMA two years after the illness. This study highlights the need for malaria chemoprevention for children in malaria endemic areas. It also provides evidence for the need to develop appropriate interventions for these children at the earliest possible time.

387

CARE SEEKING FOR AND MANAGEMENT OF FEBRILE ILLNESS IN SENEGAL IN THE CONTEXT OF MALARIA CONTROL AND ELIMINATION. WHAT DO SURVEY DATA TELL US?

Katharine M. Sturm-Ramirez[1], Yaya Ly[2], Leah Moriarty[1], Mame Birame Diouf[3], Alioune Badara Gueye[4], Moustapha Cisse[4], Samba Ndiaye[2], Doudou Sene[4]

[1]*Centers for Disease Control and Prevention and the President's Malaria Initiative, Atlanta, GA, United States,* [2]*Agence Nationale de la Statisique et de la Démographie, Dakar, Senegal,* [3]*United States Agency for International Development, Dakar, Senegal and U.S. President's Malaria Initiative, Dakar, Senegal,* [4]*Programme National de la Lutte contre le Paludisme (PNLP), Dakar, Senegal*

Senegal has made great strides against malaria with aggressive scale-up of control interventions, such as improved access to diagnosis and treatment in health facilities and communities and phasing in of universal testing of fevers for malaria. Malaria transmission remains heterogeneous but as Senegal shifts to an elimination phase, universal access to diagnosis and treatment is critical. We analyzed survey data from 2005-17 to characterize spatio-temporal trends and identify gaps in care seeking and case management. Since 2012, Senegal implements a nationally representative, continuous Demographic and Health Survey, composed of annual household surveys and health facilities' service provision assessments (SPAs). The proportion of children < 5 years (CU5) who presented with fever in the 2 weeks prior to a household survey was 29.8% in 2005, 12.7% in 2016 and 20% in 2017; medical care was sought for only half of febrile CU5 (range: 49-57%). The most frequent sources of care or advice were public health posts (57-63%) and private pharmacies (10-12%) while informal sources including traditional practitioners were sought less over time (7% in 2015 and 2.3% in 2017). Data from the SPAs (2012-17) indicate that most of the observed medical consultations in both private and public facilities included fever evaluation (range: 80-100%) yet the proportion of CU5 that were diagnosed as having fever or malaria ranged from 4-32%, with marked regional differences. The malaria service readiness index (SRI) captures availability of diagnostic capacity, treatment, trained personnel, and guidelines at health facilities. The national SRI increased from 38% in 2012 to 64% in 2017, with clear regional differences. Nationwide, primary and secondary health structures were better equipped than tertiary structures to provide malaria care and the SRI was higher for the public than the private sector (71% vs 21% in 2017). Despite improved access to and quality of malaria services in the public health sector, the rate of care seeking for febrile illness in CU5 remains low in Senegal. There is an urgent need to strengthen the malaria service readiness of the private sector.

388

MALARIA DATA QUALITY AND USE IN SELECTED CENTERS OF EXCELLENCE IN MADAGASCAR: RESULTS FROM A CROSS-SECTIONAL BASELINE SURVEY

Maurice Ye[1], Jean Marie N'Gbichi[2], Thierry Franchard[3], Solo Harimalala[3], Brune Ramiranirina[3], Mauricette N. Andriamananjara[3], Laurent Kapesa[4], Jocelyn Razafindrakoto[4], Yazoume Ye[5]

[1]*MEASURE Evaluation, ICF Macro Madagascar, Antananarivo, Madagascar,* [2]*MEASURE Evaluation, ICF USA, Chapel Hill, NC, United States,* [3]*Ministry of Public Health, National Malaria Control Program, Antananarivo, Madagascar,* [4]*U.S.President's Malaria Initiative, Madagascar, Antananarivo, Madagascar,* [5]*MEASURE Evaluation, ICF USA, Rockville, MD, United States*

In Madagascar, the U.S. President's Malaria Initiative through MEASURE Evaluation conducted a health information system performance assessment in 2015 that reported low data quality, subpar reporting completeness (65.3%) and timeliness (45.5%), and weak evidence of data analysis and use that could lead to inappropriate decision making and impaired program management. To improve data quality, the National Malaria Control Program will implement Centers of Excellence (COE). COEs will be health centers selected to receive training, equipment, data management tools, and direct coaching. In April 2018, a baseline assessment was done in 12 health centers, eight which will become COEs (intervention) and four controls. We explored the availability of data collection tools, data accuracy, completeness and timeliness of reporting, data analysis, and data use for decision making. Baseline data quality indicators were compared across intervention and control centers. Data were analyzed using Stata14. A Kruskal-Wallis test estimated the difference between the two groups and *p-values* were calculated. Completeness of reporting was similar in both groups: 95.3% and 95.0%, respectively (*p=0.240).* There was no significant difference in timeliness

of reporting: 31.8% and 44.9%, respectively *(p=0.364)*. Both groups reported similar use of rapid diagnostic tests (RDT) for malaria diagnosis. Availability of RDTs and artemisinin-based combination therapy was equally high: above 90% in both groups. Data accuracy (data in monthly reports versus data in patient registries) showed similar ranges of discrepancy in both groups: around 25%. Availability of data collection tools was 79.7% in the intervention group and 81.0% in the control group ($p>0.05$). Only 25.0% of centers in the intervention group and 28.0% in the control group were performing data analysis *(p=0.926).* Similarly, data use was low—25.5% and 27.0%, respectively—in intervention and control groups. The assessment provided baseline information on comparable groups of health facilities to measure improvement in data quality because of the implementation of COEs in Madagascar.

389

HEALTH MESSAGE ANNOUNCEMENTS THROUGH LOUDSPEAKERS BOUT MALARIA CARE - PREVENTION AND PRACTICE AMONG PEOPLE LIVING IN A MALARIA ENDEMIC AREA OF BANMAUK TOWNSHIP, SAGAING REGION, MYANMAR

Pyae Linn Aung[1], Tepanata Pumpaibool[2], Than Naing Soe[3], Myat Phone Kyaw[4]

[1]*Southeast Asia International Centers of Excellence for Malaria Research, Yangon, Myanmar,* [2]*College of Public Health Sciences, Chulalongkorn University, Bangkok, Thailand,* [3]*Department of Public Health, Ministry of Health and Sports, Naypyidaw, Myanmar,* [4]*Department of Medical Research, Yangon, Myanmar*

Various approaches towards community awareness-raising interventions have been delivered through a variety of channels, but evidence for the effect of these practices has been minimal. This study aimed to determine the effectiveness of announcements made through loudspeakers regarding malaria care and prevention practices among people living in the malaria endemic villages of Banmauk Township, Sagaing Region, Myanmar. Four villages among the most malaria-burdened areas were randomly chosen: two villages were assigned as the intervention group and another two as a control. Before the peak season of malaria (June 2018), a baseline study was conducted. The announcement was regularly repeated at 7:00pm every other day using local messages that were conveyed through loudspeakers. A six-month follow-up survey was carried out in both groups using the same questionnaire to compare them against the baseline results. Descriptive statistics, chi-square, and the *t*-test for addressing statistical differences were determined. Among a total of 270 respondents with similar socio-economic characteristics, the baseline knowledge, attitude and practice mean scores were not found to be significantly different between intervention and control groups. After six months' post intervention, improvements in scores were observed at p-value<0.001 in both groups, but the increase in score was much greater in the intervention group. The declining trend of malaria was also noticed as an impact. In addition, more than 90% of people showed positive opinions of the intervention. The intervention was found to be effective, as shown by the significant improvement in scores relating to prevention and care-seeking practices for malaria in the targeted community. An expansion of study areas and long-term follow-up measures will be encouraged in addition to the maintenance of sustainability.

390

EFFECT OF SEASONAL MALARIA CHEMOPREVENTION ON MALARIA IN CHILDREN UNDER 5 YEARS: A COHORT STUDY IN DANGASSA, MALI

Drissa Konaté[1], Sory I. Diawara[1], Mahamoud Touré[1], Seidina AS Diakité[2], Agnes Guindo[2], Ayouba Diarra[3], Bourama Keita[1], Sibe Thiam[3], Moussa Keita[3], Ibrahim Sissoko[3], Nafomon Sogoba[3], Sekou F Traoré[1], Donald J Krogstad[4], Seydou Doumbia[1], Mahamadou Diakité[5]

[1]*MRTC/FMOS/USTTB, Bamako, Mali,* [2]*MRTC/FAPH/USTTB, Bamako, Mali,* [3]*MRTC/USTTB, Bamako, Mali,* [4]*Tulane Universtity, New Orleans, WA, United States,* [5]*MRTC/FMOS/FAPH/USTTB, Bamako, MaliSeasonal*

Malaria Chemoprevention (SMC) is a new control strategy recommended by the world health organization since ^{2012} to prevent malaria during the high transmission season in children under five. In this study, we assessed change in malaria indicators after two consecutive years of routine implementation of SMC providing Sulfadoxine-pyrimethamine + Amodiaquine (SP+AQ) to children less than ^{5} years in Dangassa. We conducted a cohort study in the village of Dangassa from ^{2013} to ^{2016}. In the course of our study, a routine SMC was implemented by the National Malaria Control Program in the village from ^{2015} to ^{2016} at a monthly basis from August to October each year (corresponding to the transmission season). We tracked all clinical malaria cases in children less than five years in the health center from ^{2013} to ^{2016}. We used Cox regression model to assess the changes in malaria risk from ^{2013} (before SMC introduction) to ^{2016} (two years after SMC introduction. Results of the Cox regression model shows a significant reduction in the incidence of malaria in ^{2015}-^{2016} after SMC introduction compared with ^{2013} (HR=$^{0.23}$ [$^{0.15}$-$^{0.35}$] in October (the pick of transmission season). The gametocyte prevalence decreased from $^{15.6}$% to $^{2.1}$%, hemoglobin level increased from $^{10.32}\pm^{0.09}$ to $^{10.81}\pm^{0.05}$ and parasite density. However, a slight increase in malaria incidence was observed in December after the SMC provision ends in October. In conclusion, SMC has significantly reduced malaria incidence, gametocyte prevalence and improve hemoglobin level in children less than five years after two years of SMC implementation.

391

AN ASSESSMENT OF QUALITY OF DELIVERY OF SEASONAL MALARIA CHEMOPREVENTION USING LOW LITERATE COMMUNITY HEALTH WORKERS IN NIGERIA

Olusola B. Oresanya[1], Abraham Ahmadu[1], Olatunde Adesoro[1], Louise Maranda[1], Diego Morosso[2], Kolawole Maxwell[1]

[1]*Malaria Consortium, Abuja, Nigeria,* [2]*Malaria Consortium, Kampala, Uganda*

The effectiveness of seasonal malaria chemoprevention (SMC) depends not only on the provision of quality-assured medicines, but also on the quality of planning and implementation. Community health workers (CHWs) delivering SMC follow key steps including directly observing treatment of eligible children (3-59 months) with sulfadoxine-pyrimethamine and administering the first dose of amodiaquine (AQ). They also advise caregivers on how to administer and record subsequent doses of AQ and what to do in case of drug reaction. To ascertain the quality and effectiveness of CHWs' performance and SMC messaging, we assessed those trained to administer SMC to about 3.2 million eligible children in four states of Nigeria through interviews of caregivers from 4,090 randomly selected households in which SMC had been administered. The interviews took place immediately after the last cycle of SMC in 2018, and covered caregivers' knowledge of SMC and adherence to SMC doses. Overall, 92.9% of all eligible children seen by the CHWs had been treated at least once. However, CHWs also appear to have treated a large proportion of ineligible children (46% of those aged 5-10 years). Only 44.4% of caregivers said CHWs had administered the first dose and, although 93.6% said that CHWs had left subsequent doses with them, only around a third (35.7% and 35.4%) reported having administered the second and third doses of AQ respectively. Despite this, most caregivers

(86.8%) reported knowing how to administer these correctly. Caregivers' retention of SMC record cards was also found to be low (37.3%) and only few (13.0%) were aware of the need to record their at-home administration of AQ dose. 61.0% reported knowing that SMC was for malaria prevention; however, 28.3% believed it was to treat malaria. These findings show that although CHWs' coverage of SMC eligible children in Nigeria is high, the quality of their delivery could be better. Thus, closer monitoring and supervision of CHWs is required to ensure they correctly adhere to protocols, and provide effective messaging and support to caregivers around the importance of administering subsequent AQ doses and retaining SMC cards.

392

MALARIA PREVENTIVE PRACTICES AMONG OUTDOOR WORKERS IN BILIN TOWNSHIP, MON STATE, MYANMAR

Pyae Sone Tint

ARC/Defeat Malaria, Yangon, Myanmar

Bilin Township, one of the malaria endemic areas in Myanmar, is a township where most workers went to the forest for bamboo cutting, rubber plantation and coal making. A cross-sectional study was conducted in this township with the purpose of identifying malaria preventive practices and their related factors among outdoor workers. A two stage probability proportional to size (PPS) cluster sampling was used to select 240 outdoor workers for face-to-face interviewing with structured questionnaires. Descriptive statistics and Chi-square test of association were used for data analysis. The age of the outdoor workers ranged from 18 to 73 years, with mean of 38.4 years. More than half of them (69.2%) attended primary school and their main occupation (45.8%) were forest activities (bamboo cutting/rubber plantation/coal workers). Majority (87.9%) of them had their own bed nets. The results revealed that only 37.5% of them had good level of malaria preventive practices, while the others (62.6%) were at needed to be improved level. The knowledge on malaria were 59.6% at good level. The perception on susceptibility, severity, benefits and barriers were 95.4%, 92.9%, 77.5% and 45.4% respectively at good level. The factors significantly associated with malaria preventive practices were ownership of bed nets (p-value<0.001), owners of insecticide treated bed nets (p-value<0.001), overall knowledge on malaria (p-value <0.001), knowledge on its transmission (p-value=0.001), knowledge on malaria signs and symptoms (p-value=0.032), knowledge on malaria prevention (p-value=0.003) and perception of malaria severity (p-value=0.004). Based on the studied results, it is recommended that the improvement on malaria knowledge especially on transmission, signs and symptoms and prevention should be focused to these outdoor workers as well as their perception on severity of malaria. The ownership of the bed nets is also an important factor for better malaria preventive practice among this group.

REVIEW OF ACCESS AND USE OF LONG LASTING INSECTICIDAL BED NETS (LLINS) IN MALARIA ENDEMIC AREAS OF BANGLADESH

Akramul Islam, Shamsun Naher, Moktadir Kabir

BRAC, Dhaka, Bangladesh

BRAC has successfully implemented community health service model in close collaboration with National Malaria Elimination Programme particularly in 13 districts in the north-east and south-east areas with the specific goal of malaria free Bangladesh within the year of 2030. Started in 2007, the current thrust is on diagnosing and treating malaria cases from plain land to hard reach area by community healthcare service providers and prevention through provision of long-lasting insecticidal nets for free among the people living in malaria endemic area. To obtain the views of the access and use long lasting insecticidal bed nets (LLINs), several cross-sectional qualitative and quantitative studies have been conducted since 2008. In this present article, we used review of the published and unpublished literatures available from these studies done by BRAC. The result shows, in 2008 (one year after start of the programme), only 41% household members were sleeping under LLIN whereas in 2018 it was increased to 91.4%. In case of high risk groups, 36% under-five children and 30% pregnant women were sleeping under LLIN in 2008; while in 2018 it was increased to 96.2% and 95.4% respectively. Adequate supply of LLINs, door-to-door mobilisation of the community and regular monitoring have played major role in achieving this result. In addition, a network of mobile health services uses outreach heath worker in hard to reach pockets of remote places lacking of usual transport route since 2014. That generates a good progress to access and uses LLINs to hard reach area. These increase in LLIN coverage and use, along with other interventions, has contributed to reduction of malaria patients by 87.6% and deaths by 95.5% during the same time period. This declining trend has encouraged the country to move towards elimination strategy. Challenges remain targeting highly mobile populations who are exclusively engaged in forest work for achieving and ensure of 100% uses of LLINs.

394

MOSQUITO EXPOSURE TO ANTIMALARIALS PREVENTS TRANSMISSION OF *PLASMODIUM FALCIPARUM*

Douglas G. Paton[1], Lauren M. Childs[2], Maurice A. Itoe[1], Inga E. Holmdahl[1], Serge Yerbanga[3], Thierry Lefevre[3], Caroline O. Buckee[1], Flaminia Catteruccia[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Virginia Tech, Blacksburg, VA, United States,* [3]*Institut de Recherche en Sciences de la Sante, Bobo Dioulasso, Burkina Faso*

Since the turn of this century, efforts to prevent the transmission of malaria through the mass distribution of insecticide-treated bed nets have been extremely successful and have contributed to an unprecedented reduction in deaths from malaria. However, resistance to insecticides has become widespread in *Anopheles* populations, which has led to the threat of a global resurgence of malaria and makes the generation of effective tools for controlling this disease an urgent public health priority. We recently demonstrated that the transmission of *Plasmodium falciparum* to *Anopheles gambiae* can be rapidly and completely blocked when female mosquitoes take up low concentrations of the antimalarial atovaquone from treated surfaces. Mosquito exposure to atovaquone up to 24 hours before, or 12 hours after, *P. falciparum* infection causes full parasite arrest in the midgut preventing midgut escape and transmission of infection. Although at an early stage, targeting the parasite during human-mosquito transmission, or sporogonic development, could be a powerful and complimentary future tool for malaria elimination. Towards this goal, here, we will present data investigating the interaction of mosquito-targeted anti-parasitic compounds and vector insecticide resistance mechanisms in field-derived *An. coluzzii*, and our further work to fully characterize the effects of atovaquone on *P. falciparum* throughout sporogony and mosquito-human transmission.

395

POLYESTER OR POLYETHYLENE? DIFFERENCES IN LLIN USE DRIVEN BY FABRIC TYPES IN CAMBODIA AND MYANMAR

May Me Thet[1], Ye Kyaw Aung[1], Sochea Phok[2], Si Thu Thein[1]

[1]*Population Services International Myanmar, Yangon, Myanmar,* [2]*Population Services International Cambodia, Phnom Penh, Cambodia*

Use of Long lasting insecticide nets (LLIN) for malaria prevention is influenced by several factors. Past literature suggested that preferences existed for particular fabric type of LLINs. However, there is still no evidence that the LLIN usage per se is associated with fabric types.With the objective of examining the relationship between LLIN use and fabric type, a cross-sectional household survey was conducted in Cambodia and Myanmar in 2018. Single-stage cluster sampling approach was applied. Households with ownership of at least one polyester or polyethylene LLIN were recruited from recent distribution campaign areas. A total of 1362 households and 1414 households were recruited in rural areas of Cambodia and Myanmar.We assessed the usage of polyester and

polyethylene LLIN in two different scenarios: in households with two fabric types, and households with only one type. In Cambodia, there were 620 households with only polyester LLINs and 691 households with only polyethylene LLINs. Only 51 households owned both fabric types. In households with both fabric types, 41.8% of polyester LLINs and 29.4% of polyethylene ones were used at last night. In households with only polyester LLINs, 26.9% of those nets were used. In households with only polyethylene LLINs, only 13.1% were used. Use of polyester LLIN was higher than that of polyethylene in both scenarios. In Myanmar, 636 households had both types of LLINs, 686 had only polyester LLINs, and 92 had only polyethylene LLINs. In households with both fabric types, use of polyester LLINs was 62% and that of polyethylene was 45.1%. In households with a single fabric type, usage of either one was similar (66.5% in households with only polyester LLINs and 67.8% in households with only polyethylene ones).The preliminary findings revealed that the use of LLIN could be determined by fabric type. Given a choice, polyester LLINs enjoyed higher usage than polyethylene ones in both countries. Cambodia findings suggested strong preference of polyester LLINs regardless of availability, whereas availability appeared to determine the usage in Myanmar.

QUANTIFYING SEASONAL VARIATION IN INSECTICIDE-TREATED NET USE BEHAVIOR

Hannah Koenker[1], Cameron Taylor[2], Julie Thwing[3], Clara Burgert-Brucker[4], Tom Fish[2], Albert Kilian[5]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*ICF, Rockville, MD, United States,* [3]*US Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*RTI International, Washington, DC, United States,* [5]*Tropical Health, Montagut, Spain*

Seasonal variation in the proportion of the population using an insecticide-treated net (ITN) is well-documented and is widely believed to be dependent on mosquito abundance and heat, driven by rainfall and temperature. However, seasonal variation in ITN use has not yet been quantified controlling for ITN access. Demographic and Health Survey and Malaria Indicator Survey datasets, their georeferenced data, and public rainfall and climate layers were downloaded and pooled for 21 countries. Nine rainfall typologies were developed from rainfall patterns in Köppen climate zones. For each typology, the odds of ITN use among individuals with access to an ITN within their households ("ITN use given access") were estimated for each month of the year, controlling for region, wealth quintile, residence, year, and malaria parasitemia level. Seasonality of ITN use given access was observed over all nine rainfall typologies and was most pronounced in arid climates and less pronounced in typologies where rainfall was constant or nearly constant throughout the year. Peak ITN use occurred 1-3 months after peak rainfall and corresponded with peak malaria incidence and average malaria transmission season. Temperature was positively associated with ITN use given access in southern and equatorial zones where hot season extends through the rainy season, and negatively associated elsewhere. The observed lags between peak rainfall and peak ITN use given access suggest that net use is triggered by mosquito density. In equatorial areas, ITN use given access is likely to be high year-round given the presence of mosquitoes and an associated year-round perceived malaria risk. These results can be used to inform social and behavior change interventions to improve ITN use in specific times of the year, and to inform geospatial models of the impact of ITNs on transmission.

EVALUATION OF SIERRA LEONE'S INTERMITTENT PREVENTATIVE TREATMENT FOR INFANTS (IPTI) PILOT IN KAMBIA DISTRICT

Laura C. Steinhardt[1], Roberta Sutton[2], Oliver Eleeza[3], Adewale Akinjeji[3], Anthony Mansaray[3], Michael John[3], Brigette Gleason[4], Michael Friedman[5], Samuel J. Smith[6], Miriam Rabkin[2], Maria Lahuerta[2]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*ICAP-Columbia, New York, NY, United States,* [3]*ICAP-Columbia, Freetown, Sierra Leone,* [4]*Centers for Disease Control and Prevention, Freetown, Sierra Leone,* [5]*Centers for Disease Control and Prevention, Dhaka, Bangladesh,* [6]*Ministry of Public Health, Freetown, Sierra Leone*

Intermittent preventive treatment in infants (IPTi) with sulfadoxine-pyrimethamine (SP) is a proven strategy to reduce malaria morbidity in infants and is given at 3 routine immunization visits. Sierra Leone is the only country to implement IPTi, beginning in 4 pilot districts in 2017 and scaling up nationwide in 2018. We evaluated IPTi in the initial pilot district of Kambia to assess quality, coverage, and acceptability of IPTi, and explored potential impact on malaria morbidity in this setting. This mixed-methods evaluation included two data collection phases at 3 and 16 months after IPTi implementation. It included health facility (HF) assessments and register data abstraction at a 25% sample of HFs in Kambia (phases 1 and 2) and a household (HH) survey of children aged 3-15 months in 44 clusters using multi-stage sampling (phase 2). Vaccination coverage from the HH survey was calculated from review of child health cards and maternal recall and weighted for the sampling design. HF register data were analyzed using segmented regression comparing 12 months pre- vs. 15 months post-IPTi. Nearly all HFs (17/18 in phase 1 and 18/18 in phase 2) had SP for IPTi in stock and most had supervisory visits in the last six months that addressed IPTi provision (15/18 in phase 1 and 18/18 in phase 2). Improved drinking water for IPTi administration was available at 7/18 and 11/18 HFs in phases 1 and 2, respectively. According to the HH survey, 67.4% of 459 children at least 10 weeks old had received the first dose of IPTi, and 80.4% received Penta 2, given at the same time. Among 444 children ≥14 weeks old, 62.5% received the second dose of IPTi, and 65.4% received Penta 3. Among 217 children ≥ 9 months old, 36.4% received the third dose of IPTi and 52.2% the first measles vaccination. HF register data for patients <12 months old indicated little change in outpatient visits or confirmed malaria after IPTi, but a 23% decrease in malaria test positivity rate was found (p=0.027). Kambia district was able to scale up IPTi swiftly and provide health systems support required for introduction. IPTi coverage could be further improved, as evidenced by gaps between IPTi and childhood vaccines.

398

THE IMPACT OF INDOOR RESIDUAL SPRAYING FOR MALARIA PREVALENCE IN HOMA BAY COUNTY, KENYA: AN OBSERVATIONAL STUDY

Wataru Kagaya[1], Aya Konishi[2], Kyoko Kurihara[2], Chim Chan[1], Jesse Gitaka[3], James Kongere[4], Kinya Uchihashi[2], Gordon Okomo[5], Akira Kaneko[1]

[1]*Osaka City University, Osaka, Japan,* [2]*Sysmex Corporation, Kobe, Japan,* [3]*Mount Kenya University, Thika, Kenya,* [4]*NUITM/KEMRI, Nairobi, Kenya,* [5]*Homa Bay County Ministry of Health, Homa Bay, Kenya*

The estimated global malaria incidence and death decreased by 16% and 48% respectively between 2000 and 2017, as a consequence of increasing global financial aids to support the scale-up of novel tools such as artemisinin-based combination therapy (ACT), insecticide treated bed nets (ITNs), and rapid diagnostic test (RDT). Homa Bay County in Kenya experienced a dramatic reduction of malaria prevalence after the implementation of a large scale indoor residual spraying (IRS) campaign in February 2018. Our cross-sectional malariometric surveys in school children from 2012 to 2017 revealed high and stable malaria prevalence in the inland Ungoye area. However the prevalence significantly

decreased between January and September 2018 from 40.6% to 15.0% by microscopy. On the contrary, Ngodhe Island in Lake Victoria, where IRS was not implemented, had an increase of prevalence from 4.5% to 15.1% by microscopy over the same period. We also investigated suspected clinical malaria cases at Homa Bay County Teaching and Referral Hospital in February 2019 by testing their malaria infection status together with complete blood count (CBC). Although the number of suspected malaria cases did not significantly decrease compared with previous year, slide positivity rate significantly decreased from 11.7% to 6.5%. These results suggest that the IRS program had significant impacts on malaria prevalence and incidence in the target area. The transition of febrile cases from malarial to non-malarial causes necessitates a more precise differential diagnosis of febrile cases in health facilities. We discuss the applicability of a novel hematology analyzer, which can rapidly and simultaneously measure both malaria-infected red blood cell counts and CBC, in the context of malarial vs. non-malarial febrile case management.

399

EFFICACY OF CONTINUOUS BED NET DISTRIBUTION TO MAINTAIN HIGH COVERAGE AFTER A MASS DISTRIBUTION CAMPAIGN IN MADAGASCAR, 2017

Jacky Aubin Raharinjatovo[1], Mauricette Nambinisoa Andriamananjara[2], Fanjanirina Randrianarivony[1], Gilbert Randrianandrasana[1], Laurent Kapesa[3], Jocelyn Razafindrakoto[3], Jemima Andriamihamina[3], Sarah Baum[4], Mickael Randriamanjaka[1], Hasina Harinjaka Ramiandrisoa[2], Morgan Brown[4]

[1]*PSI Madagascar, Antananarivo, Madagascar,* [2]*NMCP, Antananarivo, Madagascar,* [3]*USAID/PMI Madagascar, Antananarivo, Madagascar,* [4]*Population Services International, Washington, DC, United States*

In 2015, Madagascar conducted a mass campaign to distribute (MCD) 10.7 million insecticide treated bed nets (ITN) in 92 malaria-endemic districts of the country. To maintain universal coverage (one ITN per two people), replace damaged ITNs and cover new sleeping spaces, the National Malaria Control Program (NMCP) and partners piloted a community-based distribution scheme called continuous distribution (CD) one year after the MCD. The pilot was conducted in 11 districts and lasted 10 months. To assess the efficacy of CD, we compared ITN use in two CD districts, Vavatenina on the east coast and Vohipeno in the south, to two non-CD districts that were near or bordering the CD districts, Soanierana Ivongo and Vondrozo districts, respectively. We used multi-stage sampling to select 300 households per district: 10 enumeration areas (EA) per district were selected with probability proportional to size; in each EA, 30 MCD households were systematically sampled. Households that refused or were unable to participate were replaced. In each study household, we identified all ITNs and recorded whether they were from CD. A questionnaire was administered to the head of household regarding ITN use and ownership. Proportion comparisons were conducted using chi-squared tests in STATA 13.0. Information was available from 1,200 households. The proportion of sleeping spaces covered with ITNs was 85.9% and 66.9% in CD and non-CD districts, respectively ($p < 0.001$). In CD districts, the proportion of households with at least one ITN was 95.7% and in non-CD districts it was 78.3% ($p < 0.001$). The proportion of households owning at least two ITNs in CD districts was 63.3% whereas in non-CD districts it was 25.7% ($p < 0.001$). The proportion of people who reported having slept under an ITN the previous night was 80.7% in CD districts compared with 62.5% in control districts ($p < 0.001$). ITN coverage and use were higher in CD districts suggesting that CD after an MCD may increase ITN access and use. Due to the success of this pilot, the NMCP will scale-up CD in 39 districts one year after the 2018 MCD and evaluate the impact of this strategy over a longer period.

400

INDIVIDUAL, HOUSEHOLD AND COMMUNITY FACTORS ASSOCIATED WITH THE UPTAKE OF THREE DOSES OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY (IPTP3) IN COTE D'IVOIRE: A MULTILEVEL ANALYSIS

Stella Babalola[1], Abdul Dosso[2], Monne Therese Bleu[3], Antoine Kouame[4], Olamide Oyenubi[1], Grace Awantang[1], Michael Toso[1], Gabrielle Hunter[1], Mieko McKay[2], Colette Yah Kokrasset[3], Blaise Kouadio[5], Antoine Mea Tanoh[3], Diarra Kamara[2]

[1]*Johns Hopkins Center for Communication Programs, Baltimore, MD, United States,* [2]*Johns Hopkins Center for Communication Programs, Abidjan, Côte D'Ivoire,* [3]*Ministry of Health and Hygiene, Cote d'Ivoire National Malaria Prevention and Control Program, Abidjan, Côte D'Ivoire,* [4]*Save the Children Cote d'Ivoire, Abidjan, Côte D'Ivoire,* [5]*United States Agency for International Development-USAID, Abidjan, Côte D'Ivoire*

The World Health Organization has recommended intermittent preventive treatment of malaria in pregnancy (IPTp) for women, achieved by taking multiple doses of Sulfadoxine/pyrimethamine (SP) during pregnancy. In Cote d'Ivoire, the policy recommends that pregnant women take at least three doses of SP. Results of the 2016 Multiple Indicator Cluster Survey reveal that only 22.6% of women that gave birth during the previous two years obtained at least three doses of SP during their pregnancy. Applying multilevel regression to data from a 2018 national malaria behavioral determinants survey, this study examines background factors that are associated with the uptake of three or more doses of SP. The sample for the study included 2225 women who had a child during the two years before the survey. The data showed that the majority (91.4%) of these women obtained at least one antenatal care (ANC) visit and a little over three quarters (78.1%) attended at least four visits. Concerning the uptake of IPTp, the majority (86.5%) received at least one dose whereas only about half (53.0%) received at least three doses. The health facility was the source of IPTp doses for most women: 86.2% received at least one SP doses from this source. It is notable that 26.7% of the women obtained one or more doses of SP from a private pharmacy. Though women who obtained at least four ANC visits were more likely than others to obtain the third dose of SP (IPTp3), less than 60% of these women obtained IPTp3. Results of the multilevel regression show that the variables most strongly and positively associated with obtaining IPTp3 were number of ANC visits, husband's engagement in antenatal care, prevalence of post-primary education in cluster of residence, and the woman's age. The analyses further suggest the existence of unmeasured variables operating at the cluster level that are associated with the uptake of IPTp3. Programs designed to promote the uptake of IPTp3 should encourage increased frequency of ANC attendance among pregnant women by targeting male partners, using community mobilization approaches, and addressing relevant health system-related factors

401

TIMELINESS OF INITIATION OF INTERMITTENT PREVENTATIVE TREATMENT OF MALARIA WITH SULFADOXINE-PYRIMETHAMINE (IPTP-SP) IN PREGNANT WOMEN: EVIDENCE FROM A CROSS SECTIONAL SURVEY IN MALAWI

Jobiba Chinkhumba[1], Ashley Malpass[2], Katherine Wright[3], Xiomara Brown[2], Dziko Chatata[4], John Munthali[4], Michael Kayange[5], Fannie Kachale[5], Don Mathanga[1], Julie Gutman[6]

[1]*University of Malawi, College of Medicine, Malaria Alert Center, Blantyre, Malawi,* [2]*U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Lilongwe, Malawi,* [3]*Management Sciences for Health (MSH), Medford, MA, United States,* [4]*Management Sciences for Health (MSH), Lilongwe, Malawi,* [5]*Ministry of Health, Lilongwe, Malawi,*

[6]*Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States*

Intermittent Preventive Treatment of pregnant women with sulfadoxine-pyrimethamine (IPTp-SP) is a key strategy to prevent malaria related adverse health outcomes among pregnant women and their infants in malaria endemic areas. Current Malawian National guidelines recommend that pregnant women receive the first dose at 13 weeks gestational age, with subsequent doses four weeks apart, for a minimum of three doses. However, coverage remains low. We aimed to assess timeliness of the first dose of IPTp-SP (IPTp-SP1; receipt between 13 and 16 weeks) among pregnant Malawian women during the initial antenatal care (ANC) visit to identify missed opportunities and highlight key points for programmatic intervention. A cross-sectional survey in two districts in Malawi recruited women who had a live birth in the previous 12 months. IPTp-SP uptake data were collected using a structured questionnaire and ANC card review. A total of 370 recently pregnant women with mean age 25 years (SD 6.2) and average parity 2.5 (SD 1.5) participated in the survey. Few (26.2%, 95%CI: 21.9-30.9) had attained secondary education. A total of 270 women had ANC cards available. At the initial ANC visit, the women's mean gestation age (GA) was 20 weeks (SD 5.1), and 86.6% (95% CI: 77.2-92.5) were ≥13 weeks; 19.0% (95% CI: 12.2-28.4) presented between 13-16 weeks. Overall, considering the 1st ANC visit only, 67.3% (95% CI: 59.9-73.9) of women who were at least 13 weeks GA received IPTp-SP during their initial ANC visit. IPTp-SP was provided to 49.6% (95% CI: 31.2-68.2), 67.6% (95% CI 51.6-86.6), 72.3% (95% CI 62.4-80.4), and 86.2% (95% CI 67.4-91.6) of women attending at 13-16, 17-20, 21-24, and 25-28 weeks, respectively. Few women attend ANC early enough to receive the first dose of IPTp in a timely fashion; even among those who do, half do not receive IPTp-SP. To increase early IPTp-SP uptake and coverage, it is critical to find effective ways to facilitate early ANC attendance, such as improved community engagement and mobilization, and to improve the quality of ANC to ensure women receive SP at all visits, per national guidelines

402

LARVIVOROUS FISH BASED MALARIA ELIMINATION IN INDIA

Susanta Kumar Ghosh

ICMR-National Institute of Malaria Research, Bangalore, India

Larval source management with larvivorous fish is an effective strategy for vector management. This method of larval control was necessitated in areas where routine indoor insecticidal spraying was not possible in most of malaria-endemic sericulture areas in Southern Karnataka State, India. Larval source management was the only option left in this area to contain malaria transmission. It was noted that villages surrounded by ponds and wells had more malaria than villages on streams. Two reported malaria vectors *Anopheles culicifacies* and *An. fluviatilis* were present. Again, sibling species complex analyses of these two vectors revealed that species A of *An. culicifacies* were more numerous in villages with ponds and wells, while species B in villages situated nearer to streams. On the other hand, all *An. fluviatilis* belonged species T. Species B of *An. culicifacies* and species T of *An. fluviatilis* are not efficient vectors. It was also observed that in most of nearby non-malarious areas larvivorous fish were present. These observations led to the release of larvivorous fish for management of malaria vectors. Following this, a detailed geographical reconnaissance was conducted to enumerate the water bodies in each village. Two Poecillid fish *Gambusia affinis* and *Poecilia reticulata* were used for the intervention. It was observed that *Gambusia* is best suited in ponds and large water bodies, while *Poecilia* in wells. A block-level task force model is in place involving the local health and block development officials. The main challenge is to implement this programme at village level where dedicated staff are needed, local government to expand the programme. In the initial stage some window period must be given to establish the fish in the local environment. Monitoring of fish once in 6-month period is good for better results. Now, village-level data through remote sensing are available, and this can be utilized in an effective manner.

403

COSTING MASS DRUG ADMINISTRATION WITH DIFFERENT TARGETING STRATEGIES

Shwe Sin Kyaw[1], Tom L. Drake[2], Wirichada Pan-ngum[1], Sasithon Pukrittayakamee[1], Yoel Lubell[1], Lisa J. White[1], Frank M. Smithuis[3]

[1]*Mahidol Oxford Research Unit, Bangkok, Thailand,* [2]*London School of Tropical Hygiene and Medicine, London, United Kingdom,* [3]*Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom*

Mass drug administration (MDA) is receiving increasing attention as an essential component in the toolkit for malaria elimination. In the Greater Mekong Sub-region (GMS), efforts to eliminate *P. falciparum* malaria must be accelerated to address the global health emergency of anti-malarial drug resistance. There are many options for the implementation of MDA including targeted approaches, each of which has different economic implications. A key piece of information missing so far has been a realistic estimate of the programmatic cost of MDA for various targeting strategies. This paper uses an evidence-based method to extrapolate programmatic costs from the financial data of a trial. We estimate the costs of implementing a range of mass interventions against *P. falciparum* malaria with a range of choices for the extent and method of targeting high-risk sub-populations. The results from this are being used to guide decision-making on malaria elimination in the GMS. An online tool is available to further enhance the utility of this research.

404

COLLECTIVE INTELLIGENCE AND MALARIA: A PRECISION PUBLIC HEALTH-MALARIA ELIMINATION MODEL

Leopoldo Villegas[1], Gustavo Bretas[1], Stephen Vreden[2]

[1]*Global Development One, Silver Spring, MD, United States,* [2]*Academisch Ziekenhuis Paramaribo, Paramaribo, Suriname*

Collective intelligence is a key feature of mankind that is being expanded with the use of computers and digital data. There are several examples of applications of CI in many fields but there is limited information on its use on malaria elimination. Here we describe a public health model for malaria elimination that uses CI. In 2004, Suriname's National Malaria Control Program (NMCP) decided to accelerate its malaria control activities with the support of the Global Fund. A precision public health model was built with all the available information about humans, vectors, and parasites involved in the transmission. An epidemiological stratification was conducted in order to target interventions aiming to eliminate malaria transmission. Three different, well-defined strata were identified, and a combination of interventions was adapted to each of the stratum. The model used included a rigorous M&E plan to track all activities and the epidemiological impact it had. Different inputs were discussed and incorporated in a forum, the National Malaria Board; researchers, malariologists, politicians, clinicians, and representatives of the communities affected. Once the general strategy was decided, a strategic partnership plan was designed to engage all key actors in the malaria elimination campaign. The result was that Suriname experienced a rapid and significant impact on malaria morbidity and mortality rates. Between 2004-2017, *P. falciparum* and *P. vivax* infectious decreased 98.5% and 67.8%, respectively. Using collective intelligence, Suriname experienced a 180-degree turn, from having the highest annual parasite incidence (API) in the Americas (207 per 1000 people) in 2003 to become one of the E2020 malaria elimination countries (API=6 per 1000 people). This is an example illustrating that CI could be used to develop precision public health models that leave an imprint on society. This model could be adapted to other malaria scenarios, benefiting from the synergies between data-driven approaches, information use, expertise, software/hardware, partners, and in-depth participation of a broad range of affected communities.

405

PERSPECTIVES OF KEY STAKEHOLDERS IN TANZANIA ON ALTERNATIVE TECHNOLOGIES FOR MALARIA ELIMINATION

Marceline F. Finda[1], Nicola Christofides[2], Javier Lezaun[3], Ann H. Kelly[4], Fredros O. Okumu[1]

[1]*Ifakara Health Institute, Ifakara, United Republic of Tanzania,* [2]*University of the Witwatersrand, Johannesburg, South Africa,* [3]*University of Oxford, Oxford, United Kingdom,* [4]*King's College London, London, United Kingdom*

Global burden of malaria has significantly reduced since 2000 due to both public health efforts and improvements in socioeconomic conditions. As we approach elimination however, it is crucial to understand and address socio-cultural factors associated with persisting transmission. Novel technologies such as mass releases of genetically-modified mosquitoes, mass drug administrations of Ivermectin and larviciding require strong collaborations between scientists and communities to ensure the technologies are effective and meet local needs. This study aims to use innovative anthropological techniques to bridge current gaps between researchers and key stakeholders on various issues relative to alternative malaria control technologies. Focus group discussions (FGDs) were held with stakeholders including scientists, policy makers, officials from regulatory bodies and community members in Tanzania. The discussions focused on exploring opinions of the stakeholders on the need for alternative technologies for malaria elimination, and their views on novel technologies that are aiming towards elimination. This is an on-going study. All participants of the FGDs agreed that while malaria prevalence and incidence have declined over the past decade, currently available strategies and their levels of utilization are not sufficient for malaria elimination in Tanzania by 2030. However there were varying opinions among the stakeholders on which alternative technologies should be put in place to achieve elimination by 2030. Popular technologies across the stakeholder groups included larviciding, genetically-modified mosquitoes, and spatial repellents. Less preferred options included space-spraying of mosquitoes and mass drug administration of Ivermectin. Community members and scientists also preferred improving housing for the lowest income people for malaria control, but policy makers challenged the sustainability of this strategy given its high costs. More FGDs are in progress and more comprehensive findings will be shared during the conference.

406

MALARIA CONTROL AND ELIMINATION IN AFRICA: WHY ARE SOME COUNTRIES DOING BETTER THAN OTHERS?

Xiaoming Wang, Guofa Zhou, Guiyun Yan

University of California Irvine, Irvine, CA, United States

This study was undertaken to determine social, economic, biological and environmental factors critical to malaria control effectiveness in African countries that are with contrasting responses to the malaria control and elimination efforts, and use this information to inform the development of improved malaria control strategies in Africa. A systematic analysis was conducted using longitudinally collected data from publically available data sources for the period of 2000 and 2016, for 8 African countries with contrasting malaria incidence dynamics. Single- and multivariable linear regression analyses were performed to determine the impact of various risk factors on malaria incidence. The risk factors included autocorrelation with a one-year time lag, study country, and economic status, internal and external malaria control budgets, bednet coverage, indoor residual spray coverage, and insecticide resistance status. Malaria incidence exhibited highly significant autocorrelation. Per capita government funding for malaria control and insecticide resistance were the two significant factors correlating with malaria incidence. In conclusion, this study indicates the significance of malaria control investment from African countries themselves and insecticide resistance management in malaria control and elimination in Africa.

407

LISTENING TO THE VOICES OF THE VULNERABLE: A MIXED METHODS STUDY ON HEALTH-SEEKING BEHAVIORS IN A MALARIA ENDEMIC DISTRICT IN LAO PEOPLE'S DEMOCRATIC REPUBLIC

Ken Ing Cherng Ong[1], Phonepadith Khattignavong[2], Sengdeuane Keomalaphet[2], Moritoshi Iwagami[3], Bouasy Hongvanthong[4], Paul T. Brey[2], Shigeyuki Kano[3], Masamine Jimba[1]

[1]*Department of Community and Global Health, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan,* [2]*Institut Pasteur du Laos, Ministry of Health, Vientiane, Lao People's Democratic Republic,* [3]*Department of Tropical Medicine and Malaria, Research Institute, National Center for Global Health and Medicine, Tokyo, Japan,* [4]*Center of Malariology, Parasitology and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic*

Lao People's Democratic Republic (PDR) aims to eliminate malaria by 2030. Past efforts were successful in reducing the number of malaria cases and 80% reduction was observed from 2012 to 2017. To eliminate malaria, previous efforts focused on vector control through the distribution of long-lasting insecticide bed nets, and biomedical approach through the distribution of antimalarials, but the social aspects of malaria always came second. The population approach where a one-size-fits-all strategy is employed through antimalarials and bed nets distribution might not be enough for vulnerable populations such as the ethnic minorities and low-income families in the rural areas. We investigated the health-seeking behaviors of the villagers in two villages in the malaria endemic area of Thapangthong district, Savannakhet Province, in October, 2018. We conducted a mixed methods study using a pre-tested questionnaire in the quantitative part and in-depth interviews and focus group discussions in the qualitative part. We targeted the villagers and the health care providers in the area. We found that although 256 out of 313 villagers (81.8%) responded that they would first go to the village health center or the district hospital to seek treatment, qualitative data from focus group discussions revealed problems faced by the villagers such as lack of medicines and medical equipment. "*Overall everything is good but only one thing is that medicine is always not enough*" (*Male, 40, Teacher)*. Although bed nets coverage was high according to the in-depth interviews with the health care providers, and 276 (88.2%) villagers responded they had bed nets at home, their understanding on the transmission of malaria varied. "*Because your house is not clean. If you drink water with mosquito eggs, you will get fever*" (*Female, 45, Government servant).* In conclusion, the vector control and parasite control strategies are undoubtedly crucial, but the social approach is equally important for malaria elimination. By understanding the local beliefs and perceptions of the vulnerable population, better strategies can be formulated to eliminate malaria.

408

IMPLEMENTATION IMPACT OF INNOVATIVE 1,7-MRCT APPROACH ON MALARIA BURDEN REDUCTION IN TANZANIA

Wang Duoquan

National Institute of Parasitic Diseases, China CDC, Shanghai, China

In 2017, China recorded its first year of zero indigenous cases of malaria transmission. New efforts are in translation of Chinese experiences and lessons to support global malaria elimination efforts in developing countries and particularly in Africa. The China-UK-Tanzania pilot project on malaria control was the first project for China to pilot Chinese experiences on malaria control in Africa. The China-UK-Tanzania pilot project on malaria control was an intervention study with two representative intervention communities receiving proposed interventions and two comparable communities serving as control sites. The project intervention included Test, Treat and Track (T3) Initiative of World Health Organization integrated with Chinese experiences on malaria control and elimination. A joint efforts of Chinese and Tanzanian teams, worked together at the ground level, and customized innovatively China's "1-3-7" model for fast-tracking malaria elimination into local approach for areas

of high and moderate transmission. This new approach, named malaria Reactive Community-based Testing and Response approach (1,7-mRCT), has been implemented through intensive use of existing health facility data to decide on the priority clusters to conduct community testing and treatment on weekly basis between 2015 and 2018. This innovative 1,7 -mRCT response approach significantly reduced malaria parasite prevalence by >70% in the intervention communities, beyond and above the benefit of long-lasting insecticide-treated nets (LLINs). The burden of malaria cases reported at health facilities was reduced by 20% from the week of 1,7-mRCT response at the respective villages and the prophylactic effect was observed to continue for five weeks since treatment. This innovative 1,7 -mRCT approach demonstrated effectiveness in significantly reducing prevalence and incidence of malaria in areas of moderate and high transmission. This could be potentially scaled-up to other areas of African countries including Tanzania, to accelerate the malaria control and elimination progress in Africa.

409

MALARIA SURVEILLANCE IN TANZANIA ELECTRONIC INTEGRATED DISEASE SURVEILLANCE AND RESPONSE (EIDSR) SYSTEM COMPLETENESS AND TIMELINES IN AREAS OF VERY LOW TRANSMISSION

Joseph Joachim Joseph[1], Ssanyu Nyinondi[1], Shabbir Lalji[1], Abdul-wahid Al-mafazy[1], Humphrey Mkali[1], Ally Mohamed[2], Renata Mandike[2], Frank Chacky[2], Anna Mahendeka[2], Chonge Kitojo[3], Naomi Kaspar[3], George Greer[3], Erik Reaves[4], Jeremiah Ngondi[5], Claud John[6], Richard Reithinger[5]

[1]*RTI International, Dar es salaam, United Republic of Tanzania,* [2]*National Malaria Control Program, Dodoma, United Republic of Tanzania,* [3]*US President's Malaria Initiative, United States Agency for International Development, Dar es salaam, United Republic of Tanzania,* [4]*US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar es salaam, United Republic of Tanzania,* [5]*RTI International, Washington, DC, United States,* [6]*Ministry of Health Community Development Gender Elderly and Children, Dodoma, United Republic of Tanzania*

Complete and timely reporting of malaria cases is crucial to detect and mitigate malaria outbreaks. Tanzania uses an electronic Integrated Disease Surveillance and Response (eIDSR) system to report weekly on aggregate malaria cases. eIDSR was piloted in 67 health facilities in 2013 and scaled-up to 7,138 facilities in 25 of the country's 26 regions by November 2018. This study aimed to describe the trends of completeness and timeliness of reports submitted through eIDSR stratified by malaria parasite prevalence, (i.e., very low <1%, low 1≤5 %, moderate 5≤30%, and high >30%), to ascertain its usefulness for malaria outbreak detection and case-based surveillance. Completeness was defined as the proportion of reports containing all malaria indicators submitted over the expected number of reports within a week; timeliness was defined as the proportion of reports submitted by the first day of the following week over the expected number of reports. Overall, the completeness of reporting increased from 51.1% (20,452/40,040) in 2014 to 66.6% (239,715/359,736) in 2018, and timeliness increased from 25.4% (10,187/40,040) in 2014 to 41.4% (149,022/359,736) in 2018. Reporting completeness and timeliness in 2018 varied by malaria prevalence, with completeness significantly higher in areas of very low prevalence compared to areas with high prevalence (90.1% vs 60.9%; p<0.0001) and timeliness significantly higher in areas of very low prevalence (60.5% vs 38.5%; p< 0.001). Both completeness and timeliness of eIDSR reports on aggregate malaria cases were greater in areas with very low malaria prevalence, which might make eIDSR a useful tool for both early outbreak detection and case-based surveillance in these settings. Opportunities remain to strengthen completeness and timeliness of eIDSR reporting across all prevalence strata.

410

A MULTIMEDIA IEC-BCC CAMPAIGN TO MODIFY MALARIA TREATMENT-SEEKING BEHAVIOR IN ESCUINTLA, GUATEMALA: DESIGN, IMPLEMENTATION AND EVALUATION IN ENDEMIC LOCALITIES

José Miguel Echeverría[1], Juan Valentín Santos Salazar[1], Beci López Ojeda[1], Rodrigo Antonio Flores[1], Javier López Sevilla[2], Melissa S. Wiles[2], Madeline Baird[3], Graziella Scudu[2], Darlene Bhavnani[3]

[1]*Ministry of Public Health and Social Assistance, Guatemala City, Guatemala,* [2]*Clinton Health Access Initiative, Guatemala City, Guatemala,* [3]*Clinton Health Access Initiative, Panama City, Panama*

Guatemala has committed to eliminate malaria by 2020. In the endemic region of Escuintla where 50% of Guatemala's 3,084 total cases occurred in 2018, people with malaria symptoms often self-medicate or go to pharmacies/informal shops to purchase low-dose chloroquine instead of visiting official points of care (POCs) (e.g. community health workers [CHWs] and public sector health facilities). These practices prolong the time between symptom onset and diagnosis, increasing risk of transmission. The Ministry of Public Health and Social Assistance (MOH) designed a multimedia campaign to reduce self-medication practices and increase uptake of appropriate POCs for malaria diagnosis and treatment and prevention methods. The campaign was piloted in 11 high-risk localities via radio and television, household visits and educational events at churches, schools and other public spaces, selected as culturally-appropriate dissemination methods based on community interviews conducted by local level MOH staff. Exposure to the campaign and behavior change among care seekers is being evaluated via pre/post-intervention program monitoring information collected by CHWs and health facility staff from all who present with fever between February and April 2019 in target localities. The impact of the various dissemination channels included in the campaign will also be assessed to effectively direct future campaign resources. Baseline results show that self-medication is common: 72% self-medicated and 20% went somewhere else to receive treatment before an appropriate POC. Results also show a difference between localities: prevalence of self-medication varied from 53% in some localities up to 100% in others. If shown to be effective for generating behavior change, this campaign could further advance country efforts for malaria elimination, reducing time between symptom onset and initiation of treatment, and ensuring that all cases are detected, diagnosed, promptly treated and investigated to further understand risk factors for persistent transmission such as treatment non-adherence and *P. vivax* relapse infections.

411

USING MODELS TO INFORM IMPLEMENTATION POLICIES OF SEASONAL MALARIA CHEMOPREVENTION

Kamaldeen O. Okuneye, Jaline Gerardin

Institute for Public Health and Medicine, Northwestern University, Chicago, IL, United States

Malaria transmission is highly seasonal in the Sahel and sub-Sahel regions of Africa, where over 60% of clinical malaria cases occur during the 3 - 4 month rainy season and about 90% of the mortality and morbidity occurs among children under the age of 5 years. In addition to the use of insecticide-treated nets and indoor residual spraying, the WHO recommends seasonal malaria chemoprevention (SMC) for children 3 - 59 months in these regions, and some countries are considering increasing the age of eligibility to 10 years. SMC is an intermittent administration of full treatment courses of antimalarial drugs (usually sulfadoxine-pyrimethamine plus amodiaquine, SP-AQ), during the malaria season to prevent illness by maintaining therapeutic antimalarial drug concentrations in the blood throughout this period. Using data from literature, we constructed pharmacokinetic models of SP and AQ in EMOD, an agent-based stochastic model, then calibrated pharmacodynamics of SP and AQ to clinical trials of SMC and of artesunate-AQ, respectively, to capture the

curative and prophylactic properties of SP-AQ across different age groups. Using this model and data collected from Sahelian regions, we describe the impact of imperfect adherence on the success of SMC and the increase of potential exposure of parasites to subcurative drug concentrations that may select for resistant phenotypes. We explore the role of a novel single-dose SMC drug could play in increasing SMC impact. We quantify the potential burden reduction achievable by expanding the SMC age range, how the gains depend on transmission intensity and seasonality, and which geographical areas stand to benefit most from expanding or introducing SMC, including East African regions. Using SMC surveillance data from multiple countries, we identified which areas have a smaller impact from SMC than expected and should be investigated to determine whether these differences are due to insufficient coverage, participation, and/or drug resistance. Results from this work can be used to improve the implementation of SMC by providing standard strategies and individual approaches to existing and new SMC regions.

412

EXPERIENCE FROM THE FIELD: HOW TO IMPLEMENT A COMPLEX INTERVENTION STUDY TO CONTROL MALARIA IN REMOTE AREAS OF THE AMAZON FOREST, WITHIN A CROSS-BORDER CONTEXT?

Muriel Suzanne Galindo[1], Yann Lambert[1], Martha Cecilia Suarez Mutis[2], Louise Mutricy[1], Helene Hiwat[3], Laure Garancher[4], Lise Musset[5], Cassio Peterka[6], Alice Sanna[7], Antoine Adenis[1], Mathieu Nacher[1], Stephen Vreden[8], Maylis Douine[1]

[1]*Centre d'Investigation Clinique Antilles-Guyane (Inserm 1424), Cayenne Hospital, Cayenne, French Guiana,* [2]*Laboratory of Parasitology, Institute Oswaldo Cruz, Rio de Janeiro, Brazil,* [3]*National Malaria Programme, Ministry of Health, Paramaribo, Suriname,* [4]*Pan American Health Organization, Barbados Office, Bridgetown, Barbados,* [5]*Laboratoire de Parasitologie, Centre National de Référence du Paludisme, Institut Pasteur de la Guyane, Cayenne, French Guiana,* [6]*National Malaria Programme, Ministry of Health, Brasilia, Brazil,* [7]*Health Regional Agency of French Guiana, Cayenne, French Guiana,* [8]*Scientific Research Center Suriname, Paramaribo, Suriname*

In complex intervention reporting, a clear definition of the intervention, including the assumptions behind it, and the description of what and how it is implemented, are often lacking. We present here our experience in implementing a pilot strategy to control malaria, titled *Malakit*, targeting illegal gold miners working in French Guiana. This population is identified as a key malaria reservoir in the Region. The principle is to provide participants with a self-diagnosis and self-treatment kit along with adequate resources to handle rapidly and adequately an episode of malaria symptoms by themselves, when isolated in the Amazon forest. The choice not to develop a usual community-based "test and treat" approach is mainly due to regulatory reasons. Developing this intervention involves facing several issues: a mobile population living in remote areas and poorly educated, and a cross-border context with three countries: France, Brazil and Surinam. Several tools to communicate remotely between stakeholders have been experimented but face-to-face meetings remain the most efficient alternative. Debating and decision-making previously undertaken in four languages, including English, were greatly improved by the presence of interpreters during international meetings. Important rear bases on the two border rivers which are transit and rest areas were previously identified as key places to recruit participants. Malakit facilitators were hired for their belonging or proximity to the *garimpeiros* community to train participants how to use a kit. The information, education and communication tools were designed by taking into account the living conditions, education level and habits of the study population *i.e.* animated and tutorial videos, illustrated instructions printed on the plastified kits and an interactive smartphone app. The training-enrollment procedure is detailed in an illustrated step by step guide but tailoring the intervention to individual participants is partially allowed. Adaptations observed are related to participants individual characteristics such as time availability, reading capacity or smartphone literacy.

413

MALARIA CASE MANAGEMENT PRACTICE AND ELIMINATION READINESS IN FIVE ELIMINATION DISTRICTS OF MADAGASCAR, 2018

Anjoli Anand[1], Favero Rachel[2], **Catherine Dentinger**[3], A. Ralaivaomisa[4], S. Ramamonjisoa[5], Elaine Razafimandimby[5], Jocelyn Razafindrakoto[6], Katherine Wolf[2], Laura C. Steinhardt[7], Julie Thwing[7], Bryan K. Kapella[7], M. Rabary[8], Sedera Mioramalala[9], Jean Pierre Rakotovao[5]

Madagascar's Malaria National Strategic Plan 2018-2022 calls for progressive malaria elimination beginning in low-incidence districts (< 1 case/1000). Although an elimination plan has not yet been developed, optimizing access to prompt diagnosis and quality treatment will be its foundation, along with improving outbreak detection and response. To assess readiness and inform planning, we surveyed health facilities (HFs) and communities to evaluate diagnosis and treatment (case management [CM]) health worker (HW) knowledge and practices, use of data to inform decision-making, and the availability of commodities, training, and supervision. In September 2018, we randomly selected 35 HFs in 5 of the 8 districts identified for elimination, surveyed 41 HWs and 34 community health volunteers (CHVs), and observed 300 clinical encounters between HWs and patients of all ages. To evaluate elimination readiness, a composite score will be assigned to each HF catchment area that incorporates all survey responses based on commodity availability, malaria CM practices, data management, and supervision practices. In preliminary results, 8 of 34 (24%) CHVs reported that they do not manage children under 5 years (CU5) with fever at the community level. Of 26 CHVs who care for CU5, 18 (69%) identified history of fever as a criterion for suspected malaria, 20 (77%) reported using a malaria rapid diagnostic test (RDT) when evaluating patients reporting fever, and 15 (58%) reported giving antimalarials for a positive RDT. Among treating CHVs, 13 (30%) reported having RDTs, and 11 (42%) reported having antimalarials currently available. Among facility-based HWs, 83% identified history of fever as a criterion for a suspected case. Of 120 patients with reported or recorded fever, 56 (47%) were tested with an RDT. Five RDTs were positive; a first-line antimalarial was prescribed to 4 of those patients. This evaluation is a baseline for CM performance as Madagascar establishes elimination targets. In the evaluated districts, CM could be improved by strategies to increase testing at CHV and HF levels and address availability of commodity stocks in the community.

414

INTEGRATED DRUG EFFICACY SURVEILLANCE OF UNCOMPLICATED *PLASMODIUM FALCIPARUM* AND *P. VIVAX* MALARIA IN THAILAND, 2013-2018

Prayuth Sudathip[1], Julien Zwang[2], Rungrawee Tipmontree[1], Suravadee Kitcharkarn[1], Thannikar Thongrad[1], Felicity Young[3], Richard Reithinger[3], Jui A. Shah[2], Pascal Ringwald[4], David Sintasath[5], Augkana Saejeng[1], Preecha Prempree[1], Darin Areechokchai[1], Jersuda Kajanasuwan[1], Cheewanan Lertpiriyasuwat[1]

[1]*Bureau of Vector Borne Disease, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand,* [2]*Inform Asia: USAID's Health*

Research Program, RTI International, Bangkok, Thailand, [3]RTI International, Washington, DC, United States, [4]WHO Global Malaria Programme (GMP), Geneva, Switzerland, [5]US President's Malaria Initiative, Regional Development Mission for Asia, United States Agency for International Development, Bangkok, Thailand

Thailand's Bureau of Vector Borne Disease (BVBD), with support from the US President's Malaria Initiative (PMI) and Inform Asia: USAID's Health Research Program, has launched an integrated drug efficacy surveillance (iDES) program to routinely monitor treatment efficacy in low transmission zones. First-line treatment for uncomplicated *Plasmodium falciparum* malaria is dihydroartemisinin-piperaquine fixed-dose combination plus primaquine (DP+P). In 2017, this replaced the artesunate and mefloquine plus primaquine combination treatment (AM+P) that was showing failure. For *P. vivax,* chloroquine plus primaquine (CQ+P) is used. We used Kaplan-Meier survival analysis with modified intent-to-treat analysis to measure crude drug efficacy, with an endpoint at Day 42 for *P. falciparum* and Day 90 for *P. vivax*. Cox multivariate models assessed risk of recurrence. All microscopy confirmed malaria cases treated according to national guidelines between 2013 and 2018 and followed up at least once after treatment were included in the analysis. Among the 29,508 cases included, 13,940 were treated with AM+P, 382 with DP+P, and 15,186 with CQ+P. The mean age was 29 years and 70% were male. Overall crude efficacy for treating *P. falciparum* was 85.4% by Day 42 (95% CI 82.7-87.7), ranging from 78.3% in 2013 to 94.8% in 2018. For *P. vivax,* the crude efficacy was 95.0% by Day 90 (95% CI 94.3-95.6), ranging from 91.0% in 2013 to 96.7% in 2018. Multivariate analysis showed the risk of recurrent infection significantly decreased for both species over time (related to declining transmission in the country), but cases from border provinces such as Sisaket and Tak were at greater risk of recurrent infection. Our analyses showed that iDES can be used as a tool for monitoring antimalarial drug efficacy. By identifying provinces with lower treatment efficacy, iDES provides strategic information for BVBD to better target resources. In the Thai context of malaria elimination, increasing routine next generation sequencing testing on Day 0 for all or a sample of cases is recommended to expand monitoring efforts to include prevalence of common molecular resistance markers.

415

THE EFFECT OF OPTIMIZED SUPPORTIVE SUPERVISION AND DATA USE ON IMPROVED QUALITY OF MALARIA SERVICES IN LIBERIA

Lauretta Nagbe Se[1], George Toe[2], Anne Fiedler[2], Thomas T. Hallie[2], Mantue Reeves[1], Birhanu Getahun[1], Gladys Tetteh[3], Lolade Oseni[1]

[1]*USAID PMI- MCSP Expansion of Malaria Services, Liberia, Sinkor, Monrovia, Liberia,* [2]*USAID PMI- MCSP Expansion of Malaria Services, Sinkor, Monrovia, Liberia,* [3]*Jhpiego Baltimore, Baltimore, MD, United States*

Malaria is the leading cause of health care seeking and of death in Liberia. Malaria prevalence among children under five years in Liberia, based on rapid diagnostic tests (RDTs) was 45% in 2016. The Ministry of Health (MOH) implemented joint supportive supervision and mentoring for health providers to improve the quality of care including malaria performance standards, particularly in rural settings with high malaria burden and limited continuous learning opportunities for providers. In April 2018, the Maternal and Child Survival (MCSP) project started to support the joint supportive supervision and mentoring visits to promote compliance to overall national quality standards at 399 health facilities (HF) in eleven Counties. Mentors and supervisors used on-the-job training/mentoring to improve areas where gaps were identified, reinforced data review and use for program improvement and ensured implementation of recommended remedial actions through follow up in subsequent visits. Information on supportive supervision and mentoring visits was obtained through direct observation and simulation using Ministry of Health revised joint integrated supportive supervision (JISS) tool. At baseline, 85% (100/117) of supported HF had cumulative JISS scores of less than 49% in all the standards, and 60% for malaria performance standards. By September 2018, after five consecutive supportive supervisions and mentoring visits at 95% (111/117) of the HF, the overall JISS scores increased to intermediate level of 70-79%, and by December 2018, all the 117 facilities reached an acceptable level with JISS scores of 80% for overall standards and above, and 85% in malaria performance standards. The ongoing supportive supervision and mentoring visits contributed to measurable improvements in meeting malaria standards and compliance to overall national quality standards. MCSP will share lessons learned in fostering quality improvement through targeted supportive supervision to health care workers to scale up and improve the quality of malaria service delivery by health care workers in rural Liberia.

416

EVALUATION OF THE CONTRIBUTION OF COMMUNITY HEALTH WORKERS (CHWS) IN IMPROVING HEALTH FACILITY ATTENDANCE, PARTICULARLY FOR TIMELY ANC ATTENDANCE AND IPTP SERVICES, IN SIX DISTRICTS IN THE PROVINCIAL HEALTH DELEGATION OF THE EASTERN LOGONE IN CHAD

Naibei Mbaibardoum[1], Ali Baggar[2], Djimodoum Moyreou[1], Noella Umulisa[1], Elana Fiekowsky[1], Kodjo Morgah[1]

[1]*Jhpiego, N'Djaména, Chad,* [2]*Provincial Health Delegation of the Eastern Logone, N'Djaména, Chad*

Malaria infection during pregnancy is a significant public health problem causing substantial risk to pregnant woman, their fetuses, and newborn children. Malaria is a leading cause of morbidity and mortality in Chad, where an estimated 2.2 million cases of malaria occur every year. Children under five and pregnant women are at increased risk. In 2017, Chad national data revealed that malaria represented 36% of outpatient consultations and 30.8% of hospitalization cases. This study evaluated potential client benefits to Community Health Worker (CHW) interaction and referral, including improvements in health facility attendance, timeliness of scheduled antenatal care (ANC) visits and adherence to intermittent preventive treatment in pregnancy (IPTp) services. From February through March 2019, a register review was conducted which included: reporting forms, referral forms and counter-referral forms for the period of January to December 2018 for all 72 CHWs trained by Improving the Quality of Malaria Control Services project funded by ExxonMobil in six districts in the provincial health delegation of Eastern Logone province in Chad. Data collectors recorded monthly total numbers of referred patients collected by CHWs, and compared them with health facility records and counter-referral documents. The data collectors then assessed whether community-level referred malaria cases and ANC visits for pregnant women resulted in treatment seeking behavior among clients receiving these services. In total, 89% of CHW referred patients accessed health centers. Among pregnant women referred for ANC and IPTp services, 77% reached health centers. Among children under five referred, 62% received malaria testing and treatment services at health centers. Of referred patients, 69% reached health centers within 48 hours after CHW referral. Findings of this evaluation show that CHWs could play a significant role in improving health facility attendance, increasing ANC/IPTp compliance and in promoting malaria curative services at health centers in six districts in the provincial health delegation of Eastern Logone, Chad.

417

DN MINI: A MINIATURIZED DOUBLE-NET TRAP FOR EXPOSURE-FREE ASSESSMENT OF INDOOR AND OUTDOOR MOSQUITO BITING RISK

Alex J. Limwagu, Emmanuel W. Kaindoa, Halfan S. Ngowo, Emmanuel E. Hape, Marceline F. Finda, Rukiya M. Njalambaha, Fredros O. Okumu

Ifakara Health Institute, Morogoro, United Republic of Tanzania

Effective malaria surveillance in residual transmission settings require accurate assessment of exposures occurring outdoors relative to indoors. Unfortunately, the best approach currently available requires human

volunteers exposing their legs to catch mosquitoes attempting to bite them (i.e. human landing catches, (HLC)), a procedure that carries significant safety concerns and is cumbersome in large scale operations. We developed and tested a miniaturized double net trap (DN-Mini) to enable exposure free monitoring of indoor and outdoor host-seeking mosquitoes without affecting natural behaviors of those mosquitoes. DN-Mini is easy-to use, scalable, efficient and small enough to be installed both inside and in the peri-domestic spaces. It is made with UV-resistant fiber glass net over four wooden / melted poles and canvas base. Collection of mosquitoes is done by a human volunteer who sits in the middle chamber and collects mosquitoes from the outer chamber without any direct contact with the mosquitoes. Using the DN-Mini, we conducted a series of experiments to sample indoor and outdoor host seeking mosquitoes, test sampling efficacies of different designs of the DN-M-trap and to assess mosquito species diversities, biting pattern, parity and insemination rate. We also compared sampling efficacies of DN-M-trap and HLC. More than twice of the *An. arabiensis* were caught outdoors than indoors (p<0.001) while for *An. funestus,* there was no significance difference in the number of mosquitoes caught between outdoors and indoors (p=0.201). These patterns match previous indoor/outdoor estimates obtained using HLC from the same villages. Catches were higher outdoors than indoors for *Mansonia* (p<0.001) and *Culex* species (p=0.593). Parity was higher outdoors than indoors for *An. arabiensis* but higher outdoors than indoors for *An. funestus.* We conclude that DN-Mini has potential to transform unsafe into a safe and scalable platform mosquito surveillance platform in malaria endemic countries, and could be effectively used for measuring indoor versus outdoor exposures

418

COMPARISON OF *IMMEDIATE EX VIVO* VERSUS *IN VITRO* CULTURE ADAPTATION GROWTH INHIBITION ASSAYS FOR TESTING ANTIMALARIAL DRUG SUSCEPTIBILITY IN FIELD ISOLATES

Agnes Cheruiyot, Hosea Akala, Redempta Yeda, Charles Okudo, Edwin Mwakio, Jackline Juma, Raphael Okoth, Benjamin Opot, Dennis Juma, Ben Andagalu, Jim Ray Managbanag

U.S. Army Medical Research Directorate-Kenya, Kisumu, Kenya

Antimalarial resistance is a major obstacle in elimination of malaria, thus necessitates need for continued surveillance. Growth inhibition testing of fresh isolates as *"immediate ex-vivo"* is increasingly being embraced as it guides treatment management of malaria infections whereas "*in vitro"* culture is further adaptation of isolates to *in vitro* conditions. As part of continued validation of this assay relative to *in vitro* assay, it is important to compare performance of antimalarial drugs in field isolates. 24 samples were collected under an ongoing epidemiology of malaria and sensitivity patterns in Kenya. Isolates were dispensed onto pre-dosed drug plates and incubated for 72 hours. Aliquot of sample was maintained in culture prior to testing against 16 antimalarials: chloroquine (CQ), quinine (QN), atovaquone (AV), primaquine (PQ), doxycycline (DX), artemisinin (AR), halofantrine (HAL), tafenoquine (TQ), dihydroartemisinin (DHA), piperaquine (PPQ), artemether (AT), lumefantrine (LU), amodiaquine (AQ), Artesunic acid (AS), Ether (EA) and mefloquine (MQ). Inhibition curves for immediate ex vivo, parallel to *in vitro* assays, were obtained from the relative fluorescence units using Graph Pad Prism. Antimalarial drugs (13) which had higher median 50% inhibition concentration in immediate *ex vivo* had their median values drop when tested after culture. (AV) had a median value of 0.7121 ng/ml (95% CI 0.4580 to 1.048) in immediate *ex vivo* decreased to 0.1946 ng/ml (95% CI, 0.1111 to 0.3200) in cultured isolates P<0.0001. (DHA) had median value of 2.797 ng/ml (95% CI 0.9972 to 4.082) in immediate *ex vivo* decreased to 0.4491 ng/ml (95% CI, 0.3801 to 0.8553) in cultured isolates P<0.0001. (PPQ) had median value of 9.689 ng/ml (95% CI 4.437 to 15.87) in immediate ex vivo decreased to 3.714 ng/ml (95% CI, 3.292 to 4.996) in cultured isolates P<0.0001. AT, AQ, EA and MQ had P<0.0001. Results showed that there could be a selection in the initial population of *Plasmodium* strains during culture resulting in higher susceptibility. Finding necessitates a strategy to be developed to harmonize both *ex vivo* and *in vitro* methods to yield comparable results.

EUPATHDB.ORG: FREE, ONLINE RESOURCES BRINGING OMICS TO EVERY PARASITOLOGIST

Jessica C. Kissinger[1], Brian Brunk[2], Omar S. Harb[2], Susanne Warrenfeltz[1], David Roos[2], For The EuPathDB Team[1]

[1]*University of Georgia, Athens, GA, United States,* [2]*University of Pennsylvania, Philadelphia, PA, United States*

The Eukaryotic Pathogen Database Resources (EuPathDB, http://eupathdb.org) are a family of 12 taxon-specific, free, online genome and other Omics data mining resources that support over 190 organisms within Amoebazoa, Apicomplexa, Chromerida, Diplomadida, Trichomonadida, Kinetoplastida and numerous phyla of oomycetes and fungi. These resources facilitate the discovery of meaningful biological relationships (hypothesis testing) from large volumes of pre-analyzed Omics data with advanced search capabilities, data visualization and analysis tools. The intuitive graphic interface allows users to take full advantage of the data without the need for programming. Data types range from genome sequence and annotation to transcriptomics, proteomics, epigenomics, metabolomics, population resequencing, clinical data, and host-pathogen interactions. Data are analyzed using standard bioinformatics workflows and in-house analyses generate data including domain predictions and orthology profiles across all genomes, which permit inferences from data-rich organisms to organisms with limited or missing data. EuPathDB offers several perspectives for data mining - record pages compile all data for genes, pathways, etc; a genome browser for visualizing sequence data aligned to a reference genome; a search strategy system that queries pre-analyzed data and returns genes or features with shared biological characteristics; a private Galaxy workspace for analyzing and viewing user data in context with public data already integrated into EuPathDB. These free resources easily merge evidence from diverse data and across species to place the power of bioinformatics with every scientist. Our planned future growth includes a merger with VectorBase, home to genome, Omic and population data for many vector species. Our active user support offers an email help desk, social media, video tutorials and a worldwide program of workshops.

ONDE É O GARIMPO? A MOBILE APPLICATION TO MAP CASES OF MALARIA ON CLANDESTINE GOLD MINING SITES IN FRENCH GUIANA

Yann Lambert[1], Muriel Galindo[1], Louise Mutricy[1], Pierre Joubert[2], Alice Sanna[3], Laure Garancher[4], Antoine Adenis[1], Mathieu Nacher[1], Maylis Douine[1]

[1]*Centre d'Investigation Clinique Antilles-Guyane (Inserm 1424), Cayenne Hospital, Cayenne, French Guiana,* [2]*Parc Amazonien de Guyane, Cayenne, French Guiana,* [3]*Agence Régionale de Santé de Guyane, Cayenne, French Guiana,* [4]*Pan American Health Organization, Barbados Office, Bridgetown, Barbados*

Dealing with malaria in remote areas is today one of the major challenges for the control and elimination of the disease. In French Guiana, South America, the most important reservoir is a population of illegal gold miners living deep in the Amazon forest. These 5,000 to 10,000 men and women mostly originating from Brazil are highly mobile and hard to reach, thus sustaining the diffusion of malaria in the region of the Guyana Shield and preventing the implementation of usual control measures. The Malakit pilot study experiments the distribution of self-diagnosis and self-treatment kits against malaria to gold miners in several rear bases on the borders of French Guiana with Brazil and Suriname. Portuguese-speaking facilitators are trained to interview participants of the study and collect data using Android tablets with the ODK Collect application after training participants how to use a kit. During inclusion and follow-up visits, mapping the

mining sites where participants got infected with malaria is essential but challenging since both participants and facilitators are not familiar with a geographical map of French Guiana. A simple, *ad hoc* Android application was developed with a database of names and coordinates of known gold mining sites and a map of French Guiana displaying the main rivers, villages, cities and main gold mining areas. The name of a mining site can be entered in a search bar while phonetically matching names are listed dynamically and corresponding mining areas are highlighted on the map. In case no matches are found, the new site name is recorded while one or several mining areas can be selected manually according to the explanations given by the participant. Once validated by the facilitator, the data is sent back to the pending ODK Collect survey. At the end of the pilot study, the geographical data collected by Malakit facilitators will be curated and maintained as a reference dataset available for international collaboration in the surveillance and control of malaria in the region of the Guyana Shield. The source code of this application will be available upon request to be adapted to different settings and environments.

421

SYNTHETIC BIOTIN LIGASE ENABLES TO LABEL SURFACE INVASION FACTORS OF CULTURED HUMAN MALARIA PARASITE, *PLASMODIUM FALCIPARUM*

Sayuki Ochiai, Julie Maeda, Makoto Hirai, Toshihiro Mita, Toshiyuki Mori

Juntendo University, Tokyo, Japan

Merozoite, an invasive form of malaria parasites, enters a mature human red blood cell (RBC), where it multiplies asexually. The repetitive rupture of newly-produced merozoites from RBCs causes host inflammatory responses, leading to cyclic fever, characteristic to malaria. Although several invasion factors residing between merozoite and RBC have been reported to date, the merozoite invasion mechanism is still elusive at the molecular level. Of those factors, the merozoite surface protein AMA1 has been known to bind to merozoite-derived RBC surface protein RON2, forming a tight junction between host-parasite membranes for completion of successful invasion. Since elucidating the whole molecular invasion system should contribute to the development of drugs and vaccines against parasite proliferation, we have been trying to detect unidentified factors, using cultured *Plasmodium falciparum*. Recently, a promiscuous protein screening method utilizing proximity-dependent biotin ligases (BioID and BioID2) has been developed. In this study, we prepared a fusion protein composed of RON2, BioID2 and GFP (RBG) as an in-vitro synthesized peptide, and added it to cultured *P. falciparum* to detect proteins surrounding AMA1-RON2 junction. As a result, we succeeded in confirming GFP signal, prevention of merozoite invasion, and biotinylation of proximal invasion factors by the RBG molecules.

422

MACHINE LEARNING IDENTIFICATION OF MALARIA PARASITE CELL DEVELOPMENT AND ANTIMALARIAL DRIVEN PHENOTYPES USING HIGH-THROUGHPUT, HIGH-RESOLUTION FLUORESCENCE IMAGING

George W. Ashdown[1], Michelle Dimon[2], Minjie Fan[2], Fernando S. Teran[1], Katrin Witmer[1], David Gaboriau[1], Jon Hazard[2], Michael D. Ando[2], Jake Baum[1]

[1]*Imperial College London, London, United Kingdom,* [2]*Google Inc., Mountain View, CA, United States*

High-throughput image-based drug screens have the potential to provide details on drug-mediated effect beyond live/dead efficacy and into the realm of characterizing the diversity of compound-dependent phenotypes on the target cells. A key challenge is the unbiased interpretation of complex cell morphology at the population level, determining normal cells versus -potentially- multiple aberrant cellular phenotypes. Here, we apply semi-supervised deep neural network analysis to high-resolution fluorescent images of malaria parasite-infected red blood cells. We demonstrate that this machine learning approach can sequentially sort asexual life-cycle stages from asynchronous *Plasmodium falciparum* parasite cultures with a fine-grain order. Additionally, the technique can successfully separate aberrant, drug-induced changes in cell morphology from mixed populations despite the wide variation seen within untreated populations. Importantly, drug-induced phenotypes showing a similar mechanism of action could be successfully segregated. Applied more broadly, this methodology provides a means to analyse large-scale imaging datasets that can drive the discovery of novel antimalarials and potentially elucidate mechanism of drug action with more sensitivity and much faster than existing methods.

423

GENERATION OF *PLASMODIUM FALCIPARUM* NF135 REPORTER LINES EXPRESSING FLUORESCENT PROTEINS FOR EXAMINING BLOOD-, MOSQUITO- AND LIVER-STAGES

Shinya Miyazaki[1], Annie S.P. Yang[2], Fiona J. A. van Pul[1], Catherin Marin-Mogollon[1], Yukiko Miyazaki[1], Takashi Imai[1], Surendra K. Kolli[1], Jai Ramesar[1], Geert-Jan van Gemert[2], Youri M. van Waardenburg[2], Adrian V. S. Hill[3], Robert W. Sauerwein[2], Chris J. Janse[1], Shahid M. Khan[1]

Malaria parasites expressing fluorescent or luminescent proteins are valuable tools, increasingly used in drug and vaccine screening assays as well as to interrogate parasite gene function. However, only a limited number of *P. falciparum* reporter lines have been generated and characterized in the laboratory gold-standard NF54/3D7 strain from West Africa. Here we describe the generation of different reporter lines, using CRISPR/Cas9 gene modification, in the recently described South East Asian *P. falciparum* NF135 strain. This strain has different drug sensitivities to a number of anti-malarial drugs and has been shown to have an increased ability to invade and develop in liver cells, compared to NF54. We first used NF54 parasites to characterize the strength and temporal expression of different gene promoters, in comparison to the previously described ef1a promoter, to select for promoters of strongly and constitutively expressed genes. We next generated and characterized three reporter lines generated in *P. falciparum* NF135 strain with the green fluorescent protein (GFP) expression driven by two novel and the ef1a promoters. Data will be presented on the genotype characterization of reporter lines as well as the different timing and strength of reporter GFP expression throughout the life cycle including liver-stages in primary human hepatocytes. We show strong differential GFP expression in the reporter lines throughout the complete life cycle. One novel NF135 reporter line showed significantly higher GFP expression in sporozoites and liver stages compared to the control ef1a-GFP reporter line. The strength of reporter expression in combination with the increased infectivity for hepatocytes by NF135 parasites makes this line a valuable novel tool for the analysis of *P. falciparum* liver stage development.

424

COST-EFFECTIVENESS OF A PUSH-PULL SYSTEM COMPRISED OF SPATIAL REPELLENTS AND ODOR-BAITED TRAPS FOR CONTROL OF MALARIA VECTORS

Matt Worges[1], Adrian Denz[2], Margaret Njoroge[3], Ulrike Fillinger[4], Joop van Loon[3], Fredros Okumu[5], Sarah Moore[5], Mgeni Mohamed[5], Adam Saddler[5], Alexandra Hiscox[3], Nakul Chitnis[2], Joshua Yukich[1]

Residual malaria transmission and insecticide resistance are threats against efforts to eliminate malaria using standard vector control interventions; therefore, additional approaches are needed. An entomological study was designed in order to evaluate the impact of a push-pull strategy for vector control implemented under semi-field conditions in Kenya and Tanzania. The system was comprised of a spatial repellent in the form of a transfluthrin-treated eave ribbon (push component) in combination with an outdoor odor-baited trap (pull component). The underlying assumption of the push-pull system is that host-seeking vectors are repelled from their human targets thereby reducing biting rates and subsequently trapped and killed. Cost models were developed for push-pull system component procurement and deployment. Additionally, malaria cases averted were estimated using the OpenMalaria modelling platform parameterized with field trial results. Costs and effectiveness measures were used in a probabilistic sensitivity analysis to estimate uncertainty around expected incremental cost effectiveness ratios under various scenarios (i.e. variable entomological inoculation rates, different dominant Anopheline species, and variable coverage levels for the push-pull system). Efficiency frontiers generally showed that a combination of high spatial repellent coverage and low- to medium-level trap coverage provided the most cost-effective approach across the majority of tested scenarios.

425

EFFICIENT TRANSCRIPTOME PROFILING ACROSS THE MALARIA PARASITE LIFE CYCLE BY FLOW SORTING

Aliou Dia, Catherine Jett, Marina McDew-White, Timothy Anderson, Ian Cheeseman

Texas Biomedical Research Institute, San Antonio, TX, United States

Plasmodium falciparum is the most virulent and widespread of the human malaria species. This parasite has a complex life cycle that involves sexual replication in a mosquito vector and asexual replication in a human host. During the 48-hour intraerythrocytic development cycle (IDC), the parasites develop and multiply through the morphologically distinct ring, trophozoite and schizont stages. The IDC is responsible for all clinical symptoms and has been recognized as an important target for drug and vaccine development making this stage of major interest to malaria investigators. Stage-specific transcriptomic approaches have shown gene expression profiles continually change throughout the IDC. Cultures of tightly synchronized parasites are required to capture the transcriptome specific to a developmental stage. However, the most commonly used synchronization methods require lysis of late stages, potentially perturbing transcription, and often do not result in tightly synchronized cultures. As a synchronous culture requires frequent sampling over a 48-hour period, producing complete transcriptome profiles of the IDC is both time consuming and labor intensive. Here we developed a method to sample the IDC densely by isolating parasites from an asynchronous culture with fluorescence activated cell sorting. We sort parasites in tight windows of IDC progression based on their DNA/RNA abundance. We confirmed the tight synchronization and stage specificity by light microscopy and RNAseq profiling. We optimized our protocol for low numbers of sorted cells allowing us to rapidly capture transcriptome profiles across the entire IDC from a single culture flask. We extend this approach to single cell transcriptomics to assay cell-to-cell variation throughout the life cycle. This methodology will allow any malaria stage-specific study to perform experiments directly from asynchronous cultures with high accuracy and without the need for labor-intensive time-course experiments.

NEW APPROACHES FOR THE REMOTE ELECTRONIC DETECTION OF INSECTICIDE TREATED BEDNET USERS

Paul Joseph Krezanoski

University of California San Francisco, San Francisco, CA, United States

Long-lasting insecticide treated bednets (LLINs) have played a large role in improvements in malaria control. However, recent reports suggest that progress is slowing and there are concerns that LLINs may not be as effective as previously. As a result, there is growing interest in maximizing the value of prevention funds by improving our understanding of LLIN effectiveness. Fundamentally, adequate LLIN use comprises two necessary behaviors: 1) unfurling an LLIN and 2) locating one's self under the unfurled LLIN during potential exposure. Existing tools can detect, with high accuracy and over long periods of time, the unfurling of LLINs; multiple studies utilizing these technologies have been published in recent years. Much more challenging, however, is the remote detection of whether one or more individuals is under an unfurled LLIN and identifying that individual. To achieve this goal, our lab has experimented with various sensor modalities (temperature, humidity, accelerometers, etc.). Furthermore, our prototype uses an open platform and consists of existing technologies for detection of LLIN unfurling plus a variety of sensors for detecting who is under an LLIN. We present data suggesting that our approach can solve the first problem of whether an individual is under an unfurled LLIN with high specificity. We also present promising data suggesting that discriminating between one or more individuals, and whether the individuals are children versus adults for example, should be possible by combining available sensors and utilizing machine learning techniques. The ideal remote LLIN adherence monitoring tool is low-cost, inconspicuous (limiting Hawthorne effects), has low power consumption and is robust to environmental conditions faced by a typical LLIN, including periodic washing. We propose using platforms such as ours to determine the optimal combination of sensors to achieve accurate remote LLIN adherence monitoring with the lowest cost and longest battery life. We believe these tools can contribute to re-igniting progress towards malaria elimination by providing researchers the tools for making LLINs as effective as possible.

MICROSCALE MAGNETIC LEVITATION FOR MULTIPLEXED ANALYSIS OF MALARIA-INFECTED BLOOD SAMPLES IN RESOURCE-LIMITED SETTINGS

Shreya S. Deshmukh[1], Naside Gozde Durmus[1], Bryan Greenhouse[2], Elizabeth Egan[1], Utkan Demirci[1]

[1]*Stanford University, Stanford, CA, United States,* [2]*University of California San Francisco, San Francisco, CA, United States*

Malaria, which infects over 200 million and kills close to 400,000 people annually, largely affects low- and middle-income countries. Here, accessible and affordable diagnostic devices are critical for effective treatment and surveillance. Antimalarial resistance adds further pressure to *Plasmodium falciparum* elimination, with an emerging artemisinin resistance crisis in Southeast Asia. There is an urgent need to contain this before it spreads to Africa, as chloroquine did in the 1980s, to devastating effect. This problem is exacerbated by the lack of point-of-care tools to rapidly measure patient-specific response to anti-malarial drugs: neither blood smear microscopy, nor antibody-based rapid diagnostic tests, can measure drug resistance. Therefore, there is a significant unmet need for a field-appropriate tool (inexpensive, rapid, operable without laboratory infrastructure or specialised training) to detect and quantify *Plasmodium* infection in blood, for sensitive, specific diagnosis as well as rapid drug response monitoring. We demonstrate an innovative magnetic levitation platform that precisely measures subtle differences in cell levitation heights as inherent biomarkers for magnetic susceptibility and density signatures. *Plasmodium* infection changes these blood cell properties, primarily through haemoglobin digestion, which we can sensitively measure as levitation height changes at single cell resolution. With this, we show

biophysical separation of ring-stage parasites, the earliest stage and the only one found in patient circulation, for the first time. We also observe that drug treatment causes physical changes in the parasites, translating to levitation height changes. This allows us to phenotypically measure drug response in real time, which we are developing to rapidly differentiate drug-resistant from drug-susceptible parasites. This platform is a portable, smartphone-interfaced device that uses less than a drop of blood (<10 μL) without refrigeration or electricity. We envision that this would equip healthcare workers' changing needs with more data-rich, contextually appropriate tools.

428

A NEW NON-HUMAN PRIMATE MODEL FOR TESTING HUMAN MALARIA VACCINE EFFICACY

Melanie J. Shears[1], Chaitra Parthiban[1], Brad C. Stone[1], B. Kim Lee Sim[2], Stephen L. Hoffman[2], Robert A. Seder[3], Sean C. Murphy[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Sanaria, Inc., Rockville, MD, United States,* [3]*Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States*

Rhesus macaques are considered the best model of the human immune system, but were previously excluded from human malaria vaccine efficacy testing because they do not support *Plasmodium falciparum* blood stage infection. Using clinical-grade 18S rRNA RT-PCR, we previously demonstrated that *P. falciparum* can robustly develop in the liver of fully immunocompetent rhesus. This discovery suggested that liver stage parasite burden could be used to evaluate vaccine efficacy in rhesus and provide a highly relevant endpoint for testing *P. falciparum* liver stage vaccines. This platform would also allow the reduction or elimination of liver stage parasite burden to be correlated with liver-specific immunological responses in the same animals. This model therefore has potential to provide translationally-relevant data and give mechanistic insight into vaccine efficacy that is currently inaccessible in other systems. In this study, we present preliminary data evaluating rhesus as a platform for testing *P. falciparum* liver stage vaccine efficacy and exploring tissue-specific immunological responses. We assess the safety, tolerability and efficacy of a two-step prime-and-trap vaccine composed of a priming DNA vaccine encoding three known malaria antigens followed by a single intravenous trapping dose of PfSPZ cryopreserved, radiation-attenuated sporozoites. This vaccine strategy was previously demonstrated to induce liver resident memory T cells and elicit long-lasting sterile protection in mice. As controls, we compare to mock-immunized animals and those given three doses of radiation-attenuated sporozoites – a regimen known to protect mice, non-human primates, and humans. We give particular focus to the relationship between vaccine efficacy and the magnitude of antigen-specific T cell responses in the rhesus liver. These data provide the first demonstration of this platform for testing the efficacy of vaccines prior to use in humans, and give key insight into how rhesus may be further used to accelerate malaria vaccine development.

429

THE EFFECT OF THE RTS,S/AS01E VACCINE FOURTH DOSE ON CELL MEDIATED IMMUNE RESPONSES TO CSP AND HBSAG ANTIGENS IN AFRICAN CHILDREN

Chenjerai Jairoce[1], Robert A. Mitchell[2], Ruth Aguilar[2], Akshayata Naidu[2], Ana Chopo[2], Maxmillian Mpina[3], Matthew B.B. McCall[4], Miquel Vázquez-Santiago[2], Gemma Ruiz-Olalla[2], Núria Díez-Padrisa[2], Nana A. Williams[2], Joseph J. Campo[2], Pedro Aide[1], Benjamin Mordmüller[4], Selidji T. Agnandji[5], Claudia Daubenberger[6], Gemma Moncunill[2], Carlota Dobaño[2]

[1]*Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique,* [2]*ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain,* [3]*Ifakara Health Institute. Bagamoyo Research and Training Centre, Bagamoyo, United Republic of Tanzania,* [4]*Institute of Tropical Medicine, German Center for Infection Research, University of Tübingen, Tübingen, Germany,* [5]*Centre de Recherches Médicales de Lambaréné (CERMEL), Albert Schweitzer Hospital, Lambaréné, Ghana,* [6]*Swiss Tropical and Public Health Institute, Basel, Switzerland*

RTS,S/AS01 is the most advanced malaria vaccine worldwide, conferring moderate protection of limited duration in African children. However, the immunogenicity of the vaccine has not been characterized in detail, and its mode of action is not known. The magnitude, quality, and type of antibody responses are thought to be the major correlates. Cell-mediated immune responses to CSP are also involved in RTS,S-induced immune mechanisms against *Plasmodium falciparum* malaria but their role remains inconclusive. We have previously investigated cellular immune responses following the primary 3-dose immunization and found that T helper (T_H)2 cytokines, particularly IL-5, correlated with lack of vaccine efficacy, while T_H1 cytokines, particularly IFN-γ, correlated with malaria protective immunity. As part of the multicenter phase 3 trial, a fourth dose was administered in one of the study groups to increase the longevity of the RTS,S efficacy. The present study aimed to evaluate the cellular immune responses from infants and children in supernatants following ex vivo stimulation of blood cell samples with vaccine CSP and HBsAg antigens using the Luminex technology. We will present cytokine and chemokine antigen-specific data associated with the immunological benefit of the booster dose of RTS,S vaccine and their kinetics. Data will be evaluated in relation to age, clinical malaria, baseline and peak responses, as well as the type and magnitude of antibody responses to the booster dose measured in parallel projects. We observed a positive correlation between the concentrations of IL-2 with IgG concentrations and avidity (R^2=0.53-0.89, $p < 0.001$) at peak response, suggesting the supportive role of IL-2 on the quality of the antibodies response. We expect that the overall levels of cytokines, particular those promoting memory T_H1 responses, will be higher in the booster group, as a result of higher frequency to antigen stimulation and quick response of memory T-cell subpopulations. Elucidation of protective $CD4^+$ T helper memory responses and their mediators is essential to design second-generation longer-lasting effective malaria vaccines.

430

GENETIC DIVERSITY, NATURAL SELECTION AND HAPLOTYPE GROUPING OF *PLASMODIUM VIVAX* VACCINE CANDIDATE, DUFFY BINDING PROTEIN OF CHINA-MYANMAR BORDER AND WESTERN MYANMAR ISOLATES

Yubing Hu

China Medical University, Shenyang, China

Border area with Myanmar is the major *Plasmodium vivax* endemic regions in China. To evaluate the genetic diversity of *pvdbp*-IIgene in isolates from the China-Myanmar border (CM) and Western Myanmar (WM), and compared it with global *P. vivax* populations, a total of 85 and 82 *pvdbp*-IIsequences from CM and WM were used, respectively. The highest peaks of nucleotide diversity were identified between 1078-1332 bp for CM and WM isolates. An annotated R391C mutation was unique to WM isolates. Evidence of positive selection was detected by Fu and Li's *F** test and Tajima's *D*test of *pvdbp*-IIgene from CM isolates ($P<0.05$). A slight genetic differentiation was detected among CM, WM, Central Myanmar, and Thailand population. Clustering analysis grouped the accessions from these four populations into three genetic groups and indicated a high degree of mixed ancestry. High levels of nucleotide diversity were found in epitopes 45 (ϖ=0.029) and Ia (ϖ=0.028) of PvDBP-IIfrom CM and WM isolates. These results will be useful for understanding the nature of the *P. vivax* population in GMS area and for development of PvDBP-II-based vaccine.

431

NATURALLY ACQUIRED TRANSMISSION-BLOCKING ANTIBODIES AGAINST *PLASMODIUM VIVAX*

Sataporn Thongpoon[1], Wanlapa Roobsoong[1], Sadudee Chotirat[1], Takafumi Tsuboi[2], Eizo Takashima[2], Liwang Cui[3], Tomoko Ishino[2], Mayumi Tachibana[2], Jetsumon Sattabongkot[1]

[1]*Mahidol University, Bangkok, Thailand,* [2]*Ehime University, Matsuyama, Japan,* [3]*University of South Florida, Tampa, FL, United States*

Plasmodium vivax is the human malaria species responsible for the majority of cases and widely dispersed in sub-tropical region including South East Asia. Thailand and main countries in GMS region have planned to eliminate malaria by 2030. Transmission-blocking vaccine (TBV) is established for transmission prevention by blocking the development of parasites inside the mosquitoes and has been proposed as a potential tool to eliminate malaria. Transmission-blocking immunity (TBI) can be induced after episodes of malaria. This study aimed to identify and characterize the naturally acquired TBI in malaria endemic population. Transmission-blocking immunity in individuals were identified by feeding their infected blood to *Anopheles dirus* mosquitoes using membrane feeding assay. Patients' blood was prepared in three different conditions (1) whole blood, (2) replace patients 'plasma with AB naïve serum, and (3) immunoglobulins (Ig)-depleted autologous plasma mixed with infected blood. Mosquitoes were examined for oocysts of the parasites on 7-9 days post-feeding. Total 47 *P. vivax* patients' blood were used and 39 of them infected the mosquitoes. Among these cases 25 individuals showed transmission blocking activities which reduced from 10%-100% of the oocyst formation when compared to the feeds that replace patients' plasma with AB naïve serum. Plasma with blocking activity were tested against 1-5 heterologous *P. vivax* isolates. The blocking activity against heterologous isolates were identified in 20 out of 25 plasma samples, although the blocking activity was not always the same as against the autologous isolates. Plasma with blocking activity reacted to gametocyte antigens examined by IFA. These plasma were also tested against *P. vivax* protein library produced by wheat germ cell-free system to screen for the target antigens using AlphaScreen technology. Potential target antigens examined by AlphaScreen will be presented. This study has identified the target antigens that induce naturally acquired TBI against *P. vivax* in population at risk. Further study to characterize these antigens as new candidates for TBV will be performed.

432

CAUSES OF SCREENING FAILURE DURING EXPERIMENTAL VACCINE TRIALS IN A MALARIA VACCINE TESTING SITES OF BURKINA FASO

Alphonse Ouedraogo[1], Daouda Ouattara[1], Maurice Ouattara[1], Moise Kabore[1], Sam Coulibaly[1], Aissata Barry[1], Aissata Barry[1], Desire W. Kargougou[1], Noely Henry[1], Issa Nebie[1], Alfred B. Tiono[1], Sodiomon B. Sirima[2]

[1]*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso,* [2]*Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso*

A safe and effective vaccine is a necessary tool to improve disease control. During early clinical development phase of vaccines, volunteers with non-inclusion criteria are excluded from participating to the trials due to safety concerns and the need to minimize any interference with the outcomes measures. This study aimed to assess screening failure patients' profiles and the reasons in the context of vaccines study sites characterization. All patients screened at the research clinics of Saponé (rural area, 35 km south east of Ouagadougou) and Banfora (suburban area, 500 km south of Ouagadougou) from 2016 to 2017 were reviewed retrospectively. Clinical and laboratory assessments were undergone to evaluate the frequency of different diseases. Among 468 subjects, 191 (40.8%) were screening failure cases; 31.2% (75/240) from suburban area and 50.8% (116/228) from rural area (p<0.000). Proportion of female screen failure was 48% (36/75) vs 51.7% (60/116) at suburban and rural area respectively. The most common causes of screening failure were due to abnormal laboratory value 37.2% (71/191), the infection of viruses 24.6% (47/191) and withdrawal of consent before the enrollment 9.9% (19/191). The main abnormal laboratory values were anemia (17.3%), elevated creatinine (16.7%) and liver disorder. The different viruses were hepatitis B (12.57%), HIV (7.85%) and hepatitis C (4.19%). The others reasons of screening failure were generally sick, heart diseases, pregnancy and refuse to use any contraception method during the study period. Sickle cell trait carriage was associated to other diseases in 6.28% of cases. In term of causes of screening failure, there were no difference according to the study area. The results are consistent with the country's reports in general population in semi urban and rural area. The eligibility rate is relatively low. These findings should be considered when planning for vaccine trials in our context.

433

THE 'ACUTE CHALLENGE' MODEL: SENSITIVE MODERATE-THROUGHPUT ASSESSMENT OF MALARIA T CELL VACCINE ANTIGENS IN MICE

Irene Cruz Talavera, Brad C. Stone, Sean C. Murphy

University of Washington, Seattle, WA, United States

Identification of novel protective *Plasmodium* antigens is thought to be crucial for developing a vaccine that can induce a broad immune response and attain durable protection against this intracellular parasite. Pre-erythrocytic vaccine development for *Plasmodium falciparum* is faced with the complex problem of selecting genuinely protective T cell antigens out thousands of candidates. There are no proven methods for efficiently testing and selecting protective antigens *in vivo*. Furthermore, there are many antigens that are highly immunogenic but ultimately non-protective. To define protective antigens, we developed an "Acute Challenge" model that rapidly and sensitively detects protective T cell responses. In this model, multiple DNA vaccines targeting individual *Plasmodium yoelii* antigens are built in parallel using codon-optimized, 500 bp synthetic fragments. DNA vaccines are delivered twice by gene gun to induce $CD8^+$ T cell responses in BALB/c mice. At the peak of the boosted immune response, we challenge the mice with $2\text{-}5x10^4$ wild-type luciferase-expressing *P. yoelii* sporozoites and measure parasite burden using IVIS imaging 40-44 hours later. The Acute Challenge model gives rapid and sensitive results and allows for moderate throughput (35 days from priming to liver burden endpoint). Our focus is to assess *P. yoelii* candidate antigens of unknown protective potential that are known or putatively involved in hepatocyte invasion or exported from the parasitophorous vacuole into the host cell cytoplasm. Protective antigens are also assessed for their intracellular localization. Data from multiple Acute Challenge screens will be presented. This protection-forward approach contrasts with prior efforts at immunogenicity screening that have often led to identification of immunogenic but non-protective T cell responses. Using the Acute Challenge strategy, we expect to be able to identify protective $CD8^+$ T cells targeting liver-stage antigens that are processed and presented by infected hepatocytes.

One of the biggest hurdles in developing a blood-stage vaccine is that malaria parasites have developed exceedingly effective mechanisms to circumvent otherwise lethal immune responses, particularly to blood-stage antigens. Blood-stage vaccine development is also compounded by antigen complexity, making recombinant expression and correct folding more difficult. In order to circumvent some of these issues and target critical epitopes of multiple antigens, an epitope-based blood-stage vaccine discovery project was initiated. This project focused on blood-stage antigens: RH5, RIPR, CyRPA, P113, EBA175 and AMA1. We began by selecting blood-stage monoclonal antibodies (mAbs) with high Growth Inhibition Activity (GIA). These mAbs were used for screening and identification of their epitope / mimotope sequences. Several mAbs selected multiple sequence motifs and exemplar epitope sequences were chosen for mouse immunization trials. Forty nine virus-like particles (VLPs) displaying exemplar epitopes were produced and used in mouse immunization trials. Ten of these VLPs elicited antisera that recognized the native antigen by ELISA. The IgG was purified from these ELISA-positive sera and tested in the GIA assay; however, none of these IgG showed sufficiently high levels of inhibition in the GIA assay to warrant moving them into confirmatory assessment. Several lessons learned through this effort will be highlighted including polyspecificity of mAbs, quality of immune response, and the need to employ adjuvants appropriate for human-use, even in preliminary vaccine evaluations. We will also present data on new mAbs targeting RIPR and P113 that were developed as part of this project.

435

FUNCTIONAL CHARACTERIZATION OF A POTENTIAL BLOOD-STAGE MALARIA VACCINE CANDIDATE.

Ojo-ajogu Akuh, Philip Ilani, Grace Opoku, Gordon A. Awandare, Emmanuel Amlabu

West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana

The search for a potent malaria vaccine continues in the face of various challenges. The completion of the genome sequence for *Plasmodium falciparum* has simplified the identification of invasion-related proteins that could be promising targets of protective immunity. We have conducted data-mining analysis for over 3,500 proteins using existing reports on the parasite transcriptome, proteome and predicted substrates for *P. falciparum* subtilisin like protease-1 (PfSUB1). Eighteen (18) top hits emerged from these analyses and most of them were already characterized blood-stage malaria vaccine candidates and a hypothetical protein. The sequence of the hypothetical protein was submitted to several bio-informatics portals and the results show that the protein possesses the structural characteristics of a potential vaccine target during merozoite invasion. We observed by immunofluorescence assays that the protein is localized on the parasite surface. Time-course imaging analysis from initial attachment to internalization shows that a portion of the protein is internalized post-invasion along with $MSP1_{19}$. Invasion inhibition assays showed that antibodies against the protein inhibits erythrocyte invasion of both laboratory strains and clinical isolates. Also, the data obtained from proteolytic processing assays, merozoite invasion inhibition assays and schizont arrest assays presents new insights on the possible mechanism of erythrocyte invasion inhibition by the target antibodies.

CYSTEINE MOTIF 1 DOMAIN IN PFS230 MOLECULE IS CRUCIAL TO MAINTAIN THE CORRECT CONFORMATION OF PFS230-BASED TRANSMISSION-BLOCKING VACCINES

Kazutoyo Miura[1], Mayumi Tachibana[2], Eizo Takashima[3], Masayuki Morita[3], Hikaru Nagaoka[3], Thao P. Phama[1], Carole A. Long[1], C. Richter King[4], Motomi Torii[2], Tomoko Ishino[2], Takafumi Tsuboi[3]

[1]*Laboratory of Malaria and Vector Research/National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States, [2]Division of Molecular Parasitology, Proteo-Science Center, Ehime University, Toon, Japan, [3]Division of Malaria Research, Proteo-Science Center, Ehime University, Matsuyama, Japan, [4]PATH's Malaria Vaccine Initiative, Washington, DC, United States*

Pfs230 is a leading transmission-blocking vaccine (TBV) candidate against *Plasmodium falciparum,* but the size and cysteine-rich nature make it difficult to express the entire Pfs230 molecule as a TBV. However, the locations of the transmission-reducing (TR) epitopes, i.e., the epitopes recognized by the functional antibodies, have not been investigated systematically. In the previous study, we produced a total of 27 proteins (either single-, 2-, or 4-CM (cysteine motif)-domain), which covered the entire Pfs230 molecule, using a wheat germ cell-free expression system, and determined the biological activity of antibodies by standard membrane-feeding assay (SMFA). The antibodies against all five proteins containing amino acid (aa) 543-730 region (a part of prodomain plus CM domain 1, called "pCM1") displayed strong inhibition in SMFA, while antibodies against constructs without pCM1 showed no inhibition. It remained an open question whether (1) all TR epitopes exist within pCM1, or (2) pCM1 supports correct folding of other domains. In this study, we further investigated the four SMFA-active antibodies; antibodies to aa 443-730 ("PCM1"), 443-904 ("PCM1-2"), 443-1132 ("PCM1-3") and 443-1274 ("PCM1-4") proteins. Each of the original antibodies was separated into anti-pCM1-specific and non-pCM1 antibodies using a pCM1-affinity column. All four anti-pCM1-specific antibodies showed significant inhibition in SMFA, but anti-pCM1-specific IgG from anti-PCM1-4 IgG showed a weaker inhibition. The result suggested that the conformation of pCM1 in the four Pfs230 constructs might not be the same. All four non-pCM1 antibodies showed weaker than the original total IgGs, but significant inhibition (>48% inhibition, $p<0.03$ for all). On the other hand, the antibodies against Pfs230 constructs containing CM2, 3 or 4, but not pCM1, did not show any activity in SMFA. Taken together, it is speculated that there are TR epitopes within aa 443-542 and 731-1274 regions, but it is crucial to include the pCM1 of Pfs230 to maintain the correct conformation of the TR epitopes in the recombinant proteins.

Science, Technology and Medicine, London, United Kingdom, [5]Mahidol Vivax Research Unit (MVRU), Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

Plasmodium vivax, one of the five *Plasmodium* species to cause human malaria, is the most widespread geographically. Although viewed for many decades as a "benign" parasite, current estimates suggest *P. vivax* accounts for 7.5 million cases each year, among 2.5 billion people living at risk of infection, with a significant burden of morbidity and associated mortality. However, efforts to develop interventions against this parasite lag far behind those for its cousin, *P. falciparum*, in large part because of critical bottlenecks in the vaccine development process. A key problem is limited access to *P.vivax* parasite inocula for use in a controlled human malaria infection (CHMI) model to provide an early indication of vaccine efficacy. To date, only groups in Colombia and the United States have routinely performed sporozoite challenges in human volunteers and the only blood-stage challenges have been performed in Australia. In 2018/19, we undertook the first proof-of-concept studies in Europe of *P. vivax* CHMI (ClinicalTrials.gov Identifiers: NCT03377296 and NCT03797989), demonstrating that we could safely infect two healthy UK adult volunteers with *P. vivax* by the bite of infected mosquitoes transported from southern Thailand. We obtained 250mL of blood from the volunteers at threshold parasitaemia/clinical criteria, and generated a viable, sterile GMP-like bank of cryopreserved *P. vivax*-infected erythrocytes for use in blood-stage CHMI studies. We tested the safety and feasiblity of blood-stage infection at three different dilutions of the inoculum in six malaria-naive volunteers. Infectivity was robust, with even a 1:20 dilution resulting in blood-stage infection. All volunteers were diagnosed within 12-16 days of infection and all had detectable gametocytaemia by qPCR within 1-3 days of peak parasitaemia. This successful model provides a platform for progression of *P. vivax* vaccine candidates to Phase I/IIa efficacy testing. We will also report on a pilot efficacy trial of the high priority blood-stage vaccine candidate *P. vivax* Duffy Binding Protein (ChAd63-MVA PvDBP_RII), scheduled to be undertaken in Oxford in September 2019.

438

EPITOPE-BASED SIEVE ANALYSIS OF *PLASMODIUM FALCIPARUM* SEQUENCES TO ASSESS FMP2.1/AS02$_A$ IS CONSISTENT WITH DIFFERENTIAL VACCINE EFFICACY AGAINST IMMUNOLOGICALLY RELEVANT AMA1 VARIANTS

Amed M. Ouattara[1], Amadou Niangaly[2], Matthew Adams[1], Drissa Coulibaly[2], Abdoulaye K. Kone[2], Karim Traore[2], Matthew B. Laurens[1], Youssouf Tolo[2], Bourema Kouriba[2], Dapa A. Highly polymorphic candidate malaria vaccine antigens can induce allele- or strain-specific immunity in response to monovalent vaccines, limiting vaccine efficacy in the field. To prevent premature elimination of promising vaccine programs, it is critical to determine if lack of efficacy in the field is due strain specific-efficacy, rather than to the lack of immunogenicity of the candidate antigen. Here we use samples collected during a field trial of the AMA1-based FMP2.1/AS02$_A$ malaria vaccine, which incorporates the AMA1 variant encoded by the reference *Plasmodium falciparum* 3D7 strain, to assess the usefulness of epitope-based sieve analysis for the detection of vaccine-induced allele-specific immune responses. The samples used are from volunteers who received the malaria vaccine FMP2.1/AS02$_A$ or a control (rabies vaccine), during a vaccine efficacy field trial, and who later developed malaria. Samples were collected during the first six months of follow-up, starting 15 days after the last immunization. In a previous study, *P. falciparum* DNA was extracted from all samples, and the *ama1* locus amplified and sequenced. Here, a sieve analysis was used to measure T and B-cell escape, and difference in 3D7-like epitopes in the two treatment arms. Overall, no difference was observed in mean amino acid distance to the 3D7 AMA1 variant between sequences from vaccinees and controls in B-cell epitopes. However, we found a significantly greater proportion of 3D7-like T-cell epitope that maps to the AMA1 cluster one loop (c1L) region in the control *vs*. the vaccinee group (p=0.02). In addition, AMA1 3D7-type epitopes in infections from vaccinees had mean estimated binding affinity higher than epitopes generated from the control group (p=0.01). These findings are consistent with a well-established vaccine-derived sieve effect on the c1L region of AMA1, and suggest that sieve analyses of malaria vaccine trial samples targeted to epitopes identified *in silico* can help identify protective malaria antigens that may be efficacious if combined in a multivalent vaccine.

Nearly half of the world population is at the risk of malaria. *Plasmodium* parasite, the causative agent of malaria, requires a vertebrate host and an arthropod vector to complete its life cycle and therefore an effective malaria vaccine should control both the infection and the transmission stages. In the mosquito gut and the human liver, *Plasmodium* traverses several cell types before it commits to the intracellular development. Cell traversal protein for ookinete and sporozoites (CelTOS) is an essential *Plasmodium* traversal protein and a potential malaria antigen. We recently solved the structure of *Plasmodium vivax* CelTOS and showed that it forms pore in the host cell membrane. However, the mechanism of CelTOS mediated pore formation is poorly understood. To determine the role of different CelTOS domains in pore formation, we performed structure-function analyses, accelerated molecular dynamics and membrane pore-forming assays. CelTOS is secreted as a soluble protein and we hypothesized that soluble CelTOS must undergo significant conformational changes to form a pore in lipid membranes. To test this hypothesis, we engineered disulfide bridges in CelTOS to prevent conformational flexibility and showed that the disulfide-locked CelTOS lost pore-forming activity compared to wild-type protein. Additional single point mutations to limit CelTOS flexibility also reduced pore-formation. We truncated distinct domains of CelTOS and observed loss of activity for a majority of mutants. Strikingly, one mutant resulted in a significant 2.5-fold gain in activity suggested CelTOS contains regulatory regions that negatively impact function. These results demonstrate that CelTOS must undergo highly regulated conformational changes to incorporate into cell membranes. These studies form the foundation for structural vaccinology of CelTOS.

In December 2018, the Health Ministers of The Gambia and Senegal put into place the Senegal-Gambia Malaria Elimination Initiative in recognition that scaling up evidence-based practices and aligning interventions was necessary to speed up progress in the high transmission cross-border region. This year, the National Malaria Control Programs (NMCPs) of Senegal and The Gambia are joining forces in the first known cooperative effort by two governments to synchronize mass bednet distribution campaigns on both sides of an international border. Mass distribution campaigns, providing an average of one net to every two people in all households nationwide, are critical for reducing mortality and malaria illness in affected areas. The NMCPs have successfully aligned the timing of their mass distribution campaigns to deliver nearly 10 million bed nets in Senegal, and another 1 million in The Gambia, between March and July 2019. This required considerable efforts, including moving The Gambia's regularly scheduled campaign one year earlier to align with Senegal's. Both countries had to align the timing of the campaign activities of household registration and distribution, ensure that similar net types were being provided, and map the massive cross-border area, defined as the entire 749 km land boundary of The Gambia, extending 2-5km into both sides of the border. The Global Fund and U.S. President's Malaria Initiative collaborated closely to support the joint planning coordination, implementation and monitoring. Geospatial mapping of health facilities, settlements and geographical landmarks along this cross-border area identified over 30 settlements with difficult access for which the neighboring country could assist to improve coverage as well as efficiency. In addition to setting a common goal and political will of neighbor countries, effective collaboration across multilateral and bilateral donors is important to optimize financial and technical resources. Further, the lessons learned from this joint campaign will help other countries that could benefit from similar cross-border malaria control initiatives.

441

INSECTICIDE RESISTANCE IN INDOOR AND OUTDOOR-RESTING *ANOPHELES GAMBIAE S.L.* IN NORTHERN GHANA

Majidah B. Hamid-Adiamoh[1], Davis Nwakanma[2], Umberto D'Alessandro[2], Alfred Amambua-Ngwa[2], Yaw Afrane[1]

[1]*West African Centre for Cell Biology of Infectious Pathogens (WACCBIP), Accra, Ghana,* [2]*Medical Research Council Unit at London School of Hygiene & Tropical Medicine, Banjul, Gambia*

Selection pressure from continued exposure to insecticides seems to drive resistance and changes in behavior of malaria vectors. We examined the association between insecticide resistance and concurrent indoor and outdoor resting behavior within members of An. gambiae s.l. in Northern Ghana. Live adult mosquitoes were collected indoors and outdoors from two communities. F1 progenies were reared from a subset of fed mosquitoes and exposed to dichloro diphenyl trichloroethane (DDT), deltamethrin, malathion and bendiocarb using WHO insecticide susceptibility tests to determine phenotypic resistance. The specific mutations to the four insecticides were analyzed using molecular assays. A statistically significant difference was observed in susceptibility to DDT and deltamethrin between indoor and outdoor mosquito populations with a 24-hour post-exposure mortality of 0% (indoor) and 9% (outdoor) for DDT; 5% (indoor) and 2.5% (outdoor) for deltamethrin [DDT: X2 = 7.58, P =0.006. Deltamethrin: X2 = 5.44, P=0.02]. Mosquitoes were found with suspected resistance to bendiocarb but the difference in mortality between indoor (90%) and outdoor (95%) populations was not significant (X2 = 2.02, df=1, P =0.16). However, mosquitoes were fully susceptible to malathion: 100% (indoor) and 98% (outdoor) mortality. Acetylcholinesterase (Ace)1-119S mutation is associated with more than two times higher odds of resistance to bendiocarb (OR =2.22, P= 0.29). Frequencies of voltage-gated sodium channel (Vgsc)-1014F and Vgsc-1575Y mutations were significantly higher in DDT and deltamethrin-resistant outdoor mosquitoes than the indoor population [Frequencies: 0.54-0.63 (indoor) and 0.66-0.68 (outdoor); X2 = 7.09, p =0.008]. However, glutathione-s-transferase epsilon 2 (GSTe2)-114T was more significantly abundant in indoor deltamethrin-resistant mosquitoes (frequency= 0.59) than the outdoor mosquitoes (frequency =0.08) [X2= 8.06, P = 0.01]. Vgsc-1014F associated strongly with deltamethrin resistance (OR =5.46, P= 0.001). Continued monitoring of vector behavior with evaluation of intra-species behavioral variations is recommended.

442

IMPACT OF INDOOR RESIDUAL SPRAY PROGRAM ON THE PREVALENCE OF *PLASMODIUM* INFECTIONS AND ANEMIA IN WESTERN KENYA: AN OPEN COHORT STUDY

Collince J. Omondi[1], Harrysone Atieli[2], David Odongo[1], Andrew K. Githeko[3], James W. Kazura[4], Guiyun Yan[5]

[1]*University of Nairobi, Nairobi, Kenya,* [2]*Maseno University, Kisumu, Kenya,* [3]*Kenya Medical Research Institute, Kisumu, Kenya,* [4]*Case Western Reserve University, Cleveland, OH, United States,* [5]*University of California, Irvine, CA, United States*

Kenya relied on long lasting insecticide treated nets, but in February 2018 indoor residual spray program was implemented in two Counties with the highest malaria prevalence in Western Kenya. Actellic insecticide was used for indoor residual spray. The objective of this study is to evaluate the impact of indoor residual spray on malaria prevalence and anemia using data from Homa Bay County where indoor residual spray was implemented and Kisumu county where there was no indoor residual spray intervention. Indoor residual spray was implemented in February 2018 and February 2019. Cross-sectional studies in open cohorts with randomly selected residents aged 6 months and above were conducted. In Homa Bay county, during January 2018 (dry season) prior to indoor residual spray intervention, overall malaria prevalence by microscopy was 12.7%, it was increased to 15.7% in the long rainy season in June 2018. Interestingly, malaria prevalence was dramatically reduced to 2.9%, 10 months after indoor residual spray. qPCR results from Homa Bay were consistent with the changes in malaria prevalence detected by microscope: 18.3% in January 2018, 17.0% in June 2018, and 10.2% in January 2019. Overall parasite density was significantly reduced in the rainy season, in comparison to dry season in 2018 (geometric mean 1,674 parasite/µl blood versus 274.8, P = 0.016), likely due to the indoor residual spray campaign in the area. In Kisumu county where no indoor residual spray intervention was implemented, malaria prevalence was not significantly changed. Indoor residual spray campaign did not significantly change anemia prevalence (38.3% in June 2018 versus 37.8% in January 2019). This data suggests a highly significant impact of indoor residual spray on malaria prevalence at least in the first year of implementation, but little impact on anemia.

443

COST PER YEAR OF EFFECTIVE LIFE CAN BE ESTIMATED FROM WHO PHASE III EVALUATION OF LONG LASTING INSECTICIDAL NETS: EVIDENCE FROM A FIELD TRIAL THAT IS WORTH SHARING!

Olukayode Ogo Odufuwa, Sarah Sjm Moore

Ifakara Health Institute (IHI), Bagamoyo, United Republic of Tanzania

Listing of Long Lasting Insecticidal Nets (LLINs) by World Health Organization Pre-Qualification Team (WHO-PQT) is based on longitudinal field studies that measure ABCD: Attrition, Bio-efficacy, Chemical content, and Damage (fabric integrity) of LLINs for 3 years under user conditions. There is a growing body of evidence to show that LLIN durability varies with long-lasting products giving better cost-effectiveness. However, it is currently assumed that all PQ-listed LLINs have a 3-year lifespan, so procurement decisions are based on LLIN unit cost. Data collected in WHO-PQT durability studies may be combined to calculate LLIN median functional survival, and allow ranking of the equivalent annual cost of each product. A double blinded household randomized prospective longitudinal cohort study was conducted for 3 years to compare the durability of two new brands of LLINs. Primary endpoint was median functional survival and secondary endpoints were LLIN bioefficacy and chemical content. Median functional survival of product A was 2.29 (1.47 - 4.30) years compared to 2.65 (1.79 - 4.34) years for Product B. Both products remained insecticidal up to the last sampling point three years (38 months) after distribution, despite having less than 50% of the initial loading dose of insecticide remaining. The proportion of nets that were in serviceable condition after 3 years was around 55% by WHO methods and 75% if the damage in the part of the net that is tucked in (and unavailable for mosquito entry) was not considered. Useful life years of LLINs is < 3 years by WHO methods and longer if the effect of tucking is considered. Procurement of LLINs should be based on cost per year of effective life using median functional survival time and this may be done using existing WHO guidelines. Adequately powered studies to measure net survival from A and D components are important with consideration of LLIN use patterns (tucking) with confirmatory bioassay testing to ensure that nets continue to kill and deter mosquitoes from feeding. Evaluation of chemical content of nets is costly and does not add to information on LLIN performance.

GREEN SYNTHESIS OF SILVER NANOPARTICLES USING *MORINGA OLEIFERA* LEAVES EXTRACT AND THEIR EFFECT ON MALARIA VECTOR CONTROL

Agnes Ntoumba, Francois Eya'ane Meva, Loick Kojom, Wolgang Ekoko, Philippe Belle Ebanda, Leopold Gustave Lehman

University of Douala, Douala, Cameroon

Malaria, dengue, chikungunya, Japanese encephalitis, and lymphatic filariasis are amongst parasitic deseases caused by mosquitoes . *Anopheles gambiae* is the principal vector of malaria in sub-Saharan Africa.[1] An approach for the control of mosquito populations have used silver nanoparticles for their properties and the potential to be use as simple, inexpensive, biocompatible, eco-friendly method. In the present case, we observe the effect of silver nanoparticles mediated leaf extract of *Moringa oleifera* against fourth instar larvae of *Anopheles gambiae*. as stipulated by standard methods for testing toxicity and susceptibility of mosquito larvae to insecticides of WHO. Fresh leaves of *Moringa oleifera* metabolites are water extracted and used as reducing and capping agents. We were mixed Silver nitrate ($AgNO_3$) solution with the plant extract for nanoparticle synthesis. The synthesized silver nanoparticles formation mechanism, characteristic plasmon resonance, nature, size and interface composition is discussed as key parameters affecting the activity. LD_{50} values and appreciable percentage mortality is recorded after 24 and 48h. This method is an innovative device using nanoparticles generated by plants to vector control of and the first report of *Anopheles gambiae* larvicidal activity using silver nanoparticles mediated *Moringa oleifera* leaf extract.

445

PRESENCE OF THE ZOONOTIC MALARIA PARASITES, *PLASMODIUM KNOWLESI* AND *PLASMODIUM CYNOMOLGI* IN MEMBERS OF SEVERAL *ANOPHELES* SUBGROUP IN TWO DISTRICTS OF SARAWAK, MALAYSIAN BORNEO

Joshua Ang Xin De[1], Khamisah Abdul Kadir[1], Dayang Shuaisah Awang Mohamad[1], Asmad Matusop[2], Khatijah Yaman[1], Balbir Singh[1]

[1]*Universiti Malaysia Sarawak, Sarawak, Malaysia,* [2]*Sarawak Department of Health, Sarawak, Malaysia*

The zoonotic malaria parasite, *Plasmodium knowlesi*, has caused all the 2,470 indigenous human malaria cases reported in Sarawak, Malaysian Borneo, in 2017 and 2018. Previously identified vectors of the parasite in nature in Malaysia and Vietnam all belong to the Leucosphyrus Group. In Sarawak, only *An. latens* was incriminated in one study conducted in the Kapit District. This project was therefore undertaken to identify malaria vectors in other locations of Sarawak. Human landing catches were conducted in forested sites of the Betong and Lawas Districts. Genomic DNA was extracted from the salivary glands of anophelines and screened with nested PCR assays for the presence of *Plasmodium*. The sequences of the SSUrRNA genes of *Plasmodium* spp. and the ITS2 and CO1 sequences of the mosquitoes were derived from the *Plasmodium*-positive samples. Collectively, 238 anophelines and 2,127 culicines were caught. *An. letifer* s. l.(44.5%, n=77) and *An. balabacensis* (47.7%, n=31) were found to be the predominant anophelines in Betong and Lawas, respectively. Phylogenetic analyses of the SSUrRNA genes confirmed the presence of *P. knowlesi, P. coatneyi, P. cynomolgi, P. fieldi, P. inui,* and other unidentified malaria parasites in 3 *An. barbirostris*, 6 *An. balabacensis*, 6 *An. latens* and 7 *An. letifer* s. l. Phylogenies inferred from the ITS2 and CO1 sequences of *An. balabacensis* and *An. barbirostris* indicate that the former is genetically indistinguishable from *An. balabacensis* sequences from Borneo while the latter is closely related to but distinct from the other described members of the Barbirostris Subgroup. The CO1 sequences of *An. latens* were separated into two different clades while those from *An. letifer* s. l. failed to form clades according to its corresponding morphological identification. This suggests that there are more potentially transmissible parasites and vectors in the forest setting than is known and that vector study is imperative, especially when nuclease-based gene drive which is sensitive to nucleotide-level variation is being considered as the novel silver bullet to tackle malaria.

446

BEDNET USE, DISPOSAL PRACTICES AND ASSOCIATED FACTORS IN RURAL WESTERN UGANDA

Alex Ndyabakira[1], Emmanuel Arinaitwe[2], Joaniter I. Nankabirwa[3], Gabriel Chamie[4], Rhodah Namubiru[3], Tobius Mutabazi[3], Daslone Kwarisiima[2], Kara Marson[4], Jaffer Okiring[2], Harsha Thirumurthy[5], Sarah G. Staedke[6], Charles Ssemugabo[7], Moses R. Kamya[3], Yeka Adoke[7]

[1]*Department of Disease Control and Environmental Health, School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda,* [2]*Infectious Diseases Research Collaboration, Kampala, Uganda,* [3]*School of Medicine, College of Health Sciences, Makerere University, Kampala, Uganda,* [4]*Department of Medicine, Division of HIV, Infectious Diseases and Global Medicine, University of California San Francisco, San Francisco, CA, United States,* [5]*Division of Health Policy, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, United States,* [6]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [7]*Department of Disease Control and Environmental Health, School of Public Health, Makerere University College of Health Sciences, Kampala, Uganda*

Bednets, in particular, Long Lasting Insecticidal Nets (LLINs) are the most cost-effective malaria control intervention, however effectiveness of LLINs depends on high coverage and consistent use. Malaria burden in Uganda remains high despite free distribution of LLINs through universal

and routine campaigns. We assessed bednet use, disposal practices and associated factors in rural Western Uganda. We conducted a household survey in 252 households from February-March 2018, approximately 4years after the last universal coverage campaign (UCC). Households were randomly sampled from a household census list. Household heads were interviewed and nets were physically observed. Association between variables were determined using prevalence ratios and factors associated with net ownership, use and disposal practices were assessed using modified Poisson regression. Households had a total of 1,206 residents and 384 bednets. A total of 187 (74.2%) households owned at least one bednet and 95.1% (365/384) of the bednets were LLINs. Only 465 (38.6%) of residents slept under a bednet the night before the survey. About 86 (34.1%) households had universal net coverage. Majority (65.7%) of nets were disposed by burning at home. Residents from households with universal net coverage were more likely to use nets (aPR=2.85, 95%CI: 2.51-3.24). Household members were less likely to use bednets if they were males (aPR=0.78, P5%CI: 0.68- 0.91), were aged between 5-17 (aPR=0.65, 95%CI: 0.52-0.81) and 18-35 (aPR=0.71, 95%CI= 0.57-0.89) years, and were unrelated to the household heads (aPR=0.61, 95%CI: 0.44-0.84). Four years after a LLIN campaign, bednet ownership and use were found to be low and bednets were improperly disposed. The country should have more frequent UCC and promote proper disposal of nets.

447

LOCALIZED VARIATIONS IN LLIN USE IN MYANMAR AND CAMBODIA

Ye Kyaw Aung[1], May Me Thet[1], Sochea Phok[2], Si Thu Thein[1]

[1]*Population Services International Myanmar, Yangon, Myanmar,* [2]*Population Services International Cambodia, Phnom Penh, Cambodia*

To enhance use of Long lasting insecticide nets (LLIN) for malaria prevention, it is important to understand the factors that determine the LLIN use at population level. This study aimed to identify the factors associated with population level LLIN use in rural areas of campaign LLIN distribution in Bago Region of Myanmar and Battambang and Siem Reap Provinces of Cambodia. A cross-sectional household survey was conducted in the areas of recent distribution campaigns in both countries. The survey covered households which received at least one LLIN during the distribution campaigns of 2017 and 2016 in Myanmar and Cambodia. A total of 1414 households in Myanmar and 1362 households in Cambodia were recruited though single-stage cluster sampling method. Population level LLIN use and under-five children LLIN use were calculated and potential associations were explored using multivariate logistic regression models in STATA 14.2. Overall LLIN use among the population living in the study area of Myanmar was 61.7% while that was only 27.7% in Cambodia. LLIN use of under-five children followed the same pattern, 65.0% in Myanmar and 23.4% in Cambodia. Coverage of LLINs (HH had a least 1 LLIN per 2 persons) was higher in Myanmar (77.8%) than Cambodia (42.8%). In both countries, population level use of LLIN was significantly higher in households with enough coverage of LLINs, (Odd Ratio (OR) 1.76, 95% CI 1.49 - 2.07 in Myanmar and OR 1.83, 95% CI 1.64 - 2.04 in Cambodia). However, other determinants varied by locality. LLIN use was lower among male household members, households with higher socioeconomic status, and households with practice of prevention to net tear in Myanmar (p>0.001). In Cambodia, these factors were associated with higher use of LLINs (p>0.001). Despite almost the same distribution time in both countries, overall population level use of LLINs was higher in the study area of Myanmar than that of Cambodia, mainly determined by high distribution coverage of LLINs. However, other determinants of LLIN usage varied by locality, and such contextual variations should be taken account in LLIN distribution activities to ensure optimal usage.

MOSQUITO AND PARASITE GENETIC DETERMINANTS OF THE EXTRINSIC INCUBATION PERIOD OF *PLASMODIUM FALCIPARUM*

Robert Shaw[1], Kristine Werling[1], Maurice A. Itoe[1], Duo Peng[1], Douglas G. Paton[1], Naresh Singh[1], Roch K. Dabiré[2], Abdoulayé Diabaté[2], Liliana Mancio-Silva[3], Allison R. Demas[3], Sandra March[3], Sangeeta N. Bhatia[3], Thierry Lefèvre[2], Flaminia Catteruccia[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso,* [3]*Institute for Medical Engineering and Science, Massachusetts Institute of Technology, Cambridge, MA, United States*

The extrinsic incubation period (EIP) of *Plasmodium* parasites, the time taken for their sporogonic development within the *Anopheles* mosquito, is a key determinant of malaria transmission; faster developing parasites are more likely to be transmitted to subsequent hosts given the relatively short lifespan of mosquitoes. However, despite its relevance, relatively little is experimentally determined regarding factors that can influence the EIP and could be manipulated in novel transmission-blocking strategies. Here we show that in *Anopheles gambiae*, the major African malaria vector, *P. falciparum* parasites accelerate their growth and shorten their EIP in response to the disruption of steroid hormone signaling following a blood meal. When reproductive investment is reduced via several mechanisms, physiological levels of circulating lipids, transported by the lipid transporter lipophorin, are elevated and exploited by the parasite to develop more quickly. Faster parasites that reach the salivary glands sooner maintain full infectivity to human hepatocytes, as determined by *in vitro* quantification of exoerythrocytic forms. Using multiple gametocyte carriers in a *P. falciparum*-endemic region we confirmed and extended these observations to field-derived colonies of *An. gambiae* and the closely related sibling species *An. coluzzii*. In these field infections we found evidence of both parasite and mosquito genetic determinants controlling the growth rate of parasites, and identified parasite isolates showing remarkably high developmental rates after perturbations of steroid hormone signaling. Combined, these data reveal that parasites have a plastic interaction with mosquito metabolism, with profound implications for vector control strategies aiming to lower mosquito fecundity.

449

INTRAZONAL DIFFERENCE IN MALARIA PREVALENCE AND FACTORS ASSOCIATED WITH MALARIA INFECTION AMONG CHILDREN AGED 0 TO 10 YEARS IN KISANTU HEALTH ZONE

Gillon Ilombe Kaounga[1], Junior Matangila[2], Baby Mabanzila[3], Sylvie Linsuke[1], Emile Manzambi[1], Eric Mukomena[2], Francis Watsenga[1], Pascal Lutumba[2], Seth Irish[4]

[1]*Institut National Recherche Biomedical, Kinshasa, Democratic Republic of the Congo,* [2]*University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [3]*Clinic University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [4]*Centers for Disease of Control, Atlanta, GA, United States*

The Democratic Republic of Congo (DRC) is the most malaria affected country. The Kongo Central (KC) Province has higher malaria cases than the national average. There is a direct relationship between malaria risk and geo-climatic environment of people. Within the same epidemiological settings, malaria transmission is not homogeneous; this contributes to the complexity of malaria and its elimination. The main of this study was to determine intra-zonal prevalence and factors associated with the malaria infection in children aged 0-10 years in the Kisantu health zone in KC. In this area, a community based cross-sectional study was conducted from October to November 2017. A multi-stage sampling was used, 30 villages from Kisantu health zone were randomly selected. Malaria prevalence was measured by thick blood smear (TBS) and rapid diagnostic test (RDT). Data were analyzed in Stata 14.0. Data were summarized using proportion and mean (with standard deviation). The Student t test and χ^2 test were used respectively for mean and proportion comparison. Logistic regression analysis identified determinants of malaria infection. The prevalence

according to the TBS and RDT was respectively 14.8% and 78.3%. The results in the different village were a heterogeneous distribution of Malaria prevalence using TBS, varying from 0 to 52.6 %. In bivariate analysis, the main type of wall, the type of ground, the main type of domestic roof (straw and thatch) and the malnutrition were factors associated at the risk of the arisen of malaria infection, respectively 2.1 (1.5-2.8); 15.7 (8.5-32.2); 4.5 (3.0-6.7) and 1.9 (1.3-2.6). In multivariate analysis, the fact of having the sand or the wood as the main type of ground 17.3 (8.86-33.76) and the fact of having a moderate or severe insufisance 1.53 (1.13-2.07) were factors associated to one arisen the malaria infection. Generalization of malaria prevalence is not a good approach; local variation impacts malaria control strategies. Malaria control programme has to go in hand with improvement in social economy, considering housing and nutrition. This call for a multi-sectorial approach to control diseases.

450

CHARACTERIZING THE MOLECULAR AND METABOLIC MECHANISMS OF INSECTICIDE RESISTANCE IN *ANOPHELES GAMBIAE*S.L. IN FARANAH, GUINEA

Caleb J. Stica[1], Claire L. Jeffries[1], Seth R. Irish[2], Yaya Barry[3], Denka Camara[3], Ismael Yansane[4], Mojca Kristan[1], Thomas Walker[1], Louisa A. Messenger[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Programme National de Lutte contre le Paludisme, Conakry, Guinea,* [4]*StopPalu, Conakry, Guinea*

The scale-up of long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) has greatly reduced malaria transmission. However, malaria remains a global health problem with the majority of the disease burden in sub-Saharan Africa. Improved understanding of increasing insecticide resistance among *Anopheles* populations is essential for continued effectiveness of control interventions. *An. gambiae* s.l. were collected from villages in the Faranah Prefecture, Guinea and CDC resistance intensity bioassays were used to measure susceptibility to seven insecticides. Vector species, presence of target site mutations (L1014F *kdr*, N1575Y and G119S *Ace-1*), *Plasmodium falciparum* infection, and relative expression of three metabolic genes (*CYP6M2, CYP6P3,* and *GSTD3*) were determined. Intense resistance to permethrin and deltamethrin was observed, with developing resistance to bendiocarb. Vectors were fully susceptible to alpha-cypermethrin, pirimiphos-methyl, clothianidin and chlorfenapyr. *P. falciparum* infection rate was 7.3% (37/508). The L1014F *kdr* mutation was found in 100% of a sub-sample of 60 mosquitoes, supporting its fixation in the region. The N1575Y mutation was identified in 20% (113/561) of individuals, with ongoing selection evidenced by significant deviations from Hardy-Weinberg equilibrium. The G119S *Ace-1* mutation was detected in 62.1% (18/29) of mosquitoes tested and was highly predictive of bendiocarb bioassay survival. When compared to a susceptible *An. gambiae* s.s. G3 laboratory colony, *CYP6M2, CYP6P3* and *GSTD3* were found to be significantly over expressed in wild resistant and susceptible *An. gambiae* s.s. populations. Furthermore, *CYP6P3* was significantly over expressed in bendiocarb survivors, implicating its potential role in carbamate resistance. The intense resistance to permethrin and deltamethrin, identified in the Faranah Prefecture, is of considerable concern, as the Guinea National Malaria Control Program relies exclusively on the distribution of pyrethroid-treated LLINs. Study findings will be used to guide current and future control strategies in the region.

451

NATIONAL MALARIA VECTOR SURVEILLANCE: A REGIONAL ANALYSES AGAINST RECOMMENDED ACTIVITIES

Tom Burkot[1], Tanya Russell[1], Min Myo[2], Abraham Mnzava[3], Effie Espino[2], Robert Farlow[4]

[1]*Australian Institute of Tropical Health and Medicine, Cairns, Australia,* [2]*Asian Pacific Malaria Elimination Network, Singapore, Singapore,* [3]*African Malaria Leaders Alliance, Dar es Salaam, United Republic of Tanzania,* [4]*Robert Farlow Consulting LLC, Burkville, TX, United States*

Malaria vector surveillance is being increasing recognized as critical to the success of national malaria control programs. The World Health Organization recently published the objectives for malaria vector surveillance and provided guidance on core vector surveillance activities by transmission scenarios and vector control interventions deployed. In order to assess the status of vector surveillance, an online survey gathered information from 35 national malaria control programs or their partner organizations. This presentation is one of three providing detailed analyses related to this survey. In this presentation an analyses of national program vector surveillance activities by transmission scenarios and interventions deployed are summarized by countries in Africa and the Asia-Pacific regions including a comparison of vector surveillance in countries attempting elimination to countries with higher transmission rates. Data on vector parameters monitored, the techniques used for their quantitation and methods to assess intervention access and use will be described. Analyses identified strengths across the regions as well as regional differences including significant limitations by comparison to the benchmarks established by the Global Malaria Programme. Additional detailed analyses from the same data set of the limitations to programmatic vector surveillance and will be presented by Dr. Tanya Russell. A complementary study defining next generation vector surveillance tools to address technical limitations of the presently deployed tools to define vector parameters will be presented by Dr Robert Farlow.

452

EFFECTIVENESS OF SELECTED CATTLE-ADMINISTERED ENDECTOCIDES TO REDUCE MALARIA-VECTOR MOSQUITOES

Takalani Irene Makhanthisa, Leo Braack, Heike Lutermann

University of Pretoria, Hatfield, South Africa

Malaria control primarily depends on two vector strategies; indoor residual spraying (IRS) and long-lasting insecticide-treated nets (LLIN). Both IRS and LLIN are indoor strategies and some of the major malaria vectors have developed resistance against them. Vector behavioural changes such as outdoor feeding on zoophagic hosts including cattle also limit the effectiveness of these strategies. Novel malaria control strategies must therefore be implemented to complement IRS and LLIN. A promising tool is the use of endectocides in alternative hosts for malaria vectors. Endectocides are broad-spectrum systemic drugs against a range nematodes and arthropods. The aim of this study was to investigate the effect of two endectocide drugs; ivermectin and fipronil on the survival and fecundity of zoophilic *Anopheles arabiensis.* Mosquitoes were reared in an insectary at a constant temperature of 25°C±2°C, 75%±5% humidity and 12 h light: 12 h darkness photoperiod. In total, six cattle individuals were used, each of them got three treatments; ivermectin® (1 ml/50 kg), fipronil® (1 ml/10 kg) and saline (control). Batches of *A. arabiensis* female mosquitoes (n=30) that were allowed to mate first were placed in cups and allowed to feed from the animals. Feeding experiments were conducted at day 0, 1, 4, 7, 13, 21 and 25 post-treatment; mortality and egg production were recorded. Preliminary results show that both ivermectin and fipronil decrease the survival and egg production of mosquitoes compared to the control group. Ivermectin was most effective at day 1 post-treatment with the highest effect at day 4 post-feeding with up to 60% higher mortality compared to control groups. The effect of ivermectin attenuated over a period of two weeks down to 12% and no differences were apparent any longer from day 21 post-treatment

onwards. For both drugs, the treated groups produced up to 70% fewer eggs than the control from day 1-13 post-treatments. Our results suggest that ivermectin may be more effective than fipronil to control zoophagic mosquitoes.

453

OPERATIONAL IMPLICATIONS OF PYRETHROID RESISTANCE AND PIPERONYL BUTOXIDE SYNERGIST ASSAYS ON VECTOR CONTROL DECISIONS IN NIGERIA

Petrus U. Inyama[1], **Lazarus M. Samdi**[1], Adedayo O. Oduola[1], Jesse C. Uneke[2], Andrew B. Yako[3], Atting A. Inyang[4], Kehinde O. Popoola[5], Auwal A. Barde[6], Yahaya M. Abdullahi[7], Manaseh Manyi[8], Joseph I. Okeke[1], Bala Mohammed[9], Okefu O. Oyale[9], Aklilu Seyoum[10], Kelley Ambrose[10], Bradford Lucas[10], Uwem Inyang[11], Jose Tchofa[11], Mark Maire[12], Jennifer S. Armistead[13], William A. Hawley[14]

Deployment of long-lasting insecticidal nets (LLINs) remains the main strategy for malaria vector control in Nigeria. Until recently, LLIN procurement decisions were not guided by local insecticide susceptibility evaluations. This study reports the outcome of insecticide susceptibility tests conducted in 2018 on *Anopheles gambiae* s.l. collected from sentinel sites representing the five ecological zones of Nigeria. Larvae of *An. gambiae* s.l. were collected in 60 Local Government Areas (LGAs) in Akwa Ibom, Bauchi, Benue, Ebonyi, Nasarawa, Oyo, Plateau, Sokoto, and Zamfara states. Adult, female *An. gambiae* s.l. reared from larvae and between 2 and 5 days old were exposed to permethrin, deltamethrin, and alpha-cypermethrin using CDC bottle bioassays. Insecticide resistance tests were done with different doses (2x, 5x, and 10x) to determine the intensity of pyrethroid resistance. Resistant *An. gambiae* s.l. were subjected to synergist assays with piperonyl-butoxide (PBO) to determine mechanisms of resistance. Pyrethroid resistance was detected in *An. gambiae* s.l. from all nine states. *An. gambiae* s.l. were susceptible to permethrin in two LGAs in Sokoto and one LGA in Zamfara. Permethrin resistance at 5x diagnostic concentration was recorded at Nasarawa and at both 5x and 10x in Akwa Ibom, Benue, Ebonyi, and Oyo. PBO restored susceptibility to permethrin in all LGAs in Akwa Ibom and Sokoto, and in five out of the six LGAs in Ebonyi. Susceptibility to deltamethrin at 2x was seen in all LGAs in Benue and Nasarawa. Deltamethrin resistance at 5x was recorded in Akwa Ibom and at 10x concentration in Ebonyi. Exposure to PBO restored susceptibility to deltamethrin in Ebonyi, Nasarawa, Plateau, and Sokoto. *An. gambiae* s.l. was also susceptible to alpha-cypermethrin in select LGAs in Bauchi, Benue, Sokoto, and Zamfara. Alpha-cypermethrin resistance at 5x or 10x was detected in Oyo and at 2x in Ebonyi. In Benue and Oyo, PBO restored susceptibility to alpha-cypermethrin. In the 2020 mass campaign, alpha-cypermethrin LLINs are planned for Zamfara, deltamethrin or alpha-cypermethrin LLINs for Benue, and alpha-cypermethrin+PBO LLINs will be procured for Oyo.

454

BIONOMICS OF *ANOPHELES* MOSQUITOES IN MALARIA ENDEMIC SENTINEL SITES IN GRACIAS A DIOS DEPARTMENT, HONDURAS

Allan Armando Reyes Garcia[1], Erik Alvarez[1], Fredy Zalasar[1], Jose Orlinder Nicolas Zambrano[2], Marissa Bordas[1], Efrain Burgos[1], Diana Nuñez Azzad[2], Neila Julieth Mina[3], Daragh A. Gibson[4], Sheila B. Ogoma[5], Tara Seethaler[4], Wilberto Montalvan[2]

[1]*Honduras Secretary of Health, Health Region N⁹ Gracias a Dios, Puerto Lempira, Honduras,* [2]*Honduras Secretary of Health, Central Level, Tegucigalpa, Honduras,* [3]*Clinton Health Access Initiative, Honduras Office, Tegucigalpa, Honduras,* [4]*Clinton Health Access Initiative, Boston, MA, United States,* [5]*Clinton Health Access Initiative, Kenya Office, Nairobi, Kenya*

The Department of Gracias a Dios (GAD) in Honduras is malaria endemic and has historically registered the greatest number of cases in the country. In 2018, the region reported 259 malaria cases, of which 82.2% were *Plasmodium vivax* and 17.8% were *P. falciparum*. In GAD, the municipalities of Puerto Lempira, Villeda Morales, and Brus Laguna reported an estimated 92.7% of these cases. Efficacy of vector control interventions is largely influenced by malaria vector bionomics. In order to reach the goal of malaria elimination in Honduras by 2020, it is critical to determine the entomological aspects that are driving transmission to best target appropriate interventions. Mosquito collections were conducted in three sentinel sites across the three municipalities: Kaukira (Puerto Lempira), Raya (Villeda Morales), and Brus Laguna (Brus Laguna). Vector species composition, their spatial and temporal distribution, and biting behavior and rates were measured using human landing catches (HLCs). Larval sampling, habitat characterization, and outdoor aspirations in animal sheds were also conducted. Sentinel sites were surveyed monthly for a week from October 2017 through December 2018. A total of 131 potential larval habitats were identified, and about 1,169 and 2,245 *Anopheles* mosquitoes were captured using HLCs and outdoor aspirations in animal sheds, respectively. Of the 1,169 mosquitoes captured via HLCs, 66.3% were morphologically identified as *Anopheles albimanus,* 29% *An. gabaldoni,* 4.5% *An. crucians*, and 0.2% identified as other species. Additionally, 74% of the 1,169 mosquitoes were captured outdoors. Across the three sites, the months with the greatest densities were November 2017, June 2018, and October 2018. The most predominant species across all sites each month was *An. albimanus* with the exception of Kaukira, where *An. gabaldoni* was more prevalent from November 2017 to January 2018. The seasonal and temporal distribution of vectors will help determine indoor residual spray timing for upcoming spray rounds and to measure impact, while additional studies are needed to understand the role of species type on transmission dynamics in GAD.

455

IDENTIFICATION OF ENTEROTOXIGENIC *ESCHERICHIA COLI* FROM INFANTS ATTENDING HEALTHCARE CENTERS IN IBADAN NORTH

Olabisi Comfort Akinlabi[1], Stella Ekpo[1], El-shama Queen Nwoko[1], Catherine O. Ladipo[1], Akinlolu Adepoju[2], Gordon Dougan[3], Iruka N. Okeke[1]

[1]*University of Ibadan, Ibadan, Nigeria,* [2]*Department of Paediatrics, College of Medicine, University of Ibadan, Oyo, Ibadan, Nigeria,* [3]*Cambridge University, Cambridge, United Kingdom*

Enterotoxigenic *E. coli (*ETEC) can cause profuse, watery diarrhea by release of heat labile (LT) and/ or heat stable (ST) enterotoxins. This study hypothesized that ETEC is a predominant cause of infantile diarrhoea in northern Ibadan, Oyo State, Nigeria. We performed a case control study among children under 5 years of age. Stool specimens were collected from 99 children with diarrhoea and 315 controls attending primary health clinics in Lagelu and Egbeda local government areas of Ibadan between November 2015 and January 2019. *E. coli* was isolated and identified using standard laboratory protocols and ETEC were identified by multiplex

PCR. ETEC were isolated from 24 (24.2%) cases and 70 (22.2%) controls. ETEC strains carrying both heat-labile (LT) and heat-stable (ST) enterotoxin-encoding genes were significantly associated with diarrhoea, being recovered from 12 (12.1%) and 14 (4.4%) cases and controls respectively (p=0.01). ETEC bearing only LT genes were isolated from 17(17.2%) cases and 49(15.5%) controls while strains with ST genes only were recovered from 5(5%) cases and 9(2.9%) controls (p>0.05). There was clustering of ETEC recovery in March 2016 and again in August to September 2016. Molecular profiling of ETEC isolates within these clusters points to possible ETEC outbreaks. In conclusion, our data suggest that ETEC strains, especially those that carry both LT and ST genes, may be important causes of diarrhoea. We also found high rates of carriage among apparently healthy children. The study further reveals that outbreaks caused by ETEC could be commonplace but beyond routine detection. Interventions that target ETEC pathotypes may have the potential to reduce the morbidity from infantile diarrhoea in Ibadan.

INVESTIGATING VITAMIN A IN TREATING DISSEMINATED INFECTIONS WITH MULTIDRUG RESISTANT NON-TYPHOIDAL *SALMONELLA*

Annica Stull-Lane[1], Kristen Lokken[1], Vladimir Diaz-Ochoa[1], Nicoel White[1], Ariel Muñoz[1], Gregory Walker[1], Daniela Hampel[2], Xiaowen Jiang[2], Charles Stephensen[2], Renée Tsolis[1]

[1]*Department of Medical Microbiology and Immunology; University of California Davis, Davis, CA, United States,* [2]*US Department of Agriculture; Western Human Nutrition Research Center, Davis, CA, United States*

Non-typhoidal *Salmonella* (NTS) serovars are common causes of gastroenteritis; however, factors including young age, malnutrition and concurrent malaria infection underlie susceptibility to disseminated disease. Annually, there are approximately 3.4 million cases and 680,000 deaths due to disseminated NTS infections, as the mortality rate is ~20%. Non-typhoidal *Salmonella* serovar Typhimurium sequence type 313 (ST313) has evolved to become more capable of causing invasive disease in the human host and is more common in sub-Saharan African countries. Our lab focuses on studying a ST313 clinical isolate that is multidrug resistant (D23580). As micronutrient deficiencies overlap with malnourished states, we have modeled in mice how vitamin A deficiency compromises the immune response to systemic NTS infection. We investigate the efficacy of therapy with antibiotics, vitamin A or co-treatment to decrease bacterial burden of *Salmonella* at systemic sites and improve survival in vitamin A deficient (VAD) mice. Our results show that VAD mice are unable to control bacterial replication at systemic sites. Importantly, vitamin A supplementation improves control of infection, and vitamin A treatment increases survival. Ultimately, our goal is to inform clinical studies assessing vitamin A as adjunctive therapy in patients suffering from disseminated NTS infection with the objective of decreasing mortality rate and improving human health outcomes globally.

457

GUT RESISTOME AFTER ORAL ANTIBIOTICS IN PRESCHOOL CHILDREN IN BURKINA FASO: A RANDOMIZED CONTROLLED TRIAL

Catherine Oldenburg[1], Armin Hinterworth[1], Ali Sié[2], Boubacar Coulibaly[2], Lucienne Ouermi[2], Clarisse Dah[2], Charlemagne Tapsoba[2], Susie Cummings[1], Lina Zhong[1], Cindi Chen[1], Samarpita Sarkar[1], Till Barnighausen[3], Thomas Lietman[1], Jeremy Keenan[1], Thuy Doan[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso,* [3]*University of Heidelberg, Heidelberg, Germany*

Antibiotic selects for resistance at the individual and community level. We used data from a randomized controlled trial of pediatric antibiotic administration to evaluate the relationship between antibiotic use and the gut resistome, defined as the collection of resistance gene determinants in a given environment. Children aged 6-59 months were enrolled in two rural communities in Nouna District, Burkina Faso. Households were randomized in a 1:1:1:1 fashion to amoxicillin (25 mg/kg/day in twice-daily doses), azithromycin (10 mg/kg on day one and then 5 mg/kg once daily for four days), cotrimoxazole (240 mg once daily), or placebo (powdered milk and sugar in bottled water). All children were treated for 5 days. Rectal samples were collected 5 days after the last antibiotic treatment and sequenced using DNA sequencing to identify antimicrobial resistance determinants, which were classified at the class and gene level. Of 124 children randomized, 120 had a rectal swab collected post-treatment. Beta-lactam resistance did not differ across study arms. Azithromycin samples were more than twice as likely to have genetic resistance determinants to macrolides (risk ratio, RR, 2.61 95% CI 1.55 to 4.42, *P*=0.0003) compared to placebo. Sulfonamide resistance was higher in samples from children in all antibiotic arms compared to placebo. Samples from children randomized to cotrimoxazole were more than 3 times as likely to have genetic resistance determinants to trimethoprim (RR 3.29, 95% CI 1.08 to 9.95, *P*=0.04) compared to placebo. Mean richness (number of unique genes) of antimicrobial resistance determinants was higher in amoxicillin-treated (42.6 versus 23.9, *P*=0.02) and cotrimoxazole-treated (40.1 versus 23.9, *P*=0.049) children compared to placebo-treated children. Richness was not significantly different between azithromycin-treated children and placebo (*P*=0.15). In conclusion, a single course of antibiotic can cause changes in the gut resistome. Regional antimicrobial resistance surveillance will be important to inform antibiotic use policy.

458

CHOLERA VACCINAL IN DRC

Sandra Musungayi,T.S Musungayi

URF/INRB, Kinshasa, Democratic Republic of the Congo

Cholera is major public health problem because of it sever mortality on the affected persons ;in epidémic regions 80% of cases notify by OMS in the world plan comes from sub_sahara africa . in DRC, the profil of infected people with cholera is less known; and strategies to prevent it by vaccine campaign is wrongly done. To determine different profiles of people affected by cholera. A retrospective analytical study was conducted in 17 health zones of the city of Kinshasa Province. Active data collection of suspected cholera cases identified between 2000-2016 was made based on national registries available in the 17 selected areas. These data were organized in excel spreadsheets with variables year, week, health zone, age, sex, occupation for the comparison between the groups and proportion; the statistics of the tests (chi square and Fisher test) were carried out using the SPSS software version 21 for each evolutionary period. The proportions of each variable were calculated with their 95% fixed confidence interval. Les commerçants, les pêcheurs, les élèves, les étudiants, les agriculteurs, les voyageurs et les conducteurs sont les plus touchés dans les zones d'endémie, avec une proportion de 78,5% (IC à 95%: 75,9-80,8). Le groupe d'âge le plus touché est celui des 5-14 ans, avec 30% (IC 95% : 29,5-31,1) dans les zones d'endémie et 25,7% (IC 95%: 22,9% à 28,8%) dans les zones non endémiques. La proportion était respectivement de 28,7% (IC à 95%: 27,3-307), de 20% (IC à 95%: 27,1 à 29,3) et 25,9% (11,5 à 44,7) dans les phases évolutives de l'immobilité, du pic de l'épidémie et de la recrudescence des zones endémiques dans la groupe d'âge de 5-14 ans. Les résultats de cette étude restent un défi car la stratégie sera appliquée en termes d'âge et d'autres aspects. Une approche multidisciplinaire est essentielle pour prévenir le choléra.

459

PATHOGEN BOX CONTAINS INHIBITORS OF ENTEROAGGREGATIVE *ESCHERICHIA COLI* GROWTH WITH ANTIBACTERIAL POTENTIAL

David Ajigasoko Kwasi[1], Adeola Oluwaseyi Bamisaiye[1], Olujide Oludayo Olubiyi[2], Olabisi Comfort Akinlabi[1], Emmanuel Oladayo Irek[2], Chinedum Peace Babalola[1], Ikemefuna Uzochukwu[3], Oladipo Aaron Aboderin[2], Iruka Nwamaka Okeke[1]

[1]*University of Ibadan, Ibadan, Nigeria,* [2]*Obafemi Awolowo University, Ile-Ife, Nigeria,* [3]*Nnamdi Azikiwe University, Awka, Nigeria*

Enteroaggregative *Escherichia coli* (EAEC) are important causes of infantile diarrhoea and often cause persistent diarrhoea, for which antibiotics are indicated. However, EAEC are commonly antibiotic resistant and therefore new and effective therapies are needed. We screened the Medicines for Malaria Venture›s (MMV) Pathogen Box for EAEC growth inhibitors that could be antibacterial forerunners. We performed a medium throughput screen of MMV›s 400-compound Pathogen Box to identify inhibitors of EAEC growth in Dulbecco›s Modified Eagle›s Medium. Hits are systematically being tested for activity against a broader range of Gram negative clinical isolates, including multiply-resistant strains. Minimum inhibitory concentrations (MICs) and minimum bactericidal concentrations of ‹hit› compounds are measured by broth microdilution. Seven compounds inhibited growth of EAEC strains 042 and MND005E in the screen. Of these compounds, rifampicin and levofloxacin had previously documented anti-Gram negative activity. (Doxycycline, another antibacterial agent present in Pathogen Box was not retrieved in the screen because both strains are tetracycline-resistant). Our screen identified five compounds with no previously documented Gram negative activity. Compounds MMV675968 and MMV002817 exhibited greater growth inhibition activity than the known antibacterials tested. MMV002817 was bactericidal against a broad range of Gram negative bacteria. For this compound, MICs against *Pseudomonas* spp, including multiply-resistant clinical isolates ranged between 4 and 32 μg/ml compared with ciprofloxacin MICs of ≤0.125 to ≥ 64 μg/ml. This study identified novel small molecules with antibacterial activity, one of which demonstrated broad spectrum Gram negative activity against multidrug-resistant Pseudomonas. MMV002817 has the potential for optimization or repurposing for EAEC-based interventions and as last line Gram-negative antibacterial.

CHARACTERIZATION OF *SHIGELLA* SPECIES CAUSING DISEASE IN CHILDREN ADMITTED TO KILIFI COUNTY HOSPITAL, KENYA

Anne Amulele[1], Michael Ooko[1], Alfred Mwanzu[1], Sam Kariuki[2], Anthony Scott[1], Nicola Claire Gordon[1]

[1]*KEMRI Wellcome Trust Research Programme, Kilifi, Kenya,* [2]*KEMRI Centre for Microbiology Research, Nairobi, Kenya*

Shigella spp is one of the leading causes of bacterial diarrhoea and related mortality worldwide especially in young children under five years in developing countries. Though childhood mortality attributed to the pathogen has reduced significantly in recent years, most of the deaths occur in Africa and Asia. Infections can be prevented by improving sanitation and hygiene practices, however, an affordable and efficacious vaccine would accelerate disease reduction in resource limited countries. At present there is no licensed vaccine though several potential candidates are in research and development. It is important to understand the epidemiology and characteristics of *Shigella* circulating in our region to estimate the impact of a potential vaccine. We undertook a descriptive retrospective study of *Shigella* gastroenteritis and bacteremia cases occurring in children presenting to a public hospital in Kilifi County from 1994 to 2016. The demographics and clinical characteristics of the patients were obtained while the antibiogram profile, species identification, *S. flexneri* serotypes and virulence diversity of stored isolates was determined by disc diffusion, agglutinating sera and PCR. We identified 200 patients from whom *Shigella spp* was cultured: 183 (91.5%) with gastroenteritis, 13 (6.5%) with bacteremia, and 4 (2%) with both. Children aged 12-59 months were the most affected accounting for 62% (124) of all cases. 11% (21) of the patients died in hospital. *S. flexneri* was the dominant species identified in both gastroenteritis and bacteremia with serotypes 2a, 3a and 6 accounting for 68% of *S. flexneri* serotypes. We observed high rates of resistance to tetracycline (96%), cotrimoxazole (92%) and ampicillin (83%) and no resistance to cephalosporins and ciprofloxacin. The most frequently identified virulence genes were *sen*, *set1A* and *sepA*, while shiga toxin gene was present in half of *S. dysenteriae*. *S. flexneri* is therefore an important pathogen and a vaccine that includes *S. flexneri* serotypes 2a, 3a, 6 and *S. sonnei* could have potentially prevented 55% of all *Shigella* disease cases and 71% of the related deaths in Kilifi County.

461

ISOLATION, IDENTIFICATION AND MOLECULAR CHARACTERIZATION OF ENTEROPATHOGENIC *ESCHERICHIA COLI* AND *PSEUDOMONAS* SPECIES OBTAINED FROM MEAT SAMPLES FROM DIFFERENT AREAS OF DHAKA CITY

Rabeya Tafsire Rudhy

BRAC University, Dhaka, Bangladesh

Meat is one of the main source of protein now a days all over the world. From the people living under boarder line of poverty to high maintenance society, beef, mutton and chicken are taken as important source of proteins. Although beef and mutton are the most desirable ones; because of the availability and low price chicken is consumed even more than the rest. Due to improper handling and poor hygiene at the time of preparing the food, meat related foods are extremely unhealthy in Bangladesh. In this study 43 samples were taken from different areas of Dhaka city, the results supported the mentioned concern. Most of the meat samples were cheap and on the list of regular intake of students studying in these areas. Some of the samples showed almost 80-90% contamination with Escherichia coli that is a coliform bacterium and found in human excreta mostly. Most of the samples were cooked and processed; nonetheless they did not lack any less of organisms or contamination. Chicken samples were collected in three states, which were cooked, semi-cooked and raw. Some of the cooked and most consumed samples showed presence of 6-7 organisms. The organisms identified so far are *Escherichia coli, Enterobacteor aerogens, Salmonella spp, Staphylococcus spp, Pseudomonas* and others. The purpose of this study is to make the authorities regulating food safety aware of such contamination and take necessary steps to avoid this sort of disorientation towards food related business. In our research biochemical tests such as streaking on EMB and MacConkey agar, MRVP, TSI etc. were done, in addition morphological characteristics of the single colonies of isolated microorganisms were also examined and interpreted. DNA from samples positive for *E. coli* were isolated and by gel electrophoresis their bands were examined where most of them gave positive bands for STEC, meaning positive for pathogenic *E. coli* strains.

IDENTIFYING GEOGRAPHIC PRIORITIES FOR CHOLERA CONTROL INTERVENTIONS

Elizabeth C. Lee[1], Mohammad Ali[1], Ahmed A. Mohamed[2], Ali Nyanga[3], Chimwaza Wiseman[4], Joseph Wamala[5], Justin Lessler[1], Andrew S. Azman[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*Tanzania Field Epidemiology and Laboratory Training Program, Dar es Salaam, United Republic of Tanzania,* [3]*Tanzania Ministry of Health Community Development Gender Elderly and Children, Dodoma, United Republic of Tanzania,* [4]*Ministry of Health, Malawi, Lilongwe, Malawi,* [5]*WHO South Sudan, Juba, South Sudan*

In 2018, the 71st World Health Assembly adopted a resolution aimed at reducing global cholera mortality by 90% by 2030. Achieving progress towards this goal requires efficient delivery of cholera control measures,

such as targeted water, sanitation, and hygiene (WASH) interventions and oral cholera vaccination (OCV) campaigns, particularly in the context of limited resources, OCV supply, and political capital. While stakeholders, including the Global Taskforce for Cholera Control, have promoted the idea of targeting control measures to cholera "hotspots," a delimited area with high historical burden of disease, there is little consensus about the methods and quantitative measures that should be used to identify and rank specific locations. Moreover, hotspot identification serves different needs at different spatial scales; ministries of health may be interested to identify areas that have relatively high risk of disease within their own countries, while decision makers at organizations such as the World Health Organization and Gavi may use hotspot identification to inform equitable and data-driven decisions about global allocation of cholera-related resources, like vaccines. In this study, we compare multiple approaches that may be used to prioritize cholera hotspots for intervention such as spatial clustering of the relative risk of incidence and a multidimensional incidence-based index. We first perform this exercise with simulated cholera data illustrating how each metric performs in settings with different cholera dynamics seen across the world (e.g., high historical incidence with endemic seasonality, low historical incidence with sporadic epidemics, etc.). Next, we apply these different prioritization methods to incidence data from Tanzania, Malawi and South Sudan to highlight the strengths and weaknesses of each approach. As more countries work towards cholera elimination, it is critical to develop nuanced guidelines for prioritizing cholera hotspots that meet country goals and global needs.

463

CLINICAL CHARACTERISTICS AND RISK FACTORS FOR *CAMPYLOBACTER SPP* GASTROENTERITIS IN THE FIRST YEAR OF LIFE IN A NICARAGUAN BIRTH COHORT

Denise T. St. Jean[1], Roberto Herrera[2], Lester Gutierrez[2], Nadja A. Vielot[3], Fredman Gonzalez[2], Yaoska Reyes[2], Margarita Paniagua[2], Natalie Bowman[4], Filemon Bucardo[2], Samuel Vilchez[2], Sylvia Becker-Dreps[3]

[1]*Department of Epidemiology, Gillings School of Global Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*Universidad Nacional Autónoma de Nicaragua, León, León, Nicaragua,* [3]*Department of Family Medicine, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [4]*Department of Infectious Diseases, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Acute gastroenteritis (AGE) is one of leading causes of morbidity and mortality in children in Nicaragua. Between June 12, 2017 and July 31, 2018, we recruited a prospective birth cohort of 444 newborns in León, Nicaragua to assess the burden of AGE. Fieldworkers conducted household surveys on a weekly and monthly basis to identify risk factors for AGE. Fieldworkers also collected routine monthly stool and stool samples from infants experiencing AGE, which were tested for *Campylobacter spp* (*Campylobacter)* by real time polymerase chain reaction. We first described the clinical characteristics of AGE episodes in which *Campylobacter* was detected. Next, we conducted a nested case-control study to assess risk factors for *Campylobacter* AGE. For each case of *Campylobacter* AGE (restricted to first episodes), we matched 2:1 to infants from the cohort with no history of *Campylobacter*, within 3-month age groups. Finally, we estimated the population attributable fraction of *Campylobacter* among infants experiencing AGE, matching infants with AGE 1:1 to infants who had not experienced AGE within 28 days of the case. Of the 287 AGE stool samples that were collected and tested, 61 (21.3%) were positive for *Campylobacter*. 55 cases (90.2%) presented with diarrhea, which lasted a median 3.4 days. 6 cases presented with vomiting only and bloody stool was observed in only 3 (5.0%) episodes. Cases were significantly more likely than controls to have experienced a prior AGE episode (p<0.001), have recent contact with a person experiencing AGE (p=0.002), and have soap at all household sinks (p=0.014). In a conditional logistic regression model adjusting for predictors of *Campylobacter* AGE, a chicken in the home (OR: 3.64, 95% CI: 1.38, 9.60), soap at all sinks (OR: 4.60, 95% CI: 1.49, 14.23), sharing a bottle in the past week (OR: 3.19, 95% CI: 1.06, 9.63), and having had a prior episode of AGE (OR: 3.82 95% CI: 1.61, 9.03) were independent significant predictors of *Campylobacter* AGE. Comparing 90 infants experiencing AGE to 90 healthy controls, an estimated 22.3% (95% CI: 11.2, 32.1) of AGE episodes in the first year of life can be attributed to *Campylobacter* exposure.

464

CHOLERA OUTBREAKS IN SUB-SAHARAN AFRICA: 1996-2016

Qulu Zheng, Joshua Kaminsky, Heather S. McKay, Andrew S. Azman, Justin Lessler

Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Cholera remains a major public health threat worldwide. Sub-Saharan Africa has a high cholera burden and, in some locations, frequent epidemics. However, comprehensive studies of the overall epidemiology of cholera outbreaks in the region are lacking. The aim of this study is to provide comprehensive descriptions of epidemic features and the diversity of outbreaks across sub-Saharan Africa. We collected and combined surveillance data from multiple data sources (WHO, ProMED, ReliefWeb, UNICEF, MSF, ministries of health, and publications). We identified outbreaks based on local incidence occurring above a locally defined threshold and classified them into three spatial scales, including the country level, the province level ,which was defined as the first subdivision of the country, and the sub-province level, which was defined as the second or lower subdivision of the country. Descriptive analysis was performed separately for outbreaks at each spatial scale. We identified a total of 1,860 cholera outbreaks from multiple spatial scales between 1992-2016 in 25 countries in sub-Saharan Africa. We conducted in-depth analysis of 338 outbreaks with at least 100 suspected cases between 1996-2016 in 22 countries. These included 22 country-level outbreaks, 16 province-level outbreaks and 300 sub-province level outbreaks. The average attack rate for country-level outbreaks was 0.51 per 1,000 (range, 0.01-4.69), for province level was 8.14 per 1,000 (range, 0.03-63.16), and for sub-province level was 9.04 per 1,000 (range, 0.05-185.30). The average case fatality rate (CFR) was 5.48% at the country level (range, 0.39%-20.07%), 3.15% at the province level (range, 0.46%-16.07%) and 4.16% at the sub-province level (range, 0-26.29%). We also observed that the maximum CFR usually occurred during the first months of outbreaks and the estimated basic reproductive number (R_0) varied between outbreaks (mean, 1.56; range, 0.59-3.67). These results show the diversity of cholera outbreaks transmission across sub-Saharan Africa and highlight the importance of early outbreak response and timely case management in the control of cholera outbreaks.

465

A QUANTITATIVE ANALYSIS USING TAQMAN ARRAY CARD TESTING OF SELF-COLLECTED STOOL SMEARS ON WHATMAN FTA ELUTE CARDS TO DETERMINE THE PATHOGEN-SPECIFIC EPIDEMIOLOGY OF TRAVELERS' DIARRHEA

Michele D. Tisdale[1], Indrani Mitra[2], Jamie Fraser[2], Eric Houpt[3], Jie Liu[3], Mark S. Riddle[4], Drake H. Tilley[5], Anjali Kunz[6], Charla Geist[7], Heather Yun[8], Christa Eickhoff[9], David Tribble[2], Michael Price[10], Tahaniyat Lalani[2]

[1]*Infectious Disease Clinical Research Program, Portsmouth, VA, United States,* [2]*Infectious Disease Clinical Research Program, Bethesda, MD, United States,* [3]*University of Virginia, Charlottesville, VA, United States,* [4]*Uniformed Services University of the Health Sciences, Bethesda, MD, United States,* [5]*Naval Medical Center San Diego, San Diego, CA, United States,* [6]*Madigan Army Medical Center, Tacoma, WA, United States,* [7]*Landstuhl Regional Medical Center, Landstuhl, Germany,* [8]*Joint Base*

San Antonio, San Antonio, TX, United States, [9]Naval Medical Center Portsmouth, Portsmouth, VA, United States, [10]Tripler Army Medical Center, Honolulu, HI, United States

PCR based detection of diarrheal pathogens is increasingly used, but its application in field studies is limited by operational challenges (i.e. stool collection and transportation in austere environments) and clinical interpretation of data (i.e. attribution of travelers' diarrhea (TD) to detected pathogens). Self-collection of diarrheal smears on FTA Whatman Elute Cards® (FTA card) by subjects during travel, and mailing to a central testing location in a multi-barrier pouch, is a practicable alternative to conventional methods and is supported by the performance characteristics of the TaqMan Array Card PCR (TAC) on smeared FTA cards vs. stool. We performed a case-control analysis, using a customized TD TAC on self-collected stool smears from adult travelers and deployed military personnel enrolled in a prospective observational cohort study (TravMil). Subjects collected a stool smear on an FTA card during a TD episode (cases) or towards the end of travel if they did not experience any diarrhea (controls), and mailed the card to a central testing site. FTA cards from 231 cases (101 mild acute watery diarrhea [AWD], 65 moderate-severe AWD, 54 febrile TD and 11 dysentery) were matched with controls based on region and duration of travel, age group and time from collection to PCR extraction and testing. Odds ratios (OR) were used to determine the association between detected pathogens and TD. The overall detection rate (60% vs. 21%) and co-pathogen detection rate (21% vs. 3%) was significantly greater in cases vs. controls. Diarrheagenic *E coli* (enterotoxigenic *E coli* (ETEC) (26%), enteroaggregative *E coli* (EAEC) (23%), and enteropathogenic *E coli* (13%) were the most common pathogens in TD cases, and EAEC was detected most in controls (15%). Detection of most bacterial pathogens was significantly associated with TD: ETEC OR: 11.7 [95% CI: 5.2-26.3]; Shigella: 8.3 [95% CI: 1.0-66.5], Campylobacter: 6.8 [95% CI: 2.0-23.3]; EAEC: 1.72 [95% CI: 1.1-2.8]). Higher ORs were observed at cycle threshold (Cq) values < 30. TAC testing of self-collected FTA stool cards is a practical alternative to standard collection and testing methods in TD field studies.

466

ISOLATION, IDENTIFICATION AND *HIL*A GENE CHARACTERIZATION OF *SALMONELLA TYPHI* ISOLATES FROM BLOOD SAMPLES

Sandeep Thapa[1], Nilam Thakur[1], Ajaya Kunwar[1], Govardhan Joshi[1], Kumar Shrestha[2], Junu Budhathoki[2]

[1]*Kathmandu Center for Genomics and Research Laboratory, Gwarko, Nepal,* [2]*St. Xavier's College, Department of Microbiology, Kathmandu, Nepal*

Salmonella enterica serovar Typhi is a gram-negative, rod-shaped facultative anaerobe which is a major causative agent of typhoid fever in the impoverished population with poor sanitation and food habits. Enteric fever is a systemic infection of the reticuloendothelial system caused by the human-adapted pathogens *Salmonella enterica* serotype Typhi and *Salmonella enterica* serotype paratyphi A, B. However, the occurrence of *Salmonella enterica* B and C infection have not been reported in Nepal so far. A cross-sectional study was designed to collect blood samples from patients with typhoid fever after inform consent form. *Salmonella enterica* serovar Typhi was isolated and identification was confirmed using a standard microbiological technique. Further, it was subjected to antibiotic susceptibility test through Kirby-Bauer technique. Moreover, amplification of the *hil*A gene was employed for the molecular diagnosis using PCR. A total of 141 (78 male and 63 female) samples were subjected for diagnosis of typhoid. In this study, PCR has high sensitive (100%) and specificity (62.5%) for *S.* Typhi followed by Widal test (26.9%) and blood culture (14.9%).Additionally, PCR positive were high prevalence in a male with incidence rate higher in age groups 0-15 (14.8%) years followed by 15-30 (12.7%) and 30-45 (9.1%). Twenty-one samples were found to be culture positive with 100% sensitive to tetracycline, ampicillin, cotrimoxazole, and chloramphenicol. Likewise, 71.4 % were sensitive to ofloxacin and azithromycin, 57.4 % to nitrofurantoin. Subsequently, 9.5% and 23.8% of isolates were intermediate to ofloxacin and nitrofurantoin respectively. In contrast, all the isolates were 100% resistance to nalidixic acid. None of the isolates were found MDR. In conclusion, it can be affirmed that PCR is a sensitive, rapid and better alternative than conventional method which can be used in clinical diagnosis that may allow early detection of the causative organism and facilitate initiation of prompt treatment.

467

ANTIBODY GLYCOSYLATION AND THE CORRELATION TO FUNCTIONAL ASSAY ACTIVITY

Anthony R. Vortherms, Hailey P. Weerts, Robert W. Kaminski

Walter Reed Army Institute of Research, Silver Spring, MD, United States

While traditional ELISA quantitates the level of antibodies, these assays do not evaluate the functionality of these antibodies. The *Shigella*-specific bactericidal assay (SBA) is an immunoassay that measures direct bacterial killing by antibody-mediated complement activation. Antibody activity in the SBA requires a surface exposed target and the ability to interact with complement. While antibody isotype plays a major role in immunological function, glycosylation of the antibody also contributes to determining antibody function. Glycosylation of the antibody heavy chain is an important modification that modulates the recognition of the antibody by the immune system. Glycosylation changes can occur in response to external signaling during both *in vivo* and *in vitro* production of the antibody. Monitoring antibody glycosylation may provide insight into the functional activity of the humoral immune response. To develop this relationship, glycan profiles of anti-*Shigella* LPS monoclonal antibodies (mAbs) were correlated to their effectiveness in the SBA. The correlation suggests the best mAb to use in the assay as a control and can be used to compare the lot-to-lot variability of mAb produced to ensure consistency in the SBA. Furthermore, by understanding glycosylation patterns of functionally active antibodies, inducing comparable responses after vaccination can be monitored, which could inform the rational design of Shigella vaccines and be used as a parameter to up or down select candidates for future development.

468

ROLE OF GEOSPATIAL MAPPING TO COMPARE *SALMONELLA TYPHI* CULTURE RESISTANT CASES PRE- AND POST-VACCINATION

Abdul Momin Kazi, Ayub Khan, Mohammad Tahir Yousafzai, Hussain Kaleem, Zabin Wajidali, Farah Naz Qamar

Aga Khan University, Karachi, Pakistan

Pakistan is facing one of the largest epidemiological outbreaks of ceftriaxone-resistant *Salmonella typhi* with outbreak isolates reported mainly in Hyderabad and Karachi; however, cases are being reported in all districts of Sindh and spreading all over Pakistan. The WHO Strategic Advisory Group of Experts has recommended use of typhoid conjugate vaccine (TCV) in endemic countries, prioritizing use in high disease burden areas. Since Nov 2016 to March 2019, 1801 *S. typhi* resistant culture positive cases have been confirmed by Aga Khan University Hospital main lab and collection point and based on this information location based GIS maps stratified according to all 17 towns of Karachi using geospatial mapping techniques have been plotted. The catchment area of Saddar town according to geospatial map and number of *S. typhi* resistant culture positive cases (124) showed highest burden of disease in Saddar town, and hence a TCV vaccination campaign is being conducted as part of outbreak response in high risk Saddar town of Karachi. We aim to use the location of cases along with regional demographic data to project location based geospatial maps before and after this immunization campaign in Saddar town. Depending on the resolution of the data, we may be able to examine whether there are any changes in the spatial distribution of incidence over time. We can additionally extend this analysis to Hyderabad, where TCV is being distributed through an emergency campaign, ongoing since last year. Finally, we will use spatio-temporal analysis to examine the spatial distributions of typhoid before and during the vaccine roll-out, to

assess the need for responsive vaccination strategies in outbreak scenarios. This is work in progress but will be completed by August/September 2019. In conclusion we will show difference between pre and post vaccination cases in high XDR epidemic areas.

469

A LOOP MEDIATED ISOTHERMAL AMPLIFICATION (LAMP) ASSAY FOR THE DETECTION OF *TREPONEMA PALLADIUM*

Laud Anthony Wihibeturo Basing

Komfo Anokye Teaching Hospital, Kumasi, Ghana

The eradication of yaws caused by *Treponema pallidum subsp. pertenue*, is constrained by the lack of rapid, accurate diagnosis. We sought to develop a molecular point-of-care test for the diagnosis of yaws. A Loop-mediated isothermal amplification (LAMP) assay with primers targeting the conserved gene, *tp0967,* with visual detection by lateral flow test strip was developed and optimized. The limit of detection was evaluated while 63 samples from clinical cases of yaws and 5 samples with PCR-confirmed syphilis were used to determine the sensitivity and specificity of the assay compared to the current molecular testing protocol. The developed LAMP assay was found to be optimal when run at 65^{o}C for 30 minutes. The limit of detection was $2.7*10^4$ DNA copies/ml. The sensitivity of the LAMP assay using unextracted and DNA extracted samples were 0.67 and 1.00 respectively. None of the syphilis samples tested positive in any of the assays. In conclusion, we show the development of a fast and sensitive LAMP assay for *yaws* detected by lateral flow test strip. Using extracted DNA, the assay sensitivity is at par with gold standard detection. The assay can be adapted to minimal sample processing required for in-field detection without DNA extraction.

470

RIFAMPIN-OFLOXACIN-MINOCYCLINE (ROM) FOR THE TREATMENT OF PAUCIBACILLARY LEPROSY: A SYSTEMATIC REVIEW

Michael A. Klowak[1], Shareese Clarke[1], Shveta Bhasker[1], Olamide Egbewumi[1], Celine Lecce[1], Alexandra Stoianov[1], Samed Asmer[1], Sharmistha Mishra[2], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada*

Leprosy is a complex tropical infection from a diagnostic and management perspective, as patients with leprosy are at risk of numerous related complications from the disease itself and its treatment. Standard WHO multi-drug treatment (MDT) consists of medications that are potentially harmful and cause a range of adverse systemic effects. Monthly- or single dosing of ROM has emerged as a potential treatment option for leprosy, however, a synthesis of the evidence supporting ROM does not exist. Paucibacillary leprosy, characterized by limited skin lesions and a low bacillary load, may be most amenable to a fluoroquinolone-based treatment protocol. We performed a systematic review of relevant literature to evaluate the safety and efficacy of ROM-based treatment for paucibacillary leprosy. Various databases were searched from inception to March 2019, using a combination of search terms "leprosy", "rifampin", "ofloxacin", "minocycline", and "ROM", while also accounting for alternative disease and chemical identifiers. The systematic review will focus on assessing and reporting on the efficacy, and safety of monthly ROM in the treatment of paucibacillary leprosy within a human population. 1139 records were retrieved for title and abstract screening, however, after a multi-step de-duplication pipeline, 568 articles remained. Subsequent title screening yielded 288 studies that were eligible for final inclusion. Main outcome measures to be assessed are lesion clearance, treatment failure, relapse, side effects and reversal reactions. A cursory review of relevant abstracts suggests that important determinants of health in the treatment of leprosy are: social environments, patient education, health services, gender and income. Synthesizing the current evidence discussing the efficacy of monthly ROM, will strengthen the current body of knowledge surrounding the treatment of paucibacillary leprosy, and may allow for the development of standardized fluoroquinolone-based treatment protocols.

471

THE TREATMENT OF MULTIBACILLARY LEPROSY UTILIZING RIFAMPIN-OFLOXACIN-MINOCYCLINE (ROM): A SYSTEMATIC REVIEW

Shareese Clarke[1], Michael A. Klowak[1], Shveta Bhasker[1], Olamide Egbewumi[1], Celine Lecce[1], Alexandra Stoianov[1], Samed Asmer[1], Sharmistha Mishra[2], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON, Canada*

From a diagnostic and management perspective, leprosy is a complex tropical infection. Patients who are affected by leprosy are at risk of several complications associated with the disease itself and its treatment. Standard WHO multi-drug treatment (MDT) is comprised of medications that are potentially harmful and can induce a variety of adverse systemic effects. Alternative options for potential treatment have emerged such as monthly dosing of Rifmapin-Ofloxacin-Minocycline (ROM) combination therapy, however, there is limited synthesized evidence of efficacy. Multibacillary leprosy, characterized by numerous skin lesions and a high bacillary load, requires more prolonged daily treatment compared to paucibacillary disease. Monthly ROM-based protocols may enable reduced pill burden and translate to fewer adverse effects associated with the clofazimine and dapsone components of standard MDT, in particular. To assess the safety and efficacy of monthly ROM treatment and to determine how this may be affected by determinants of health, we conducted a systematic review of relevant literature. Various databases were searched from inception to March 2019, using a combination of search terms "leprosy", "rifampin", "ofloxacin", "minocycline", and "ROM", while also accounting for alternative disease and chemical identifiers. 1139 records were retrieved for title and abstract screening, after which 288 studies were eligible for final inclusion. Primary outcome measures to be evaluated are lesion clearance, treatment failure, relapse, side effects and reversal reactions. A perfunctory review of relevant abstracts proposes that the major determinants of health to be considered in the treatment of leprosy are: social environments, education level of the patient, access to health services, gender and income. By synthesizing the current evidence discussing the efficacy of monthly ROM in treating multibacillary leprosy, we will map the current body of knowledge that exists with the ultimate goal of enabling more simplified standardized treatment protocols.

472

RISK FACTORS FOR BACTEREMIA IN SEVERELY MALNOURISHED UNDER-FIVE PNEUMONIC CHILDREN AND THEIR OUTCOME

Abu sadat mohammad sayeem Bin Shahid, Tahmeed Ahmed, Km Shahunja, Mohammod Jobayer Chisti

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh

Bacteremia is quite common in severe acute malnourished (SAM) children with pneumonia, who often experience a fatal outcome, especially in developing countries. There is limited information in the medical literature on the risks of bacteremia in SAM children with pneumonia. We have examined the factors associated with bacteremia and their outcome in under-five children who were hospitalized for the management of pneumonia and SAM. In this unmatched case-control study, SAM children of either sex, aged 0-59 months, admitted to the Dhaka Hospital of the International Centre for Diarrheal Disease Research, Bangladesh (icddr,b) with cough or respiratory distress and radiological pneumonia during April 2011 to July 2012 were enrolled (n=405). Those with pneumonia as well as bacteremia constituted the cases (n=18), and randomly selected SAM children with pneumonia without bacteremia constituted controls

(n=54). A wide range of bacterial pathogens were isolated among the cases of which 13 (72%) were Gram negatives. Death rate was higher among the cases than the controls (28% vs. 9%) but the difference was not statistically significant (p=0.111). In logistic regression analysis, after adjusting for potential confounders, such as the lack of DPT/oral polio/HIV/hepatitis vaccination, measles vaccination, vomiting, and clinical dehydration (some/severe) the SAM children with pneumonia as well as bacteremia more often had the history of lack of BCG vaccination (95% CI=1.17-29.98) and had diastolic hypotension (<50 mm of Hg) (95% CI=1.01-12.86) not only after correction of dehydration but also in its absence.The results of our study suggest that history of lack of BCG vaccination and presence of diastolic hypotension in absence of dehydration on admission are the independent predictors of bacteremia in SAM children with pneumonia. The results indicate the importance of continuation of BCG vaccination to produce benefits beyond the primary benefits.

473

SEROEPIDEMIOLOGY OF *BURKHOLDERIA PSEUDOMALLEI*, ETIOLOGIC AGENT OF MELIOIDOSIS, IN THE OUEST AND SUD-EST DEPARTMENTS OF HAITI

Thomas A. Weppelmann[1], Michael H. Norris[2], Michael E. von Fricken[3], Bernard A. Okech[2], Anthony P. Canella[2], Herbert P. Schweizer[2], Apichai Tuanyok[2]

[1]*Herbert Wertheim College of Medicine, Miami, FL, United States,* [2]*University of Florida, Gainesville, FL, United States,* [3]*George Mason University, Fairfax, VA, United States*

Burkholderia pseudomallei, the etiological agent of melioidosis, has been hypothesized to be endemic throughout the Caribbean, including Haiti. Due to the protean clinical manifestations, presence of asymptomatic infections, and limited diagnostic capacity, the identification of active melioidosis cases remains challenging. A seroepidemiological study was conducted using a novel enzyme-linked immunosorbent assay (ELISA) to detect antibodies toward *B. pseudomallei* in the native population. The performance of an indirect ELISA with purified lipopolysaccharide (LPS) from *B. pseudomallei* was evaluated using serum collected from rhesus macaques exposed to aerosolized *B. pseudomallei*. After optimization, serum collected from asymptomatic population members (n=756) was screened for polyvalent (IgM/IgG/IgA) and monoclonal (IgG or IgM) immunoglobulins against *B. pseudomallei* LPS. The population seroprevalence was 11.5% (95% CI: 9.2, 13.8) for polyvalent immunoglobulins, 9.8% (95% CI: 7.7, 11.9) for IgG, and 1.7% (95% CI: 0.8, 2.6%) for IgM. The seroprevalence was not significantly different by gender (P =0.16), but increased significantly (P <0.001) with age, yielding an estimated annual seroconversion rate of 1.05% (95% CI: 0.81, 1.3). In conclusion, the detection of both recent (IgM+) and previous (IgG+) exposure to *B. pseudomallei* provides serological evidence that melioidosis is endemic in Haiti.

474

MELIOIDOSIS AND SEROLOGICAL EVIDENCE OF EXPOSURE TO *BURKHOLDERIA PSEUDOMALLEI* AMONG PATIENTS WITH FEVER, NORTHERN TANZANIA

Michael J. Maze[1], Mindy Glass Elrod[2], Alex Hoffmaster[2], Holly M. Biggs[3], Philoteus Sakasaka[4], Wilbrod Saganda[5], Bingileki F. Lwezaula[5], Blandina Mmbaga[4], Venance P. Maro[4], Matthew P. Rubach[3], John A. Crump[6]

[1]*University of Otago, Christchurch, New Zealand,* [2]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [3]*Duke University, Durham, NC, United States,* [4]*Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania,* [5]*Mawenzi Regional Referral Hospital, Moshi, United Republic of Tanzania,* [6]*University of Otago, Dunedin, New Zealand*

Prediction models indicate that melioidosis may be common in parts of East Africa, but there are few empiric data. We evaluated the prevalence of melioidosis among patients presenting to hospital with fever in northern Tanzania. Patients with fever were enrolled at Kilimanjaro Christian Medical Centre and Mawenzi Regional Referral Hospital 2007-08 and 2012-14. Participants had aerobic blood culture performed and bloodstream isolates were identified by conventional methods. Following testing on the API20NE (BioMérieux, Marcy-l'Étoile, France) biochemical identification system, non-glucose fermenting gram-negative bacilli were further tested by *B. pseudomallei* latex agglutination (Mahidol University, Thailand) test. In addition, acute serum was collected at enrolment and convalescent serum 4-6 weeks later. The convalescent serum of a subset of participants considered at high epidemiologic risk of melioidosis: those admitted within 30 days of rainfall was tested using *B. pseudomallei* indirect haemagglutination assay serology (IHA). We performed *B. pseudomallei* IHA on acute and convalescent sera of participants with a reciprocal titer ≥40 on their convalescent serum. We defined a confirmed case of melioidosis as isolation of *B. pseudomallei* from blood culture; probable melioidosis as a ≥4-fold rise in antibody titers between acute and convalescent sera; and seropositivity as a single antibody titer ≥40. We enrolled 2,663 participants and isolated 4 (0.2%) non-enteric gram-negative bacilli from blood culture; none were *B. pseudomallei*. We tested 323 participants by IHA. Of participants, 142 (44.0%) were male, the median (range) age was 27 (0-70) years, and the median (range) duration of fever was 4 (1-60) days. We identified no cases of confirmed melioidosis; 2 (0.6%) of probable melioidosis; and 57 (17.7%) were seropositive. The high proportion of seropositive participants may suggest that either *B. pseudomallei* or an antigenically similar organism is present in northern Tanzania. Further research into the presence of *Burkholderia* spp. as a cause of illness and in the environment is warranted.

475

ETIOLOGY OF NEONATAL SEPSIS IN SUB-SAHARAN AFRICA: PATHOGENS AND THEIR ANTIBIOTIC SUSCEPTIBILITY PATTERNS

Elias Impens[1], Piet Cools[2], Ann Impens[3], Guy Mulinganya[4], Steven Callens[2]

[1]*Pennsylvania Hospital, Philadelphia, PA, United States,* [2]*Ghent University, Ghent, Belgium,* [3]*Midwestern University, Downers Grove, IL, United States,* [4]*Université Catholique de Bukavu and Hôpital Provincial Général de Référence de Bukavu, Bukavu, Democratic Republic of the Congo*

Neonatal sepsis is the leading cause of neonatal mortality in sub-Saharan Africa (SSA), but data on the etiology of neonatal sepsis in developing countries are limited in both quality and quantity. Current recommendations for empiric treatment of neonatal sepsis are primarily based on data from high-income countries, where Group B *Streptococcus* and *Escherichia coli* are the predominant pathogens. Better knowledge about pathogens causing neonatal sepsis in SSA, as well as their antibiotic susceptibility patterns, is needed to design and implement strategies based on pathogens that locally predominate. Therefore, a systematic literature review was conducted, with the objective of providing an overview of these pathogens and their antibiotic susceptibility patterns. A protocol was submitted to PROSPERO, an international prospective register of systematic reviews, prior to starting the review. Studies were identified using the stepwise approach specified in the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) Statement. MEDLINE/Pubmed, EMBASE, Web of Science, Cochrane Library, African Index Medicus, African Journals Online and Hindawi journals were searched. An exhaustive grey literature search was conducted as well. All studies were screened by two independent reviewers based on eligibility criteria, and approximately 150 original studies will be included for analysis. To our knowledge, we are conducting the first and most comprehensive systematic review and meta-analysis on this topic. This information on pathogens and their susceptibility patterns by region will be useful for local guideline development and appropriate treatment of neonatal sepsis.

476

DESIGN AND EVALUATION OF NOVEL LIPOSOME-BASED PEPTIDE VACCINES FOR IMPROVED EFFICACY AGAINST GROUP A STREPTOCOCCAL INFECTIONS OF MUCOSA AND SKIN

Victoria Ozberk[1], Mehfuz Zaman[1], Emma Langshaw[1], Sharareh Eskandari[1], Ainslie Calcutt[1], Jessica Powell[1], Michael R. Batzloff[1], Jes Dietrich[2], Manisha Pandey[1], Michael F. Good[1]

[1]*Institute for Glycomics, Griffith University, Southport, Australia,* [2]*Statens Serum Institut, Copenhagen, Denmark*

Victoria Ozberk *Streptococcus pyogenes* (Group A Streptococcus; GAS) infections and their sequelae are responsible for significant morbidity and mortality worldwide. A vaccine that can prevent GAS infection at the primary sites of infection is urgently needed to block the onset of potentially life threatening GAS-associated diseases. We demonstrated that intranasal administration of a liposomal delivery system, incorporating GAS peptide antigens, J8 and S2, protects against upper respiratory tract (URT) infection with wild-type and hypervirulent GAS strains. Addition of an immunostimulatory glycolipid to the mucosally active liposomal vaccine significantly enhanced vaccine efficacy to protect at both mucosal and systemic compartments of immunity. We show that secretory IgA is not necessary in vaccine-mediated protection against URT GAS infection but that a vaccine-specific IL-17A response is associated with protection. Furthermore, we show that prime-pull immunisation with J8-DT and K4S2-DT formulated with another novel liposomal delivery system promotes high and sustained antibody levels in the airway mucosa and in the serum. The same vaccine also leads to the establishment of cellular immunity and protection against skin and URT hypervirulent GAS infections. In conclusion, the findings reported here represent a significant advancement in overcoming many obstacles impeding the development of GAS vaccines to prevent infection at mucosal and systemic sites.

BACTERIAL MENINGITIS IN MALAWIAN CHILDREN, 2000-2018

Markye Nielsen[1], **Stephen TJ Ray**[1], Kondwani Kawaza[2], Brigitte Denis[1], Stephen B. Gordon[1], Michael J. Griffiths[3], Enitan Carrol[3], Neil French[3], Queen Dube[2], Pui-Ying Iroh Tam[1]

[1]*Malawi-Liverpool-Wellcome Trust, Blantyre, Malawi,* [2]*University of Malawi, College of Medicine, Blantyre, Malawi,* [3]*Institute of Infection and Global Health, University of Liverpool, Liverpool, United Kingdom*

Bacterial meningitis represents a significant burden of infectious disease in hospitalised children in sub-Saharan Africa, where antimicrobial resistance (AMR) is a growing problem. We describe trends of bacterial meningitis infections in children ≤5 years admitted to a tertiary referral hospital in Blantyre, Malawi between 2000 and 2018. We determined the total number of cerebrospinal fluid (CSF) culture pathogens and associated AMR profiles. A total of 2,375 pathogens (48.5% Gram-positive, 51.5% Gram-negative) were identified in children ≤5 years. There was an absolute decrease in number of CSF pathogens identified across three periods (2000-2014), most notably in *Haemophilus influenzae* type b, *Streptococcus pneumoniae* and nontyphoidal Salmonella. However, compared to the third period (2010-2014), the last period (2015-2018) has seen an absolute increase in CSF pathogens, 8% for Gram-positives and 97% for Gram-negatives. Children ≤60 days of age accounted for 35% of positive isolates overall, but 45% of positive isolates in the last period. An increase in AMR was noted across four periods, with resistance to ceftriaxone increasing from 20.0% to 95.8% for *Klebsiella pneumoniae* and 0% to 62.8% for *Escherichia coli*. Absolute numbers of culture proven bacterial meningitis cases in hospitalised children at our tertiary referral hospital decreased overall during the last 19 years. Rollout of conjugate vaccines and improvement in hygiene/sanitation are in large part responsible for the overall decrease. However, that decreasing trend has recently been reversing, with an increase in drug resistant pathogens, particularly larger numbers of Gram-negative CSF pathogens resistant to first-line antimicrobials. These data mirror the worrisome emergence of AMR in childhood blood stream infections in our setting.

478

ASSESSING THE ROLE OF POSTMORTEM MICROBIOLOGY IN DETERMINING THE CAUSE OF FATAL FEBRILE ILLNESS, KILIMANJARO, TANZANIA

Cristina Costales[1], Matthew P. Rubach[1], Alex Mremi[2], Patrick Amsi[2], Manuela Carugati[1], Ann M. Nelson[3], Venance P. Maro[4], John A. Crump[1]

[1]*Division of Infectious Diseases and International Health, Duke University, Durham, NC, United States,* [2]*Department of Pathology, Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania,* [3]*Department of Pathology and Laboratory Medicine, Duke University, Durham, NC, United States,* [4]*Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania*

Understanding infectious cause of death (COD) is critical, yet the role of postmortem (PM) microbiology is debated. To evaluate the contribution of PM microbiology to identify causes of fatal febrile illness in northern Tanzania, from November 2016 through October 2018 families of all inpatient febrile deaths at two referral hospitals were offered autopsy with multi-site aerobic and mycobacterial cultures. Culture of venous blood, bone marrow (BM), cerebrospinal fluid (CSF), liver and lung tissue was done to assess the yield and concordance of the different specimen sites. COD was assigned by panel adjudication based on review of medical charts, autopsy gross and histologic findings, and culture results. Microbiology was 'contributory' if there was clinical or histologic evidence to support infection by the isolated organism and the organism was a pathogen associated with intermediate or immediate COD diagnoses. Among 179 PMs, 119 (67%) had ≥3 aerobic cultures collected. The most common aerobic isolates were *Escherichia coli, Klebsiella pneumoniae,* and *Staphylococcus aureus*. Of samples, 38 (56%) of 68 blood, 16 (52%) of 31 BM, 12 (71%) of 17 CSF, and 22 (37%) of 60 liver cultures were contributory to COD. When considering only febrile deaths where the same organism was isolated from ≥2 sites, 24 (71%) of 34 blood, 13 (59%) of 22 bone marrow, 11 (79%) of 14 CSF and 18 (72%) of 25 liver cultures were contributory to COD. Of 122 febrile deaths with mycobacterial cultures, 116 (95%) had ≥2 specimen collection sites. Of PMs with tuberculosis as COD, *Mycobacterium tuberculosis* grew in 11 (65%) of 17: 4 (7%) of 52 CSF, 8 (7%) of 115 liver, and 5 (4%) of 113 lung, and all were contributory. We found that when the same organism was isolated from ≥2 sites, PM aerobic cultures from blood, CSF, and liver tissue, provided contributory information to determine COD in over two-thirds of febrile deaths. Mycobacterial cultures were infrequently positive but were universally contributory.

479

CHANGING PATTERN OF STREPTOCOCCAL INFECTIONS

Don W. Kannangara, Dhyanesh Pandya

St Luke's University Health Network, Phillipsburg, NJ, United States

Group A Streptococcal infections (GAS) are usually a problem in developing countries. In a study of 296 isolates of hemolytic streptococci in India 74% were group A and only 3.7% belonged to group B. Worldwide, an estimated 18 million people are believed to suffer from GAS related illnesses. Recently there was a resurgence of scarlet fever in England with over 19,000 cases reported in 2016. In Ireland there was an upsurge of GAS in 2012-2015 period. An outbreak of GAS was reported in a homeless community in Anchorage, Alaska (2016-2017) and other outbreaks in Hong Kong (2012-2015) and South Korea (2011-2016). Also, there were reports of resurgence of GAS in injection drug users (New Hampshire) and a mental health facility (Singapore). Group B *Streptococcus* (GBS) is classically considered a problem in neonates and puerperal sepsis. In 2018, Los Angeles county reported 62% Clindamycin resistance in GBS. A 32% reduction in GBS incidence in infants was

recently reported from Germany. We studied 1321 isolates of Streptococci reported by our network labs from adults. GBS was the predominant isolate (481). Blood cultures were positive in 199. 175 were from urine and others were from wounds, tissue and body fluids. Group A was found in 80 blood cultures (BC), followed by *S. anginosus* 66, Group G 54, Group C 51, S. intermedius 31, *S. constellatus* 11 and *S. dysgalactiae* 3. Source of the blood cultures for majority of the isolates was lower extremity cellulitis. The commonest Streptococcal isolate from BC, urine, Soft tissue and joint fluid in adults was GBS. *S anginosus* incidence was higher than expected. A detailed analysis of all isolates will be presented.

Jackson Foundation, Bethesda, MD, United States,* [2]*Naval Medical Research Unit Number* [2]*, Phnom Penh, Cambodia,* [3]*Takeo Provincial Referral Hospital, Takeo, Cambodia,* [4]*Naval Medical Research Unit Number* [3] *Ghana Laboratory, Accra, Ghana,* [5]*Komfo Anokye Teaching Hospital, Kumasi, Ghana,* [6]*Duke University, Durham, NC, United States*

Expeditious and accurate information for clinical decision-making is critical for improving outcomes for patients with sepsis, particularly in low- and middle-income countries, and can be enhanced using host-response biomarkers indicative of sepsis type and prognosis. The Austere environments Consortium for Enhanced Sepsis Outcomes (ACESO) is a consortium of military medical and academic research institutes aiming to improve early recognition, diagnosis and treatment of sepsis in low-resource settings. The aim of this study was to identify gene and protein expression phenotypes in sepsis patients enrolled in an observational study from sites in Cambodia, Ghana and the USA (n=586). Topological data analysis (TDA) was used as an unsupervised method for identifying clusters of patients with similar molecular phenotypes, as well as broader trends in gene and protein expression across the TDA network. Differences in clinical presentation and clinical laboratory measurements between TDA clusters were tested for statistical significance to inform on sepsis endotypes associated with the molecular expression phenotypes. Our analysis highlighted two major trends in the protein data and identified six distinct but partially overlapping patient clusters. Protein concentrations along the primary TDA axis were predictive of mortality within the first 28 days of disease, representing a two-fold increase in mortality risk for patients at either end of the spectrum, independent of enrollment site. At least six distinct patient clusters were identified in the gene expression TDA, with corresponding differences in clinical presentation and a five-fold difference in 28-day mortality. In summary, TDA of protein and gene expression in patients with sepsis identified multiple host-biomarker phenotypes with distinct clinical presentations and significant differences in sepsis outcome. The ability to accurately stratify patients by mortality risk at presentation would inform decisions regarding the urgency of care required, direct medical resources to patients with the greatest need, and would do so early when the impact is greatest.

BACTERIOPHAGE THERAPY: RENEWED STRATEGY TO TARGET DRUG RESISTANT *STAPHYLOCOCCUS AUREUS*

Rutu M. Dave[1], Robert P. Fort[1], Ricardo Abadie[2], Patrick Schukraft[1], Jose Chu Luo[1], Gillian Naro[1], David W. Craft[1], James Regeimbal[2]

[1]*Pennsylvania State College of Medicine, Hershey, PA, United States,* [2]*Naval Medical Research Unit No.* [6]*, Lima, Peru*

As antibiotic overuse and misuse is increasing the incidence of drug resistant bacterial species worldwide, the value of bacteriophage as a bactericidal agent has become increasingly important. Revisiting this strategy from the annals of history may serve as an opportunity for targeting drug resistant bacteria. We sought to identify and isolate bacteriophages with infectivity specific to drug resistant *Staphylococcus aureus* (SA) isolated from clinical samples including wound cultures in Iquitos, Peru. Ten strains of drug resistant SA were used to isolate phages. Each strain was incubated with sewage water and TSB overnight to amplify phages specific to the drug resistant SA strain. Serial dilutions of the supernatant were subsequently plated on the corresponding strain of drug resistant SA. Individual plaques were isolated, purified and tested for cross-infectivity against a panel of 20 drug resistant SA clinical strains. Five phages were isolated on five of the ten drug resistant SA strains used for phage harvesting. Here we present the infectivity profile of these five potential phages. Each phage infected the same 16 across the panel of 20 drug resistant SA strains, suggesting that all the phages were the same virus. These findings raise the possibility of homogeneity among drug resistant SA surface receptors or a lack of diversity among SA specific bacteriophages within the environmental samples used. While challenges remain in the development of bacteriophage therapy, phages isolated in this and partnering studies will contribute to a greater library of bacteriophages which has the potential to revolutionize existing antimicrobial therapy as greater resistance to standard therapies emerges.

482

A FIELD PORTABLE THERMOCYCLER T-COR 8™ FOR MULTIPLEX DETECTION AND DIFFERENTIATION OF *BURKHOLDERIA PSEUODOMALLEI* AND *BURKHOLDERIA MALLEI*

Neeraja Venkateswaran, Tracy Fecteau, Patricia Valencia, Kodumudi S. Venkateswaran, William M. Nelson

Tetracore, Inc., Rockville, MD, United States

CDC classifies *Burkholderia pseudomallei* (Bp), and *Burkholderia mallei* (Bm) as Tier 1 select agents and they cause melioidosis and glanders respectively in humans and solipeds such as horses. Clinical diagnostics currently use isolation and culture of these two organisms as the gold standard which is painstakingly slow. Phylogenetic similarities between Bp, Bm and *B. thailandensis* (Bt) which is a very similar saprophyte make the accurate detection and differentiation of these organisms very challenging. We have developed a multiplex assay that uses two different Burkholderia genomic targets and an internal control that acts as an amplification control. The first target is a flagellin *fliC* gene variant that is positive for both Bp and Bm and negative for Bt, and the second target is a unique sequence that was designed by subtractive hybridization and is present on chromosome II of both Bp and Bt and not Bm. Thus, a sample is identified as Bp if it is positive for both markers, a sample positive only for fliC assay is Bm, and a sample positive for the second marker only is identified as Bt. Analytical sensitivity of this multiplex assay was determined by titration of genomic DNA isolated from Bm strain ATCC 23344 and Bp strain ATCC 11668. We tested each target individually and in the multiplex format to determine the assay characteristics and assure that the addition of multiple targets does not negatively affect the performance of the test. Next, we tested the heat inactivated cultures directly without any genomic DNA extractions in the assay to determine the robustness of the multiplex assay. We tested 20 different strains of Bm, Bp, Bt, and 4 near neighbors with this multiplex assay. We found that this assay was able to detect accurately and differentiate between Bp, Bm, and Bt. All the near neighbors tested here were found to be negative for both markers. No false positive with the high concentration of Bm sample for Bp-specific assay were observed. Either Bp / Bt assay did not detect one out of 7 Bt. The 4 near neighbors tested were negative for both the targets. We conclude that this multiplex assay can successfully detect and differentiate between Bm and Bp.

483

RISING AWARENESS OF LEPTOSPIROSIS IN PANAMA

Laia Jimena Vazquez Guillamet[1], Ana Belen Arauz[2], Jose Antonio Suarez[3], Emma Gonzalez[4], Jose Domingo Obaldía[3], German Henostroza[1], Blas Armien[3]

[1]*University of Alabama at Birmingham, Birmingham, AL, United States,* [2]*Hospital Santo Tomas, Panama City, Panama,* [3]*Instituto Conmemorativo Gorgas de Estudios de La Salud, Panama City, Panama,* [4]*Hospital Aquilino Tejeira, Cocle, Panama*

Global leptospirosis burden is significant; however, inadequate diagnosis has affected the awareness of the disease. Despite favorable environmental transmission conditions, Panama has a significantly lower incidence of cases and alerts than its neighbor countries. We would like to expand the knowledge of leptospirosis in Panama and discuss diagnostic yield of current tests available. A cohort of patients admitted from January 2013 to December 2018 to Santo Tomas Hospital (STH) with suspected leptospirosis was retrospectively reviewed. Patients were selected if a serology test for leptospirosis was requested. Demographic data, clinical signs and symptoms, laboratory profile and treatment regimens were collected. Microagglutination assay results were used for confirmation. We retrieved 107 medical records from a total of 188 cases with suspected leptospirosis (56.9%). Mean age was 45.2 years (SD 17.2), 68.2%(73/107) were male, and 67.6%(71/107) were from Panama district. The most prevalent signs and symptoms were fever (75.7%, 81/107), nausea/vomiting (57%,61/107), abdominal pain (53.3%, 57/107), and jaundice (43%, 46/107). First serology for Leptospira was obtained in 91.6%(98/107), and second serology was obtained in 34.8%(34/98). Time from admission to first IgM was in average 7 days. Leptospirosis was ruled out in 34.8%(34/98) and confirmed in 14.3%(14/98), leaving 55.1%(59/107) probable cases. Antibiotics were initiated in average 2.1 days after admission and were appropriate in 59.6%(53/89) of cases. Confirmed cases happened mostly during wet season 92.9%(13/14) and 50%(7/14) had severe disease. Mortality was 28.6%(4/14) among confirmed cases and 23.8%(14/59) among probable cases. Features of leptospirosis in STH were like those reported in other series. High prevalence of severe disease among confirmed and probable cases correlates with tertiary nature of the hospital and highlights the need of early diagnosis. Cost-effectiveness of PCR analysis should be considered in this setting.

484

EFFECTIVENESS OF COMMUNITY VERSUS FACILITY DELIVERY OF DIHYDROARTEMESININ-PIPERAQUINE FOR POST-DISCHARGE MALARIA CHEMOPREVENTION IN MANAGEMENT OF SEVERE ANEMIA IN MALAWIAN CHILDREN: A CLUSTER RANDOMIZED TRIAL

Thandile Nkosi-Gondwe[1], Bjarne Robberstad[2], Mavuto Mukaka[3], Richard Idro[4], Robert Opoka[4], Feiko Ter Kuile[5], Saidon Banda[1], Bjorn Blomberg[6], Kamija Phiri[1]

[1]*University Of Malawi, College Of Medicine, Blantyre, Malawi,* [2]*University of Bergen, Department of Global Public Health and Primary Care, Centre for International Health, Bergen, Norway,* [3]*Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Bangkok, Thailand,* [4]*Department of Pediatrics and Child Health, Makerere University College of Health Sciences, Kampala, Uganda,* [5]*Kenya Medical Research Institute (KEMRI), Centre for Global Health Research (CGHR), Kisumu, Kenya,* [6]*Department of Health Promotions and Development, University of Bergen, Bergen, Norway*

Evidence shows that provision of post-discharge malaria chemoprevention (PMC) for a child with severe malarial anemia reduces the risk of death and hospital re-admissions. We aimed to evaluate the most effective delivery method of PMC. We conducted a 5-arm, cluster-randomized trial at Zomba Central hospital in Southern Malawi. Severely anemic children aged less than five years were randomized to receive dihydroartemisinin-piperaquine (DHP) within the community or facility at 2, 6 and 10 weeks after discharge. In community arms, all DHP doses were given at discharge and caregivers collected from hospital in facility arms. Trial arms were: 1) community without a short-text message service (SMS) reminder; 2) community with an SMS; 3) community with a CHW reminder; 4) hospital without an SMS or 5) hospital with an SMS. Factorial design analysis for pooled effect of delivery method was utilized and a Poisson regression model was fitted. The primary outcome was adherence. Between March 2016 and October 2018, we recruited 375 children and followed them up for 15 weeks. When PMC was delivered through the community; adherence was higher compared to facility-based methods (IRR=1.24; 95%CI1.06, 1.44 p=0.006) and this was observed in both the SMS recipients (IRR=1.41;CI1.21, 1.64,p<0.001) and in the non-SMS recipients (IRR=1.37;CI1.18, 1.61,p<0.001). However, there was no evidence that SMS reminders resulted in greater adherence (IRR=1.03;CI0.088, 1.21,p=0.677). When compared to the standard of care, delivery utilizing CHWs resulted in higher adherence (IRR=1.32;CI1.14, 1.54,p<0.001). But there was no difference in adherence between facility delivery with SMS and the standard of care (IRR=1.16;0. 99,1.37,p=0.066). Delivery of DHP for PMC resulted in higher adherence when delivered using community-based methods compared to facility-based methods with or without SMS.

485

THE CLINICAL MANIFESTATIONS AND HEPATIC INVOLVEMENT OF DENGUE INFECTION IN ADULTS

Bo Bo Thet Ko[1], Weerapong Phumratanaprapin[2], Benjaluck Phonrat[2], Jittima Dhitava[2], Vorada Choovichian[2], Maleerat Sutherat[2]

[1]*University Research Co.LLC, Dawei, Myanmar,* [2]*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand*

A retrospective study was conducted in the Hospital for Tropical Diseases, Bangkok, Thailand to describe the hepatic involvement in dengue infection, describe the clinical manifestation of dengue, determine the risk factors for DHF and describe the outcome of dengue infection. After reviewing 534 patients records during January 2007 to September 2010 were reviewed and 315 patients who fulfilled the inclusion criteria were enrolled in this study. Out of 315 patients, 250 were DF and 65 were DHF. Hepatitis was found in 132 (42.9 %) during hospitalization. The mean level of peak AST and ALT level during hospitalization were 262.8 (±257.4) U/L and 212 (±214.4%) U/L. Severe hepatitis was found in 10 patients and the percentage of severe hepatitis on DF group was higher than that of DHF group. Eighty percent of the patients who had increased ALT and AST levels returned to normal at follow up within 4 weeks duration. Moreover, ALT and AST levels of female population were higher than that of male. Common clinical presentation of dengue infection in this study were malaise (98.7 %), anoraexia (93.5%), headache (92.7 %), nausea (77.7 %), chills (75.2 %), vomiting (66.4 %) and diarrhoea (37.6 %). Two risk factors for developing DHF found by this study were platelets count < 50 (x 10^3 cells/μL) on admission and gum bleeding. The mean duration of fever in this study was 5.9 (±1.5) days. The mean duration hospital stay was 3.6 (± 1.5) days.

486

COLONIZATION AND INFECTION WITH ANTIBIOTIC-RESISTANT ORGANISMS IN A VIETNAMESE INTENSIVE CARE UNIT

Duong Bich Thuy[1], James Campbell[2], Chung The Hao[2], Stephen Baker[2], Nguyen Van Vinh Chau[1], Ronald Geskus[2], Le Thanh Hoang Nhat[2], Guy Thwaites[2], Louise Thwaites[2]

[1]*Hospital for Tropical Diseases, Ho Chi Minh, Vietnam,* [2]*Oxford University Clinical Research Unit, Ho Chi Minh, Vietnam*

Little is known about colonisation and subsequent infections with antibiotic-resistant organisms (AROs) in Vietnam, particularly from intensive care units (ICUs). There are several reasons for this, but include the unregulated antibiotic use, lack of infection control, and limited funding. A prospective longitudinal study was conducted in Adult ICU,

Hospital for Tropical Diseases, Vietnam from 10th November 2014 to 14th January 2016 to characterize colonisation, and understand its relationship with infections by *Staphylococcus aureus*, *Escherichia coli*, *Klebsiella* spp., *Pseudomonas aeruginosa*, and *Acinetobacter* spp.. In the first 48 hours of ICU admission, 63.1% (529/838) of patients were colonised with AROs. The colonisation proportion with AROs among patients admitted from the community was comparable to those transferred from other hospitals (62.2% vs 63.8%). During ICU stay, 61.3% (223/364) of patients with a ICU stay >48 hours acquired AROs colonisation. The proportion of patients with hospital-acquired infections (HAIs) was 23.4% (85/364), and AROs accounted for 41.5% (44/106) of pathogens causing HAIs. Multilocus sequence typing analysis indicated matching sequence types of infecting and previously colonizing isolates in 90% (9/10) and 94.4% (17/18) patients with HAIs by *Staphylococcus aureus* and *Klebsiella pneumoniae*, respectively. Phylogenetic analysis confirmed that ICU patients became infected with their previously colonizing *Staphylococcus aureus* ST188 (4 patients) or *Klebsiella pneumoniae* ST17, ST23 and ST86 (6 patients). It is also noteworthy that some hypervirulent *Klebsiella pneumoniae* clones with the acquisition of siderophore and *rmpA* are circulating in Vietnam. This study provides strong evidence of the high burden of antimicrobial resistance in Vietnam along with high rate of colonisation and infections with AROs not only in ICU but also in the community. Therefore, the implementation of infection control measures and antimicrobial stewardship programs is urgently needed in Vietnam.

487

ARE WE CLINICALLY MISSING LEPROSY IN ERA OF ELIMINATION?

Neena Khanna

AIIMS, New Delhi, India

With elimination of leprosy from most parts of the World including India, its diagnosis is becoming challenging. We retrospectively reviewed case files of 1543patients registered during 2009-2015 in leprosy clinic of All India Institute of Medical Sciences, New Delhi, India to determine number of patients in whom diagnosis of leprosy had initially been missed resulting in delay in starting antileprosy treatment (ALT). We also identified the spectrum of diseases diagnosed in these patients. Of the 1543files reviewed, we observed that 156 (1.01%) patients had been misdiagnosed at presentation to the doctor and institution of ALT had been delayed for periods varying from 1- 36 months. In 27 (17.3%) of these patients the diagnosis of leprosy was missed at the primary health center, in 46 (29.5%) by the general practitioner, in 34 (21.8%) by practitioners of alternate systems of medicine, in 39 (25%) by a dermatologist, in 9 (6.4%) by an internist and in 1 (0.6%) by a surgeon. In 92 (59.0%) patients, the delay in the diagnosis had led to development of disability (grade I: 60; grade II: 32). In 110 (70.5%) patients, the patient's prescription did not have any diagnoses and the patient had been treated variously with topical steroids, vitamin supplements and antihistamines. Of the 36 patients in whom a diagnoses of dermatological conditions was made, 22 (14.1%) were diagnosed to have a fungal infection and in other 14 (9.0%) a spectrum of dermatological diseases were diagnosed including orofacial granulomatosis (2 patients), post kala azar dermal leshmaniasis (3), granuloma annulare (2), erythema annulare centrifugum (1) and sarcoidosis (2). One patient each with erythema nodosum leprosum (ENL) was misdiagnosed as erythema nodusum and Sweet's syndrome. Nine (5.8%) patients with ENL presented to the internist due to the presence of conspicuous constitutional symptoms. Three of these were misdiagnosed as lymphoma, and 6 as different connective tissue disorders. The patient who presented to the surgeon was misdiagnosed as neurosarcoma. In conclusion, leprosy remains a great mimicker and clinicians really need to think of leprosy, even in era of elimination.

488

SPECTRUM OF CLINICAL PRESENTATIONS OF *FASCIOLA* INFECTION AMONG CHILDREN IN A COMMUNITY-BASED STUDY

Karen E. Neira[1], Maria L. Morales[2], Martha Lopez[2], Clinton White[3], Andrés G. Lescano[1], Miguel M. Cabada[3]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*Universidad Peruana Cayetano Heredia-University of Texas Medical Branch Collaborative Research Center, Cusco, Peru,* [3]*University of Texas Medical Branch, Galveston, TX, United States*

Three presentation patterns were recognized in our community-based studies on fasciolasis: acute (no eggs in stools eggs, a positive Fas2 ELISA test and increased eosinophils and/or transaminases (E/T), chronic with inflammation (eggs in stools, Fas2 ELISA positive and increased E/T) and chronic (eggs in stools with normal E/T). However, not all diagnosed cases match these presentations. We analyzed data from a cross-sectional study of 2473 children from Anta - Cusco to determine the characteristics of *Fasciola* infections. To identify subjects matching the above presentations and classify unmatched subjects we compared signs and symptoms between the different groups using latent class analysis (LCA). We identified two groups of unmatched subjects: UM1 (4%: eggs in stools but negative Fas2 ELISA and increased E/T) and UM2 (32%: no eggs in stools, a positive Fas2 ELISA test, and normal E/T). UM1 mean age was 10.2 ± 3.5 years, their most frequent symptoms were headache (70%), nausea/vomiting (50%) and cough (50%). In general, UM1 presented a higher symptom frequency and had less differences with chronic cases with negative Fas2 ELISA (31, 13%) results. UM1 may include chronic cases with Fas2 negative and altered markers values near the cutoff. UM2 mean age was 11.2 ± 3.8 years and the most common symptoms were right upper quadrant pain (29%) and headache (23%). UM2 had similar frequencies of signs and symptoms with the acute cases (18, 7%) and chronic with positive Fas2 ELISA (84, 34%). UM2 can be chronic with positive Fas2 ELISA with a false negative stools test or can be acute cases with normal markers values near the cutoff to be considered altered. The LCA identified four classes: Class 1 (42%, "subclinical cases"), Class 2 (24%, "cases with mild hepatic symptoms)", Class 3 (17%, "cases with early symptoms") and class 4 (18%, "symptomatic cases"). UC1 were more frequent in classes 3 and 4 (30% on each), while UC2 were most frequent in class 1 (60%). Results suggest that Fas2 ELISA sensibility and specificity may lead to unclassified cases.

TOPICAL SUNFLOWER SEED OIL THERAPY IN THE MANAGEMENT OF SEVERE ACUTE MALNUTRITION IN CHILDREN UNDER TWO YEARS OF AGE: A RANDOMIZED CONTROLLED CLINICAL TRIAL IN BANGLADESH

Km Shahunja[1], Tahmeed Ahmed[1], Md Iqbal Hossain[1], Mustafa Mahfuz[1], Lindsay Kendall[2], Xinyi Zhu[2], Krishan Singh[3], Jonathan M Crowther[4], Sunita Singh[2], Rachel A Gibson[2], Gary L Darmstadt[5]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh,* [2]*GlaxoSmithKline R&D, Stevenage, United Kingdom,* [3]*GlaxoSmithKline R&D, Collegeville, PA, United States,* [4]*JMC Scientific Consulting Ltd, Egham, Surrey, United Kingdom,* [5]*Stanford University School of Medicine, Stanford, CA, United States*

Children with severe acute malnutrition (SAM) often present with complications, including infections, due in part to compromised skin barrier function. Sunflower seed oil (SSO) which contains high quantity of essential fatty acid (EFA) including linoleic acid, can augments skin barrier function, reduces transepidermal water loss (TEWL) and risk of bloodstream infection, and promotes weight gain in preterm infants by its topical application. We hypothesized that topical treatment of hospitalized children with SAM using SSO, in addition to standard-of-care for SAM, would improve weight gain, skin barrier function, reduce risk of nosocomial infection, and accelerate clinical recovery. We conducted a randomized, two-arm, controlled, unblinded clinical trial in 212

participants aged 2 to 24 months admitted to icddr,b hospital, Dhaka, Bangladesh during January 2016 to November 2017 with SAM (weight for length <-3 SD). Enrollment was age-stratified into 2 to <6 and 6 to 24 months age groups in a 1:2 ratio. All children received SAM standard-of-care, and the SSO group was also treated with 3 g of SSO per kg body weight three times daily for 10 days. At day 10 we found, rate of weight gain was higher in the SSO than the control group [adjusted mean difference (AMD) 0·90 g/kg/day, 95% CI: -1·22 to 3·03] in the younger age stratum, but was not statistically significant. Nosocomial infection rate was significantly lower in the SSO group in the older age stratum (adjusted odds ratio 0.41, 95% CI: 0·19 to 0·85). Skin condition score improved (AMD: -14·88, 95% CI: -24·12 to -5·65) and TEWL was reduced (AMD: -2·59, 95% CI: -3·86 to -1·31) significantly in the SSO group compared to the control group at day 10. Reduction in CRP level was also significantly greater in the SSO group (median: -0·28 mg/dl) than the control group (median 0·00 mg/dl) in the younger age stratum at day 10. Topical therapy with SSO was beneficial for children with SAM when applied as an adjunct therapy. However, a community-based trial with a longer intervention period is recommended to validate these results.

490

EVALUATION OF SUSCEPTIBILITY OF CLINICAL BACTERIA ISOLATES TO HONEY, GINGER AND MUSHROOM

Evangelyn Chiemerie Agochukwu[1], Sampson Tonye[1], Edward Chieke Nwanegbo[2], Renner Renner Nrior[1]

[1]*Rivers State University, Porthacourt, Nigeria,* [2]*Nnamdi Azikiwe University Awka, Awka, Anambara State, Nigeria*

Applications of honey in treatment of diseases were reported in the world's oldest medical literatures. It was reported to possess antimicrobial as well as wound healing properties. In addition, edible Mushroom has also been deployed in traditional medicine as antibacterial and antiviral therapies. Equally used in traditional medicine is Ginger, a perennial plant that has been deployed for human and animal ailments. In this study, the antibacterial properties of these products will be investigated using clinical bacteria isolates from wound care unit in a General Hospital in Southern Nigeria. The antimicrobial effect of honey, ginger and mushroom extracts was tested against each 10 identified samples of S. aureus, S. Pyogenes, P. aeruginosa and E. coli wound isolates from patients. Isolates were harvested from culture media when organisms were at their exponential phase of growth and susceptibility evaluated using serially diluted purified extracts of ginger, mushroom or honey. Inhibition of bacterial growth of the various agents was analyzed and compared. Study is ongoing, and data is being collated. Data from this study may provide rationale for further development of honey, mushroom or ginger for clinical applications in wound care units in developing countries where antibiotics are not readily available and antibiotics resistant remain a major public health concern.

A SYSTEMATIC REVIEW OF SOLID ORGAN TRANSPLANTATION IN ACUTE PRESENTATIONS OF TROPICAL INFECTIOUS DISEASES

Shveta Bhasker[1], Emma Hagopian[1], Celine Lecce[1], David Harris[1], Shareese Clarke[1], Priyanka Challa[1], Michael A. Klowak[1], Eric Shao[1], Kimberley Marks - Beaubrun[1], Katherine Faith Tan[1], Mofe Adeosun[1], Osaru Omoruna[1], Christian Lecce[1], Avinash N. Mukkala[1], Rachel Lau[2], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario, Toronto, ON, Canada*

Fulminant life-threatening presentations of acute tropical infections such as yellow fever, dengue, malaria, hepatitis E, and leptospirosis, may occur, and the degree of end-organ impairment may qualify patients for solid-organ transplantation (SOT) in centres with such capacity. However, due to a paucity of synthesized data, there is a knowledge gap around indications for and outcomes in SOT for severe acute tropical infectious diseases. We therefore aim to synthesize such knowledge, focusing on patient outcomes in order to inform triage and treatment protocols in centres where acute tropical infectious diseases and SOT capacity may intersect. Five electronic databases were searched (PubMed, Embase, Scopus, Cochrane, and LILACS) using combinations of search terms such as the following: "liver" or "hepatic" "transplant," "yellow fever" "dengue" and "*Plasmodium* spp.," from database inception to March 4, 2019. A total of 6317 articles were retrieved: 2324 articles on PubMed, 3839 on Embase, 244 on Scopus, 43 on Cochrane, and 108 on LILACS. After eliminating duplicates using Mendeley software, a total of 4944 articles remained for title screening. Titles, abstracts, and full-text articles will be systematically double screened by two reviewers with a tertiary arbitrator. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) will be implemented. Data extraction will be performed by two reviewers and the quality of the articles will be critically evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach. The data will be summarized to systematically map published literature that will illuminate the frequency, indications for, and health outcomes of SOT recipients in the treatment of acute tropical infectious diseases. Where SOT capacity exists alongside the occurrence of endemic or imported tropical infectious diseases, such synthesized information, particularly in the form of a clinical resource, is essential for appropriate resource allocation and informed clinical decision-making.

492

EPIDEMIOLOGICAL UPDATE ON FEVER IN RETURNING TRAVELERS TO ONTARIO FROM THE 'RAPID ASSESSMENT OF FEBRILE TRAVELERS' (RAFT) PROGRAM

Aisha Khatib[1], Shareese Clarke[1], Michael A. Klowak[1], Emma Hagopian[1], Farah Jazuli[2], David Harris[1], Ruwandi Kariyawasam[3], Rachel Lau[4], Stefanie A. Klowak[1], Evan Belsky[1], Andrea K. Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Department of Emergency Medicine, McMaster University, Hamilton, ON, Canada,* [3]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [4]*Public Health Ontario, Toronto, ON, Canada*

Fever in returning travelers may indicate a life-threatening infection, such as malaria. However, most cases are due to more benign, self-limited etiologies such as traveler's diarrhea. In the absence of a priori predictors of which febrile travelers will develop severe clinical sequelae from their imported infection, which remains undifferentiated pending confirmatory diagnostics, close follow-up and monitoring of travelers during the initial few days of illness is required. The rapid assessment of febrile travelers (RAFT) programme was implemented to standardize the evaluation and disposition of febrile returned travelers in Toronto. We herein provide an epidemiological update on travelers assessed via RAFT from 2016 to 2018, and the illnesses with which they returned from travel. Criteria for RAFT referral include: presentation to participating EDs, reported fever, and travel outside of Canada within the past year. Exclusion criteria include *Plasmodium falciparum* malaria, and fulfilment of admission criteria such as unstable vital signs or major lab derangements. Demographic, clinical, and travel-related data were collected, and analyzed using descriptive statistics. From January 2016 to December 2017, 302 ill returned travelers were evaluated via RAFT: 147(49%) were men and 155(51%) were women. Median age was 34 years (range 16-93 years). Travelers returned from 82 countries with the most represented countries being: India (25, 8%), Mexico (21, 7%), Thailand (18, 6%), Cuba (17, 6%), and Costa Rica (13, 4%). Common diagnoses included: viral syndrome (78, 26%), traveler's diarrhea (34, 11%), viral respiratory infection (27, 9%), dengue (16, 5%), lab-confirmed influenza (16, 5%), and typhoid fever (10, 3%). Among lab-confirmed cases of influenza evaluated in RAFT, off-season transmission accounted for a quarter. Cases of Zika virus (6, 2%) only occurred in 2016. An additional 207 travelers referred in 2018 will also be reported. Understanding the range of illnesses imported by febrile returned travelers will inform pre-travel counseling and both clinical and laboratory algorithmic approaches to care of such travelers.

493

BURDEN OF NON-COMMUNICABLE DISEASES AND THEIR RISK FACTORS IN A KENYAN CASUALTY DEPARTMENT

Thomas Kedera[1], Christine Ngaruiya[2], Mbatha Wambua[3], Mugane Mutua[4], Frances Ogudebe[2], Morgan Muchemi[4], Daniel Owambo[4], Kipkoech Rop[4], Benjamin Wachira[5]

[1]*Kakamega County Referral Hospital, Kakamega, Kenya,* [2]*Yale University, Stamford, CT, United States,* [3]*Kenyatta National Hospital, Nairobi, Kenya,* [4]*University of Nairobi, Nairobi, Kenya,* [5]*Aga Khan University Hospital, Nairobi, Kenya*

It has been noted with some concern that in LMIC, there is little information on NCDs, and even less so I the a&e settings. It is necessary to determine the burden of disease for the main NCDs (diabetes, CVS disease, cancer and chronic respiratory disease) affecting the population. It is a Cross sectional Pilot Study, conducted at the casualty department of the Kenyatta National Hospital. Ethical approval for the study was obtained from the UoN-KNH Ethics Committee. A little under 23990 patients are seen at the outpatient department monthly. Our sample size was calculated as 10% of the general estimated visitors to KNH Casualty Department. This is a standard number as recommended for pilot studies, which for us translated to a target of 2400 patients. Mini-STEPs & SQR - 20 were the validated survey tool used to collect date from the patients. The questionnaires were self-administered electronically. Convenience sampling was employed, recruiting willing participants soon after triage. The data was analysed using STATA version 14.1. 12.7% of respondents smoke tobacco with a mean starting age of 20.4yo; 42.3% of the respondents indicated smoke exposure at work. 53.1% of participants reported engaging in alcohol use; 5.25% had stopped drinking due to health reasons or medical advice. 19.44% reported having been told that they have raised blood pressure but only 9.3% reported receiving treatment. 6.8% reported being told that they have elevated blood sugar; only 1.5% reported being treated with insulin. 8.64% reported having had chest pain or suffered a stroke with; <1% receiving treatment with statins. 16.5% reported history of suicidal ideation. A high burden of NCDs exists among patients in the Casualty Department, one that is comparable to, or supersedes, the general population. However, treatment targeting NCDs or NCD risk factors in Casualty Department patients is minimal. This highlights the importance of developing interventions including clinical policies, education for practitioners on NCDs in Casualty, and other interventions unique to this population.

494

EXAMINING MALNUTRITION AS A CAUSE AND CONTRIBUTOR TO DEATH IN CHILDREN AGED 6-59 MONTHS WITHIN THE CHILD HEALTH AND MORTALITY SURVEILLANCE (CHAMPS) NETWORK

Kasthuri Sivalogan[1], Shams El Arifeen[2], Victor Akelo[3], Quique Bassat[4], Beth A. Tippett Barr[3], Richard Chawana[5], Emily Gurley[6], Karen Kotloff[7], Shabir Madhi[5], Inacio Mandomando[8], Dickens Onyango[9], Rebecca Philipsborn[10], Samba Sow[11], Parminder Suchdev[1], Dianna Blau[12], Robert Breiman[1]

[1]*Emory Global Health Institute, Emory University, Atlanta, GA, United States,* [2]*International Centre for Diarrhoeal Diseases Research, Dhaka, Bangladesh,* [3]*United States Centers for Disease Control and Prevention, Kisumu, Kenya,* [4]*ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain,* [5]*Medical Research Council: Respiratory and Meningeal Pathogens Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,* [6]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [7]*Center for Vaccine Development, University of Maryland School of Medicine, Baltimore, MD, United States,* [8]*Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique,* [9]*Kisumu County Public Health Department, Kisumu, Kenya,* [10]*Emory Global Health Institute, Atlanta, GA, United States,* [11]*Center for Vaccine Development, Bamako, Mali,* [12]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Up to 50% of all under-5 deaths in low and middle-income countries may be associated with malnutrition, characterized by protein energy malnutrition or micronutrient deficiencies. The relationship between malnutrition and morbidity is complex and bidirectional; severely ill children are more susceptible to malnutrition, and poor nutritional status increases risk of severe morbidity and mortality. The Child Health and Mortality Surveillance Network (CHAMPS) actively identifies under-5 deaths and uses demographic and clinical information, post-mortem tissue specimen testing, and verbal autopsy to determine the underlying cause and sequence of events leading to death in catchment areas with high child mortality. Malnutrition was assessed in 148 cases aged 6-59 months with cause of death determined from five surveillance sites in South Africa, Mozambique, Kenya, Mali and Bangladesh from July 2017-March 2019. Nutritional status was assessed by postmortem anthropometric measurements, photographs obtained during the tissue sampling procedure, histopathology results, clinical records and VA responses. Malnutrition was listed as the underlying cause or in the sequence of events leading to mortality in 41.2% (n=61) of cases. Among all 61 cases, 78.7% of cases were considered moderately or severely underweight (weight-for-age z-score ≤ -2), 62.3% of cases were considered moderately or severely stunted (height-for-age z-score ≤ -2), and 73.8% of cases were considered moderately or severely wasted (weight-for-height z-score ≤ -2). Malnutrition was considered present in 60.7% of cases according to data abstracted from clinical records and 63.9% of cases according to VA responses. The most common underlying causes of death were malnutrition (57.4%), congenital birth defects (11.5%), lower respiratory infections (8.2%), and HIV infection (6.6%). The most common immediate causes of death were sepsis (42.6%), lower respiratory infections (37.7%), and malaria (8.2%). Early data suggests that malnutrition, frequently associated with infections, is an important cause of under-5 mortality in high child mortality areas.

495

SEQUENTIAL MIXED METHODS STUDY ON NOMA, NORTHWEST NIGERIA 2017 AND 2018

Elise Farley[1], Modupe Juliana Oyemakinde[1], Jorien Schuurmans[1], Aisha Abubakar[1], Fatima Saleh[2], Gloria Uzoigwe[3], Karla Bil[4], Bukola Oluyide[5], Nma Muhammed Jiya[6], Simba Tirima[5], Adolphe Fotso[5], Mohana Amirtharajah[4], Jorieke Vynke[4], Raphael Brechard[4], Adeniyi Semiyu Adetunji[7], Koert Rietmeijer[4], Saskia van der Kam[4], Denise Baratti-Mayer[8], Ushma Mehta[9], Shafiu Isah[7], Chikwe Ihekweazu[2], Beverley Stringer[10], Cono Ariti[11], Annick Lenglet[4]

[1]*Medecins Sans Frontiers, Sokoto, Nigeria,* [2]*Nigerian Centre Disease Control, Abuja, Nigeria,* [3]*Department of Dentistry, Nigerian Ministry of Health, Abuja, Nigeria,* [4]*Medecins Sans Frontiers, Amsterdam, Netherlands,* [5]*Medecins Sans Frontiers, Abuja, Nigeria,* [6]*Usmanu Danfodiyo University Teaching Hospital, Sokoto, Nigeria,* [7]*Department of Clinical Services, Noma Children's Hospital, Sokoto, Nigeria,* [8]*GESNOMA (Geneva Study Group on Noma), Service of Plastic, Reconstructive and Aesthetic Surgery, Geneva University Hospitals, Geneva, Switzerland,* [9]*University of Cape Town, Cape Town, South Africa,* [10]*Medecins Sans Frontiers, London, United Kingdom,* [11]*Centre for Medical Education, Cardiff University School of Medicine, Cardiff, United Kingdom*

Noma, a rapidly progressing infection of the oral cavity affecting children <5 years, has a 90% mortality rate. In 2017-2018 we conducted a three stage sequential mixed methods study on noma to guide prevention and health programming for this disease in NW Nigeria. Stage 1 was a qualitative study exploring language and beliefs through 12 in-depth interviews with hospital staff and five focus group discussions with caretakers of noma patients. Stage 2 was a case control study to estimate risk factors for diagnosed noma. Consenting caretakers of noma patients (<15 years) and matching controls (age, sex and village) answered questionnaires. Risk factors were estimated with odds ratios (ORs) using

logistic regression. Stage 3 was a two stage cluster survey in Kebbi and Sokoto states. We conducted oral screening on all persons <15 years using WHO noma classification:S0:simple gingivitis;S1:necrotizing gingivitis;S2: oedema;S3:necrosis;S4:healing; S5:sequela. A weighted analysis of noma prevalence with 95% confidence intervals (CI) was completed. Caretakers referred to noma as "ciwon daji" and staff as "noma". Participants believed noma was caused by spirits, insects, birds or previous illness. The case control study (74 cases and 222 controls) identified the following risk factors for diagnosed disease: the mother not being the primary caretaker (OR 0.1; CI 0.05-0.4), the caretaker being unmarried (OR 0.01; CI 0.004-0.04), colostrum not being given (OR 0.3; CI 0.1-1.1) and the child being fed maize porridge every day (OR 5.0; CI 1.2-20.8). In the prevalence survey we included 7120 children; 181 children presented as S0 (3.11%; CI 2.6, 3.8%), 10 children as S1 (0.1%; CI 0.1, 0.3%) and three children as S2 (0.04%; CI 0.01, 0.1%). No S3-5 was detected. Noma is a poorly understood disease, social conditions and infant feeding practices are associated with it. We demonstrated that in this part of Nigeria, precursor stages of noma are prevalent. Prevention efforts for noma must target nutrition, oral hygiene and improved access to care.

496

ASSESSMENT OF THE DATA QUALITY AND STANDARD OF OUT PATIENT REGISTRATION FOR DETECTION OF CHOLERA CASES IN CAMEROON

Ayok M. Tembei[1], Martin Yakum[1], Maurice Ebode[1], Anthony Chebe[2], Sonia Nafack[3], Pascal Goura[1], Manualla Cheugeu[4], Nelson Guemechio[4], Joliette Azakoh[3], Anne Cecile Bissek[5], Jerome Ateudjieu[1]

[1]*Meilleur Accès aux Soins de Santé (M.A. SANTE), Cameroun, Yaoundé, Cameroon,* [2]*Meilleur Accès aux Soins de Santé (M.A. SANTE), Cameroun, Kousserri, Cameroon,* [3]*Meilleur Accès aux Soins de Santé (M.A. SANTE), Cameroun, Douala, Cameroon,* [4]*University of Dschang, Dschang, Cameroon,* [5]*Division of Health Operations Research, Ministry of Public Health, Yaoundé, Cameroon*

Data from out-patient units are expected to provide information for monitoring health program effectiveness and disease distribution. Reliable epidemiological data from active surveillance is crucial for efficient implementation of prevention and preparedness measure for epidemic prone diseases. Data quality and the standardization of out-patient registration tools at health facility level was assessed to determine whether external consultation registers can be used to detect cholera cases in Cameroon. A descriptive cross sectional study was conducted in 22 health facilities selected from Far North and Littoral regions of Cameroon. External consultation registers were reviewed using a grid. In each current register, the 100 recently consulted patient records and the last 10 diarrhoeal consulted cases were reviewed for presence, completeness, adequacy and standardization of data available. Descriptive statistics was used to summarize and describe data in SPSS. A mixture of locally adapted and nationally provided registers often not standardized is in place. Of 20 variables assessed, level of data completeness was very low with only 4.3% of 47 registers reported as complete. All variables assessed had at least 01 missing patient record. Of 427 diarrhoeal patient records reviewed, 87% of variables present in registers are useful for cholera detection. But, with an exception of age (0.9%) and symptoms (1.4%), other variables had high levels of missing records for key cholera parameters reporting 96.3%, 93.9% and 70.7% non-completeness for duration of diarrhoea before consultation, number of stools within 24hours and type of diarrhoea patients were experiencing respectively. The Cameroon national health information system is hindered with poor data quality and standardization of data tools for out-patient registration. Data provided in registers are not adequate to effectively inform cholera surveillance system for prompt response in case of an epidemic. A discussion is thus needed to standardized and contextualized registers and make sustainably available for all external consultation purposes per health facility.

497

A DOCTOR'S EXPERIENCE: THE DILEMMA FACED USING PERSONAL PROTECTIVE EQUIPMENT WHILE WORKING IN AN EBOLA TREATMENT UNIT

Mohamed Boie Jalloh[1], May C. Chu[2]

[134] *Military Hospital, Republic of Sierra Leone Armed Forces, Freetown, Sierra Leone,* [2]*Colorado School of Public Health, Aurora, Colorado, CO, United States*

We have a daunting task to design a piece of personal protective equipment (PPE) ensemble to improve safety and comfort for the health workers at the frontline. During the 2014-2015 Ebola outbreak, I was tasked to set up the Ebola Holding Unit at the 34 Military Hospital. I had not set eyes on PPEs or even heard the term but was aware of the Ebola outbreak that was ravaging the Eastern districts. The very first time I was trained to use PPE, it gave me so much sense of security and confidence to provide clinical care to Ebola patients. It made me feel beyond the reach of the ominous hand of Ebola. I even wondered: Can we not end the outbreak by providing PPE to all and requiring each to put them on for at least 4 weeks, far beyond the incubation period? However, it was in the first 20 minutes of using PPE for the first time to assess an Ebola case that I realized the complexity of PPE and the fact that my thinking earlier was impractical. The enthusiasm I had for PPE turned into doubt and I started asking questions like" was this PPE made for us?", and by us, I meant, clinical care providers in Africa whose climate is hot and humid. Finally, I struggled with the very basic question: Is PPE that covers with no bit of exposed skin necessary? Or am I safer with a limited level of PPE? Why do we have to put on full PPE for all Ebola patients regardless of their clinical profile (wet or dry)? To date, I am of the view that we do not need the current prescribed full PPE for patients who are not wet. I know there is no data that can help decide where to draw the line on the level of exposure of skin. In the end, though, I chose safety over comfort where I could, even though at times the two are inseparable. Comfort for me could mean less safety for me or the patients. I followed the infection prevention control requirements of PPE-use religiously. However, this reduced my reaction time to emergencies in the ETU, my contact time with patients and inevitably may have reduced the survival rate of my patients. For how much care can I provide to a patient when on an 8-hour shift, I can only withstand working for 135 minutes? Compare this to 400 minutes contact time expected in an 8-hour shift. We need a science-based discussion and solution.

498

PREVALENCE AND ASSOCIATED FACTORS OF ANEMIA IN WOMEN CHILDBEARING AGE IN POPOKABAKA, DEMOCRATIC REPUBLIC OF CONGO

Gisele M. Mvumbi, Marc M. Bosonkie, Vitus L. Okitolonda, E. W. O

ESP-KINSHASA/DRC, Kinshasa, Democratic Republic of the Congo

l'anémie continue à être une barrière majeure à la santé maternelle et au développement socio-économique particulièrement dans les pays sous-développés. Popokabaka est un territoire de la province de Bandundu qui est dans un contexte de faible disponibilité en aliments riches en fer, faible connaissance des mères sur les aliments riches en fer et monotonie alimentaire. L'étude avait pour objectif de déterminer la prévalence et les facteurs associés à l'anémie chez la femme en âge de procréer à la cité Popokabaka. Une étude transversale a été menée dans les ménages de la cité Popokabaka pendant la période allant du 2 au 30 avril 2017. Les potentiels facteurs sociodémographiques, gynécologiques et cliniques, la connaissance des femmes sur l'anémie, l'état nutritionnel et la fréquence de consommation d'aliment riche en fer étaient recherchés. La régression logistique était utilisée pour déterminer les facteurs associés à l'anémie. Un total de 393 femmes en âge de procréer a constitué notre échantillon. Le taux moyen d'hémoglobine était de 1.8 ± 1.2 g/dl. La prévalence de l'anémie était de 50.6% (95% CI: 45.7- 55.6). Environ deux tiers de nos sujets (64.3%) avait un score moyen de diversité alimentaire. Plus

de la moitié 58.5% (95% CI 53.6-63.4) avait une faible connaissance sur l'anémie. Environ 38.1 % et 6.1% avaient consommé les aliments riches en fer deux fois la semaine. Le fait d'avoir 2 ou 3 enfants [Odds Ratio Ajusté (ORa) =2.06, 95 % CI: 1.07–3.97] et la consommation des fruits riches en vitamine c au moins une fois la semaine (ORa=0.56, 95 % CI: 0.33–0.98) étaient les facteurs indépendamment associés à l'anémie.L'anémie chez la femme en âge de procréer constitue un problème majeur de Santé Publique à la cité Popokabaka. Le fait d'avoir 2 ou 3 enfants; et la consommation des fruits riches en vitamine c au moins deux fois la semaine étaient révélés comme facteurs associés à l'anémie à Popokabaka. L'éducation nutritionnelle basée sur la consommation régulière des fruits et la supplémentation en fer seraient donc des interventions efficaces pour la prévention de l'anémie chez la femme en âge de procréer à cité Popokabaka.

THE INCIDENCE OF ACUTE FEBRILE ILLNESS AMONG CHILDREN IN BUTAJIRA, SOUTH-CENTRAL ETHIOPIA

Mekonnen Teferi Mekonnen[1], Mulualem Desta[2], Biruk Yeshitela[1], Tigist Beyene[1], Ligia Maria Cruz Espinoza[3], Justin Im[4], Hyon Jin Jeon[4], Jong-Hoon Kim[4], Frank Konings[4], Soo Young Kwon[4], Gi Deok Pak[4], Jin Kyung Park[4], Se Eun Park[4], Melaku Yedenekachew[1], Stephen Baker[5], Won Seok Sir[6], Florian Marks[4], Abraham Aseffa[1], Ursula Panzner[4]

[1]*AHRI, Addis Ababa, Ethiopia,* [2]*Science and Technology Information Center (STIC), Addis Ababa, Ethiopia,* [3]*International Vaccine Institute, Seoul, Republic of Korea,* [4]*IVI, Seoul, Republic of Korea,* [5]*The Department of Medicine, The University of Cambridge, Cambridge, United Kingdom,* [6]*Graduate School of Public Health, Yonsei University, Seoul, Republic of Korea*

A clear differentiation of causes of febrile illnesses is challenging for health professionals in locations were diagnostic capacities are limited. A lack of an etiological diagnosis often results in poor patient management. Here, we aimed to investigate the incidence of pediatric acute febrile illnesses in Butajira, Ethiopia during the Typhoid Fever Surveillance in Africa Program (TSAP). Febrile children aged ≤15 years were enrolled at primary/secondary healthcare facilities. Aerobic blood culture, malaria microscopy, and complete blood count were performed on samples of patients' blood. Microbiological, biochemical, species/sub-species, and antimicrobial susceptibility testing of positive cultures were performed. A scheme for classifying children with acute febrile illness, malaria, acute respiratory tract, gastrointestinal, and urinary tract infections was developed. Incidence rates were calculated and a multivariate logistic regression analysis was performed to determine predictors for febrile illnesses. Results Among 513 children recruited during January 2012 to January 2014, we found that hospitalization was low (4.1%, 21/513),as was stunting(0.8%, 4/513), being underweight(0.2%, 1/513) and wasting(0.2%, 1/513).The blood culture positivity for true pathogens was 1.6% (8/513); the malaria prevalence was13.5% (69/513).Temporal and spatial incidences, derived from the case classification scheme, revealed a higher incidence of febrile disease in children aged ≤5 than >5 to ≤15 years. The average annual incidence per 100,000 population were694.3 (95%CI: 644.7-747.7) for acute febrile illness, 301.3 (95%CI: 269.2-337.2) for malaria, 1,860.1 (95%CI: 1778.0-1946.0) for acute respiratory tract infections, and 379.9 (95%CI: 343.6-420.0) for gastrointestinal infections in children aged ≤5 years. In conclusion, we find that fever is common in this location but its origin is often unknown. Findings from this study may prompt healthcare personnel and decision makers in the development of revised policies and frameworks for the diagnosis & management of febrile illnesses in children.

A RANDOMIZED PILOT CLINICAL STUDY ON THE USE OF HERBAL PRODUCT HB01, IN TREATMENT OF HIV POSITIVE PATIENTS IN ANAMBRA STATE, NIGERIA

Uchenna C. Ogwaluonye[1], Joseph I. Ikechebelu[1], Ngozi N. Ikechebelu[2], George Eleje[1], Izuchukwu Ibeagha[3], Charles O. Esimone[1], Edward C. Nwanegbo[1]

[1]*Nnamdi Azikiwe University, Awka, Awka, Nigeria,* [2]*Chukwuemeka Odimegwu Ojukwu University Teaching Hospital, Awka, Nigeria,* [3]*University of Nigeria Teaching Hospital, Enugu, Nigeria*

In Nigeria, herbal medicines are heavily used but poorly documented, lacking safety and efficacy data, therefore presents a liability in orthodox practice. This study was designed to clinically evaluate the efficacy and safety of an anti-HIV herbal formulation, HB01 in treatment of HIV positive adults in Anambra, South eastern Nigeria. A randomized double-blind clinical study was carried out with 7 consenting, HIV positive adults for a duration of three months. Following recruitment, each patient was sequentially assigned a number which was randomized into treatment and control group using the online research randomizer, resulting in 4 persons in treatment group and 3 persons in the control group. Primary outcome parameters, including viral load and CD4 count, were measured at the beginning and end of the study while microbial safety studies, Liver function test and Electrolyte concentration were performed on a monthly basis using specialized test kits. The clinical study revealed a statistically insignificant decrease in the viral load (20,609 to 1,323 copies/ml) and increase in CD4 count (565 to 640 cells/mm3) when compared to the control. There was no negative change in the liver function test and electrolyte levels of participants between the test and control groups. Side effects recorded among participants included increased appetite and micturition, self-limiting diarrhea, vomiting and menstrual pains. Antimicrobial evaluation of HB01 revealed no activity against test bacteria, yeast and mould cultures. HB01 was generally well-tolerated, showing no negative outcome on HAART goals for HIV infection among the study participants and complied with BP limits for microbial load. Our findings also indicate positive changes in the viral load and CD4 count but being insignificant, would require further studies in order to ascertain its potential as a viable adjunct to HAART.

501

CLINICAL PROFILE AND OUTCOME OF TETANUS AMONG ADULT PATIENTS IN ETHIOPIA

Godana Jarso

Adama Medical College, Adama, Ethiopia

Tetanus is a major health problem in developing countries as it is associated with high morbidity and mortality. There is scarcity of data regarding patterns of disease and outcomes in our Ethiopia and the study area. This study was undertaken to assess treatment outcome and predictors among adult patients admitted with tetanus. A cross sectional study design was conducted based on secondary data recorded over five year from January 2014 to December 2018. Records and charts of all adult patients admitted with tetanus at Adama hospital were included in the study. Accordingly out of 80 patients, 66 with complete data were included. Data was collected using structured checklist, then entered and analyzed using SPSS 22.0. The patients' characteristics were explored using descriptive statistics. The association was analyzed using binary logistic regression and magnitude were estimated using odds ratio with 95%CI. The significance of association was declared at p-value < 0.05. About 57 (86.40%) of patients were male and 44(66.7%) were under 40 years of age. In about 42(63.6%) patients the site of injury was lower limbs. The median incubation period was 12.50(IQR: 8-18.5) days. Sixty (91%) of the patients had generalized tetanus and 38(57.6%) had severe forms of tetanus. Complications were reported in 41(62.1%) of patents. Death occurred in 38 patients with case fatality of 57.6% (95%CI: 45.5, 69.7). The predictors of death were severe tetanus [AOR=16.41; 95%CI 2.20, 122.21] and presence of complication [AOR=6.23; 95%CI: 1.05,

36.81] and being admitted to ward [AOR=33.95; 95%CI: 3.12, 369.07] compared to ICU. In conclusion, tetanus still remains to be major health problem in our setup with unacceptably high mortality. Even though majority present had severe diseases and complications, only few patient were managed in intensive care unit (ICU) due to lack of such facility earlier. The burden and mortality of tetanus can be reduced via effective immunization, identification of severe cases and proper management in ICU.

502

RETROSPECTIVE REVIEW OF BLOOD STREAM INFECTIONS IN A GOVERNMENT HOSPITAL IN MAHARASHTRA, INDIA

Kananbala Avinash Yelikar[1], Jyoti Anil Iravane[1], Anil Gaikwad[1], Poonam Korpe[2]

[1]*Government Medical College, Aurangabad, Aurangabad, India,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Antimicrobial resistance (AMR) has become a global crisis. In India, efforts to study AMR have been hindered by lack of public health infrastructure and lack of a robust national surveillance system. This study was conducted to identify the most common pathogens involved in blood stream infections and to characterize their AMR. This was a retrospective chart review of all positive blood cultures at the Government Medical College Aurangabad hospital in 2016. Blood specimens were collected and cultured as per standard protocol. Antibiotic susceptibility testing was performed by disk diffusion testing using modified Kirby Bauer methods. From January 1, 2016 to December 31,2016, a total of 543 blood cultures returned positive. Of these 189 were due to *Staphylococcus aureus* (34.8%), 192 due to *Klebsiella pneumoniae* (35.4%), 56 from *Pseudomonas aeruginosa* (10.3%), and 45 due to *Escherichia coli* (8.3%). Of *Staph aureus* isolates, 77 were tested for cefoxitin resistance and 57 (74%) returned as methicillin-resistant *Staph aureus*. Of the *Klebsiella* isolates, 81.6% met CLSI criteria for extended-spectrum beta-lactamase producers (ESBL) and 57.9% met criteria for carbapenem-resistant Enterobacteriaceae (CRE). 42.2% of the *E. coli* isolates were ESBL, and 60.0% were CRE. Resistance testing for the *Pseudomonas* isolates revealed 62.5% were ESBL and 57.9% were carbapenem resistant organisms. The most common pathogens involved in blood stream infections were *Klebsiella, Staph aureus, and Pseudomonas*. The majority of *Staph aureus* BSIs were attributed to MRSA. There was a high level of cephalosporin and carbapenem resistance among the gram-negative organisms,with rates consistent with other studies from Maharasthra, India. Routine surveillance of microbiology results in Indian hospitals is necessary to understand trends in antibiotic resistance and to prevent spread of resistant organisms.

503

ECONOMIC BURDEN OF ANTIMICROBIAL RESISTANCE IN LOW AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW AND EXPERT CONSULTATION

Kyaw Zay Ya

International Rescue Committee, Yangon, Myanmar

Antimicrobial resistance (AMR) is a global challenge which is associated with the utilization of more healthcare resources as result of high medication costs, prolonged hospital stay, and decreased in productivity. Therefore, it is expected to have a major negative impact on economic sector especially for low and middle income-countries (LMICs). To assess the economic burden, it is great of importance to find out comprehensive definition of costs and cost items attributable to AMR. Additionally, it is crucial to identify current evidence related to the costs of AMR in LMICs. The methodology for this study was a systematic review from Pubmed and Embase in line with PRISMA guidelines and expert consultations. Defining AMR cost is a complex methodology involving a series of assumptions and estimation methods. The systematic review found that additional length of hospital (LOS) was used to calculate AMR direct cost in hospital settings (n=19), and the attributable cost for AMR was estimated by comparing infections with non-resistant strains. Few studies tried to estimate societal cost to some extent (n=5) while most studies only concentrated on direct medical costs (n=18). Expert consultations highlighted the costs for basic health infrastructure and supply chain management are new items to be considered. Experts suggested to estimate financial consequences of losing the efficacy of existing therapies. There is a significant gap in the development of methodology for cost estimation in LMICs. Theoretical framework is needed to categorize and measure the costs associated with AMR but those are not being used in LMICs due to methodology limitation and lack of expertise. Cost identification is one of the requirements for subsequent economic evaluations. New additional cost items were identified with this study, but it is still an issue how to estimate those items. These findings suggest for methodology development is needed in LMICs.

504

URINARY TRACT INFECTION IS A COMMON REASON FOR POTENTIALLY INAPPROPRIATE ANTIMICROBIAL USE AMONG INPATIENTS IN SRI LANKA

Tianchen Sheng[1], Gaya B. Wijayaratne[2], Thushani M. Dabrera[3], Richard J. Drew[1], Ajith Nagahawatte[2], Champica K. Bodinayake[2], Ruvini Kurukulasooriya[4], Truls Østbye[1], Kristin J. Nagaro[1], Cherin De Silva[4], Hasini Ranawakaarachchi[4], Arambegedara Thusitha Sudarshana[3], Deverick J. Anderson[1], Christopher W. Woods[1], L. Gayani Tillekeratne[1]

[1]*Duke University, Durham, NC, United States,* [2]*Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka,* [3]*Sri Lanka Ministry of Health, Colombo, Sri Lanka,* [4]*Duke-Ruhuna Collaborative Research Centre, Galle, Sri Lanka*

Urinary tract infection (UTI) is a common reason for inappropriate antimicrobial use globally. Reducing inappropriate antimicrobial use is important for tackling the current crisis in antimicrobial resistance. We determined the prevalence of UTI and associated inappropriate antimicrobial use among inpatients in Sri Lanka. A point-prevalence study of antimicrobial use was conducted using one-day cross-sectional surveys at five public hospitals in Southern Province, Sri Lanka from Jun-Aug 2017. Inpatients' medical records were reviewed for clinical data including antimicrobials prescribed. Inappropriate antimicrobial use was identified as 1) antimicrobial use discordant with the Sri Lanka College of Microbiologists' guidelines, and 2) redundant combinations of antimicrobials. Of 1,709 surveyed patients, 935 (54.7%) received antimicrobials, of whom 779 (83.3%) had a specified or inferred indication for antimicrobial use. Among these patients, UTI was the third leading indication for antimicrobial use (91 patients, 11.7%). Commonly used antimicrobials for UTI included amoxicillin & clavulanic acid (34.9%), fluoroquinolones (31.4%), and third-generation cephalosporins (23.2%). Antibiotic combinations were used in 28.6% of UTI patients. Urine cultures were obtained in only 26 (28.6%) of UTI patients, with 11 of UTI patients (12.09%) having positive cultures. Potentially inappropriate antimicrobial use was observed in 36.3% of UTI patients, with redundant antibiotic therapy observed in 6.6% of UTI patients. Patients in pediatric compared to medical/surgical wards (81.82% versus 29.11%, p<.001) were more likely to receive inappropriate therapy. UTI was a common reason for antimicrobial use, with one-third of patients receiving potentially inappropriate antimicrobial therapy. We identified targets for future antimicrobial stewardship efforts.

505

PROFILE OF ADVERSE EVENTS FOLLOWING ROUTINE IMMUNIZATION IN 5 HEALTH ZONES OF KINSHASA, THE DEMOCRATIC REPUBLIC OF CONGO

Trésor Bodjick Muena Mujobu, Gaston Tona Lutete

Clinical Pharmacology and Pharmacovigilance Unit , University of Kinshasa, Kinshasa, Democratic Republic of the Congo

Millions of doses of vaccines are regularly administered to Congolese infants each year as per a schedule inspired from the World Health

Organization (WHO). But the safety profile of routine vaccines is unknown. Reporting adverse events following immunization maintains the safety of vaccines and the confidence of the community. We initiated a project to collect adverse events occurring in the context of routine immunization in 5 health zones of Kinshasa, the capital city of the Democratic Republic of Congo. Mothers reported the events they noticed after the previous session of vaccination and the nurses recorded all the relevant information in forms that were submitted to the National Pharmacovigilance Center. The collected data were reviewed and uploaded into the Vigiflow® system (a web-based safety report system supported by the World Health Organization). The reports entered from October 2017 to December 2018 were extracted for statistical analysis using Excel 2016. A total of 1075 vaccinated children developed 1216 adverse events that were reported by their mothers. The most common events according to crude incidence rates were fever (66.9%), persistent crying (11.6%), injection site pain (6.9%) and injection site swelling (3.9%). There were also 11 other reactions that were reported at a lesser rate: injection site induration (3.1%), injection site erythema (1.9%), Asthenia or fatigue (1.3%), myalgia (1.15%), Diarrhea (1.15%), Vomiting (0.8%), decreased appetite (0.3%), injection site abscess (0.3%), rash (0.25%), injection site irritation (0.2%) and vaccination site inflammation (0.1%). The subjects were predominantly males (51%). Injection site pain, swelling and induration (local reactions) were mostly reported in females (52.35%). None of the reported adverse events was serious. The vaccines routinely administered to Congolese infants have a good safety profile, comparable to what is published internationally. This is the kind of information that needs to be shared with the general public to maintain and improve confidence in the health system.

506

THE ROLE OF NUTRITIONAL STATUS IN THE EFFICACY OF AZITHROMYCIN TO REDUCE CHILD MORTALITY IN NIGER: A SUBGROUP ANALYSIS OF THE MORDOR TRIAL

Kieran S. O'Brien[1], Ahmed M. Arzika[2], Ramatou Maliki[2], Sun Y. Cotter[1], Elodie Lebas[1], Catherine Cook[1], Kathryn J. Ray[1], Sheila K. West[3], Robin L. Bailey[4], Catherine E. Oldenburg[1], Jeremy D. Keenan[1], Thomas M. Lietman[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*The Carter Center, Niamey, Niger,* [3]*Johns Hopkins University, Baltimore, MD, United States,* [4]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

A large simple cluster-randomized trial demonstrated that biannual azithromycin distribution to children 1-59 months old reduces child mortality. Although the mechanism of effect remains to be determined, the likely pathway involves reducing the infectious disease burden. The mortality effect might be more pronounced in malnourished children, who face an increased risk of infectious mortality compared to well-nourished peers. Indeed, targeting distributions to malnourished children could maximize the mortality benefit while minimizing selection for antimicrobial resistance. To determine whether biannual azithromycin has a differential effect on mortality by nutritional status, we used data from children 1-11 months old with weight recorded for azithromycin dosing from the Niger site in the MORDOR trial. We calculated weight-for-age Z-scores (WAZ) using the World Health Organization's Child Growth Standards, categorizing children as malnourished (WAZ < -2) or not (WAZ ≥ -2) at a child's entry into the study. We used a Cox proportional hazards model with a shared frailty for cluster and an interaction between treatment arm and baseline nutritional status to assess effect modification on the multiplicative scale. There were 26,242 children 1-11 months in Niger with baseline weight recorded, and 1,152 deaths in this group over the 2-year study. Comparing children in azithromycin-treated communities to placebo-treated communities, the hazard of death was 33% lower (HR 0.67, 95% CI 0.53 to 0.84) in malnourished children and 24% lower (HR 0.76, 95% CI 0.65 to 0.89) in non-malnourished children within communities. The interaction was not statistically significant ($P = 0.33$). As mortality is a rare event even in high mortality settings, it is plausible that this study was not powered to detect an interaction. On the other hand, even if the effect was stronger in malnourished children, the absolute number of deaths prevented will be greatest in the overall group. To maximize the societal impact of biannual azithromycin to reduce child mortality, these results support treatment of all children 1-59 months, regardless of nutritional status.

507

RICKETTSIA FELIS ASSOCIATED WITH FATAL CENTRAL NERVOUS SYSTEM INFECTION IN INDONESIA

Arthur Mawuntu[1], Edison Johar[2], Riane Anggraeni[1], Feliana Feliana[1], Janno Bernadus[1], Dodi Safari[2], Frilasita Yudhaputri[2], Rama Dhenni[2], Yora Dewi[2], Cecilia Kato[3], Ann Powers[3], Ronald Rosenberg[3], **Amin Soebandrio**[2], Khin Saw Myint[2]

[1]*Universitas Sam Ratulangi, Manado, Indonesia,* [2]*Eijkman Institute for Molecular Biology, Jakarta, Indonesia,* [3]*Centers for Disease Control and Prevention, Fort Collins, CO, United States*

Rickettsia felis has recently emerged worldwide as a cause of human illness. Typically causing mild, undifferentiated fever, it has been implicated in several cases of neurological diseases. Although rickettsial etiology of acute febrile cases is well documented in Southeast Asia, there is limited information on central nervous system (CNS) rickettsioses due to limited laboratory capability and low clinical awareness. Cerebrospinal fluid (CSF) specimens from patients over 15 years of age admitted to adult wards at Kandou General Hospital in Manado, North Sulawesi, Indonesia from August 2015-February 2017 with presumed CNS infections were screened for *O. tsutsugamushi and Rickettsia spp.* DNA using real-time PCR targeting 47-kDa and 23S rRNA genes. *Rickettsia spp.* positive specimens were further characterized using semi-nested PCR targeting the 17-kDa, *ompB*, and *gltA* genes. In addition, sera and CSF specimens were tested for rickettsial antibodies with scrub typhus, spotted fever group and typhus group *Rickettsia* IgM ELISA. Two out of 38 available CSF samples were positive for *Rickettsia* DNA as determined by genus-specific qPCR, both from fatal cases. Amplicons were subsequently confirmed to be *R. felis* by Sanger sequencing. The 17-kDa and *ompB* sequences shared 100% similarity with reference strain *R. felis* upon BLAST analysis whereas *gltA* sequences of both cases matched 99% with the *R. felis* sequences. In addition, both cases were negative for Rickettsial IgM antibodies. *R. felis* usually associated with non-specific febrile illness, was found to cause a fatal CNS infection in our study. Further studies on this undocumented syndrome are urgently needed as morbidity and mortality could be considerably reduced through recognition, timely and available pharmacotherapy.

508

WHEN MALIGNANCY AND INFECTION INTERTWINE: A DIAGNOSTIC CHALLENGE IN THE TROPICS

Jessica Tuan[1], Janvier Murayire[2], Alain Prince Kubwayo[2], Thomas Havanabakize[2], Felix Manirakiza[2], Leway Kailani[2], Menelas Nkeshimana[2], Florence Masaisa[2]

[1]*Yale University, New Haven, CT, United States,* [2]*University of Rwanda, Kigali, Rwanda*

A 38-year-old Rwandan male presented to an urban Rwandan hospital with a painful, 6/10 left axillary mass and chest pain for 2 weeks. He had fevers and weight loss for 1 month. For 1 year, he had pain with swallowing solids initially, then liquids. He had 3 days of emesis. On exam, he was cachectic. T was 40°C, HR 106 bpm, BP 91/50 mmHg, RR 20 bpm, and O_2 92% on RA. He had a tender, fixed, 4-cm left axilla mass. He had a white, coated tongue. He had WBC of 48,800 cells/μL with 68% eosinophils, 23% monocytes, 3% neutrophils. Hb was 9.1 g/dL, MCV 101 fL, and PLT 88,000 cells/μL. HIV was negative. On day 1, he started antibiotics in the setting of neutropenic fever and fluconazole for thrush. Fine needle aspiration (FNA) cytology of the mass revealed lymphocytes, granulomatous formations, and giant cells in a protein-necrotic background. On day 3, Auramine stain of FNA cytology of the mass showed acid-fast bacilli, supporting the diagnosis of *Mycobacterium*

tuberculosis lymphadenitis. He started rifampicin, isoniazid, pyrazinamide, ethambutol with pyridoxine. On day 4, peripheral blood smear showed 95% myeloblasts, consistent with M4 acute myeloid leukemia (AML). On day 8, CT chest showed enlarged left axilla and subpectoral lymph nodes, some necrotic and bilateral pulmonary emboli. Enoxaparin was started. CT abdomen demonstrated mild splenomegaly. Endoscopy revealed ulcerative esophagitis. On day 10, he transferred to Butaro Cancer Center in Rwanda, for bone marrow biopsy which confirmed acute monomyelocytic leukemia. TB lymphadenitis typically occurs due to reactivation of TB at a hematogenously seeded site during primary TB. AML, a myeloid blood cell line cancer, is the most common adult acute leukemia. Few case reports describe TB lymphadenitis and concurrent AML. Hematologic malignancies increase relative risk of TB by 2-40 fold. Clinical suspicion for malignancy should be high in a patient with leukocytosis, constitutional symptoms, and persistent fevers. An important lesson to highlight in this case is to not overlook concurrent opportunistic infections, such as TB, particularly in endemic regions in Africa, in the tropical clinical setting of Rwanda.

509

LAUNCH OF A NEW FECAL MOLECULAR EXTERNAL QUALITY ASSESSMENT (EQA) SCHEME BY UK NEQAS PARASITOLOGY

Jaya Shrivastava, Peter L. Chiodini, Agatha C. Saez

Public Health England, London, United Kingdom

Protozoan infections are responsible for a large proportion of infectious gastroenteritis world-wide. The common pathogenic protozoa are *Giardia intestinalis*, *Cryptosporidium hominis* or *C. parvum* and *Entamoeba histolytica*. Because of the clinical importance of these parasites, recent years have seen increased use of molecular methods for their detection with current clinical algorithms relying on qualitative detection of these parasites using molecular methods. Thus, the need for a fit-for-purpose qualitative EQA or Proficiency testing scheme for these parasites is very clear. In February, 2019 UK NEQAS Parasitology sent out a questionnaire to all participants within its existing microscopy-based Faecal Parasitology EQA scheme in order to determine whether the need for such an EQA scheme exists. The survey was sent to about 550 laboratories and 87 responded. 52 participants confirmed existing or planned capability in molecular testing for faecal parasites, with 43 labs confirming plans to use molecular diagnostic methods in near future. 65 labs expressed an interest in participating in a UK NEQAS scheme for molecular detection of faecal parasites. Responding to the results of this survey, UK NEQAS parasitology is developing a fit-for-purpose qualitative EQA scheme for the faecal parasites *G.intestinalis*, *Cryptosporidium* spp and *E.histolytica* using freeze dried faecal specimens. The *Giardia* and *Cryptosporidium* specimens were created using clinical samples obtained from patients attending the Hospital for Tropical Diseases in London; whereas the *E. histolytica* samples were prepared using cultured amoebae mixed in negative faeces. The specimens have been successfully freeze-dried and they are working well in molecular assays. The homogeneity and stability of these specimens at various temperatures and time points is currently being tested, with initial results showing very high homogeneity and stability for up to 12 weeks. We shall send the first pilot distribution to the labs that expressed a definite interest by the end of May, 2019.

510

A PROTEOMICS APPROACH TO IMPROVE THE DIAGNOSIS OF NEGLECTED TROPICAL DISEASES

Markus Winterberg, Joel Tarning

Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

The challenge for the management of tropical diseases is often not the treatment, but the diagnosis. In many cases, patients have nonspecific symptoms like fever, headache or rash, which can have their origin in bacterial or viral infections. Although the symptoms are similar, the treatment differs between pathogens. Conventionally used diagnostic tools like serology or microscopy may deliver reliable results, but are often only possible in later stages of the infection. Time consuming cultures of the pathogen and sophisticated equipment may be required to deliver a clear identification. Examples of these difficult to differentiate diseases are typhus fevers caused by intracellular bacteria of the genus *Rickettsia* or *Orientia*, leptospirosis, melioidosis and various viral diseases like dengue and chikungunya. To simplify the diagnosis of these diseases, a rapid diagnostic test (RDT) is needed. This would provide point-of-care identification of the causative pathogen without the need for elaborate laboratory tests, allowing for a rapid and targeted treatment of the patients. The bases of such RDTs is an easily accessible, pathogen-specific biomarker. Using a proteomics approach, we screened the urine of patients with undefined fevers and patients with confirmed differential diagnosis. We were able to identify specific protein biomarkers for some of the most prevalent febrile illnesses in South-East Asia giving rise to the possibility of developing non-invasive RDTs for these diseases.

511

SEROLOGICAL INFERENCE OF PAST PRIMARY AND SECONDARY DENGUE INFECTION: IMPLICATIONS FOR VACCINATION

Ha Minh Lam[1], Huynh Thi Phuong[1], Nguyen Ha Thao Vy[1], Nguyen Thi Le Thanh[1], Pham Ngoc Dung[2], Thai Thi Ngoc Muon[3], Nguyen Van Vinh Chau[4], Isabel Rodríguez-Barraquer[5], Derek A. Cummings[6], Bridget A. Wills[1], Maciej F. Boni[7], Maia A. Rabaa[1], Hannah E. Clapham[1]

[1]*Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam,* [2]*An Giang Central General Hospital, Long Xuyen, An Giang Province, Vietnam,* [3]*Quang Ngai General Hospital, Quang Ngai City, Quang Ngai Province, Vietnam,* [4]*Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam,* [5]*University of California, San Francisco, CA, United States,* [6]*University of Florida, Gainesville, FL, United States,* [7]*Pennsylvania State University, University Park, PA, United States*

Due to the finding that Dengvaxia® (the only licensed dengue vaccine to date) increases the risk of severe illness among seronegative recipients, the World Health Organisation has recommended screening individuals for serostatus prior to vaccination. To decide whether and how to carry out screening, it is necessary to estimate the transmission intensity of dengue and to understand the performance of the screening method. In this study, we inferred the annual force of infection (FOI, a measurement of transmission intensity) of dengue virus in three locations in Vietnam: An Giang (FOI=0.04 for the below-ten-years age-group and FOI=0.20 for the above-ten-years), Ho Chi Minh City (FOI=0.12), and Quang Ngai (FOI=0.05). In addition, we show that using a quantitative approach to IgG levels (measured by indirect enzyme-linked immunosorbent assays, ELISAs) can help to distinguish individuals with primary exposures (primary-seropositive) from those with secondary exposures (secondary-seropositive). We found that primary-seropositive individuals - the main targets of the vaccine - tend to have a lower IgG level, and thus a higher chance of being misclassified as seronegative, as compared to secondary-seropositive cases. Nevertheless, we demonstrated that screening performance can be improved by incorporating patient age and transmission intensity into the interpretation of IgG levels.

512

SELECTION AND VALIDATION OF LABORATORY INSTRUMENTATION TO SUPPORT CLINICAL RESEARCH INVOLVING HIGH-CONSEQUENCE PATHOGENS DURING OUTBREAKS

Willy Kayondo[1], Sharon Kagabane[1], Sharon Atukunda[1], Lydia Tumubeere[1], Daniel Kibombo[2], Brenda Kusiima[2], Joseph Wandege[1], Prossy Naluyima[1], Karen Martins[3], Chi Ritchie[3]

[1]*Makerere University Walter Reeed Project Uganda, Fort Portal, Uganda,* [2]*Infectious Diseases Instititute Uganda, Fort Portal, Uganda,* [3]*US Army Medical Research Institute of Infectious Disease, Fort Detrick, MD, United States*

The 2014-2016 Ebola outbreak in West Africa exposed the dire need for medical interventions for high-consequence pathogens. The Joint Mobile Emerging Infectious Disease Intervention Clinical Capability (JMEDICC) was established in Fort Portal, Western Uganda, with an objective to train a local team ready to conduct clinical research of Investigational Drug Interventions in an outbreak setting. As part of the laboratory capability development, instruments were selected based on the following: size, to enable appropriate biocontainment as well as movement to remote sites; availability of consumables; and US FDA approval status so as to capitalize on the minimized validation requirements and maximize reliability. Good clinical laboratory practices (GCLP) were introduced and instruments were validated at the study hub site in Fort Portal by assessing accuracy, precision (within day and between day), and linearity. Instrument verification was unfamiliar to the study team, which increased the complexity of the validation process and the time required for verification. Overtime, following training and repeated execution as new instruments were brought on board, the time of method validation was greatly shortened. The team then developed a mobile verification plan to re-verify the assays and instruments after they are moved to the field. From the perspective of outbreak preparedness, strict adherence to GCLP may not be feasible in a mobile, rapid-response environment. Achieving instrument validation in an outbreak response is a challenge because a rapid response is required yet GCLP requires time-consuming validation of test methods prior to testing of study participants. Defining a minimum re-verification procedure and the samples required to execute that procedure will assist with project execution in an outbreak setting. The lessons learned from the JMEDICC laboratory team may assist other outbreak preparedness teams in establishing high quality laboratory support for high consequence pathogen clinical trials in remote settings.

COMBAT AND NON-COMBAT MORTALITY AMONG U.S. MILITARY ADVISORS IN SOUTHEAST ASIA: 1956-1964

David Adams, Valerie Adams

Point University, Midway, GA, United States

The French presence in Southeast Asia came to an ignominious end at the surrender of Dien Bien Phu in spring of 1954. Their defeat came despite millions of dollars of materiél—not ground troops--supplied by the United States. When asked why he refused to commit manpower to aid the French with manpower, the American President Eisenhower famously remarked that, when he looked at Southeast Asia, he saw it swallowing division after division of his troops. Prophetic words, indeed, in light of the next two decades that would do exactly that, killing more than 58,230 military personnel in all. But Eisenhower—and later Kennedy—sent several thousand erstwhile American military "advisors" well before the arrival of the Marines at Da Nang in 1965. Their job? To assist South Vietnamese troops (Army of the Republic of Vietnam) in their struggle against the communist North Vietnamese. But what of so-called American military advisors prior to 1965? Utilizing archival data from the Southeast Asia Combat Casualty File located at the U.S. National Archives, this presentation will analyze cause-specific mortality among advisory military personnel. The results will suggest that "combat" deaths, although numerous, were accompanied by substantial mortality from disease and, perhaps most importantly, non-combat causes such as suicide.

514

CARDIAC EVALUATION IN ADULTS WITH DENGUE INFECTION BY SERIAL ECHOCARDIOGRAPHY

Chayasin Mansanguan[1], Weerapong Phumratanaprapin[1], Borimas Hanboonkunupakarn[1], Sant Muangnoicharoen[1], Arun Huntrup[1], Akkapon Poolcharoen[2]

[1]*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [2]*Medical Eepartment, Bhumibol Adulyadej Hospital RTAF, Bangkok, Thailand*

Background: Dengue viral infection has been a major health problem worldwide. The clinical spectrum of dengue infection is broad ranging from asymptomatic to dengue infections to a severe disease. Although cardiac involvement has been reported in dengue infection, the incidence and cardiac involvement are not well established. A better understanding of cardiac involvement in dengue infections is required. Methods: From Jan 2016 to Dec 2018, patients hospitalized at Bangkok Hospital for Tropical Diseases with dengue confirmed by positive NS1 antigen or positive dengue IgM. We characterized the incidence and change in cardiac function by serial echocardiography, troponin T and CK - MB level at the day of admission, day of defervescence, day of hypotension (if the patient develop hypotension) and two – weeks follow up. Results: Seventy – three patients were evaluated and 5 patients (%) presented with elevated biomarker levels. There was no difference in clinical presentation between dengue (DF), dengue hemorrhagic fever (DHF) and dengue shock syndrome (DSS). Cardiac involvement were found 24.65% in this present study including left ventricular systolic dysfunction 4(5.5%), transient diastolic dysfunction 3(4.1%), increased levels of at least 1 cardiac biomarker (Troponin T, CK-MB) 5(6.85%) and small pericardial effusion6(8.2%), respectively. Only one case that suspected myocarditis in DHF patient. Three patients develop DSS during admission and transfer to intensive care unit (ICU). We found that dengue hemorrhagic fever was the associate risk factor to develop cardiac involvement with clinically significant ($p < 0.006$). Conclusion: Cardiac involvement in adults with dengue infection was found 24.65% ranging from elevated cardiac biomarker, transient left ventricular systolic and diastolic dysfunction and pericardial effusion. The functional abnormality spontaneously resolved at the day of follow up without specific treatment. Myocarditis in dengue infection patients were uncommon.

515

EFFICACY AND TOLERABILITY OF MILTEFOSINE FOR THE TREATMENT OF CUTANEOUS LEISHMANIASIS

JeanAnne M. Ware[1], Elise M. O'Connell[1], Kawsar R. Talaat[2], Thomas B. Nutman[1], Theodore E. Nash[1]

[1]*Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States,* [2]*Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States*

Miltefosine is an oral drug approved for the treatment of cutaneous leishmaniasis (CL), but its efficacy in varied species and its associated side effects have not been well studied. We reviewed the treatment courses of 18 patients (2 not yet assessable for cure) seen at the National Institutes of Health with CL due to the following species: *Leishmania braziliensis* (Lb; n=6); *L. aethiopica* (La; n=3); *L. panamensis* (Lp, n=2); *L. infantum (n=1)*; *L. donovani chagasi (n=1)*; *L. tropica (n=1*); *L. major* (n=1) ; and unspeciated (n=3). Among the 8 patients given miltefosine (with or without topical imiquimod) at the time of presentation, 6 (75%) healed, 1 (12.5%) failed to heal, and 1 (12.5%) was intolerant of treatment. In 8 additional patients who had been treated previously with other therapies, miltefosine resulted in 4 healed, 3 failed to heal, and 1 was intolerant of treatment. All patients who failed miltefosine were effectively treated with alternative

medications, thermal therapy or self-healed. Three of those who failed to heal despite optimal therapy (1 immunosuppressed patient with *La* and 2 with *Lb*-like organisms) were cured with combined miltefosine and Ambisome treatment. An additional patient with complicated severe disseminated CL and mucosal disease due to *Lp* responded to 56 days of miltefosine after failing liposomal amphotericin B. Overall, miltefosine resulted in cure in 62.5% (10/16), 12.5% (2/16) failed to cure, and 25% (4/16) remained unhealed. Nausea, vomiting, anorexia, and/or diarrhea occurred varyingly in all patients and frequently required decreased dosing. Two patients (11.1%) stopped drug prematurely, 8 (44%) required reduced dosing, and 6 (33%) were started on a lower dose in an attempt to prevent symptoms. Gout occurred in one patient during 2 separate miltefosine courses. Miltefosine either alone or in combination with Ambisome cured 81.3 % and was effective for most species encountered. Side effects were frequent and led to decreased dosing. Further evaluation is needed to determine the efficacy and optimal dosing of miltefosine.

516

PATIENT CENTERED MANAGEMENT OF BURULI ULCER IN CAMEROON: INTEGRATING LOCAL DIAGNOSIS, MENTAL HEALTH AND TRADITIONAL CONSIDERATIONS

Lucrece Eteki[1], Radhika Sundararajan[2], Rodrigue Ntone[1], Joel Djatche[3], Franck Wanda[4], Yves Hako[5], Jacques Minyem[6], Earnest Njih[7], Sara Eyangoh[8], Alphonse Um Boock[9], **Yap Boum**[1]

[1]*Epicentre, Yaoundé, Cameroon,* [2]*Cornell University, New York, NY, United States,* [3]*UNIPSY, Yaoundé, Cameroon,* [4]*Cires, Yaoundé, Cameroon,* [5]*HRRA, Yaoundé, Cameroon,* [6]*FAIRMED, Yaoundé, Cameroon,* [7]*CNLP²LUB, Yaoundé, Cameroon,* [8]*Centre Pasteur Cameroun, Yaoundé, Cameroon,* [9]*Fairmed, Yaoundé, Cameroon*

Early diagnosis and adherence to treatment are crucial to control chronic wounds including Buruli Ulcer (BU). However, diagnosis and treatment are frequently delayed, resulting in significant morbidity and mortality. This study sought to improve clinical diagnosis of BU through use of a clinical diagnosis score (CDS), describe the patients' mental health status, and understand current perceptions about the disease. Our mixed methods study was conducted in three BU endemic Districts in Cameroon: Akonolinga, Ayos, Bankim, where patients were enrolled at district hospitals and health centers. Health care workers (HCW) administered a CDS that is compared to Polymerase Chain Reaction (PCR) for detection of BU. BU patients also completed psychological scales (MINI and QSCPGS) and questionnaires. Current perceptions regarding BU were assessed through Focus Group Discussions (FGDs) and interviews with patients, community traditional healers and HCWs. The CDS was administered to 162 patients; 73 (45%) of them were BU patients confirmed by PCR. Positive Predictive Values (PPV) of physicians' clinical diagnosis compared to PCR was 62% without CDS, and 86% with the use of CDS. Psychometric testing (N=73) demonstrate that 36% (N=26) of patients suffered from depression and 25% (N=18) of them were suicidal. The majority (75%, N=55) of patients reported feeling of stigmatization and discrimination. Qualitative data (N=58) also showed 1) general belief in the mystical origin of the disease, 2) patients combine both traditional and biomedical treatment to heal faster and 3) traditional healers are more open to collaboration than physicians. Our preliminary data show that the CDS increases PPV of the clinical diagnosis of BU from 62% to 86%, beyond the 70% WHO recommendation for BU. Given the elevated rates of psychological pathologies among patients and the impact of local beliefs in the choice of treatment, it is crucial to implement holistic culturally competent programs that integrate accessible and effective diagnostic tools, patients' cultural beliefs, and psychological effects of BU.

517

GENE EXPRESSION ANALYSIS OF ANTI-FILARIAL ACTIVITY OF NATURAL AND SYNTHETIC SESQUITERPENE LACTONES FROM THE PLANT *NEUROLAENA LOBATA*

Lizzette Perez-Perez, Jessica Grant, Susan Haynes, Kevin M. Shea, Steven A. Williams

Smith College, Northampton, MA, United States

Lymphatic filariasis (LF) is a common vector-borne disease in many regions of the tropics and the leading cause of permanent and long-term disability worldwide. Current drugs used to treat LF are given annually for about five years due to poor activity in killing the adult worms. However, because of the prolonged administration, therapeutic resistance to current antihelminthics has become increasingly important. Therefore, there is a need to develop novel, safe and short course micro- and macrofilaricide treatments that can help accelerate the elimination and eradication of LF. Our work has focused on studying the bioactivity of natural sesquiterpene lactones, available from *Neurolaena lobata,* and synthetic analogs against the lymphatic filarial parasite *Brugia pahangi.* These analogs were created by modification of the neurolenin scaffold including esterification at the reactive secondary alcohol position. The bioactivity of natural neurolenin and the synthetic analogs was measured *in vitro* against male and female adult nematodes by adding one dose (3μg/mL) of the respective drug and then monitoring worms loss of motility as the read-out over a period of 100 hours. Interestingly, the activity of the sesquiterpene lactones varies between male and female nematodes, indicating the presence of some mechanism resulting in gender selectivity. The basis of the bioactivity of neurolenin B, one of the neurolenins from *N. lobata* to exhibit a strong activity against the motility of adult worms, was studied using RNA-seq analysis. In this study, transcription profiles were compared between drug-treated and untreated *B. pahangi* female adults. Studying the effect of neurolenin B on the transcriptome will provide us with insight into the molecular target and mechanism of action of the compound in killing adult worms. These results will provide further useful information on the impact of sesquiterpene lactones as promising alternatives for the treatment of LF and perhaps other diseases caused by parasitic nematodes.

ANTI-FILARIAL DRUGS INHIBIT EXTRACELLULAR VESICLE RELEASE FROM PARASITIC NEMATODES

Hannah J. Loghry, Wang Yuan, Michael J. Kimber

Iowa State University, Ames, IA, United States

Strategies to control parasitic nematode infection rely on mass administration of anthelmintic drugs in endemic areas. For Lymphatic filariasis, a disease caused by filarial nematodes, these drugs are ivermectin (IVM), albendazole (ABZ) and diethylcarbamazine (DEC). Despite their widespread use, the therapeutic mode of action of these drugs is not clear. For example, IVM binds parasite glutamate-gated chloride channels but how this molecular activity results in the rapid clearance of larval stage parasite *in vivo* is obscure. There is a clear need to better understand anti-filarial drug mechanisms of action. Extracellular vesicles (EVs) are membrane-bound vesicles secreted into the extracellular environment by eukaryotic and prokaryotic cells and are important mediators of cell-to-cell signaling. We have previously reported that filarial nematodes secrete EVs and that their cargo has immunomodulatory properties. We propose that nematode EVs are essential for parasitism and hypothesize that effective anti-filarial drugs inhibit their release. To test this hypothesis, we used Nanoparticle Tracking Analysis to quantify the effect of IVM, ABZ and DEC treatment on EV release from a panel of filarial nematode species and life stages. We included *Ascaris*, a gastrointestinal nematode, and the nicotinic agonist levamisole (LEV), for comparison. We show that effective anti-filarial drugs inhibit EV release but with marked variations in efficacy between species, sex and life stage. IVM exerted the most broadly effective inhibitory effects, followed by DEC and LEV. Where testable, females were the life stage most sensitive to drug treatment whereas males were not affected by any drug. ABZ had little effect on EV release,

except in *Brugia pahangi.* Drug effects on *Ascaris* supported those seen in filarial nematodes suggesting broadly conserved processes. Our data show release of immunomodulatory EVs by parasitic nematodes is inhibited by some anti-filarial drugs, shedding new light on the mechanism of action of these drugs and suggesting a novel phenotype in screening strategies for novel anti-filarial drugs.

519

GENOME SEQUENCES OF THE *WOLBACHIA* ENDOSYMBIONTS FROM THE FILARIAL PARASITES *MANSONELLA PERSTANS* AND *MANSONELLA OZZARDI*

Zhiru (Liz) Li[1], Amit Sinha[1], Catherine B. Poole[1], Richard D. Morgan[1], Laurence Ettwiller[1], Nathalia F. Lima[2], Marcelo U. Ferreira[2], Samuel Wanji[3], Clotilde K. Carlow[1]

[1]*New England Biolabs, Ipswich, MA, United States,* [2]*University of Sao Paulo, Sao Paulo, Brazil,* [3]*University of Buea, Cameroon, Cameroon*

Wolbachia, an alpha-proteobacterium closely related to Rickettsia, is a maternally transmitted, intracellular symbiont of arthropods and most filarial nematodes. *Wolbachia* have also been observed in *Mansonella ozzardi* and occasionally in *Mansonella perstans*, using PCR to detect 16S rDNA, *ftsZ* and *wsp* markers. These analyses have placed these *Wolbachia* into the supergroup F, while other filarial *Wolbachia* are members of supergroup C, D and J of *Wolbachia* phylogeny. The supergroup F is unique as it contains both arthropod and nematode *Wolbachia*. In the current study, we have obtained the first draft genome of the *Wolbachia* from *M. perstans* (*w*Mpe) as well as *M. ozzardi* (*w*Moz). The *Wolbachia* draft genomes are both ~ 1Mb in size. These draft genomes contain ~500 contigs, probably due to the low sequencing coverage, reflecting the low *Wolbachia* titers in *Mansonella* microfilariae. The completeness of these genomes was evaluated using BUSCO, a software that measures the fraction of single copy orthologs expected to be conserved within a taxa. The BUSCO score for *w*Moz is ~80%, similar to the scores of other *Wolbachia* with complete genome sequences, indicating the high quality of these *Wolbachia* genomes. The *w*Mpe and *w*Moz genomes show ~97% average nucleotide identity (ANI) over their entire genome, and are most similar to the *Wolbachia* present in the bed bug *Cimex lecturalius* (*w*Cle), with ANI scores ~ 93%. These results are particularly interesting, as they represent the first draft genomes from nematode-associated supergroup F *Wolbachia*. The availability of genomes sequences from *w*Mpe and *w*Moz will provide further insight into the evolution and phylogenetic relationships of these *Wolbachia*. They will also enable further biochemical, molecular and genomic studies on the symbiotic relationship, and facilitate the development of new drugs targeting *Wolbachia*.

520

DEVELOPMENT OF A QUANTITATIVE PCR ASSAY FOR THE DETECTION OF *MANSONELLA PERSTANS* IN HUMAN BLOOD

Tamara S. Thomas, Nils Pilotte, Lori J. Saunders, Steven A. Williams

Smith College, Northampton, MA, United States

Here we describe a novel, species-specific, quantitative, real-time PCR assay for the detection of the parasite *Mansonella perstans*. *M. perstans* is closely related to *Wuchereria bancrofti*, the causative agent of lymphatic filariasis in Africa, and has the potential to cause false positive results when using antigen detection-based tests. To combat this problem, we capitalized on the sensitivity and specificity of PCR-based assays to develop a new quantitative PCR (qPCR) assay for *M. perstans* based on the detection of species-specific repetitive DNA sequences using our previously published genomics/bioinformatics-based platform. *M. perstans* was sequenced using Illumina next-generation sequencing and the raw sequence reads were ported to the bioinformatic tool RepeatExplorer to screen for the most highly repeated DNA sequences. These sequences were used to design qPCR primer and probe sets to optimize the sensitivity and specificity of the qPCR assay. The primer and probe set that produced the best sensitivity and specificity was selected for further study and tested using *M. perstans* DNA, human DNA and the DNA of several related filarial parasites. Results from the real-time amplification plots showed that only the *M. perstans* DNA was amplified and that attogram levels of DNA could be detected. Following these laboratory-based studies, field samples collected in several countries in Africa will be tested and results will be compared to the standard antigen detection-based method for lymphatic filariasis (FTS strip test). One goal is to determine the proportion of LF positive tests that are due, in fact, to the presence of *M. perstans*.

521

POPULATION GENOMICS AND MOLECULAR PHYLOGENETIC RELATIONSHIPS OF *SIMULIUM* VECTORS OF ONCHOCERCIASIS IN GHANA: LARGE INTERBREEDING SYMPATRIC POPULATIONS AND LARGE TRANSMISSION ZONES

Warwick Grant, Ernest Gyan, Shannon Hedtke

La Trobe University, Bundoora, Australia

Onchocerca volvulus, the causative agent of onchocerciasis, is transmitted by anthropophilic flies of the genus *Simulium*. Taxonomic identification of African *Simulium* vectors is challenging, relying on a combination of cytogenetics derived from banding patterns of polytene chromosomes in the salivary glands of aquatic larvae and/or on a suite of overlapping morphometric characters. Several attempts have been made to construct molecular phylogenies of the *Simulium* vectors of *O. volvulus* but in general there has been poor concordance between the molecular phylogenies and the cytogenetic/morphometric phylogenies. The low level of polymorphism observed in the mitochondrial barcode amplicons that have been used is the most likely cause of the poor resolution achieved to date using molecular methods. We show here that relatively low depth whole genome sequencing of single flies yields sufficient data to reconstruct the entire mitochondrial genome of individuals at >50X depth, and a nuclear genome that is >90% complete by CEGMA and BUSCO criteria. We have constructed molecular phylogenies using (a) conventional, relatively short barcode amplicons (b) a single amplicon spanning >3kb of the mitochondrial genome and (c) whole mitochondrial genomes of >60 flies reconstructed from low-depth whole genome sequences, and (d) partial CEGMA and BUSCO genes. The flies were collected from 3 river basins across an approximately 250km east-west transect in central Ghana (the "transition zone" between forest and savannah) during the dry season. Even with whole mitochondrial genome sequence, there was no evidence of significant population structure between river basins. This implies a history of frequent long-range fly movement and is consistent with a parallel lack of population structure in parasites sampled from the same locations. Phylogenetic analysis also suggested either the flies are most likely a single species or an unusual case of sympatric species between whom there is still gene flow.

522

EFFECT OF DIFFERENT ALBENDAZOLE-BASED TREATMENT REGIMENS ON *LOA LOA* MICROFILARAEMIA IN AN ENDEMIC REGION OF GABON PRELIMINARY RESULTS OF AN OPEN-LABEL RANDOMIZED CONTROLLED CLINICAL TRIAL

Rella Zoleko-Manego[1], Ghyslain Mombo-Ngoma[1], Ruth Kreuzmair[2], Wilfrid Ndoumba[1], Michael Ramharter[3]

[1]*CERMEL, Lambarene, Gabon,* [2]*Institute of Tropical Medicine, University of Tuebingen and German Centre for Infectious Diseases (DZIF), Tuebingen, Germany,* [3]*Bernhard Nocht Institute for Tropical Medicine, World Health Organization Collaborating Centre for Arbovirus and Hemorrhagic Fever Reference and Research, Hambourg, Germany*

Loiasis is a parasitic infection caused by the filarial worm *Loa loa*. Despite its wide range of clinical symptoms, loiasis is not even considered a neglected tropical disease and its importance was only highlighted when the implementation of mass drug administration programs for lymphatic filariasis and onchocerciasis had to be stopped in Loa Loa co-

endemic areas. However, with more than 10 Mio people affected, there is a need for a safe and effective treatment of loiasis. Currently, there is no sufficiently safe treatment option for mass drug administration for the interruption of *L. loa* transmission available. Potent drugs such as ivermectin or diethylcarbamazine have led to severe post-treatment adverse events in patients with high *Loa Loa* microfilaremia. While albendazole treatments seem to be safe, it is unclear if this leads to complete suppression of microfilaremia. Here we present an open label clinical trial evaluating different albendazole based regimen alone or in combination with ivermectin for loiasis in Gabon. Forty-two adults of both sexes with initial filarial count between 7000-50000 were randomized in four arms and followed up to six months. Arm 1 (6 subjects) untreated controls; arm 2 (12 subjects): albendazole 400 mg twice daily for 21 days; arm 3 (12 subjects): albendazole 400 mg twice daily for 21 days followed by additional albendazole 400 mg twice daily for 14 days; arm 4 (12 subjects): albendazole 400 mg twice daily for 21 days followed by a single dose of 150 μg/kg of ivermectin. L. loa microfilaraemia was measured before each treatment and twice weekly for three weeks and then weekly follow-up visits took place from week 4 through week 8; thereafter, twice monthly visits took place until the end of follow-up. Post treatment adverse events were similar in the three treatment arms, one adverse event recorded was considered probably treatment related. In all treatment arms, microfilarial levels decreased significantly ($p<0.05$) following the first round of albendazole. More detailed results of the respective treatment arms will be presented at the congress.

523

POTENTIAL CROSS REACTIVITY OF *MANSONELLA PERSTANS* WITH *WUCHERERIA BANCROFTI* BY FILARIASIS TEST STRIPS

Yaya Ibrahim Coulibaly[1], Lamine Soumaoro[1], Benoit Dembele[2], **Mary Hodges**[3], Yaobi Zhang[4]

[1]*International Center for Excellence in Research, Bamako, Mali,* [2]*Helen Keller International, Bamako, Mali,* [3]*Helen Keller International, Freetown, Sierra Leone,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Lymphatic filariasis is considered endemic where mapping using Immunochromatographic test (ICT) cards or night blood films find antigenemia or microfilaria (mf) prevalence of *Wuchereria bancrofti* to be ≥1% in persons over 15 years of age. Elimination is considered achievable by annual mass drug distribution (MDA) with ivermectin and albendazole for a minimum of 5 years. In recent years, Filariasis Test Strips (FTS) have been used to replace ICT cards to detect *W. bancrofti* antigen with the advantage of being cheaper than ICT, with greater sensitivity and simplicity than mf (day versus midnight sampling). However, concerns over the specificity of ICT or FTS were raised where *Loa loa* or *Mansonella perstans* co-exists. In Mali, stored day and night blood samples from a study on the impact of high dose of albendazole and ivermectin on *W. bancrofti* mf clearance supported by NIH were examined by microscopy and by Trop-Bio ELISA for *W. bancrofti* in Bamako. Three thick smear slides were made per sample, and microfilaremia positives for either *W. bancrofti* or *M. perstans* were confirmed by another technician. Ninety (90) confirmed positives samples for *W. bancrofti* and/or *M. perstans* were subsequently selected and tested by FTS: 30 samples with *W. bancrofti* positive only (Wb+Mp-), 30 samples with *M. perstans* positive only (Wb-Mp+, Wb- confirmed by microscopy and ELISA/ICT), and 30 samples with both positive (Wb+Mp+). The results showed that 25/30 Wb+Mp- samples and 21/30 Wb+Mp+ samples were FTS positive. However, 3/30 Wb-Mp+ samples were also FTS positive. Although the sample sizes tested were relatively small, it highlights potential cross reactivity between *W. bancrofti* and *M. perstans* antigens by FTS. *M. perstans* infection is often asymptomatic, but reported manifestations include transient subcutaneous swellings, urticaria, pruritus, arthralgia, abdominal pain, and fatigue. The presence of this parasite may have significant implication in assessing LF MDA impact by FTS in areas where both parasites co-exist, such as in Sierra Leone. Further research is needed to clarify this.

524

EVALUATION OF THE THERAPEUTIC COVERAGE OF MASS TREATMENT CAMPAIGN AGAINST LYMPHATIC FILARIASIS IN A CONTEXT OF PERSISTENT TRANSMISSION OF THE DISEASE

Roland Bougma[1], **Mamadou Serme**[1], Christophe Nassa[1], Micheline Ouedraogo[2], Appolinaire Kima[1], Clarisse Bougouma[1], Dieudonné Nare[2], Jean-Paul Djiatsa[2], Fanny Yago-Wienne[2], Amy Veinoglou[3], Yaobi Zhang[4]

[1]*NTD Control Program, Ministry of Health, Ouagadougou, Burkina Faso,* [2]*Helen Keller International, Ouagadougou, Burkina Faso,* [3]*Helen Keller International, New York, NY, United States,* [4]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Burkina Faso has been implementing preventive chemotherapy against lymphatic filariasis since 2001. While 61 health districts (HDs) have stopped mass drug administration (MDA), transmission persists in nine HDs despite good MDA coverage reported. To validate the reported coverage, an independent post-MDA coverage survey was conducted in Tenkodogo and Fada N'Gourma HDs in September 2018. The study population consisted of all persons in the communities. The Coverage Survey Builder (CSB) tool was used to calculate the sample size and to conduct the random selection of households. A total of 30 villages per HD were selected. The investigators were Ministry of Education agents and health workers not involved in MDA. Data were collected on smartphones through the KoBo Collect application on age, sex, ingestion of the drugs (ivermectin + albendazole), adverse events, and appreciation of MDA and strategies. Stata Version 14 and QGIS 3.4 were used for data analysis. A total of 3,741 individuals were surveyed, 53.3% were female and the average age was 20.4 years. Surveyed epidemiological coverage was 73.9% [95% CI: 72.6-76.5] in Fada N'Gourma and 79.3% [95% CI: 77.8-81.5] in Tenkodogo, compared to reported coverages of 82.6% and 82.0%, respectively. Village-level coverage ranged from 32.9% to 100% in Fada N'Gourma and from 56.7% to 93.3% in Tenkodogo. In total, 99% of those treated said they had swallowed the drugs in front of the community drug distributor (CDD) and confirmed the use of dose poles. The main reasons for non-treatment were CDD did not come (54%) and absence during MDA (43%). A total of 98 (0.34%) people reported developing adverse events including breathing difficulties, drowsiness, diarrhea and nausea. Results showed that surveyed coverage was lower than reported coverage in both HDs, yet both were above the 65% threshold recommended by WHO. However, major variations among villages raised alarm for attention. Directly observed treatment appeared to have been well respected. The main challenges to increase coverage will be the systematic revisit of households with absentees and the targeting of all households in each village.

525

STANDARDIZATION OF DIAGNOSTIC METHODS FOR THE DETECTION OF MICROFILARIAEMIA IN BLOOD FOR LYMPHATIC FILARIASIS: A REVIEW AND META-ANALYSIS

Natalie Vivian Vinkeles Melchers, Luc E. Coffeng, Sake J. de Vlas, Wilma A. Stolk

Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Active lymphatic filariasis (LF) infection is generally diagnosed through parasitological identification of microfilariae (mf) in the blood. Blood samples can be tested through various diagnostic techniques. We have derived transformation factors to standardise mf prevalences as measured by a wide variety of diagnostic tests, blood volumes, and time of sampling (day versus night blood). This way, we can express any mf prevalence as obtained by the historically most commonly used night thick blood smears (TBS) in 20 μL blood volume. We first performed a systematic review to identify studies that reported on comparative mf prevalence data as measured by more than one diagnostic test for the same study population. Results from different diagnostic tests were then related to mf prevalences as obtained by TBS 20 μL/blood using a meta-regression

model based on odds-ratios (OR). Resulting ORs were translated to transformation factors as a function of prevalence measured by the more sensitive diagnostic tool. We identified 607 articles matching our search strategy and included 17 surveys, all conducted in the period 1971-1998. The mf prevalences as measured by the more sensitive nuclepore filtration (1 mL/blood) should be multiplied with a range in transformation factors of 0.45-0.69, depending on the transmission setting (here 10% and 40% mf prevalence as measured by TBS 20 μL respectively), to standardise to mf prevalences as obtained by TBS in 20 μL blood. For TBS in >40 μL/blood this corresponding range of transformation factors was 0.59-0.82; for Knott's technique 0.63-0.83; and for counting chamber (≥50 μL/blood) it was 0.67-0.87. Our results allow comparison of LF survey data through mf prevalence standardisation to reflect mf prevalences as detected by TBS 20 μL blood volumes. This will facilitate use of more datasets in e.g. meta-analyses and geographic mapping initiatives.

526

CYTOKINE SIGNATURES ASSOCIATED WITH MICROFILARIA CLEARANCE FOLLOWING SINGLE DOSE OF IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE THERAPY FOR LYMPHATIC FILARIASIS IN COTE D'IVOIRE

Charlene Aya Yoboue[1], Sarah Frischmann[2], Claudia Daubenberger[1], Juerg Utzinger[1], Benjamin Guibehi Koudou[3], Christopher Lee King[2]

[1]*Swiss and Tropical Public Health, Basel, Switzerland,* [2]*Center for Global Health and Diseases, Case Western Reserve University, Cleveland, OH, United States,* [3]*Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Univerité Nangui Abrogoua, Abidjan, Côte D'Ivoire*

The combination of Albendazole, Ivermectin and Diethylcarbamazine (IDA) constitutes the new therapy against Lymphatic Filariasis for mass drug administration outside sub-Saharan African. A single dose of IDA demonstrated sustained clearance in ~95% of individuals for up 3 years in Papua New Guinea and similar efficacy was observed at 1 year in other areas (Indonesia, Haiti). However, initial results of IDA in Africa showed less success; the case of Côte d'Ivoire with 50% of microfilariae clearance 24 months post treatment. This failure sustain Mf clearance may be due to reinfection, regional differences in drug absorption and metabolism, less susceptibility of parasite to the drugs, or immune suppression by chronic infection. It is well established that host immune response is required for IDA to work effectively *in vivo*. Here we examined the hypothesis that individuals that showed greater immune modulation by increased production of immunoregulatory cytokines (e.g. IL-10 and TGF-β), and reduced production of pro-inflammatory cytokines (e.g. IFNg, TNF, IL-17) prior to treatment and 24 hours following treatment would be associated with impaired clearance of Mf 1 year after treatment. We examined both ex vivo, BMA and mitogen induce cytokine release in whole blood from participants who cleared Mf (N=15) and those that did not (N=6) 1 year following IDA administration because re-infection is unlikely in 1 year. We examined both plasma cytokines supernatants (IL-2, IL-13, IL4, IL-5, IL-10, IL12p70, GMCSF, IFNg and TNFa) from whole blood at 16 and 72 hours in cultures. Our initial results failed to show significant differences in plasma cytokine levels in culture supernatant before or after treatment with exception of TNFa which was consistently higher plasma and culture supernatants from individuals that cleared Mf compared to those that did not (P=0.02 to <0.003). Thus, these preliminary results failed to show clear evidence of immune suppression by individuals who failed to clear Mf at 12 months, but further assays are underway examining the frequency of antigen-specific lymphocytes, antibody levels and immune responses at later time points.

ASSESSING THE IMMUNOGENICITY OF ADJUVANT-ANTIGEN FORMULATIONS IN A NATURAL BOVINE - *ONCHOCERCA OCHENGI* INFECTION MODEL FOR HUMAN ONCHOCERCIASIS

John Graham-Brown[1], Lisa Luu[1], Catherine Hartley[1], Bin Zhan[2], Maria-Elena Bottazzi[2], David Abraham[3], Nikolai Petrovsky[4], Nicholas Bayang[5], Germanus Bah[5], Vincent Tanya[5], Sara Lustigman[6], Benjamin Makepeace[1]

[1]*Infection and Global Health, Liverpool, United Kingdom,* [2]*Baylor College of Medicine, Houston, TX, United States,* [3]*Thomas Jefferson University, Philadelphia, PA, United States,* [4]*Flinders University, Adelaide, Australia,* [5]*L'Institut de Recherche Agricole Pour le Développement, Yaounde, Cameroon,* [6]*New York Blood Center, New York, NY, United States*

Human onchocerciasis (river blindness) is a neglected tropical disease affecting 15.5 million people in sub-Saharan Africa. The first-stage larvae (microfilariae) of the filarial worm, *Onchocerca volvulus*, cause severe dermatitis and keratitis, with the latter leading to irreversible blindness. In Africa, efforts to eliminate *O. volvulus* via mass administration of the microfilaricidal drug ivermectin over 30 years has seen a 31% reduction in prevalence. Disease elimination is complicated by both the emergence of ivermectin-resistant *O. volvulus* and the restricted use of this drug in areas where *O. volvulus* and another filarial nematode, *Loa loa,* are co-endemic. Development of new control methods, including prophylactic vaccines, are therefore indicated. To determine optimal formulation for vaccines in a bovine - *Onchocerca ochengi* natural infection model for *O. volvulus*, twelve immunologically naïve calves were split into four groups of three. Three groups were immunised with recombinant versions of the *O. volvulus*-derived antigens RAL-2 and 103 formulated with one of three adjuvants: Alum, Advax-2 or Montanide ISA 206VG. Immunisations consisted of a 500 μg primary and 250 μg 4 week booster dose of each antigen administered separately via intra-muscular injection. The fourth group served as an unvaccinated control. Weekly serum collection to measure antibody responses revealed detectable levels of IgG and IgE against both RAL-2 and 103 antigens in all immunised animals by week 6 post-primary immunisation. Additional results comparing the humoral and cellular responses to the different adjuvant formulations and unvaccinated controls will be presented, with discussion on how these results have informed formulation for a full-scale bovine - *O. ochengi* vaccine efficacy trial.

528

IMMUNE ACTIVATION IN PATIENTS WITH FILARIAL LYMPHEDEMA BEFORE AND AFTER TREATMENT WITH DOXYCYCLINE

Inge Kroidl[1], Anja Feichtner[1], Sacha Horn[1], Upendo Mwingira[2], Abdallah Ngenya[3], Godfrey Chotta[4], Ute Klarmann-Schulz[5], Janina Kuehlwein[5], Achim Hoerauf[5], Jubin Osei-Mensah[6], Linda Batsa Debrah[6], Alexander Y. Debrah[6]

[1]*Medical Center of the University of Munich (LMU), Munich, Germany,* [2]*National Institute for Medical Research, Dar es Saalam, United Republic of Tanzania,* [3]*National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania,* [4]*Sokoine Regional Hospital, Lindi, United Republic of Tanzania,* [5]*Institute of Medical Microbiology, Immunology and Parasitology, Bonn, Germany,* [6]*Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana*

Lymphatic filariasis is a mosquito-transmitted helminth infection caused by *Wuchereria bancrofti* and *Brugia* spp., characterized by lymphangitis, lymphedema (LE) and hydrocele. Disabling pathology affects about 30% of the 68 million infected people worldwide. Former studies have shown improvement or halt of progression of filarial lymphedema after treatment with Doxycycline (DOX) 200mg/d for 6 weeks. Double-blind, randomized, placebo-controlled trials (TAKeOFF-LEDoxy) are being conducted in Ghana and Tanzania to confirm the effect of DOX 200mg/d and to test the effect of a dose reduction to DOX 100mg/d for 6 weeks on filarial LE. Potential changes in pathology will be recorded at several time points

over a 24-month period. In addition we address immunological aspects both before and after treatment with DOX or placebo. Enrolment is still ongoing, however the first baseline, 6 weeks and 6 month data are available. Peripheral blood mononuclear cells were characterized for the presence of memory CD4 or CD8 T cells (CD45, CD27), regulatory CD4 T cells (FoxP3, CD25), transcription factors for TH1 and TH17 cells (Tbet, RORyt) and immune activation markers (CD38, HLADR). When comparing individual baseline and 6 weeks data in the first analyzed 43 participants, we saw stable values for various T cell subgroups (central and effector memory CD4+ T cells, regulatory T cells). However, when looking at a immune activation parameter there was a significant decline for HLADR+, p =0.03 and HLADR+/CD38+ CD4 T cells, p=0.0015, (median 7.15% before and 6.1% after Doxycycline treatment, relative reduction of 14.7%) between pre- and post-treatment paired values. Since these are double blinded studies, clear conclusions can only be drawn after unblinding of the study participants, which will be done 24 months after treatment onset. However, as two thirds of the study group were treated with DOX, we anticipate that the measured decline in immune activation parameters might be a result of the larger group of DOX treated participants.

529

DEVELOPMENT OF A TWO-STEP FLOW CYTOMETRY METHOD FOR A FIELD SETTING USING WHOLE BLOOD FOR THE DESCRIPTION OF PHENOTYPIC MARKERS ON PERIPHERAL BLOOD CELLS

Sacha Horn, Mohamed I. Ahmed, Christof Geldmacher, Michael Hölscher, Inge Kroidl

Medical Center of the University of Munich (LMU), Munich, Germany

Neglected tropical diseases are often found in remote areas. In resource poor settings, research activities are limited because local laboratories lack equipment or trained personnel. For immunological evaluations, usually a flow cytometer is needed, if possible with 2 or 3 lasers, which is not available in many areas. To circumvent the problem, peripheral blood mononuclear cells can be processed and preserved; measurements can then be later performed in specialized laboratories. However, this usually requires a larger blood draw which is not possible in small children and not agreed to by many adults. We have developed and optimized a method for measuring up to 9 phenotypic markers using 100 µl of blood, which can potentially be taken via finger prick. Blood was collected with EDTA or heparin collection tubes. Extracellular antibodies (b7-PE, CD4-PerCpC5.5, HLADR-PeCy7, CD38-APC, CD27-APC-H7, CD45RA-Bv421, CCR5-APC, CD8-V500, CD25-Bv605) were added and after a 30 minute incubation time, cells were lysed, frozen and stored in liquid nitrogen for transport and further processing. After a period of up to 6 months, cells were thawed, permeabilized, and stained with intracellular antibodies (CD3-ECD, FoxP3-FITC, Tbet-PE, Eomes-PeCy7) before imaging on the Cytoflex and analyzing with FlowJo software. Initial testing showed highly comparable results between freshly drawn and cryopreserved samples. This method has now been performed in two studies, one conducted in Ghana and one in Tanzania, focusing on the immunology of individuals infected with *Wuchereria bancrofti.* Over 200 participant samples have been analyzed with promising results. The participant samples that were preserved for up to 6 months before analysis are comparable to those that were freshly processed and analyzed. Due to the minimal amount of blood required and the robustness, we believe that the method is useful for both evaluating immunological parameters in children and field studies in remote settings.

530

IMPROVED PERFORMANCE OF A SEROLOGY RAPID DIAGNOSTIC TEST FOR ONCHOCERCIASIS BY USING DRIED BLOOD SPOTS

Guilherme Maerschner Ogawa[1], Allison Golden[2], Jui A. Bhingarde[3], Andreas Nshala[4], Eugene Liu[1], Austin Newsam[1], Ryan Wiegand[1], Paul Cantey[1], Vitaliano Cama[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*PATH, Seattle, WA, United States,* [3]*Emory, Atlanta, GA, United States,* [4]*Tanzania Onchocerciasis Program, Dar el Salam, United Republic of Tanzania*

The SD Bioline™ Onchocerciasis IgG_4 Rapid Test (RDT) was developed to facilitate serological assessments for onchocerciasis. It has not been used as widely as expected due to concerns about sensitivity in low prevalence areas compared to ELISA. To determine if RDT sensitivity could be boosted, we compared the performance of the RDT using whole blood (RDT-WB) to performance using blood eluted from dried blood spots (RDT-DBS) in the CDC laboratory. We evaluated samples from Tanzania (n=931) and Togo (n=999), where transmission had been suppressed after >15 years of ivermectin treatment. Sampling occurred across 5 predefined age groups in villages close to *Simulium* breeding sites. Data were analyzed for agreement with OV-16 ELISA. Overall seroprevalence rates by RDT-WB, RDT-DBS and ELISA were 4%, 8.5% and 8.6% respectively for the specimens from Tanzania. Positive and negative agreement with OV-16 ELISA were 40% and 98.9% for RDT-WB and 75% and 97.5% for RDT-DBS, respectively. Among the specimens from Togo, sero-prevalence rates for RDT-WB, RDT-DBS and ELISA were 2.5%, 5.3% and 8.8% respectively. Positive and negative agreement with OV-16 ELISA were 28.4% and 99.9% for RDT-WB, and 55.7% and 99.6% for RDT-DBS. Using eluted DBS resulted in improved agreement between RDT and ELISA, suggesting improved sensitivity, though the magnitude was not predictable. Using eluted DBS may produce results from RDTs that are similar to those obtained by ELISA. Further evaluation of RDT sensitivity using DBS might facilitate RDT use in low prevalence settings (e.g. for mapping hypoendemic zones).

531

DEVELOPMENT OF AN EXPERIMENTAL NEUROTOXOCARIASIS IN A PORCINE MODEL

Luis A. Gomez-Puerta[1], Katherine Robles[1], Ana Vargas-Calla[1], Gianfranco Arroyo[2], Armando Gonzalez[1], Hector H. Garcia[2], Alessandra Nicoletti[3]

[1]*Universidad Nacional Mayor de San Marcos, Lima, Peru,* [2]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [3]*Universita' Degli Stdudi di Catania, Catania, Italy*

Human toxocariasis is a parasitic zoonosis caused by larval stages of *Toxocara canis*, a common parasite of dogs, and probably also by *Toxocara cati*, a parasite of cats. *Toxocara* larvae can cross the blood-brain barrier, invade the central nervous system and produce neurotoxocariasis. However, the frequency and clinical significance of neurotoxocariasis remains unknown until now. In the present study cerebral toxocariasis was produced in a porcine model by intraperitoneal inoculation of *T. canis* larvae. Ten pigs of 8 weeks of age from a technified farm were used. *T. canis* eggs were collected directly from the uterus of adult nematodes obtained from naturally infected dogs. The eggs were placed in a 2.5% potassium dichromate solution for 30 days until the larvae developed. Then, egg hatching was induced and the infectivity of the larvae was evaluated in 20 Balb/C mice. Mice were inoculated intraperitoneally with 500 larvae, and toxocariasis was confirmed at 5 days post infection (PI). After this, all pigs were infected intraperitoneally with 3000 larvae. Pigs had brain magnetic resonance imaging exams taken immediately before necropsy, at days 7 (two pigs), 12 (two pigs), 19 (three pigs) and 49 (three pigs). Neurotoxocariasis development in pigs was confirmed by presence of larvae in brain tissue. No abnormalities were detected by magnetic resonance imaging. While no larvae were detected on microscopic

examination in the pigs sacrificed at day 7 post infection, one pig from day 12 was infected with three larvae in the brain (one in the right posterior lobe and two in the right anterior lobe). All three pigs from day 19 had neurotoxocariasis with 1, 3 and 9 larvae, respectively. Finally, one pig from day 47 was infected with 1 larva in the right posterior lobe. Intraperitoneal infection of *Toxocara* larvae results in neurotoxocariasis in the pig model. Unfortunately, magnetic resonance is not sensitive to detect *Toxocara* larval infection in the brain of pigs.

532

RWANDA NEGLECTED TROPICAL DISEASE CONTROL PROGRAM: WHAT IS THE IMPACT OF DEWORMING OF SCHOOL-AGE CHILDREN 6 YEARS AFTER IT STARTED?

Eugene Ruberanziza[1], Denise Mupfasoni[2], Aimable Mbituyumuremyi[1], Jamie Tallant[3], Jean Bosco Mbonigaba[1], Ursin Bayisenge[1], Michee Kabera S.[1], Innocent Turate[1]

[1]*Rwanda Biomedical Center/Ministry of Health, Kigali, Rwanda,* [2]*World Health Organization, Geneva, Switzerland,* [3]*The END Fund, New York, NY, United States*

Soil–transmitted helminth (STH) infections are among the most important Neglected Tropical Diseases (NTDs) that affect a high number of population in 102 tropical countries. Rwanda launched the NTD control program in 2007 with initial national mapping survey completed in 2008, followed by bi-annual preventive chemotherapy (PC) targeting pre-school and school-age children (pre-SAC, SAC). From 2008 to 2014, nine rounds of PC for pre-SAC and eight rounds for SAC were implemented at national level. In line of evaluating the morbidity of STH infection after 6 years of PC, a national morbidity assessment survey was conducted in 2014. STH data were collected from 186 schools and 9,252 pupils. Stool samples were collected and analysed using Kato-Katz method. The overall prevalence of STH decreased from 65.8% in 2008 to 45.2% in 2014. Hookworms and *T. trichiura* prevalence decreased from 31.7% to 4.5% and from 27.0% to 22.8% respectively while *A. lumbricoides* did not decrease much. The proportion of moderate or heavy intensity of STH infection increased from 11.5% in 2008 to 12.2% in 2014 but the difference was not statistically significant. The main species causing the morbidity were *A. lumbricoides* while *T. trichiura and* hookworm intensity were mostly light across the districts. Northern and Western provinces bearded most of the burden in 2008 and remained the more severely affected in 2014. These settings were also the ones showing a high proportion of moderate or heavy intensity of STH infections. In conclusion, the present analysis suggests to adapt the control strategy to the different epidemiological situations: i) in areas where STH prevalence was not reduced, PC can be extended to all at-risk groups which include pre-SAC, SAC, women of reproductive age and adults at high risk occupation, and if resources are available PC every 3 to 4 months can be considered; ii) in areas where the present intervention reduced the STH prevalence but transmission is still present the intervention could be maintained; iii) in areas in which STH prevalence is very low, the frequency of intervention can be reduced.

533

HELMINTH MEDIATED MODULATION OF THE SYSTEMIC AND MYCOBACTERIAL ANTIGEN - STIMULATED CYTOKINE PROFILES IN EXTRA-PULMONARY TUBERCULOSIS

Gokul Raj Kathamuthu[1], Saravanan Munisankar[1], Baskaran Dhanaraj[2], Subash Babu[1]

[1]*NIH-ICER-NIRT, Chennai, India,* [2]*NIRT, Chennai, India*

Helminth infections are known to regulate cytokine responses in both pulmonary and latent tuberculosis infection. Whether helminth infections also modulate cytokine responses in extra-pulmonary tuberculosis, specifically tuberculous lymphadenitis (TBL), has not been studied thus far. Hence, our study examines the cytokine profile in helminth-TBL co-infection. We measured the systemic and mycobacterial-antigen stimulated levels of Type 1, Type 2, Type 17, regulatory and pro-inflammatory cytokines in TBL individuals coinfected with (n=44) or without (n=44) *Strongyloides stercoralis*(Ss) infection by multiplex ELISA. Chi-square and Mann-Whitney U test were used to measure the significance. TBL-Ss+ individuals have significantly higher bacterial burdens in the affected lymph nodes in comparison to TBL-Ss- individuals. TBL-Ss+ individuals exhibit significantly enhanced plasma levels of Type 2 (IL-5 and IL-13), Type 17 (IL-17 and IL-22) and regulatory (IL-10) cytokines in comparison to TBL-Ss- individuals. In contrast, TBL-Ss+ individuals exhibit significantly diminished plasma levels of pro-inflammatory cytokines (IL-1$\alpha$and GM-CSF) in comparison to TBL-Ss- individuals. TBL-Ss+ individuals also exhibit significantly diminished unstimulated or mycobacterial - antigen stimulated levels of Type 1 (TNFα), Type 17 (IL-17 and IL-22) or pro-inflammatory (IL-1$\alpha$and IL-1β) cytokines in comparison to TBL-Ss- individuals but no differences seen in mitogen stimulated cytokine levels. In contrast to the cytokine profile in plasma and peripheral blood, helminth coinfection had no significant impact on the unstimulated or mycobacterial - antigen stimulated expression of Type 1, Type 2, Type 17, regulatory and pro-inflammatory cytokines at the site of infection i.e. the affected lymph nodes in TBL individuals. Therefore, our data reveal a profound influence of Ss infection on the bacteriological profile of TBL and suggest that the underlying modulation of cytokine responses might be a mechanism by which this helminth infection could impart a detrimental effect on the pathogenesis of TBL disease.

534

THE IMPACT OF FIFTEEN YEARS OF IVERMECTIN AND ALBENDAZOLE TREATMENT FOR THE CONTROL OF LYMPHATIC FILARIASIS ON SOIL-TRANSMITTED HELMINTHS

Dziedzom K. de Souza[1], Edward Dumashie[1], Joseph Otchere[1], Collins S. Ahorlu[2], Irene Ayi[1]

[1]*Department of Parasitology, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana,* [2]*Department of Epidemiology, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Accra, Ghana*

Ivermectin and albendazole, the drugs used for lymphatic filariasis (LF) control in areas co-endemic for onchocerciasis, also have an impact on soil-transmitted helminths (STH). However, the importance of this on achieving the 2025 STH goals has not been effectively assessed. In the Western Region of Ghana, yearly mass treatment of entire communities for LF control has been on-going since the year 2000. This presents the opportunity to assess the impact of ivermectin and albendazole treatment on STH. In this study, 1042 participants from 18 communities were assessed for STH infections using the Kato-Katz method. Infections were observed in individuals 5 to 80 years old (mean 34.1 ± 18.8). The community mean egg count for Hookworms, *Ascaris lumbricoides*, *Trichuris trichiura* and *Hymenolepis nana* were 1.64 eggs per gram (epg) (CI: -0.09 - 3.38; range: 120 - 720 epg; n= 5), 119.3 epg (CI: 40.25 - 198.3; range: 24 - 29676 epg; n = 36), 197.9 epg (CI: -47.38 - 443.1; range: 12 - 123396 epg; n = 56) and 0.01 epg (CI: -0.01 - 0.03; egg count of 12 1 epg; n = 1), respectively. Majority of infections were reported in females, with 83%, 54% and 62% for Hookworm, *A. lumbricoides* and *T. trichiura*, respectively. The analysis of variance revealed the results of *A. lumbricoides* and *T. trichiura* infections were significant ($P < 0.0001$). These results point to a very low infection prevalence for *H. nana* (0.1%) and hookworm (0.5%), and not so much impact on *A. lumbricoides* (3.5%) and *T. trichiura* infections (5.4%). The results suggest that while ivermectin and albendazole may have an impact on Hookworms, other strategies will need to be adopted for the control of other STH.

535

STAKEHOLDER SURVEY ON 2030 WORLD HEALTH ORGANIZATION TARGETS FOR SOIL-TRANSMITTED HELMINTHIASIS

Jasmine L. Irish, Girija Sankar, Michael R. Diaz, Sanjaya Dhakal, Alexander H. Jones, Rubina Imtiaz

Children Without Worms, Decatur, GA, United States

The World Health Organization (WHO) sets global monitoring targets for soil-transmitted helminthiasis (STH) control. Existing targets intend to measure progress toward the goal of eliminating STH as a public health problem by 2020. As 2020 approaches, it is apparent that the goal will not be met. WHO has drafted 2030 targets for STH in conjunction with the 2018 STH Advisory Committee (STHAC) in October 2018. From November 9 to December 15, 2018, we surveyed STH stakeholders using a commercial online survey platform for data collection. Data were collected on proposed 2030 targets and the need for updating existing WHO guidance. The response rate for this survey was 17% (34/202), low because of the wide variance in targeted respondents' engagement in STH activities. Responders represented non-governmental development organizations (44%), researchers (20%), donors (9%), NTD Program implementing partners (9%), National NTD/STH programs (6%), and others (12%). Overall, respondents (52%) agreed with the proposed STH target of elimination of morbidity by 2030, but a majority (59%) expressed concern around the lack of a clear definition of "elimination of morbidity" within the target. Respondents were given space to provide text feedback on each of the targets. The 73 total comments collected were grouped into four categories: feasibility of target (37%); unclear definitions (37%), needs more evidence (16%), and generally positive (10%). Respondents (41%) indicated that changes were needed in the deworming guidance that is available to country programs. The majority (59%) indicated their satisfaction with the "timeliness and content of policy and guidance" issued by WHO. Respondents also indicated the need for additional clear and consistent guidance, including a clear and measurable definition of "elimination of STH morbidity". Of particular note in the responses is the expressed (30%) need for changes to guidance and forms to include deworming for women of reproductive age as an additional risk group beyond 2020. The survey results were shared with WHO to help inform the 2030 targets finalization process by 2020.

536

DEVELOPING NEW THERAPIES FOR SOIL TRANSMITTED NEMATODE INFECTIONS

David M. Gazzola, Hanchen Li, Ambily Abraham, Yan Hu, Kelly Flanagan, You-Mie Kim, Anand Sitaram, Tasia Kellogg, Florentina Rus, Martin Nielsen, Anne Zajac, Joe Urban, Jennifer Ketzes, Gary Ostroff, Raffi V. Aroian

University of Massachusetts Medical School, Worcester, MA, United States

Soil-transmitted nematodes (STNs), most notably, hookworms, whipworms, and *Ascaris*, infect over 1.5 billion of the poorest people and are amongst the leading causes of morbidity and financial constraint worldwide. New anthelmintics, particularly drugs with novel mechanisms of action, are urgently needed to overcome emerging resistance to currently used drugs and to produce higher cure rates. An enormous challenge for STN infections, in contrast to other diseases is the requirement that therapies be very cheap, scalable and have a long shelf life in potentially harsh environments. Our lab has pioneered development of anti-nematode Crystal (Cry) proteins, in particular Cry5B, made by *Bacillus thuringiensis (Bt)*, as promising new therapy for STNs. Cry5B has excellent *in vitro* activity against parasitic nematodes as well as *in vivo* efficacy against multiple STN infections in rodents, pigs, and dogs. We will present the development efforts to produce a deployable, formulated version of Cry5B and other Crystal proteins that are cheap, safe, scalable, and stable. We will also provide updates on additional investigations to discover new crystal protein cures for STN infections using microbiology and bacterial engineering, including efforts to develop quantitative high through-put drug screening for novel anthelmintic candidates.

537

GLOBAL EPIDEMIOLOGY OF STRONGYLOIDIASIS: FILLING THE KNOWLEDGE GAP

Donal Bisanzio[1], Dora Buonfrate[2], Antonio Montresor[3], Micheal French[1], Richard Reithinger[1], Giovanni Giorli[4], Zeno Bisoffi[2]

[1]*RTI International, Washington, DC, United States,* [2]*Centre for Tropical Diseases, IRCCS Sacro Cuore Don Calabria Hospital, Negrar, Verona, Italy,* [3]*Department of Control of Neglected Tropical Diseases, Geneva, Switzerland,* [4]*Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and The London School of Medicine & Dentistry, Queen Mary University of London, London, United Kingdom*

Strongyloidiasis is a common neglected tropical disease (NTD) in tropical and sub-tropical climatic zones. At the worldwide level, there is high uncertainty about strongyloidiasis burden. The range of estimated infected people varies from 30 to 370 million. This is an important knowledge gap which affects the planning of intervention to reduce the burden of strongyloidiasis in endemic countries. Similar to other soil-transmitted helminths, strongyloidiasis can be prevented and treated by preventive chemotherapy (PC) through mass drug administration (MDA). However, due to the limited knowledge on strongyloidiasis epidemiology no endemic country is conducting any infection or disease prevention and control efforts. Having an estimate of the global strongyloidiasis burden is crucial to plan prevention and control programming and reduce its toll on the global population. This study aimed to estimate the global strongyloidiasis burden and calculate the population of school-age children needed to be covered with MDA in 2018 Epidemiological data on strongyloidiasis were gathered by literature review and merged with data on country characteristics obtained from public data sources. Prediction of strongyloidiasis prevalence for each country was performed using a spatio-temporal statistical modeling approach. The country prevalence obtained from the model was used to calculate the number of infected people and the fraction of school-age children to be covered by MDA. We estimate the global prevalence of strongyloidiasis in 2018 to be 8.1% (95% CI: 4.2-12.4%), corresponding to 613.9 M (95% CI: 313.1-910.1 M) people infected; SEARO, AFRO, and WPRO regions accounted for 76.1% of the global infections. Moreover, we estimated that at least 238.8 M (95% CI: 134.1-317.4 M) school-age children live in areas where strongyloidiasis prevalence is over 5% and therefore need MDA. The results of our study highlighted that global strongyloidiasis prevalence has been underestimated. Our results could be used to identify those countries in which strongyloidiasis prevalence is highest and MDA should be deployed for its prevention and control.

538

SYSTEMATIC LITERATURE REVIEW OF GLOBAL SOIL-TRANSMITTED HELMINTHIASIS PREVALENCE AND INTENSITY STUDIES: IDENTIFYING KNOWLEDGE GAPS, METHODOLOGICAL CONCERNS AND GUIDING FUTURE RESEARCH

Michael R. Diaz, Jasmine L. Irish, Zena Belay, Stacy L. Davlin, Sanjaya Dhakal, Alexander H. Jones, Rubina Imtiaz

The Task Force for Global Health, Decatur, GA, United States

To understand the existing evidence on global soil-transmitted helminthiasis (STH) prevalence and intensity, we undertook a systematic literature review of related peer-reviewed journal articles. The review included all published articles with data collected between January 1st, 2006 and February 26, 2018, to align with the start of the global drug donation for deworming children. Eligible studies were from countries requiring preventive chemotherapy for STH, in English, from cross-sectional surveys, and provided basic demographic information such as age or age

groupings, sample size, type of laboratory testing performed, and parasites tested. This presentation focuses on the status of the recent published literature, in terms of survey design methodology, surveyed risk groups, and the geographical distribution of studies. Overall, 209 studies from 54 countries met the inclusion criteria and were fully reviewed by two independent reviewers. The geographic distribution of studies revealed significant gaps in available data, exemplified by no published studies from Bangladesh but 17 from neighboring India. In total, 140 (67%) of the studies came from just 15 (of 103 endemic) countries. Of the studies, 127 (61%) employed school-based sampling while the remaining 82 (39%) employed community-based sampling. A majority of studies (86%) included school-age children, while 117 (56%) included preschool-age children. Adults were included in slightly less than half the study populations (45%). Of concern, only 118 (56%) studies used random sampling designs that were clearly explained in the methods section. In conclusion, this review identified critical knowledge gaps, specifically the lack of parasitologic data among preschool-age children and adults, research inefficiencies, and methodological concerns. Clear and actionable guidance is needed to direct global STH research to link with the known, critical knowledge gaps. This would facilitate policy and operational decisions to increase the efficiency of resource allocation and generate comparable results across studied populations.

539

DIFFERENT SOIL-TRANSMITTED HELMINTHS INFECTIONS AMONG TWO NEIGHBORING INDIGENOUS POPULATIONS FROM PUERTO IGUAZÚ, MISIONES, ARGENTINA

Ernesto Candela-Senti[1], Carolina Goizueta[2], Marta Cabrera[3], Carla Muñoz-Antolí[1], **Maria V. Periago**[4]

[1]*Departamento de Biología Celular y Parasitología, Facultad de Farmacia, Universidad de Valencia, Valencia, Spain,* [2]*Fundación Mundo Sano, Puerto Iguazú, Misiones, Argentina,* [3]*Departamento de Parasitología. Instituto Nacional de Enfermedades Infecciosas. ANLIS "Dr. Carlos G. Malbrán", Buenos Aires, Argentina,* [4]*Fundación Mundo Sano/CONICET, Buenos Aires, Argentina*

Soil-transmitted helminths are a serious health problem for indigenous communities in Argentina, studies from Misiones Province have documented a high prevalence of STHs. Most of these studies usually report indigenous populations as a homogeneous group, without considering the different cultural and hygienic habits that could predispose them to different infections. The aim of this study was to determine the STH prevalence of two neighboring indigenous populations from Puerto Iguazú (Misiones), namely Fortín Mbororé and Yryapú, both belonging to the Mbyá-Guaraní ethnicity and separated by only two km. Fortín is composed of around 200 families while Yryapú is composed of around 100. The main income for both communities comes from guided tours through the villages, crafts and social government plans. Both populations were characterized and georeferenced and 128 households were included (63 from Fortin and 65 from Yryapú). In total, 327 fecal samples (218 and 109 samples, respectively), were obtained and analyzed. Samples were processed through sedimentation and Baermann techniques. The age range was from 1 to 87 years old (mean 20 yrs) in Fortín and from 1 to 54 (mean 10 yrs) in Yryapú, with females being 53.2% and 55.9% of the population, respectively. The prevalence of STH infection was 72.9% in Fortín and 75.2% in Yryapú, this difference was not statistically significant (p=0.55). Moreover, a similar prevalence of hookworm infection was detected in both communities (63.8% vs 68.8%). However, results revealed statistically significant differences of other species of STHs between both communities, showing a prevalence of 11.4% for *Strongyloides stercoralis* in Fortín vs 32.1% in Yryapú (p<0.001) and a prevalence of 0.9% of *Ascaris lumbricoides* in Fortín vs 18.4% in Yryapú (p<0.001). Although the study detects both villages as endemic for hookworm, the differences of prevalence for *S. stercoralis* and *A. lumbricoides* can be appreciated. This could probably be explained by the different hygienic habits among both communities. Future studies would be necessary to elucidate the reasons for the different transmission patters of STHs observed.

540

IMPACT OF ASSORTATIVE MIXING ON STABILITY OF TRANSMISSION AND FEASIBILITY OF CONTROL OF SOIL-TRANSMITTED HELMINTH INFECTIONS

Luc E. Coffeng

Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands

Soil-transmitted helminths (STH) are currently targeted for control by 2020, defined as less than 1% of moderate-to-heavy intensity of infection in high-risk groups. Mathematical models suggest that this goal can be achieved by preventive chemotherapy (PC), if effectively targeted at these high-risk groups and implemented at sufficiently high coverage. However, an important limitation of existing models is that they assume homogeneous mixing, meaning that individuals in a community are assumed to mix perfectly by being exposed to one central reservoir of infection. In reality, eggs are distributed throughout the environment in a patchy manner and individuals contribute and are exposed to different patches in a differential manner. Most likely, individuals with higher infection loads share specific patches because they are members of the same social unit (e.g. household, school), meaning that they are more likely to infect one another and themselves than individuals in other social units. This process of assortative mixing is known to have an important stabilising effect on transmission and to impede the impact of interventions that do not necessary reach all of the population at risk (like PC). To investigate the impact of assortative mixing on feasibility of achieving the STH control target, we developed a new individual-based transmission model that incorporates a bipartite network as a representation of humans and environmental reservoirs of infection, and quantify it to represent households as social units within a larger community. Model predictions suggest that correlation between exposure and an individual's household membership has a strong stabilising effect on transmission, which in some settings may mean that the 1% target cannot be met. The net effect of PC was further predicted to depend strongly on patterns in individual participation in PC and clustering of individual participation by household. These findings stress the need to investigate who typically infects whom in endemic communities, and to better quantify and understand participation patterns at both the individual and household level.

SOCIO-CONTEXT INTERLINKAGES OF NEGLECTED TROPICAL DISEASES AND WATER SANITATION AND HYGIENE INTERVENTIONS IN TWO RURAL DISTRICTS IN AFRICA: POLICY IMPLICATIONS OF CONTROL AND ERADICATION OF NEGLECTED TROPICAL DISEASES IN GHANA

Martin Amogre Ayanore

University of Health and Allied Sciences, Ho, Ghana

Ghana is one of the countries with the highest number of reported cases of Neglected Tropical Disease globally. Ghana is ranked as second to Cote D'Ivore with regards to the prevalence of Buruli Ulcer in sub-Saharan Africa. Effective Water Sanitation and Hygiene interventions are known to be cost-effective in supporting the eradication of Neglected Tropical Disease in some settings. This study examined socio-context interlinkages for Neglected Tropical Disease and Water Sanitation and Hygiene interventions in two rural districts of Ghana. Data was collected between February-March 2019 among persons identified to have Neglected Tropical Disease conditions, health staff, and community opinion/change leaders, health policy actors and staffs working with local Non-Governmental Organization on Water Sanitation and Hygiene projects for the control of Neglected Tropical Diseases. Surveys (n=240), document reviews (3), in-depth interviews (n=30) and focus group discussions (n=8) were tools applied to illicit information from respondents. Low self-esteem and poor health seeking behaviours was significantly associated with poor Neglected Tropical Disease outcomes in both study districts. Social safety nets and social systems such as faith-based organizations play mediating

roles in Neglected Tropical Disease control efforts. Travel distance and cost, unsustainable community water systems, ineffective behaviour change interventions led by local community actors and systemic challenges in clinic level referrals for persons suffering from Neglected Tropical Disease impacts negatively on Neglected Tropical Disease control strategies. Continuum of clinic-community care and sustained Water Sanitation and Hygiene behaviour change interventions that address cultural barriers are effective for community level control on Neglected Tropical Disease A health system policy that prioritizes clinic-community knowledge sharing on Water Sanitation and Hygiene improvements and delivers holistic primary health care services in an integrated approach is foundation to reducing Neglected Tropical Disease burden in Ghana

542

DO COMMUNITIES PERCEIVE THE NEED FOR A COMMUNITY-WIDE DEWORMING PROGRAM? QUALITATIVE RESULTS FROM THE DEWORM3 STUDY, INDIA

Kumudha Aruldas[1], Angelin Titus[1], Yesudoss Jacob[1], Rajeshkumar Rajendiran[1], Surya Kulasekaran[1], Jabaselvi Johnson[1], Saravanakumar Puthupalayam Kaliappan[1], Marie-Claire Gwayi-Chore[2], Mira Emmanuel-Fabula[2], Judd Walson[3], Sitara Swarna Rao Ajjampur[1], Arianna Rubin Means[2]

[1]*Christian Medical College, Vellore, Vellore, India,* [2]*University of Washington, Seattle, WA, United States,* [3]*Natural History Museum, University of Washington, Seattle, WA, United States*

Interest in moving Neglected Tropical Disease programs from disease control towards elimination has prompted the evaluation of interventions that may interrupt the transmission of specific infections. Recent mathematical modeling studies suggest that community-wide deworming programs targeting individuals of all ages may interrupt transmission of soil-transmitted helminths. In the context of India's school deworming program, we conducted a qualitative study in 2018 in two blocks of Tamil Nadu, India to evaluate community members' perceptions of community-wide deworming programs and identify opportunities to optimize community-wide deworming. Eight focus group discussions, guided by the Consolidated Framework for Implementation Research, were conducted among 65 purposively selected adult men and women. Data were analyzed in ATLAS.ti 8.0 using primarily *a prior thematic* coding. Participants were aware of the effectiveness of medications to treat intestinal worm infections and the current national deworming program. The participants noted that adults can also be infected with intestinal worms but as the treatment for adults is not supported by the current program, they must purchase deworming medications from medical shops or consult a doctor for treatment. There was confusion as to whether adults can take the same deworming tablets that are given to children and whether they may have side effects. Participants also acknowledged that people who think they are not at risk for intestinal worms may be hesitant to be treated. Many participants were aware of how these infections are transmitted and knew that hygiene behaviors may help in preventing spread. Participants stated that family members who defecate in the open or those who walk around where people had defecated can be infected and transmit the infection to others, making everyone in the community susceptible. The study suggests that adults may be amenable to a policy shift towards adult deworming programs, particularly where sanitation practices are poor. The study also suggests the importance of informing adults about their risk of intestinal worm infections.

543

MASS DEWORMING CAMPAIGN: ACHIEVEMENTS, PROSPECTS AND CHALLENGES IN THE CONTEXT OF NIGERIA PROGRESS TOWARDS THE WHO 2020 GOAL

Obiageli O. Nebe[1], Chukwuma C. Anyaike[1], Evelyn E. Ngige[1], Ima Ip Chima[2], Ima Ip Chima[2], Francisca F. Olamiju[3], Francisca F. Olamiju[3], Rita R. Oguntoyinbo[4], Ikenna I. Nwoye[1], Rita R. Urude[1]

[1]*Federal Ministry of Health, Abuja, Nigeria,* [2]*Deworm The World Initiative/ Evidence Action, Abuja, Nigeria,* [3]*Mission To Help The Helpless, Jos, Nigeria,* [4]*Amen Health Care and Empowerment Foundation, Abuja, Nigeria*

Nigeria has the highest burden in terms of the number of preschool and School-Age Children (SAC) requiring preventive chemotherapy against schistosomiasis and Soil Transmitted Helminthiasis (STH) within the continent of Africa. The national baseline mapping report (FMOH 2017) shows that among the total of 582 schistosomiasis endemic districts, 10 districts are high-risk (&gt 50% prevalence), 293 districts moderate-risk category (&gt 10% but &lt 50% prevalence), while 279 districts are low-risk (&lt 10% prevalence). Nigeria has a total of 429 endemic districts for STH (&gt 20% prevalence), of which 107 can be classified as high-risk STH LGAs &gt 50% prevalence) and 322 as moderate-risk districts (&gt 20% to 50% prevalence). School and Community based approaches have been leveraged to implement cost-effective preventative chemotherapy in Nigeria. The recent data analysis initiated by the Federal Ministry of Health and World Health Organization showed that of the 450 schistosomiasis implementing districts, 305 (67.8%), districts have achieved 75% effective therapeutic coverage at least once. Out of this number, 68 (22.3%) districts have maintained at least 3 effective treatment rounds. As for STH, 353 (87.3%) of the 404 implementing districts have reached 75% therapeutic coverage at least once and of the 353; 196 of them (55.5%) districts have successfully maintained 75% effective therapeutic coverage for at least three rounds of MDA. Achievements and prospects of the National deworming Programme include: availability of policy and guidelines specific to NTDs, established coordinating mechanisms, completion of Schistosomiasis and STH baseline mapping and availability of donated medicines. These modest achievements notwithstanding, the National Programme contends with such challenges as highly populated and difficult terrain; huge treatment gaps and insufficient funding remains a critical barrier to program ownership and sustainability. Given the new global momentum to control / eliminate NTDs the foregoing situates a clarion call for Nigeria to urgently scale up interventions in all the endemic districts.

544

MASS DRUG ADMINISTRATION COVERAGE SURVEY IN THREE DISTRICTS THAT FAILED A REPEAT PRE-TRANSMISSION ASSESSMENT SURVEY IN 2017

Ibrahim Kargbo Labour[1], Habib I. Kamara[2], Benoit Dembele[3], Mohamed Turay[2], Abdul Conteh[1], Abdulai Kandeh[2], Victoria Redwood-Sawyer[2], Amy Veinoglou[4], **Mustapha Sonnie**[2], Mary H. Hodges[2], Yaobi Zhang[5]

[1]*Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone,* [2]*Helen Keller International, Freetown, Sierra Leone,* [3]*Helen Keller International, Bamako, Mali,* [4]*Helen Keller International, New York City, NY, United States,* [5]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

Four health districts (HDs) in Sierra Leone had high *Wuchereria bancrofti* microfilaremia (mf) prevalence at baseline. Despite effective reported epidemiological coverage (≥65%) with mass drug administration (MDA) with ivermectin and albendazole, these HDs failed a pre-transmission assessment survey (pre-TAS) with night blood test after five rounds of MDA and a re-pre-TAS using Filarial Test Strips (FTS) after 3 more rounds of MDA. To investigate potential reasons for repeated failure a coverage survey was performed in 2017 according to the WHO guidelines within 3 months of MDA in the 3 HDs with the highest FTS prevalence. In each HD, 30 subunits were selected with probability proportional to the number of

segments in the subunits, assisted by the Coverage Survey Builder. These were segmented, households randomly selected, and heads of households interviewed. Data were collected on smartphones and uploaded using Open Data Kit, then extracted to excel and analyzed using SPSS. A total of 6016 respondents were interviewed with 1977 in Bombali, 2668 in Kailahun and 1371 in Koinadugu. Proportion of those reported receiving ivermectin or albendazole and was 79.0% and 79.1% in Bombali, 76.1% and 76.4% in Kailahun and 61.8% and 62.2% in Koinadugu. Less than 1% admitted they had not swallowed either drug. Koinadugu did not reach effective epidemiological coverage. Top reasons cited for not taking the drugs were: CDDs did not come (472), unaware (172), afraid of side effects (142), distance too far (111), busy (54), medicines do not work (51), breastfeeding (33), etc. Some respondents (376) were ineligible at the time of the MDA: underage (204), sick (62), pregnant (95), very old (13), below the minimum height (2). Mild adverse events ranged from 22.2% in Koinadugu to 45.6% in Kailahun. Responses such as 'CDD did not come' or 'distances too far' accounted for 40% of non-compliance. Koinadugu has the lowest number of 75 health facilities compared to Bombali (111) and Kailahun (88). The catchment area covered by health facility is greatest in Koinadugu 162 km^2 versus Bombali 71 km^2 and Kailahun 44 km^2 making all forms of public health interventions challenging.

STUDIES ON SCABIES IN IMO STATE SOUTH EASTERN NIGERIA

Chinyere N. Ukaga, Ann I. Ogomaka, Betram E. Nwoke, Lillian C. Chimechefulam, Evangeline C. Uwalaka

Imo State University, Owerri, Nigeria

Prevalence of scabies among boarding schools in Orlu L.G.A. of Imo State Scabies being included to the list of neglected tropical disease as well as associated with resource-poor conditions, informed this study to investigate the prevalence of scabies among boarding school students in Orlu L.G.A. of Imo State. This study was conducted through the months of June to October 2018. A total of 2639 students from 5 out of the 8 boarding schools visited, took part in the screening. The sample comprised of three age ranges 9-11, 12-14 and 15-17 years as well as male and female genders from four different locations in Orlu L.G.A. Data on scabetic parameters such as pruritus status, periodicity/frequency of scabies occurrence and morbidities associated with scabies were collected using an interview based questionnaire. 384 (14.6%) students were infected with scabies. Using chi-square analysis, more female students 341 (16.1%) were infected than male students 43 (8.3%) with significant difference at ($P<0.05$). Age range 9-11 years recorded the highest disease prevalence 135 (17.4%) followed by 12-14 years 164 (14.2%) and then 15-17 years 85 (11.9%); ($P<0.05$). With regard to schools having highest scabies prevalence represented by location, Okporo-Orlu had 96 (16.8%) infected students closely followed by Ihioma-Orlu 101 (16.6%) infected students then Amaifeke-Orlu 74 (14.3%) infected and the least being Umudioka-Orlu 113 infected (11.9%). Using SPSS analysis pruritus showed that out of 384 infected students, 361 (96.3%) had constant severe pruritus while 14 (3.7%) had infrequent mild pruritus. 144 (37.5%) were experiencing scabies for the first time, 135 (35.2%) were having it for the second time while 105 (27.3%) have had the disease severally. This study thus established that scabies has a high prevalence among students in boarding schools, recommends that overcrowding and poor personal hygiene should be curbed while improved health services should be made available to students in hostels.

546

INTERRUPTING TRANSMISSION OF SOIL-TRANSMITTED HELMINTHS AND SCHISTOSOME PARASITES IN ETHIOPIA - THE GESHIYARO PROJECT PROTOCOL

Kalkidan Mekete[1], Alison Ower[2], Julia C. Dunn[2], Heven Sime[1], Gemechu Tadesse[1], Ebba Abate[1], Nebiyu Nigussu[3], Fikreselasie Seife[3], Emily McNaughton[2], Anna Phillips[2], Roy M. Anderson[2]

[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia,* [2]*Imperial College London, London, United Kingdom,* [3]*Federal Ministry of Health, Addis Ababa, Ethiopia*

Soil-transmitted helminths (STH) and schistosomiasis are neglected tropical diseases (NTDs) that are estimated to affect over 1.4 billion people globally. Recent research, including longitudinal epidemiological studies and analyses of transmission dynamics, have suggested that mass drug administration (MDA) should be community-wide to interrupt transmission of STH in areas of medium to high transmission (as measured by the basic reproductive number R_0) instead of solely targeted at school aged children (SAC). This is especially the case where hookworm is the dominant infection. The Geshiyaro project seeks to interrupt transmission of STH and SCH in the Wolayita zone of south-western Ethiopia. Two interventions will be implemented and assessed through the project (i) expanded MDA through biannual community-wide treatment with a target of 90% treatment coverage, and (ii) provision of water sanitation and hygiene (WaSH) with complementary behaviour change communication (BCC) in combination with MDA. These interventions should allow the suppression of STH and SCH infection to very low levels that is achieved through MDA, to be sustained once transmission is infrequent. The Geshiyaro project is a five-year project which began in July 2018 and is currently ongoing. The impact of these interventions will be evaluated through epidemiological assessments of infection (prevalence and intensity) across all age groups using sensitive diagnostics at baseline and endline, as well as through the monitoring of longitudinal sentinel site cohorts. Treatment coverage and individual compliance to treatment will be monitored by employing fingerprint biometric technology and barcoded identification cards, and an independent treatment coverage validation survey. The outcomes of this project will help to inform country NTD programmes on steps to be taken once STH and SCH infections are at low prevalence following sustained MDA. The focus on cost-effectiveness and scalability may also provide a sustainable model for country programmes to follow to achieve transmission elimination in defined settings.

547

COMMUNITY-BASED SURVEY FOR PROGRAM MONITORING OF SOIL TRANSMITTED HELMINTHIASIS IN SIERRA LEONE

Ibrahim Kargbo Labour[1], Jusufu Paye[2], Stacy Davlin[3], Abdul Conteh[1], Victoria Redwood-Sawyer[2], Amy Veinoglou[4], Mustapha Sonnie[2], Mary H. Hodges[2], Alexander H. Jones[3], **Yaobi Zhang**[5]

[1]*Neglected Tropical Diseases Program, Ministry of Health and Sanitation, Freetown, Sierra Leone,* [2]*Helen Keller International, Freetown, Sierra Leone,* [3]*Children Without Worms, Task Force for Global Health, Atlanta, GA, United States,* [4]*Helen Keller International, New York, NY, United States,* [5]*Helen Keller International, Regional Office for Africa, Dakar, Senegal*

World Health Organization currently recommends sentinel site surveys in school-age children (SAC) for impact assessment of soil-transmitted helminth (STH) control programs. The new STH guidelines recommend targeting additional risk groups, e.g. preschool-age children (PSAC), and high-risk adults. The sentinel site survey of SAC alone provides insufficient data for different risk groups. Using a methodology developed by Children Without Worms, in May 2018, we conducted a multi-stage, cluster household survey in two Sierra Leone districts that produced equal-probability samples of all three risk groups: PSAC (1–4 years), SAC (5–14 years), and adults (≥ 15 years). Standardized questionnaires were administered and fresh stool samples (1 slide) examined by Kato Katz. In total, 1,270 persons (M:48.0%, F:52.0%) in Bo and 1,508 (M:54.6%,

F:45.4%) in Kenema were tested. Prevalence of hookworm, *Ascaris lumbricoides*, and *Trichuris trichiura* was 5.0% (95%CI: 3.8-6.2), 4.0% (95%CI: 2.9-5.0) and 1.2% (95%CI: 0.6-1.8) in Bo and 10.4% (95%CI: 8.9-11.9), 7.4% (95%CI: 6.2-8.9) and 0.9% (95%CI: 0.4-1.4) in Kenema respectively. Overall prevalence in PSAC, SAC and adults was 7.7% (95%CI: 5.8-11.7), 7.4% (95% CI: 7.7-12.7) and 9.2% (95%CI: 7.7-13.9) for hookworm; 6.5% (95%CI: 3.6-8.3), 4.2% (95%CI: 2.4-5.7) and 9.2% (95%CI: 6.4-10.2) for *A. lumbricoides*; and 0.9% (95%CI: 0.2-2.2), 0.7% (95%CI: 0.2-1.1) and 1.5% (95%CI: 0.2-1.9) for *T. trichiura*, respectively. There was <1% STH infections with moderate-to-high intensity in all risk groups. There were no significant differences by sex and any STH infections in either district. Prevalence for all species was lower among individuals who always wore footwear compared to those who sometimes wore footwear (p<0.0001). Both districts had low prevalence for all STHs in all risk groups and the new protocol was relatively easy to use.

548

PREVALENCE AND INTENSITY OF STH INFECTIONS IN TWO SETTINGS WITH A CONTRASTING HISTORY OF IVERMECTIN MASS DISTRIBUTIONS: INDICATIONS OF COLLATERAL IMPACT

Hugues Nana Djeunga[1], Linda Djune Yemeli[1], Cédric Lenou Nanga[1], André Domche[1], Floribert Fossuo Thotchum[1], Yannick Niamsi Emalio[1], Thérèse Nkoa[2], Joseph Kamgno[1]

[1]*Centre for Research on Filariasis and other Tropical Diseases (CRFilMT), Yaoundé, Cameroon,* [2]*Faculty of Medicine and Biomedical Sciences, University of Yaounde I, Yaounde, Cameroon, Yaoundé, Cameroon*

Onchocerciasis and Soil Transmitted helminthiases (STH) are among neglected tropical diseases that have been targeted by the national control programs for several years because of their heavy burdens on infected populations. The control of these diseases relies on preventive chemotherapies (PCT) with ivermectin (IVM) for onchocerciasis and mebendazole (MEB)/albendazole (ALB) for STH. IVM, a broad spectrum endectocide, was found to exhibit antiparasitic activity on STH. IVM-based mass drug administrations (MDA) have led to the interruption of transmission of onchocerciasis in many *foci*. The objective of this study was then to compare the trends in prevalence and intensities of STH infections in two settings with very contrasting history of IVM-PCT. Cross-sectional surveys were carried out in the Yabassi health district where IVM-PCT to fight against onchocerciasis were ongoing for 20 years, and in the Akonolinga health district where no IVM-based MDA was never implemented because of hypo-endemicity of onchocerciasis and high endemicity of loiasis. Stool samples were collected from all volunteers aged ≥2 years and analyzed using the Kato-Katz technique. A total of 799 individuals (52.2% female), aged 2 to 90 years old (Median: 17 years old; IQR: 7- 45), provided stool samples and were enrolled in this study. As expected, school aged children were most infected than the other surveyed participants. Two STH species were found in the study population, *Ascaris lumbricoides* and *Trichuris trichiura*, with respective prevalence of 20.0% (95% CI: 17.4-22.9) and 17.0% (95% CI: 14.6-19.8). Importantly, both prevalence and intensities of infection were significantly lower in the IVM-treated area than in IVM-naïve area ($P \leq 0.0001$). This study revealed that the prevalence and intensity of STH infections were significantly lower in the IVM naïve area compared to areas where repeated rounds of IVM-based MDA have been implemented since two decades. This observation thus confirms the collateral impact of IVM-PCT on STH transmission, supporting an optimal timing of IVM- and MEB/ALB-based PCTs in controlling onchocerciasis and STH in co-endemic areas.

549

THE IMPACT OF ADJUSTED MOBILE TREATMENT POSTS STRATEGY ON MASS DRUG ADMINISTRATION COVERAGE IN AN URBAN SETTING: CASE STUDY OF DAR ES SALAAM, TANZANIA

Alistidia Simon[1], Cecilia Uisso[1], Upendo Mwingira[2], Jeremiah Ngondi[3], Hailey Mableson[1], Andreas Nshala[4]

[1]*NTD Control Program, Dar Es Salaam, United Republic of Tanzania,* [2]*NTD Control Program, Dar es Salaam, United Republic of Tanzania,* [3]*RTI, Washington, DC, United States,* [4]*Uppsala University, Uppsala, Sweden*

Tanzania has been conducting Neglected Tropical Diseases (NTD) control and elimination activities for lymphatic filariasis (LF), schistosomiasis (SCH) and soil transmitted helminths (STH) since 2001. By 2018, 27 districts were still undergoing mass drug administration (MDA) for LF, 56 districts progressed through TAS, and the remaining 65 districts were classified as non-endemic. These 27 districts under MDA have a total of 10.2 million people at risk of infection and 56% of them live in Dar es salaam city. Since 2013, Centre for Neglected Tropical Diseases (CNTD) has supported the national NTD Control Programme (NTDCP) to deliver the MDA in Dar es Salaam city. With the country progressing towards elimination of LF, it is essential to ensure that optimal coverage is attained during MDA especially in urban settings. MDA coverage evaluation survey report of 2017 recommended the use of mixed strategy in order to improve the MDA coverage in urban areas but also to raise awareness and increase demand for MDA. In 2018 MDA various approaches were implemented to improve MDA coverage, including: house to house sensitization combined with mobile treatment teams (drug distributors), mass media campaign through radio and television, Town crier's announcements; and social media platforms such as WhatsApp, twitter, Instagram and Facebook pages. Post MDA coverage evaluation survey was conducted in two districts in 2017 and 2018. Survey results showed increased MDA coverage in 2018 compared to 2017 in Kigamboni (74% vs. 53% and Ubungo (80% vs. 53%). The MDA coverage findings suggest the strategies implemented in 2018 improved MDA coverage and will facilitate elimination of LF in Dar es Salaam. Lessons learned from Dar es Salaam can be implemented in other urban settings experiencing low MDA coverage.

550

AN INNOVATIVE INTEGRATIVE APPROACH FOR NEGLECTED TROPICAL DISEASES (NTD) CONTROL IN ETHIOPIA: SUSTAINED REDUCTION IN PREVALENCE OF SCHISTOSOMA AND SOIL-TRANSMITTED HELMINTHIASIS (STH) INFECTIONS IN RURAL AND URBAN POPULATIONS

Zvi Bentwich, Nala Team

NALA/Ben Gurion University, Tel Aviv, Israel

Ethiopia has one of the highest burdens of neglected tropical diseases (NTD) in Africa, with more than 75 million people at risk of infection from soil-transmitted helminthiasis (STH) and schistosomiasis. To control these diseases, the Ethiopian Federal Ministry of Health (FMoH) has instituted regular mass drug administration (MDA) campaigns. However, these campaigns have not prevented reinfection, which occurs due to poor hygiene practices and a lack of adequate sanitation in affected communities; therefore, the high prevalence of infections has remained high in many parts of the country. Since 2008, the organization NALA has developed an integrated model for controlling schistosomiasis and STH that complements MDA by promoting behavioral change and community-led improvements to water, sanitation, and hygiene (WASH) infrastructure in order to create an enabling environment for sustained disease prevention. In 2015, the urban and rural districts of Adwa were selected as a project area by NALA and the Tigray Regional Health Bureau due to its high prevalence of intestinal worms and schistosomiasis. From 2015-2019, the NALA team provided behavioral change health education to children in nearly 60 schools, trained thousands of community members to be health messengers, and strengthened the capacity of local health workers and government officials. In addition, NALA recruited the community

to be integral partners and owners of the program and also provided small grants for community-led WASH infrastructure projects in selected schools. As a result of this work, stool surveys have shown a significant and sustained decrease in helminth prevalence. Between March 2015 and March 2019, the prevalence of helminth infections in eight intervention schools dropped from 26% to 1.5% (!!) and the prevalence of *Schistosomiasis mansoni* in these 8 schools dropped from 11.8% in 2015 to 0% in 2019. These results demonstrate that an integrative approach can attain remarkable results in the control of these neglected tropical diseases, especially if the approach is strongly focused on community partnership and cooperation with the health authorities.

551

HEALTH EDUCATION AND BEHAVIOR CHANGE OF CHILDREN ARE ESSENTIAL FOR CONTROLLING NTDS: LESSONS FROM A SUCCESSFUL PILOT TRIAL IN ETHIOPIA

Zvi Bentwich, Liat Rennert

NALA, Maccabim, Israel

Neglected tropical diseases (NTD) are a major cause in undermining childrens' potential for both physical and mental development. Soil transmitted helminths (STH), schistosomiasis and trachoma have a direct effect on stunting and on cognitive capabilities and skill learning. That is why their control is so critical in young children, and why it is essential to have a comprehensive program that is focused on children and started at an early age, and that combines behavioral change, improved water sanitation and hygiene (WASH), and mass drug administration (MDA). During the past nine years we have developed a comprehensive integrated model intervention that combines all these elements and has been successfully implemented by now in several locations in Ethiopia where it has achieved a significant and sustained decrease in prevalence of both schistosomiasis and STH and more lately of Trachoma. Since children are at the highest risk to contract these diseases we launched an innovative pilot program in 2017, focused on children attending kindergarden, training educators, parents and community leaders to playfully create healthy hygiene habits for young children in Ethiopia. This program took place in 9 districts and 300 schools focusing on early childhood (ages 3-6) instilling habits that can help prevent the diseases at a younger age. Schools, educators and community leaders were trained in early childhood education methods, focusing on innovative ways to transmit messages and reinforce behaviors and habits in young children and support health and hygiene. We are now scaling up the program and assessing : 1) The effectiveness of our model intervention program 2) The processes through which behavior change interventions influence the practices and understanding of the children leading to lowered disease prevalence primarily by prevention of infection. The results of this study have already given us an insight into the mechanisms that determine behavioral change in children and that may help us expand the program and apply it universally for the control of NTDs in Ethiopia and elsewhere.

552

KNOWLEDGE, ATTITUDE AND PRACTICE (KAP) SURVEY IN PRIMARY SCHOOL STUDENTS IN BENCH MAJI ETHIOPIA: THE URGENT NEED FOR BEHAVIOR CHANGE AND HEALTH EDUCATION IN THE FIGHT AGAINST NTDS

Zvi Bentwich, Asrat Meleko, Dorin Turgeman

NALA, Maccabim, Israel

Water, sanitation and hygiene are essential for preventing diseases such as soil transmitted helminths, trachoma and other related neglected tropical diseases . Access to safe drinking water and adequate sanitation facilities, together with promotion of knowledge, attitude and practice of students on water, hygiene and sanitation related factors are key components for prevention of these diseases. We therefore tried to assess the knowledge, attitude and practice of students at baseline and before the beginning of a behavioral intervention project by NALA. A school based descriptive cross-sectional study was conducted from April to May, 2018 in primary schools of one of 11 districts in Bench Maji zone, Ethiopia. The study population was primary school students from grade 5 to 8 consisting of students able to fill the self-administered questionnaires. Verbal and formal consent for the usage of the questionnaire was obtained from teachers. The main results of the study revealed the following: a) Only 93 (31%) of students knew that walking barefoot and bathing in the river may lead to parasitic infections and schistosomiasis . b) Only one third of students knew that washing or cooking vegetables is important for preventing infection. c) only 120 (40%) knew that flies are carriers of the trachoma pathogen. d) 182 (69%) practice frequently open defecation. e) 172 (57.%), are afraid of taking drugs during mass drug administration campaigns because they fear from side effects. f) 66 (22%), did not wash their hands regularly , and 114 (38%) wash their face only when there is discharge from eyes or nose. g) only 69 (23%) boil water before drinking regularly. This study demonstrates the low awareness of school children about transmission, symptoms and preventive measures for trachoma schistosomiasis and soil transmitted helminths and their poor attitude and practice of water, hygiene and sanitation related preventive behaviors. These findings clearly indicate the essential need for an immediate and comprehensive health education and behavior change intervention in this population as a major condition for controlling NTDs in this region.

553

EVIDENCE FOR GLOBAL HEALTH INTERVENTIONS: PERSPECTIVES FROM THE AFRICAN GREAT LAKES ON EVIDENCE IN MASS DRUG ADMINISTRATION PROGRAMMES FOR SCHISTOSOMIASIS AND SOIL-TRANSMITTED HELMINTHS

Cristin Alexis Fergus[1], Georgina Pearson[2], Bianca D'Souza[2]

[1]*London School of Economics, London, United Kingdom,* [2]*Firoz Lalji Centre for Africa, London School of Economics, London, United Kingdom*

In many places, public health practitioners are part of a larger global health system, wherein they are responsible for the implementation of disease-specific health interventions, largely financed by external actors through a variety of mechanisms. Emphasis on the need for evidence-informed decision-making often includes rhetoric for the localization of this approach to assist practitioners in resource allocation. In practice its realisation has been challenging. For one, decision-making processes are heterogenous at different localities and the evidence needs of local practitioners are not well understood. Additionally, evidence development and knowledge synthesis pertaining to health interventions are rarely linked in ways that feedback and respond to local implementation and decision-making practices. The goal of this research was to identify local evidence needs and examine acceptability of various forms of evidence, e.g. modeled disease estimates. Decision-making processes around implementation, including political and social factors, were examined to understand how these evidence and decision-making processes interact. Mass Drug Administration (MDA) for schistosomiasis and soil-transmitted helminths was utilized as a representative global health intervention, with a focus on the epidemiologically relevant areas of Kenya, Malawi, Tanzania, and Uganda. We used complementary qualitative approaches to collect data, which included 4 workshops with district- and national-level MoH personnel, and key informant interviews and electronic survey questionnaires from a sample of relevant organisations, including NGOs and International/Global Health Organisations. Data were coded and analyzed thematically. The results provided important insights as to the sources, types, and formats of evidence which local public health practitioners find acceptable and useful. The social and political pressures were found to influence the decision-making around resource allocation and uptake of evidence. These results are intended to assist in the translation and uptake of evidence for decision-making in global health.

INTEGRATING SOIL/TRANSMITTED HELMINTHIASES AND SCHISTOSOMIASIS CONTROL PROGRAMS IN PRIMARY HEALTH CARE: A STEP TO FORWARD FOR UNIVERSAL HEALTH COVERAGE

Arancha Amor Aramendia[1], Melaku Anegagrie Mekonen[2], Elena Barrio Miguel[1], Birhanu Tashu[3], Juan Jose de los Santos[1]

[1]*Mundo Sano Foundation, Madrid, Spain,* [2]*Mundo Sano Foundation, Bahir Dar, Ethiopia,* [3]*Amhara National Regional Health Bureau, Zenzelema Health Center, Bahir Dar, Ethiopia*

Soil-transmitted-helminthiases (STH) and schistosomiasis (SCH) are major control programs of WHO agenda for neglected tropical diseases (NTDs). Periodic mass drug administration for at-risk population is the main strategy for reducing their burden. Despite all the efforts made, so far STH-SCH are far from control in Africa endemic areas. Recently, WHO encourages for integrating NTDs into the primary health system, to ensure a universal health coverage (UHC). The aim of this study was to support the improvement of a diagnosis protocol in a primary health center in a rural area of Ethiopia integrating, in an effective and efficient manner, STH-SCH control program in the primary health system. According to the Ethiopian national guidelines, the wet mount technique is used for the diagnosis of STH-SCH infection in the health centres. We compared the results of this technique with the ones obtained by a comprehensive protocol that included three easy to perform techniques: formol-ether concentration, Kato-Katz and Baermann methods. From October to December 2018, 186 patients from the outpatient department of a health center in the rural area of Ethiopia were included in the study. Infections by hookworm, *Ascaris lumbricoides*, *Trichuris trichiura*, *Strongyloides stercoralis* and *Schistosoma mansoni* were recorded. 24 (13%) patients were diagnosed by the wet mount technique in the routine laboratory, while with our protocol the number of diagnosis increased until 131 (70.4%) (p=0.0008). The vast majority of patients carrying intestinal helminths are not diagnosed in this health center. This pattern could be similar in other facilities in endemic areas, working with the same diagnosis procedure, as is stated in the guidelines. Integrating a comprehensive management of intestinal helminth infection in primary health facilities, including an accurate diagnosis, will be a step forward to reach UHC. It will also be a turning point for the control of NTDs, as this under-diagnosis (and therefore the lack of treatment) perpetuates these infections in endemic areas. More studies are necessary and make new and more promising steps to achieve UHC.

555

DATA QUALITY ASSESSMENT AS A PROJECT MONITORING TOOL IN MASS DRUG ADMINISTRATION FOR NEGLECTED TROPICAL DISEASES IN GUINEA

André Géopogui[1], Christelly Badila Flore[2], Mamadou Siradiou Baldé[1], Lamine Lamah[2], Bamba Foungotin Ibrahim[2]

[1]*Ministry of Health, Conakry, Guinea,* [2]*Helen Keller International, Conakry, Guinea*

The transfer of quality data from the community level to the central level is important for impactful decision-making for the national NTD program. Yet, data received at the national level are often incomplete, late or of questionable accuracy. The Guinean MOH conducted a data quality assessment (DQA) through the National NTD reporting pathway after the integrated treatment for lymphatic filariasis (LF), onchocerciasis (OV) and soil transmitted helminths (STH) in 2016. Data from two health districts (HDs) in two regions were selected for analysis and these data came 4 health centres (2 from each HD) and 12 communities (3 in each health centre). Availability, accuracy and completeness of MDA data were reviewed and compared with the reported data. The data management and reporting system was also assessed. At the national level, the results show that LF coverage (indicator 1) was 98.7%. compared to the 99.6% reported during the MDA. The number of remaining ivermectin and albendazole tablets (indicators 2 & 3) indicated an accuracy of 94.0% and 84.8% respectively. With respect to the number of SAC treated (indicator 4), the results indicated 90.39% percent of accuracy. No data were available at the regional level. At the HD level, the result show 79.9% accuracy for indicator 1, 55.3% and 168.5% respectively for indicators 2&3 and 109.5% accuracy for indicator 4 (data only available from one HD). At the health centre level the verification percentage varied from 74.8% to 92.4% for indicator 1, no data were available for indicators 2&3 and 74.4% and 109.5% for indicator 4. Completeness and availability of reports were 100% at national and health centre levels. For data management and the reporting system, the DQA showed deficiencies in filling in data at the HD and the health centre level; data are usually transmitted daily by phone and even though templates for MDA reporting exist at all levels, the quality control is not systematic. NTD data are currently not integrated in the national health system information. The recommendations resulting from this evaluation will improve the understanding of reported data and will be used to improve program performance.

556

GETTING OUT OF THE COMFORT ZONE: INTEGRATED APPROACH OF SKIN NTDS

Patrick Suykerbuyk[1], Pierre Umba[2], Osman El Tayeb[3], Tine Demeulenaere[1]

[1]*Damien Foundation, Brussels, Belgium,* [2]*Damien Foundation, Kinshasa, Democratic Republic of the Congo,* [3]*Damien Foundation (DFB) Nigeria, Nigeria, Nigeria*

Damien Foundation (DF) was established in 1964. Since then, it has traveled a long way, from a Belgian Medical development NGO solely focused on leprosy to one dealing also with tuberculosis and further widening its horizon to leishmaniasis and other poverty-related diseases. Through the years, DF had to adapt its way of working and its approach to development aid to fit the new realities of a changing international community: Recently, the WHO is promoting an integrated strategy for skin-related NTDs that require active detection, management and control, and is harnessing the experience of many experts involved in skin diseases to provide guidance to implement the integrated strategy in countries where skin related NTDs are a major burden. Furthermore, the integration of skin diseases should provide an opportunity to build the capacity of primary health care workers to detect and treat a number of diseases using the same resources. However, such an integrated management of skin NTDs, forces organizations as DF to step out of its comfort zone; i.e., to evolve from a historic vertical-oriented, disease-specific approach to an integrated approach whereby strategic partnerships, knowledge transfer and synergies are key to success. Here we provide insights in the internal kitchen of a NGO to respond to this international call to action. We identified 4 main transition zones on the roadmap for integration: the comfort zone, fear zone, learning zone and growth zone. We discuss how this transitions zones have an impact on (i) the internal organizational model of DF; (ii) capacity building of human resources (e.g., training) and infrastructure (e.g., sensitization support, diagnosis and treatment); (iii) funding challenges and opportunities; (iv) research (cost-effectiveness of integration); (v) communication and advocacy; as well as (vi) local and international partnerships. Moreover, we illustrate this transition zones using pilot projects in Nigeria and the Democratic Republic of the Congo and discuss how the Global Partnership for Zero Leprosy could play a catalyzing role in the integrated approach to control skin NTDs.

557

CENTRIN-DEFICIENT *LEISHMANIA MEXICANA* AS A SAFE AND EFFECTIVE VACCINE AGAINST CUTANEOUS LEISHMANIASIS

Greta Volpedo[1], Sanjay Varikuti[1], Wen Wei Zhang[2], Patrick Lypaczewski[2], Sreenivas Gannavaram[3], Ranadhir Dey[3], Subir Karmakar[3], Nevien Ismail[3], Abu Musa[4], Risa Nakamura[4], Shinjiro Hamano[4], Greg Matlashewski[2], Hira L. Nakhasi[3], Abhay R. Satoskar[1]

[1]*The Ohio State University, Columbus, OH, United States,* [2]*McGill University, Montreal, QC, Canada,* [3]*Food and Drug Administration, Silver Spring, MD, United States,* [4]*Nagasaki University, Nagasaki, Japan*

Leishmaniasis is a neglected protozoan disease affecting over 12 million people in more than 90 tropical and subtropical countries. Despite the high morbidity and mortality of this condition, there are no approved vaccines for human use. Using the CRISPR/Cas9 technique, our group has generated live attenuated *Centrin* knock out (*Cen-/-*) *Leishmania* parasites. Centrin is a cytoskeletal protein important for cellular division in eukaryotes and, in *Leishmania*, it is only necessary for amastigote replication. We hypothesize that *Leishmania Cen-/-* parasites are able to infect the host cells and induce a protective immune response, but due to the lack of Centrin, they are not able to establish and spread the infection. Our data shows that *Leishmania (L.) mexicana Cen-/-* amastigotes present a growth defect, which results in significantly lower survival within murine bone marrow-derived macrophages and dendritic cells and in the augmented production of the protective cytokine interleukin (IL)-12, compared to the wild type (WT) strain. *In vivo*, we confirmed that *L. mexicana Cen-/-* parasites are safe in a susceptible murine model and do not lead to clinical symptoms. *L. mexicana Cen-/-* inoculated mice produced higher ratios of protective cytokines, such as interferon (IFN)-γ, vs. disease exacerbating cytokines, such as IL-10 and IL-4, compared to the group infected with *L. mexicana* WT. Additionally, *L. mexicana Cen-/-* parasites are effective in the protection against *L. mexicana* WT challenge, as they elicit a protective immune response while obliterating the clinical symptoms of cutaneous leishmaniasis. Taken all together these results suggest that live attenuated *Cen-/-* parasites are effective candidate prophylactic vaccines for protection against leishmaniasis.

558

DRIVERS OF INFLAMMASOME ACTIVATION IN IMMUNOPATHOLOGIC CUTANEOUS LEISHMANIASIS

Christina K. Go, Fernanda O. Novais, Phillip Scott

University of Pennsylvania, Philadelphia, PA, United States

In cutaneous leishmaniasis, the host immune response is critical for controlling parasite burden as well as for the severity and duration of disease. Although parasite control may be accomplished, many patients continue to exhibit severe disease due to dysregulation of the inflammatory response. We have previously reported that blocking IL-1β signaling in infected mice ameliorated pathology. This supports that IL-1β is a major component of pro-inflammatory signaling in cutaneous leishmaniasis. Cleaving of pro-IL-1β to its mature form is mediated by inflammasome signaling pathways, which can be triggered by a variety of stimuli including DAMPs and PAMPs and can lead to pyroptosis. Therefore, inflammasome signaling mediates both response to and generation of pro-inflammatory factors. In particular, blocking NLRP3 in experimental leishmaniasis or in human skin biopsies of leishmanial lesions reduced IL-1β levels, suggesting its production is downstream of the NLRP3 inflammasome in human disease and mouse models of leishmaniasis. Given the role of IL-1β in dysregulating inflammation, we are investigating how inflammasome signaling is activated in leishmaniasis. Our preliminary results indicate that parasites induce a low level of IL-1β production in LPS-stimulated cells infected with *L. major*. Since we previously reported that CD8+ T cell-mediated cytotoxicity promotes IL-1β production, we also investigated if cytotoxicity induced inflammasome activation. We found that co-culture of cytolytic CD8 T cells and antigen-pulsed target cells induced inflammasome assembly and IL-1β production in an antigen presentation-dependent manner. Thus, our findings have identified leishmania infection and cytotoxicity as pathways for initiating IL-1β and immunopathology in cutaneous leishmaniasis. Understanding these and other mechanisms of IL-1β release will be important for addressing severe disease caused by uncontrolled inflammation in cutaneous leishmaniasis.

560

OVEREXPRESSION OF THE KINASE *JEAN3* FROM *LEISHMANIA MAJOR* MAY ATTENUATE PARASITES INFECTIVITY IN BALB/C MICE BY IMPAIRING THE TH2-TYPE IMMUNE RESPONSE THROUGH THE DOWNREGULATION OF *IL4, IL10,* AND *ARG1*

Andres Vacas[1], Celia Fernandez-Rubio[1], Esther Larrea[1], Jose Pena-Guerrero[1], Miriam Algarabel[1], Fabio Rocha Formiga[2], **Paul Nguewa**[1]

[1]*University of Navarra, Istun Institute of Tropical Health, Pamplona, Spain,* [2]*Departamento de Imunologia Instituto Aggeu Magalhães - IAM Fundação Oswaldo Cruz - FIOCRUZ, Recife/PE, Brazil*

No human vaccine is currently available to prevent the diverse clinical pathologies caused by *Leishmania* parasites. Nevertheless, the evidence that most patients that have suffered from leishmaniasis are resistant to subsequential infections provides the ground for making efforts in this task as it will not be unfruitful. Our laboratory has developed an *L. major* mutant cell line (pXG-*LmJean3*) overexpressing the conserved trypanosomatid kinase *Jean3*. This study outlines *LmJean3*-overexpressing parasites infectivity *in vitro* and *in vivo*. Furthermore, we have examined in these mutants the expression of some known virulence factors such as *SHERP* and *GP63*. *LmJean3*-overexpressing parasites displayed lower phagocytosis rates *in vitro* and a significantly smaller footpad swelling in susceptible BALB/c mice when compared to Controls. Gene expression of Th2-associated cytokines and effectors allowed the observation of a significant reduction in *IL4*, *IL10,* and *ARG1* levels; no expression change was found in Th1 associated cytokines except for *IL12*. Our analysis indicates that the significantly smaller swelling of the infected mice foot pads is probably caused by an impaired Th2 immune response that benefits Th1 prevalence. These studies depict Jean3 as a new putative target for studying the immune responses to *Leishmania* and may allow the improvement of vaccination research.

561

TRYPANOCIDAL AND APOPTOSIS-INDUCING PROPERTIES OF *ANOGEISSUS LEIOCARPUS* AND *PSEUDOCEDRELA KOTSCHYI* ROOT EXTRACTS

Olakunle O. Kassim[1], Hilaire M. Kenguele[2], Oladapo Bakare[3], Kwashie A. Ako-Nai[4], Winston A. Anderson[3], Clarence M. Lee[3]

[1]*Howard University College of Medicine, Washington, DC, United States,* [2]*Universite des Sciences et Techniques de Masuku, Franceville, Gabon,* [3]*Howard University, Washington, DC, United States,* [4]*Obafemi Awolowo University, Ile-Ife, Nigeria*

Years of intensive research have not produced a protective vaccine against Chagas disease, which is caused by *Trypanosoma cruzi*. Current therapeutic drugs are also not very effective therapeutically. It is therefore imperative to find new drugs that are more effective and with minimum side effects. We undertook *in vitro* evaluation of methanol root extracts of *Anogeissus leiocarpus* and *Pseudocedrela kotschyi* against *T. cruzi* epimastigotes for their trypanocidal and apoptosis-inducing properties. Nifurtimox was used as a positive control. Dose response determinations at 96 hrs of culture yielded an IC_{50} of 0.82 μg/ml for *A. leiocarpus,* 8.94 μg/ml for *P. kotschyi* and 7.70 μg/ml for nifurtimox ($p < 0.05$). These results indicate that *A. leiocarpus* extract was significantly more potent than *P. kotschyi* extract and nifurtimox ($p < 0.001$). *T. cruzi* epimastigotes treated with the two plant extracts were also doubled stained with Annexin V and propidium iodide and analyzed by flow cytometry for distribution of epimastigotes that underwent apoptosis and necrosis. The results

showed that the percentages of early and late apoptotic epimastigotes were 2.98 % for *A. leiocarpus,* 9.55% for *P. kotschyi* and 12.37 % for nifurtimox. In contrast, the percentages of epimastigotes that underwent necrosis were 0.10% for *A. leiocarpus*, 14.6% for *P. kotschyi* and 0.48% for nifurtimox. These results suggest different modes of action for the individual plant extracts and nifurtimox. Morphological examination of treated epimastigotes by scanning electron microscopy revealed swelling of the perinuclear region and ruffling of cell membrane as well as impaired flagella growth. The overall results from this study strongly suggest that the two root extracts possess potent trypanocidal properties and can be used as sources of potential antichagasic drugs.

562

PARASITE BURDEN IS ASSOCIATED WITH THERAPEUTIC FAILURE IN HUMAN CUTANEOUS LEISHMANIASIS

Mauricio Nascimento, Rubia Costa, Maíra Saldanha, Sergio Arruda, Paulo Machado, Edgar M. Carvalho, **Lucas P. Carvalho**

Instituto Gonçalo Moniz- Fiocruz, Salvador, Brazil

Ulcer development in cutaneous leishmaniasis (CL) patients is associated with exaggerated inflammatory response with high levels of TNF and IL-1 beta. We have been able to identify CL patients in the very early phase of the disease (before ulcer development). These individuals are known as early cutaneous leishmaniasis (ECL) patients. Pentavelent antimony is the preconized drug to treat leishmaniasis in Brazil. Despite pentavalent antimony treatment, 75% of ECL patients go on to develop ulcer while only 35% of CL will have already ulcerated lesion. Here we worked with two hypothesis for high therapeutic failure rate in ECL: 1) High parasite amounts is associated with treatment failure. 2) Individuals that fail therapy have defects in immunoregulatory mechanisms. This study was conducted in Northeast Brazil and *Leishmania braziliensis* was the causative agent in all patients. We found that the parasite burden is higher in ECL than in CL lesions and that the higher the parasite load the longer the healing time. We also assessed immune response on day 0, day 15 after treatment had been started. Peripheral blood mononuclear cells from patients in the early phase of CL produced high levels of inflammatory cytokines in response to soluble *Leishmania* antigen (SLA). However, non of the cytokines tested were associated with therapeutic failure. Addition of recombinant IL-10 to cells extracted from lesion biopsies decreased the levels of TNF, IL-1 beta, IL-2, IL-15 and IL-17, cytokines known to be involved in the pathogenesis of CL. Together, our data suggest that parasite number may serve as an indicative of therapeutic failure at point-of-care and that induction of IL-10 at lesion site may benefit the patient by decreasing inflammatory response.

563

IMPAIRED TH1 RESPONSE IS ASSOCIATED THERAPEUTIC FAILURE IN PATIENTS WITH CUTANEOUS LEISHMANIASIS AND NEGATIVE LEISHMANIA SKIN TEST

Augusto M. Carvalho[1], Luiz Guimarães[1], Iana Prates[1], Rubia Costa[1], Lucas P. Carvalho[1], Phillip Scott[2], Edgar M. Carvalho[1]

[1]*Federal University of Bahia, Salvador, Brazil,* [2]*Department of Pathobiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA, United States*

Cutaneous leishmaniasis (CL) caused by *Leishmania braziliensis* is characterized by an exaggerated inflammatory response with high systemic production of Th1 cytokines such as IFN-γ and TNF to soluble *Leishmania* antigens (SLA). This inflammatory response contributes for the control of parasite multiplication but is also associated with tissue damage and ulcer development. Moreover, Th1 response is usually observed *in vivo*, by a positive delayed type hypersensitivity to the *Leishmania* skin test (LST). Despite, there are few CL patients with negative LST in the endemic area. Here we compare the clinical presentation, immune response and response to therapy in CL patients with a negative and positive LST. Participants include 13 patients with CL with LST- (cases) and 26 CL patients with LST+ (controls). The diagnosis was performed by the detection of DNA of *L. braziliensis* by PCR. All subjects had a negative test for HIV. Cytokine levels were determined by ELISA in supernatants of mononuclear cells stimulated with SLA and the ability of macrophages to kill *Leishmania* in the presence or absence of autologous lymphocytes was determined by optical microscopy. There was no difference in the size of the lesions in those with LST+ and LST-. However, while failure to antimony (Sb5) therapy was observed 9 of 13 (69,2%) of the cases it was found in 9 of 26 (34,6%) of controls (P< .05). IFN-γ and TNF levels were lower in those with LST-, while IL-1β, IL-6, IL-17 and MMP-9 levels were similar in both groups. There was no difference regarding the *Leishmania* killing by macrophages among the groups. However, while addition of lymphocytes in the culture decreased the percentage of infected cells and the number of intracellular amastigotes in LST+ group, no difference in infection rates was observed in LST- patients after coculture. Our study pointed out that impairment in Th1 immune response is associated with therapeutic failure and high levels of inflammatory cytokines IL-1β, IL-6, IL-17 contributes to o immunopathology in CL.

564

BLOOD MONOCYTES IN HUMAN VISCERAL LEISHMANIASIS ARE SKEWED TOWARDS NON INFLAMMATORY PHENOTYPE AND DISPLAY DEFECTIVE PHAGOCYTOSIS AND OXIDATIVE BURST

Neetu Singh[1], Christian Engwerda[2], Shyam Sundar[1]

[1]*Institute of Medical Sciences, BHU, Varanasi, Varanasi, U.P., India,* [2]*QIMR Berghofer Medical Research Institute, Herston, Australia, Australia*

Monocytes are important effector cells during Leishmania infection, and changes in their functions may impact development of immunity. However, functional characteristics of monocytes in patients with visceral leishmaniasis (VL) remains poorly understood. Peripheral blood monocytes from patients with VL and healthy endemic controls from Muzaffarpur, India, were isolated and compared in an ex vivo setting, using cell-culture techniques, flow cytometry, and reverse transcription quantitative polymerase chain reaction analysis. A blood monocyte population with a gene signature comprising upregulated expression of TGM2, CTLRs, VDR, PKM, SOCS1, and CAMP1 and down regulated expression of NOS2 and HIF1A was observed in patients with VL but not in controls. Monocytes from patients with VL also had impaired expression of pro inflammatory cytokines and their receptors. Importantly, monocytes from patients with VL had a markedly reduced capacity for phagocytosis and killing of engulfed promastigotes. Monocytes from patients with VL express antiinflammatory molecules and lack a classically activated phenotype. They have reduced expression of molecules related to activation and antiparasitic effector functions, indicating that monocytes are skewed toward an anti inflammatory phenotype. These findings provide insights into the functional status of monocytes during VL and advise that therapeutic manipulation of this important cell population may result in favorable patient outcomes.

565

IMPACT OF THE INTRODUCTION OF PCV7/13 ON ANTIMICROBIAL RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASE IN INDONESIA

Ebrima Jobarteh, Mustapha Danso, Dawda Kairaba Jawara, Mam Mass Sey

Universitas Islam negeri Uin syariff hidayatullah jakarta, Jakarta, Indonesia

We describe antimicrobial resistance in invasive pneumococcal disease due to all serotypes and non-vaccine types (NVT) pre and post pneumococcal conjugate vaccine (PCV) implementation in Indonesia in all age groups. We identified, serotyped, and performed antimicrobial susceptibility testing using disc diffusion methods on pneumococcal isolates obtained from invasive samples collected from standardised population-based pneumococcal disease surveillance in the Tangerang Health & Demographic Surveillance System. The study commenced in June 2006. PCV7 was introduced in August 2008 and PCV13 in May 2010. Antibiotic

susceptibility was interpreted using the Clinical Laboratory Standard Institute guidelines. 455 Pneumococcal isolates were screened against five antimicrobial agents. There was a moderate decline in antibiotic resistance in all age groups in invasive pneumococcal disease during vaccine implementation. In the 2-23 month age group, annual counts of oxacillin, chloramphenicol, and tetracycline resistant cases fell from 10-15 in 2009 and 2010 to 6-7 in 2014 and 2015. In the 24 – 59 month age group, there was a large fall in tetracycline resistant cases. In those >5 years, oxacillin, chloramphenicol, and tetracycline fell to zero cases in 2013 and 2014. Resistance fell primarily due to reductions in vaccine-serotypes 1, 5, 14 and 23F. The proportion of resistant NVT cases increased over time, particularly in the 2-23 month age group. Although there is an overall reduction in cases of antimicrobial resistant, we hypothesise that increased transmission of NVT after the introduction of PCV and exposure to antimicrobials facilitates the emergence of resistance in NVT. On-going surveillance is important to determine future trends in resistance as it has both clinical and public health importance in PCV era.

566

EVIDENCE OF EXOGENOUS AND ENDOGENOUS RE-INFECTION WITH *MYCOBACTERIUM TUBERCULOSIS* COMPLEX STRAINS AMONG PULMONARY TB PATIENTS WITH RECURRING TB EPISODES IN GHANA; A CALL FOR INTENSIFYING TB MONITORING

Prince Asare[1], Stephen Osei-Wusu[1], Adwoa Asante-Poku[1], Isaac D. Otchere[1], Dina A. Prah[1], Sonia Borrell[2], Edmund Bedeley[1], Audrey Forson[3], Kwadwo A. Koram[1], Sebastien Gagneux[2], Dorothy Yeboah-Manu[1]

[1]*Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana,* [2]*Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland,* [3]*Department of Chest Diseases, Korle-Bu Teaching Hospital, Korle-Bu, Accra, Ghana*

This study sought to analyze *Mycobacterium tuberculosis* complex (MTBC) strains obtained from pulmonary TB (PTB) individuals with recurring TB episodes in Ghana to provide necessary data to aid TB control. Following a 3½ year population-based sampling, mycobacterial isolates were obtained from individuals clinically diagnosed of PTB and confirmed as members of the MTBC using PCR targeting IS*6110, rpoB* and/or spacer oligonucleotide typing (spoligotyping) analysis. MTBC isolates obtained from both episodes among individuals with recurring disease after lineage assigning using spoligotyping, were subjected to standard 15-*loci* MIRU-VNTR typing for strain differentiation. Using the combined resolution power of spoligotyping and MIRU-VNTR data, phylogenetic trees were reconstructed with the aid of the miru-vntr*plus* online tool to aid in the mapping of the various strains and also for differentiating endogenous re-infection (classical relapse case and a proxy for treatment failure) from exogenous re-infection (new secondary case). Participants' clinical and socio-demographic characteristics were analyzed together with the molecular data. Sixty (60) out of 2,309 participants (2.6%) were classified as suspected relapse cases and found not to significantly differ from the national average of 3% (p-value > 0.05). We obtained MTBC isolates from both TB episodes for 35 participants. Compared to the primary case, 54% (19/35) were resulting from the same strain (endogenous re-infection) with the remaining being either similar (11/35, 32%) or different (5/35, 14%) strains (exogenous re-infection). Prominent among these cases was a case with three different episodes with the third episode harboring a drug resistant strain. There is substantial evidence of the occurrence of both endogenous and exogenous re-infection of MTBC strains in the country and a clear indication of the predominance of the former probably resulting from treatment failures which can contribute to the development of drug resistant strains thus we advocate for increased TB monitoring. Whole genome sequencing and analysis is underway to confirm these observations.

567

ASSESSMENT OF HEALTH RELATED QUALITY OF LIFE OF ADULTS TREATED FOR PNEUMONIA IN NAIROBI HEALTH FACILITIES

Apollo Odhiambo Maima[1], Faith Apolot Okalebo[2], Dan Owino Kaseje[3]

[1]*United States International University - Africa, Nairobi, Kenya,* [2]*University of Nairobi, Nairobi, Kenya,* [3]*Great Lakes University of Kisumu, Kisumu, Kenya*

Pneumonia is a common cause of hospitalization in Kenya, causing major health and psycho-social impacts, with about 11% of patients dying. In Kenya, there has been little monitoring of the burden of adult pneumonia and, especially, Health-Related Quality of Life (HRQoL) after recovery. We set out to assess the HRQoL of adults treated for pneumonia in health facilities in Nairobi. The study was conducted in 2016 in Nairobi, a densely populated city burdened by chronic urban poverty, slum life, pollution and disease. The over-arching design of the study was descriptive cross-sectional survey. Adult pneumonia patients were surveyed as a census after giving signed consent to the study. The 8 sampled health facilities had both in-patient and out-patient services; and had laboratory and radiological capacity to confirm a pneumonia diagnosis. Basic patient data and demographics were collected on open data kit (ODK) platform using android phones. The Standard RAND 36-Item Health Survey (Version 1.0) questionnaire was used to assess the HRQoL. Data obtained was programmed and coded. It was then entered, decoded and analysed in Windows EXCEL, SPSS and in STATA 13. Descriptive statistics, inferential statistics and Correlation coefficients were generated. The median age for the male participants was 32(IQR: 28-42) and 28(IQR: 24-36) for females, which ages are much lower than those of pneumonia patients elsewhere like Karachi (60); Enugu (53); and Yaounde (40). The 18-29 year age group had an overall HRQoL median score of 32(IQR, 27-40). These rose with age to cap at median score of 62.5(IQR, 50-75) for the 65+ years age group. This is at odds with the findings elsewhere. Overall, women had higher HRQoL scores than men. Both sexes had comparable social functioning, pain, general health and emotional health role limit. But females fared much better in the physical functioning, energy/fatigue, and emotional wellness. Overall women had higher HRQoL scores than men, which is diametrically different from other findings, possibly because of the steeliness of Kenyan women.

568

A PROSPECTIVE STUDY FOR THE TREATMENT OF MULTIDRUG-RESISTANT *KLEBSIELLA PNEUMONIAE* USING CIPROFLOXACIN-CHLORAMPHENICOL COMBINATION THERAPY

Sinthia Kabir Mumu, Akash Ahmed, M. Mahboob Hossain

BRAC University, Dhaka, Bangladesh

Pneumonia has become the leading cause of child death since many decades in developing countries. It is also a form of acute respiratory infections that affect lungs eventually. The purpose of the study was to develop a new approach to treat antibiotic-resistant *Klebsiella pneumoniae* infection. This study aimed in quest of a drug to combine with ciprofloxacin, a broad spectrum antibiotic frequently used to treat lung infections. A total of 23 lung infection bacterial samples were collected and studied against 14 antibiotics of different classes. The combination of ciprofloxacin with several drugs and the synergy screening, MIC value and qualitative toxicity analysis of ciprofloxacin and chloramphenicol combination done by the disk diffusion method. After the primary screening of antibiotic susceptibility, they were categorized into multidrug-resistant (MDR), extensively drug-resistant (XDR) and pan drug-resistant (PDR) pathogens where 9 isolates were MDR, 5 were XDR and 3 isolates were PDR. Furthermore, they were trialed in combination ciprofloxacin along with other 7 drugs in disk diffusion to explore synergistic effect. The combination of ciprofloxacin and moxifloxacin, ciprofloxacin and chloramphenicol were found to be synergic. Then the MIC test was

done for the combination Ciprofloxacin and chloramphenicol. When the MIC result was generated, the MIC of the respective combination was analyzed. Furthermore, the fractional inhibitory concentration (FIC) was calculated and in accordance with the results of FIC index, the ciprofloxacin-chloramphenicol combination has shown value 0.4510 which revealed a synergistic effect against multi-drug resistant *K. pneumoniae*. The qualitative analysis of ciprofloxacin and chloramphenicol combination was done and the result revealed no higher toxicity against eukaryotic cell Saccharomyces spp. All things considered, developing countries should grab the chance to combat antibiotic-resistant *K. pneumoniae* from this combination therapy and reduce the mortality rate from prolonged pneumonia since this pathogen is emerging as a superbug and developing resistant mechanism smartly.

STANDARDIZATION OF A GENE COMPLEMENTATION TECHNIQUE PNCA IN MYCOBACTERIUM TUBERCULOSIS PNCA-KNOCKOUT: TOOL FOR THE STUDY OF THE RELATIONSHIP BETWEEN MUTATIONS IN PLAIN AND PHENOTYPIC PARAMETERS

Yudith Cauna Orocollo, Patricia Sheen Cortavarría, Mirko Zimic Peralta

Universidad Peruana Cayetano Heredia, Lima, Peru

Mutations in the pncA gene are the major cause of resistance to pyrazinamide (PZA), but there are alternative mechanisms that also provide resistance. The objective of the study was to standardize the technique of complementing the pncA gene in Mycobacterium tuberculosis H37Rv pncA-KO to evaluate the effect of mutations in the pncA gene on phenotypic parameters, in a scenario controlled by the genetic variability of the clinical isolates from which they originated. the mutant pncA genes. Strains supplemented with pncA WT genes and mutants D49N, H51R, G78C, and F94L were generated through the pNIT-1 expression system to evaluate PZAsa activity by quantitative Wayne test, the expression level of the pncA gene and susceptibility to PZA using concentrations PZA gradients under uninduced and induced conditions.The pNIT-pncA expression system restored the phenotype of the pncA-KO strain and the plasmids remained stable intracellularly during the observation period that lasted 18 weeks. The basal expression levels were constant and similar to that of the H37Rv strain. The complemented pncA WT strain showed PZAsa activity and PZA Minimum Inhibitory Concentration similar to that of the H37Rv strain. However, the pncA complemented mutant strains were resistant to PZA in both conditions and the overexpression of pncA mutant genes allowed to verify the total or partial loss of PZAsa activity.

EVALUATION OF SAME, DAY DIAGNOSIS OF TUBERCULOSIS MICROSCOPY IN COMPARISON TO THE SPOT-MORNING-SPOT METHOD IN SELECTED HEALTH INSTITUTION IN ADDIS ABABA, ETHIOPIA

Shemsu Kedir Juhar[1], Sisay Kebede Gebregorgis[2]

[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia,* [2]*Ethiopian public health institute, Addis Ababa, Ethiopia*

Over six million new cases of tuberculosis (TB) are diagnosed each year throughout the globe, and each year witnesses 1.3 million TB-related deaths. One smear-positive patient can infect 10-15 people in a year, and 10% of them will develop this disease. The need to collect serial sputum specimens over multiple patient visits for pulmonary tuberculosis results in a protected diagnostic process with rates of patients with high rates of patient dropout. Recent studies on spot morning spot (SMS) method of examination PTB reported that the first two specimens have high smear positivity in line with this WHO changed its policy to minimize the number of sputum specimens from three to two. Across-sectional study was conducted in 16 conveniently selected private clinics, governmental health centers, public and private hospitals from September - December 2017. Individuals attending the selected health institutions for the diagnosis of MTB submitted three sputum samples for routine diagnosis (the standard approach). One additional sample was collected 1 h after the first sputum (the same-day approach). One sputum sample was cultured. The diagnosis was performed using ZN sputum smear microscopy and light-emitting diodes fluorescent microscopy (LED-FM) technique. Data were entered and analyzed using SPSS version 16. We used sensitivity, specificity and predictive values for the different methods.A total of 209 participants enrolled, 43(21%) were identified culture positive, 39 (18.7%) were detected by the same day approach and 40(19.1%) by the standard approach.On the other hand, LED-FM and ZN microscopy detected 39(18.1%) and 48(23%) tuberculosis cases respectively. Sensitivity was 88.4% for ZN microscopy and 95.3% for LED-FM and the specificity was 99.4% and 95.9% for ZN and LED -FM microscopy respectively.Using same day approach together with LED-FM would reduce workload, TAT, patient drops out and increases the smear detection rate. Therefore it is necessary to give in-service and off service training for health personnel towards the use of LED-FM, conventional approach and the same day approach in the diagnosis of TB.

571

ASSESSMENT OF EFFLUX PUMPS FROM *MYCOBACTERIUM TUBERCULOSIS* BY CRISPR INTERFERENCE IN *MYCOBACTERIUM SMEGMATIS* IN VIVO MODEL AND ITS EFFECT ON SUSCEPTIBILITY TO PYRAZINAMIDE

Stefany Quinones-Garcia[1], Patricia Sheen[1], Mirko Zimic[1], Jeremy M. Rock[2], Robert H. Gilman[3]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*The Rockefeller University, New York, NY, United States,* [3]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Tuberculosis (TB) is an infectious disease caused by *Mycobacterium tuberculosis* (MTB). In 2017, 1 400 000 deaths and 100 000 new cases were reported. Among the several therapeutic schemes, pyrazinamide stands out for being the only drug that is used for both types of TB, as it has a bactericidal effect on the latent forms of the tubercle bacillus. However, the mechanism of action of PZA and its active derivative, pyrazinoic acid (POA), remains unknown on the current field. In a previous study of our MTB research group, genes efflux pumps were identified in MDR or XDR strains, which showed a negative correlation with the kinetics of POA efflux, suggesting that such efflux pumps could contribute to the resistance mechanism on POA. The objective of this study is to explore the correlation of MTB of homologous efflux pumps with their respective kinetics of POA efflux. Transcriptional repression by CRISPRi was conducted using the *in vivo* model of *Mycobacterium smegmatis*. Nine genes will be silenced and analyzed with their individual response to POA as well as their collective response in groups of two. So far, genes Msmeg_0250 and Msmeg_3815 have been silenced successfully, to which their kinetics are being evaluated. With regard to the other seven, different gRNAs are currently being cloned in the plasmid pJR962, until the silencing induced with anhydrotetracycline can be corroborated through real-time PCR. Multiple silencing for the collective POA response will be performed in function of the total individual results, which is to be expected by June of 2019.

HEALTH CARE UTILIZATION SURVEY OF CHILDREN UNDER FIVE WITH PNEUMONIA IN PERI URBAN COMMUNITIES OF KARACHI, PAKISTAN

Bushra Abid Iqbal Mufti, Salima Kerai, Imran Nasir, Muhammad Ilyas, Sana Qaiser, Khalid Feroz, Azhar Raza, Azhar Raza, Faizan Khalid, Benazir Balouch, Fyezah Jehan

Aga Khan University Hospital, Karachi, Pakistan

Pneumonia is regarded as leading cause of child mortality worldwide, accounting for 15 million deaths every year in children under five years of age.Timely recognition of symptoms, appropriate care seeking and management are key to survival. We assessed health care utilization

pattern among caregivers of children under five with fast breathing pneumonia in urban slums of Karachi, Pakistan. Random sample stratified on age was drawn from an existing line listing obtained from ongoing demographic surveillance. Data on household demographics, pneumonia specific symptoms, care seeking, air quality and knowledge regarding preventive measures for pneumonia was gathered on a standardized questionnaire from caregivers of children by community health workers (CHWs). A weight was assigned to each child in the sample representing the number of children in the population. Predictors of care seeking were estimated using weighted logistic regression. Information on 1152 children was included in the analysis. About 95% of caregivers sought care; 68.5% privately. Care seeking was higher for infants. Primary health center utilization was comparatively higher for non-severe (fast breathing) pneumonia (29%), whereas, private care was sought for conditions like chest indrawing and/or danger sign (70%). About 5% did not seek any care. Reasons identified were clinic too far from home, siblings at home who could not be left alone and high cost of treatment. Odds ratios for predictors of seeking care were younger age of child (OR 3.6, 95% CI 2.65,4.87), caretaker with primary education compared to none (OR 3.4, 95% CI 2.46,4.70), vaccination of child (OR 1.28, 95% CI 1.12,1.46) and presence of symptoms like fever (OR 1.51, 95% CI 1.30,1.76), tachypnea (OR 1.57, 95% CI 1.35, 1.83), chest indrawing(OR 2.56, 95% CI 2.05, 3.18), persistent vomiting (OR 1.69, 95% CI 1.37, 2.09), recurrent illness (OR 2.57, 95% CI 2.23, 2.97) and vaccine (OR 1.65, 95% CI 1.45,1.87) and breastfeeding awareness (OR 1.32, 95% CI 1.13,1.53). The study findings indicate high health care utilization for pneumonia in these communities.

573

AN OUTBREAK OF ADENOVIRUS CAUSING SEVERE RESPIRATORY ILLNESS IN SOUTHERN SRI LANKA, 2018

Weerasinghe M. D. G. B. Wijayaratne[1], Sky Vanderburg[2], Vasantha Devasiri[1], Ajith Nagahawatte[1], Champika K. Bodinayake[1], Eelizabeth Petzold[2], Sunethra Gunasena[1], Nayomi Danthanarayana[3], Bhagya Piyasiri[3], Muhunthan Sellathurai[3], Nayani P. Weerasinghe[1], Chathuranga L. Fonseka[1], Ruvini P. Kurukulasooriya[1], Nishantha C. Gunasekara[1], Brad P. Nicholson[2], Chris W. Woods[2], L. Gayani Tillekeratne[2]

[1]*University of Ruhuna, Galle, Sri Lanka,* [2]*Duke University, Durham, NC, United States,* [3]*Teaching Hospital Karapitiya, Galle, Sri Lanka*

In Sri Lanka, influenza activity peaks during March- June annually. In southern Sri Lanka, paediatricians noted a rapid increase in admissions of children with serious, and in some cases fatal, respiratory illnesses from April to June 2018. Consequently, active surveillance of cases was initiated at Teaching Hospital Karapitiya (THK) the largest tertiary care hospital in the Southern Province, Sri Lanka, to better characterize cases. Patients in all pediatric wards and intensive care units at THK were systematically screened daily from 28/05/2018 to 25/06/2018 using a case definition of fever with one or more features of respiratory tract infection. Nasopharyngeal (NP) and oropharyngeal (OP) swab samples were collected from each case for real time-PCR (RT-PCR) identification of adenovirus, influenza A, and respiratory syncytial virus (RSV). Blood samples were collected from a subset of patients to determine viremia. During the period of active surveillance, 170 pediatric and 12 adult cases were identified, of which 9 (5.3%) paediatric cases and 3 (25%) adult cases were fatal. Fifty-three (31.2%) paediatric patients needed respiratory support by means of oxygen, intubation, ICU care or a combination of these. Adenovirus was detected in 43.7%, RSV in 29.6%, and influenza A in 26.7% of 135 pediatric NP/OP swab samples tested by RT-PCR. Of 11 adult NP/OP swab samples tested, adenovirus was detected in 45.5%, influenza A in 27.2%, and RSV in 0%. In 25 (13.2%) of samples, ≥2 viruses were detected. Adenovirus was detected in blood samples of all cases (N=3) tested, corresponding to adenovirus detection in NP/OP samples from the same individuals. Further serotyping of adenovirus positive subset of samples revealed that these isolates belong to adenovirus type B. This severe outbreak of respiratory viral infection in the Southern Province of Sri Lanka turned out to be due to adenovirus, although clinicians were expecting influenza. This outbreak signifies the importance of continued surveillance of all major respiratory viruses across the year.

BIOMARKERS OF PEDIATRIC PNEUMONIA: THE POSSIBILITY OF A FINGERSTICK DIAGNOSTIC TEST

Jack Underschultz[1], Jeremy Soo[1], Ravi Bhargava[1], Robert Opoka[2], Andrea Conroy[3], Sophie Namasopo[4], Michael Hawkes[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Makerere University, Kampala, Uganda,* [3]*Indiana University School of Medicine, Indianapolis, IN, United States,* [4]*Kabale Regional Referral Hospital, Kabale, Uganda*

Chest x-ray (CXR) is commonly used as a diagnostic tool for pediatric pneumonia, but is not available in many resource-limited areas of the world where a large number of pneumonia deaths occur. We hypothesized that plasma biomarkers of inflammation, endothelial activation, and lung injury, which could be adapted to a point-of-care platform, would be associated with CXR consolidation and could be used as a diagnostic test to replace the CXR. We conducted a cross-sectional study of 108 children under 13 years of age who were hospitalized with clinical pneumonia at two resource-limited hospitals in Uganda. Chest radiography was performed locally and interpreted by a Canadian certified (FRCPC) pediatric radiologist. Enzyme-linked immunosorbent assays were performed in order to measure the following serum host response biomarkers: C-reactive protein (CRP), Chitinase 3-like 1 (CHI3L1), Lipocalin-2 (LCN2), Tie-2, Intercellular adhesion molecule-1 (ICAM1), endoglin, Tissue Inhibitor of Metalloprotease-1 (TIMP1), and surfactant protein-D (SP-D). A total of 108 children were included (39% female) with median age 10 months (IQR 3-20 months). Based on x-ray findings, children were categorized as primary end-point pneumonia (n=24), other infiltrates (n=49), or normal chest x-ray (n=35). Compared to children with normal x-ray, children with end-point pneumonia had significantly higher levels of CRP, CHI3L1, LCN2, and SP-D. CRP had the best discriminatory power (AUROC 0.73 (95%CI 0.57, 0.88) p=0.0036). Using the optimal cutoff (>35 μg/mL), CRP had a sensitivity of 71% (95%CI 53-89%) and a specificity of 79% (95%CI 65-93%) to discriminate between end-point pneumonia and normal chest x-ray. The probability of CXR consolidation increased in a step-wise manner with the number of elevated biomarkers (8% if none to 79% in children with all five biomarkers elevated). In summary, among Ugandan children with clinical pneumonia, host biomarkers distinguished between end-point pneumonia and normal chest x-ray. Together, this group of biomarkers may have clinical utility in predicting alveolar consolidation.

575

DETECTION AND MOLECULAR CHARACTERIZATION OF *GIARDIA DUODENALIS* IN PATIENTS WITH CHRONIC AND PERSISTENT DIARRHEA

Sumeeta Khurana, Monika Jangra, Usha Dutta, Rakesh Sehgal, Br Thapa, Nalini Gupta, Ritambhra Nada

Postgraduate Institute of Medical Education and Research, Chandigarh, India

Giardia duodenalis is an important cause of diarrhoeal illness in humans worldwide. The clinical manifestations range from asymptomatic to acute or chronic diarrhoea. This high variability depends on interplay between various factors like inoculum size, host factors and parasitic factors like assemblage. Stool samples were collected from 100 patients with chronic diarrhoea (excluding celiac and inflammatory bowel disease) and 50 patients without gastrointestinal symptoms attending Postgraduate Institute of Medical Education and Research, Chandigarh, India for microscopy (3 consecutive stool samples), Nested PCR (triosephosphateisomerase gene (tpi)) and Assemblage specific PCR for Giardia. Duodenal biopsy samples were available for 30 patients only. The sensitivity and specificity of nested PCR was initially evaluated on 40 Giardia microscopy positive and 50 negative stool samples. Overall prevalence of *G. duodenalis* infection in patients with chronic diarrhoea

was found to be 48%. In children less than 14 years, prevalence of 53.33% was seen which was higher compared to 45.71% prevalence seen in adult patients. Assemblage B (60.60%) was found to be the more common than assemblage A. There was no assemblage specific difference in severity or chronicity of clinical manifestations. In stool samples, sensitivity and specificity of nested PCR was found to be 100% each while that of microscopy was 70.45% and 100%, respectively. Duodenal biopsy PCR additionally detected 4 patients of giardiasis that were negative by stool PCR; however former missed 5 stool PCR positive Giardia infections. Thus, it was found that nested PCR can be used as a new gold standard for detecting giardiasis in chronic diarrhoea patients. However, neither stool sample nor duodenal biopsy alone can exclude giardiasis in all the cases. 26.67% of infections can still remain undetected if only stool samples are tested by PCR. This can be due to intermittent shedding of the parasite. In such situation, PCR of duodenal biopsy samples can help in picking up the remaining cases of giardiasis who are not detected by stool nested PCR.

576

GIARDIA ASSEMBLAGES AND DIARRHEA IN CHILDREN BELOW FIVE YEARS IN SIAYA COUNTY, KENYA

Esther Omuseni[1], Benjamin Ochieng[1], Jane Juma[1], Evans Apondi[1], Richard Omore[1], Irene N. Kasumba[2], Anna Rose[2], Jie Liu[3], Eric Houpt[3], Sharon Tennant[2], Karen Kotloff[2]

[1]*Kenya Medical Research Institute, Kisumu, Kenya,* [2]*Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States,* [3]*Division of Infectious Diseases and International Health, Department of Medicine, University of Virginia, Charlottesville, VA, United States*

Giardia is one of the most common pathogens known to cause diarrhea among children in underprivileged communities. *Giardia duodenalis* is the species affecting humans and is comprised of eight distinct groups, called assemblages. Only A and B are associated with human infection. Asymptomatic infected children persistently contaminate their environment by shedding cysts. We assessed the association of *G. duodenalis* assemblages and diarrhea with the aim to find a common genotype among children with moderate-to-severe diarrhea (MSD) in the case-controlled, prospective Vaccine Impact on Diarrhea in Africa (VIDA) study. 408 stool samples were randomly selected from symptomatic and asymptomatic children positive for *Giardia* by Enzyme Immunoassay. Samples were tested by real-time PCR for *Giardia spp.* and assemblages A and B. Number of cycles required for the fluorescent signal to cross the threshold (Ct) was used to analyze the parasite load (Ct lt 25, abundant target; 25-35; moderate amounts; and, 36-40 indicates minimal amounts of target). Of the 408 stool samples, 293 (71.8%) were positive for *Giardia*, of which 32 (10.9%) and 218 (74.4%) were positive for A and B respectively. There was an increase in *Giardia* with age (16.7%, 34.1% and 49.1% in 0-11, 12-23 and 24-59 months respectively) in both symptomatic and asymptomatic children.. Within age groups, *Giardia* detection in symptomatic children decreased (55.1% to 44.4%) and increased in asymptomatic children (44.9% to 55.6%) from youngest to eldest age group with assemblage B being the most common. Proportion of cases increased as the Ct value increased (44% for CT lt 25 to 64% for CT 30-35). The reverse was observed for controls suggesting a protective mechanism. Our data suggest that B is the most common assemblage in both cases and controls. Asymptomatic infections increase with age hence these children could serve as potential reservoirs of *Giardia* and this parasite could have a protective effect against diarrhea. Future investigations should focus on understanding the potential mechanisms that contribute to carrier status.

577

COMPARATIVE EFFICACY OF DNA ISOLATION FROM RECTAL SWABS AND BULK STOOL FOR MOLECULAR DETECTION OF *GIARDIA INTESTINALIS*

Jacqueline R. Maasch[1], Ahmed M. Arzika[2], Catherine Cook[3], Elodie Lebas[3], Nils Pilotte[1], Jessica R. Grant[1], Steven A. Williams[1], Jeremy A. Keenan[3], Kristen A. Aiemjoy[4]

[1]*Smith College, Northhampton, MA, United States,* [2]*University of California San Francisco, Niamey, Niger,* [3]*University of California San Francisco, San Francisco, CA, United States,* [4]*Stanford University, San Francisco, CA, United States*

Enteropathogen control and elimination efforts require sensitive, cost-effective, and practical diagnostics that yield accurate and reproducible results. While bulk stool remains the gold standard specimen type for enteropathogen diagnosis, evidence suggests that rectal swabs may offer comparable diagnostic sensitivity with greater ease of sample collection for select bacterial and viral pathogens. We sought to evaluate the validity and reproducibility of rectal swabs for the molecular detection of the protozoan parasite *Giardia intestinali*s in a population-based sample of young children. We collected paired rectal swab and bulk stool samples from 86 children ages 0-5 years living in the Boboye and Loga departments of Niger. Duplicate rectal swab and bulk stool samples were collected among a subset of 50 children. Both swabs and stool samples were stored without any media preservative and frozen at -20°C on the day of collection. For detection of *G. intestinalis*, we used an in-house real-time PCR assay targeting a segment of the 16S ribosomal RNA repeat determined to be conserved across three strains that commonly infect humans. *G. intestinalis* was detected in 63.95% (55/86) of bulk stool and 41.86% (36/86) of rectal swab samples. The kappa evaluating test agreement among children with duplicate samples was 0.91 (95% CI 0.63-1.00) for bulk stool and 0.80 (95% CI 0.52-1.00) for rectal swabs. The PCR sensitivity of rectal swabs relative to bulk stool was 62.0% (95% CI 48.0-75.0%) and the specificity was 94.0% (95% CI 79.0-99.0%). The PCR sensitivity and specificity of rectal swab samples were not affected by visible presence of fecal matter, the child's age, or the consistency of the matched bulk stool sample. While rectal swabs may be a viable source of pathogen DNA for select diagnostic targets, these findings suggest that rectal swabs provide less sensitive and reproducible results than bulk stool for the real-time PCR diagnosis of *G. intestinalis*. However, the high specificity and fair reliability of swabs indicate that they may still be of value in situations where bulk stool collection is logistically infeasible or cost-prohibitive.

578

MOLECULAR CHARACTERIZATION OF *ENTAMOEBA* COMPLEX IN HUMAN STOOL SAMPLES FROM CASES AND CONTROLS IDENTIFIES *ENTAMOEBA MOSHKOVSKII* FOR THE FIRST TIME IN KENYA

C. Kyanya[1], F. Eyase[2], E. Odundo[2], E. Kipkirui[2], N. Kipkemoi[2], R. Kirera[2], C. Philip[2], J. Ndonye[2], M. Kirui[2], A. Ombogo[2], M. Koech[2], W. Bulimo[2], A. Flynn[2], C. E. Hulseberg[3]

[1]*Jomo Kenyatta University of Science and Technology, Nairobi, Kenya,* [2]*United States Army Medical Research Directorate-Africa, Nairobi, Kenya,* [3]*United States Army Medical Research Institute of Infectious Diseases, Silver Spring, MD, United States*

Amoebiasis caused by *Entamoeba histolytica* is a leading cause of diarrhea globally. Indistinguishable in morphology from *E. histolytica* are non-pathogenic *E. dispar* and *E. moshkovskii* which all form the *Entamoeba* complex. Microscopy remains the mainstay for diagnosis of *E. histolytica*, especially in low resource settings. WHO recommends treatment of only *E. histolytica*, but this is only possible with an accurate diagnosis. In Kenya, the distribution of *E.* complex is not well-defined. We sought to speciate *E.* complex species from stool samples for an ongoing enteric pathogen surveillance study in Kenya. A total of 46 paired case-control archived stool specimens collected between April 2013 and September 2014 across

seven sites in Kenya were analyzed. Twenty-three had previously been identified as positive for *E.* complex by microscopy. DNA was extracted using the QIAamp DNA Stool Mini Kit. Species detection was done using nested PCR with the resulting amplicons sequenced by Sanger method. Consensus sequences were compared to those on GenBank database and maximum likelihood phylogenies reconstructed using phyML 3.1. Out of the 46 samples, 22 (47.8%) were positive for *Entamoeba* species. Of these, 16 had initially been identified as microscopy positive for *Entamoeba* complex. Among the 22 PCR-positives *Entamoeba* complex species were identified as follows: 9 were *E. dispar* (40.9%), 2 were *E. moshkovskii* (9.1%), and 1 was *E. histolytica* (4.5%). Combinations of *Entamoeba* species detected were: 3 *E. histolytica* and *E. dispar* (13.6%), 2 *E. histolytica* and E. *moshkovskii* (9.1%), 4 *E. moshkovskii* and *E. dispar* (18.2%) and 1 *E. histolytica* and *E. dispar* and *E. moshkovskii*. Sequence analysis revealed 99% identity to *E. dispar* (SAW 760), *E. moshkovskii* (Laredo) and *E. histolytica* (HM-1: IMSS). Reconstruction of phylogenetic relationships revealed distinct species-specific clustering. It's possible that *E. moshkovskii* infections have been in circulation in Kenya for some time and are only now being reported. It is important to establish the molecular epidemiology of *E.* complex, so as to accurately treat amoebiasis in endemic areas like Kenya.

579

PREVALENCE OF *BLASTOCYSTIS SP.* AND ASSOCIATED FACTORS TO INFECTION AND SYMPTOMATOLOGY IN PERIURBAN COMMUNITIES OF AREQUIPA, PERU

Victor Luis Vasquez Huerta[1], Renzo Sadath Salazar Sánchez[1], Elí Martínez Barrios[1], Kasandra Lizzeth Ascuña Durand[1], Ana Leila Maza Santillán[1], Mónica Yauri Huamani[1], Almendra Del Rosario Ascuña Durand[1], Jorge Andrés Ballón Echegaray[1], Ricardo Castillo Neyra[2]

[1]*Universidad Nacional de San Agustín, Arequipa, Peru,* [2]*University of Pennsylvania, Philadelphia, PA, United States*

Entero-parasitic infections are one of the most important causes of acute illnesses in humans. They are mainly present in poor areas with unhealthy environmental conditions. Periurban communities usually experience some of these conditions, including limited access to safe drinking water and inadequate disposal of human feces. Among entero-parasites, *Blastocystis sp.* is the most common protozoa in the human gut with wide distribution around the world. People infected with *Blastocystis sp.* do not show specific symptoms or are asymptomatic, making it difficult to assess its pathogenic potential and determine if and how much zoonotic transmission occurs. The aim of this study was to determinate the prevalence of *Blastocystis sp.* and the factors associated with infection, and symptomatology presentation in periurban communities from Arequipa city. We conducted epidemiological surveys and analyzed stool samples from 189 participants and 144 animals from participants' households using the concentration-spin method and direct stool exam by microscopy. We compared individual-level and household-level covariates between infected and uninfected participants and between symptomatic and asymptomatic cases. 49.2% of participants were infected with *Blastocystis sp.* Among infected, 61.3% had non-specific gastrointestinal symptomatology. We found an association between *Blastocystis sp.* infection and lack of access to safe drinking water (p=0.004) and inadequate disposal of human feces (p=0.03). Other variables such as age, sex, presence of animals or vectors at home, food consumption, and hygienic habits were not associated. Additionally, we found 34.4% of coinfections between *Blastocystis sp.* and other intestinal parasites. Only 8.3% of the animals were infected with *Blastocystis sp*. Our results suggest that *Blastocystis sp.* infection does not present a clear symptomatology and that the main factors associated with *Blastocystis sp.* infections ocurr at the household-level: water supply and the feces final disposition. The implications of these findings on the control and transmission of *Blastocystis sp.* are discussed.

580

HEALTHY COMMUNITY STOOL SCREENINGS IN RURAL NICARAGUA REVEAL HIGH PREVALENCE OF PROTOZOAL INTESTINAL PARASITES AND POLYPARASITISM

Jolie Starling[1], Anna Strasma[2], Reyna Silva[3], **Rebecca S. Fischer**[1]

[1]*Texas A&M University Health Science Center, College Station, TX, United States,* [2]*Baylor College of Medicine, Nephrology, Houston, TX, United States,* [3]*Amigos for Christ, Chichigalpa, Nicaragua*

Individuals in tropical, rural regions of the world are at high risk for infectious diseases, including parasitic diseases. Protozoal and worm parasites are a public health challenge in low-income settings, where prevention, surveillance, detection, and access to treatment are stressed by limited infrastructure and resources. Identifying epidemiologic patterns within high-risk communities can inform vulnerable populations and serve as evidence to develop efficient treatment and prevention measures, such as water sanitation and filtration, education, and targeted surveillance. Stool and urine specimens were collected from individuals attending health fairs in 2 rural, agricultural communities in western Nicaragua. Stool was analyzed by microscopy. We generated descriptive statistics and report prevalence and characteristics with Chi-squared and ANOVA using Stata 15. We analyzed stool from 221 residents, ages 3 months to 89 years (median 21 years). *Endolimax nana* (67%), *Entamoeba coli* (44%), *Entamoeba histolytica* (33%), and *Giardia lamblia* (23%) were most common; *Necatur americanus* eggs were recovered from one 87-year old. One community had higher prevalence of *E. histolytica* (56%;p=0.004) and *E. coli* (51%;p=0.005) than the other. 28% harbored 3 or more species, but *G. lamblia* and *E. histolytica* were negatively correlated (p<0.05). Only 18 individuals (8%) were parasite-free. We document a high prevalence of parasites and polyparasitism, and we suggest widespread exposure or frequent transmission is likely occurring within these and neighboring communities. Although not all organisms identified are perceived as pathogenic, there is clearly a need for health education and interventions to reduce exposure to protozoal parasites in the community-at-large. Geographic differences we found may guide treatment campaigns, interventions to break transmission cycles, and health campaigns to prevent disease. These data can inform targeted public health efforts to reduce morbidity, mortality, and long-term health consequences of parasitic infections in high risk communities.

581

INFLUENCE OF HOST NUTRIOME ON IMMUNOLOGICAL CONTROL OF PROTOZOAL INFECTIONS

Emma Hagopian[1], Shveta Bhasker[1], Ruwandi Kariyawasam[2], David Harris[1], Priyanka Challa[1], Celine Lecce[1], Rachel Lau[3], Andrea Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Institute of Medical Sciences, Department of Medicine, University of Toronto, Toronto, ON, Canada,* [3]*Public Health Ontario Laboratories, Toronto, ON, Canada*

Immunologic control of parasitic infections arises from a combination of humoral and cellular mechanisms, both of which may be influenced by host nutritional status. Micronutrient depletion or over-repletion impairs the functioning of the immune system, potentially resulting in increased susceptibility to and poor immunologic control of protozoal infections. We aim to synthesize the knowledge surrounding the interplay between host micronutrient status and tissue-based protozoal infections. Specifically, we will map the literature of how nutrient deficiencies such as zinc, iron, and vitamin A impact immune response and defenses in infectious diseases such as malaria, Chagas disease, and leishmaniasis. Five electronic databases were searched including PubMed, Embase, Medline, Scopus, and LILACS with combinations of search terms such as Parasite* AND (Immunology OR Immunity OR Immune System OR Immune Function OR Immune Impairment OR Immune Response OR Immune Status) from database inception to March 13, 2019. A total of 30 872 articles were retrieved: 15 254 articles on PubMed, 8192 on Embase, 5909 on Medline,

1411 on Scopus, and 106 on LILACS. After eliminating duplicates using Mendeley software, a total of 21 821 articles remained for title screening. Titles, abstracts, and full-text articles will be systematically double screened by two reviewers with a tertiary arbitrator. The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) will be implemented. Data extraction will be performed by two reviewers and the quality of the articles will be critically evaluated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) approach. The data will be summarized to systematically map published literature that will illuminate a number of ways in which nutrient deficiencies or abnormal micronutrient status alter and impair immune function in persons with protozoal infections. This synthesized body of information will ultimately inform adjunctive therapeutic decisions in the context of protozoal infections, which has the potential to improve patient prognosis.

582

THE ROLE OF PROTOZOAN PARASITES IN FEVERS OF UNKNOWN ORIGINS IN GHANA

Georgina I. Djameh, Annabella Nkansah, Senyo Botchie, Irene Ayi

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Fever is a major feature of many illnesses and remain one of the most challenging clinical evaluations for pediatric clinicians. In Ghana, parasitic diagnosis of fevers in children have focused on malaria but only half or less the number of such cases are observed to have malaria parasite. This study sought to determine other etiologies of FUO besides *Plasmodium* parasites and profiling cellular immune responses to parasitic infections in children. Children younger than 13 years who reported at the pediatric ward of the Cape Coast Teaching Hospital, Ghana with fever (a high temperature ≥ 38°) were enrolled in the study. Venous blood and stool samples were collected from 143 participants and transported to the Noguchi Memorial Institute for Medical Research for analysis. Differential diagnosis was performed for the presence or absence and further genotyping of *Plasmodium*, *Toxoplasma gondii*, *Babesia*, *Cryptosporidium*, *Giardia lamblia* and *Entamoeba* spp. using Polymerase Chain Reaction (PCR). Enzyme-linked immunosorbent assay was performed to obtain and compare the levels of cytokines with respect to infection status. *Plasmodium falciparum* was detected in 27.3% (39/143) of participants. Out of the 104 *P. falciparum* negative samples, 18 (16.7%) *G. lamblia*, 2 (1.9%) *E. histolytica*, 2 (1.9%) *Toxoplasma gondii* and 1 (0.9%) *Cryptosporidium* spp. were detected. Cytokine analysis revealed that, *Plasmodium* negative detected parasites had lower cytokine level than *Plasmodium* positive samples. Also, the level of cytokines established between *Plasmodium* positive infection and *Plasmodium* negative detected parasites were not significantly different (*P*-value > 0.05). Varying levels of parasites virulence can lead to modulating effect by either aggravating or alleviating immune responses.

583

EPIDEMIOLOGY AND CLINICAL PRESENTATION OF *CRYPTOSPORIDIUM*-ASSOCIATED DIARRHEAL DISEASE IN CHILDREN UNDER FIVE FROM THREE COUNTRIES IN SUB-SAHARAN AFRICA

M. Jahangir Hossain[1], Anna Roose[2], Samba Sow[3], Sanogo Doh[3], Richard Omore[4], Ben Ochieng[4], Joquina Chiquita M. Jones[1], Syed M.A. Zaman[1], Henry Badji[1], Sharon M. Tennant[2], Irene Kasumba[2], Helen Powell[2], Dilruba Nasrin[2], Jie Liu[5], James Platts-Mills[5], Martin Antonio[1], Eric Houpt[6], Karen L. Kotloff[2]

[1]*Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia,* [2]*Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States,* [3]*Center for Vaccine Development-Mali, Bamako, Mali,* [4]*Kenya Medical Research Institute, Kisumu, Kenya,* [5]*Division of Infectious Diseases and International Health, Department of Medicine, University of Virginia, Charlottesville, VA, United States,* [6]*Division of Infectious Diseases and International Health, Department of Medicine, University of Virginia, Charlottesville, VA, United States*

Cryptosporidium causes significant diarrheal morbidity and mortality in children worldwide, including over 40,000 deaths in sub-Saharan Africa. We describe the epidemiology of *Cryptosporidium* in children <5 years of age from the Vaccine Impact on Diarrhea in Africa (VIDA) study in The Gambia, Mali and Kenya (2015-2018). VIDA enrolled healthcare-seeking cases with moderate-to-severe diarrhea (MSD, defined as diarrhea [≥3 loose stools/day] with dysentery or signs of dehydration, IV fluids or hospitalization). Diarrhea-free controls matched for gender, age, time, and community were enrolled at home. Each case and one control provided a stool sample at enrolment to be tested for a panel of enteropathogens, including *Cryptosporidium* species, by TaqMan Array Card quantitative PCR. Using conditional logistic regression, the association between *Cryptosporidium* and MSD status was assessed, adjusting for other pathogens and including interactions with age stratum and site. Episode-specific attributable fractions (AFes) were calculated for each case; cases with an AFe ≥ 0.5 were considered etiologic. Altogether, 4738 cases and 4738 matched controls were enrolled and analysed. *Cryptosporidium* was frequently detected among both groups (23.3% in cases v. 18.3% in controls) and common at all three sites (29.5% of MSD cases in The Gambia, 23.9% in Mali, 16.0% in Kenya). *Cryptosporidium* peaked annually in both The Gambia and Mali coinciding with the rainy season, but was prevalent year-round in Kenya. Among cases, *Cryptosporidium* detection was considered etiologic for 49.9% of detections. MSD cases with etiologic *Cryptosporidium* were younger than non-etiologic cases (median 13 v. 17 months), and 81.5% of etiologic cases were less than 24 months of age. *Cryptosporidium* cases had a longer duration of illness compared to watery diarrhea cases attributable to other causes (Median (IQR): 6 days (4-9) vs. 5 days (3-8), p<0.01) and had higher mean modified Vesikari severity scores (10.0 vs. 9.3, p<0.01). Our results suggest that *Cryptosporidium* infection is prevalent and pathogenic in the populations examined in VIDA.

584

ENVIRONMENTAL EXPOSURES ARE A RISK FACTOR FOR *TOXOPLASMA GONDII* INFECTION IN AN URBAN SLUM IN SALVADOR, BRAZIL

Arnau Casanovas-Massana[1], Joyce Wang[1], Elsio A. Wunder[1], Ridalva D. Felzemburgh[2], Renato B. Reis[2], Nivison Nery[2], Guilherme S. Ribeiro[2], Federico Costa[2], Peter J. Diggle[3], Mitermayer G. Reis[2], Claudia Munoz-Zanzi[4], Albert I. Ko[1]

[1]*Yale School of Public Health, New Haven, CT, United States,* [2]*Oswaldo Cruz Fundation, Salvador, Brazil,* [3]*University of Lancaster, Lancaster, United Kingdom,* [4]*University of Minnesota, Minneapolis, MN, United States*

Toxoplasmosis, caused by the parasite *Toxoplasma gondii*, is one of the most common zoonotic diseases globally. Urban slum communities in tropical developing countries are especially vulnerable to the disease because of low socioeconomic status, increased exposure to contaminated environments, and the lack of sanitation infrastructure. Yet, our understanding of the transmission of the disease in these high-risk settings is very limited. Here, we performed a retrospective longitudinal study and an environmental survey of the pathogen in an urban slum in Salvador (Brazil). We enrolled a cohort of 728 young residents (aged 5-18) and followed them for 5 years. Serum samples were tested annually for *T. gondii* IgG antibodies with an enzyme immunoassay. We collected information on demographic and social status, household environment, and household related behaviors. We also measured the occurrence of *T. gondii* by qPCR in sewage from the precarious open sewer system. The overall prevalence of *T. gondii* antibodies was 49.0% (95% CI 44.3-51.5) with a cumulative incidence of 2.9% infections (95% CI 1.9-6.5) per 1,000 follow-up events. We used binomial regression multivariate analysis to evaluate risk factors for *T. gondii* antibodies and found that males were at greater risk than females (OR 1.9, 95% CI 1.4-2.6) and seroprevalence increased with age from 23.4% (95% CI 15.0-30.2) in the 4-6-year-old

group to 64% (95% CI 54.8-69.1%) in the 16-18-year-old group. Low per capita income was an independent risk for infection and contact with sewage near the house was associated with a 96% increased risk of antibody acquisition. A one-meter increase in household elevation was associated with a 2% decrease in infection odds (95% CI 0%-3%), indicating higher risk in the lower elevation areas, which are more prone to flooding during seasonal rainfall. Furthermore, 9 of 72 (13%) sewage samples were positive for *T. gondii* with an average concentration of 3.5 ± 1.9 oocysts/L. Overall our findings indicate that urban slum dwellers are at high risk for *T. gondii* infection at young ages and that environmental exposures at the household level are a key risk factor for infection.

585

THE FECAL MICROBIOME ASSOCIATED WITH *CRYPTOSPORIDIUM*-INFECTION AND DIARRHEAL SYMPTOMS IN BANGLADESHI CHILDREN

Maureen A. Carey[1], Gregory L. Medlock[1], Sultan Uz Zaman[2], Md Jashim Uddin[1], Emtiaz Ahmed[2], Masud Alam[2], Shahnawaz Ahmed[2], Mamun Kabir[2], Jason Papin[1], A. S. G. Faruque[2], Rashidul Haque[2], William A. Petri, Jr.[1], Carol A. Gilchrist[1]

[1]*University of Virginia, Charlottesville, VA, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh*

Diarrhea is a leading global cause of morbidity and mortality in young children, and the *Cryptosporidium* parasites are the 5th leading cause of diarrhea in this population. Acute *Cryptosporidium* infection results in 50,000 deaths annually, primarily in children. Infection early in life is also associated with long term consequences like growth stunting, even in the absence of diarrheal symptoms. Here, we sought to identify the role of the microbiome in cryptosporidiosis using samples from a longitudinal birth cohort in Bangladesh. Infants were enrolled at birth and were actively monitored for diarrhea for two years. Both monthly surveillance and diarrheal stool samples were collected and tested for enteric pathogens, including *Cryptosporidium*. We conducted 16S ribosomal RNA gene sequencing on matched stools samples (time-of-detection *Cryptosporidium*-positive sample and the surveillance stool immediately prior) from 157 children infected with *Cryptosporidium*. Using univariate statistics, principal component analysis, and random forest analysis, we interrogated the relationship between the members of the microbiota, infection, and clinical outcomes. We observed high variability from child-to-child with most sequence variants in fewer than 50% of all samples. No individual bacterial sequence variant discriminated between the pre-detection and time-of-detection samples and, accordingly, no consistent microbial signature was associated with the development of cryptosporidiosis. Additionally, no members of the microbiome differentiated subclinical from diarrheal infection. Thus, the gut microbiota is highly variable in this cohort and we hypothesize that host or pathogen genetics explain variability in symptoms, not a conserved difference detectable in the fecal microbiota.

586

EVOLUTION OF THE *THEILERIA PARVA* REPEAT (*TPR*) GENE FAMILY IS CONSISTENT WITH ADAPTATION TO MAMMALIAN HOST SPECIES

Nicholas C. Palmateer[1], James B. Munro[1], Roger Pelle[2], Lucilla Steinaa[2], Vish Nene[2], Richard P. Bishop[3], Donald P. Knowles[3], Ine De Goeyse[4], Dirk Geysen[4], Ivan Morrison[5], Joana C. Silva[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*International Livestock Research Institute, Nairobi, Kenya,* [3]*Department of Veterinary Microbiology and Pathology, Pullman, WA, United States,* [4]*Institute of Tropical Medicine, Antwerp, Belgium,* [5]*The Roslin Institute, University of Edinburgh, Edinburgh, United Kingdom*

The most rapidly evolving genes in *Theileria parva* are those that form the *T. parva* repeat (*Tpr*) gene family. Each *Tpr* gene typically contains one to three complex domain structures, reminiscent of a system that has evolved because of its role in the generation of protein sequence diversity. This gene family is comprised of a tandem array of highly conserved open reading frames on chromosome 3, termed the *Tpr* locus, along with several other *Tpr* genes distributed throughout the other three nuclear chromosomes. The function of the *Tpr* genes is currently unknown. Here we characterized the genomic and taxonomic distribution of *Tpr* gene family members, under the hypothesis that their evolution will contribute to our understanding of the function of *Tpr* genes. The *Tpr* gene family is found in *T. parva* strains isolated from both cattle and the African Cape buffalo, as well as in a closely related but undescribed *Theileria* species, also found in the buffalo, called *Theileria* sp. (buffalo). Novel sequencing approaches have allowed us to generate whole genome assemblies for several *Theileria* isolates and obtain representatives of their *Tpr* gene families. In this study, we analyzed 93 nearly complete *Tpr* sequences from 12 genome assemblies, four each from three sets of *Theileria* strains: *T. parva* from cattle, *T. parva* from buffalo and *Theileria* sp. (buffalo). We found that the *Tpr* genes are organized in three main subclasses, each characterized by a different number of complex domains. All subclasses were found in the three sets of *Theileria* strains analyzed. Phylogenetic analyses showed that *Tpr* sequences often cluster based on their genomic location, with all genes that fall within the *Tpr* locus forming a monophyletic clade, suggestive of concerted evolution. Interestingly, *Tpr* alleles from *T. parva* from buffalo clustered with those from *Theileria* sp. (buffalo) rather than with those from *T. parva* from cattle, consistent with a role in host adaptation. We are currently analyzing the composition and structure of the motifs encoded by *Tpr* genes, as well as their relative transcript abundance, with the intent to better understand the protein function of the *Tpr* gene.

BEI RESOURCES: A BIOLOGICAL RESOURCE CENTER SUPPORTING NEGLECTED AND EMERGING PARASITIC DISEASES

Robert E. Molestina, Biniam Hagos, Ioana Brasov

ATCC, Manassas, VA, United States

Neglected parasitic diseases represent a major cause of morbidity and mortality across the developing world. To succeed as parasites, organisms such as *Toxoplasma gondii*, African trypanosomes, *Trypanosoma cruzi*, *Leishmania*, and *Giardia*, have evolved a series of complex strategies to evade the host immune system and establish chronic infections. In this setting, the accessibility of reference parasite strains and specialized reagents is critical to the generation of studies focused on new targets for therapeutic intervention or vaccine development. For 16 years, BEI Resources has served as a centralized repository for the advancement of infectious disease research. Our primary mission is the acquisition, authentication, preservation, and distribution of cultures and related reagents to the scientific community. Parasite strains deposited at BEI Resources are characterized using a variety of tests, including: (i) verification of viability and purity; (ii) phenotypic properties (morphology, antibiotic susceptibility); and (iii) genotypic analysis (PCR-based tests, RFLP, sequencing). Establishment of seed and distribution stocks for every strain ensures that cultures distributed to researchers are minimally passaged from the material provided by the depositor. Over the last decade, parasite resources have expanded to include *Babesia* sp., an emerging tick-borne parasite in the United States, as well as a variety of recombinant parasites expressing transgene reporters and knockout strains. Specialized reagents for parasite research include polyclonal and monoclonal antisera, purified genomic DNAs, and expression vectors. This presentation will provide an overview of the biological resources available to the parasitology researcher, the benefits of registering and depositing with BEI Resources, methods of characterization and future perspectives.

588

INTESTINAL PARASITES CAUSING DIARRHEAL ILLNESS IN KENYA

Cliff Odhiambo Philip[1], Nancy Kipkemoi[1], Janet Ndonye[1], Margaret Koech[1], Abigael Ombogo[1], Mary Kirui[1], Ronald Kirera[1], Erick Kipkirui[1], Elizabeth Odundo[1], Brook Danboise[2], Christine Hulseberg[3], Stacey Bateman[4], Alexander Flynn[1], Brett Swierczewski[5]

[1]*Kenya Medical Research Institute/U.S Army Medical Research Directorate-Africa, Kericho, Kenya,* [2]*University of Michigan Medical School, Michigan, MI, United States,* [3]*US Army Medical Research Institute of Infectious Diseases, Fort Detrick, MD, United States,* [4]*Madigan Army Medical Center, Tacoma, WA, United States,* [5]*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

Kenya is among the developing countries where diarrheal illness is a significant source of morbidity and mortality. We identified intestinal parasites circulating in Kenya through an ongoing case-control study titled "Surveillance of Enteric Pathogens Causing Diarrheal Illness in Kenya" to determine incidence of parasites among cases presenting with diarrhea and asymptomatic controls of all ages as well as co-infection with other enteric pathogens. Stool samples collected from 6,252 subjects enrolled from September 2009 to February 2019 were concentrated using Mini Parasep® SF Fecal Parasite Concentrators (Apacor). Microscopy was conducted by wet preparation for identification of intestinal parasites. Modified acid-fast staining was used for detection of *Cryptosporidium* spp, *Cyclospora* spp and *Isospora* spp. Parasites were detected in 29% of the subjects. The most common parasite detected was *Blastocystis hominis* (29%) followed by *Giardia lamblia* (25%), *Entamoeba coli* (15.6%), *Ascaris lumbricoides* (8.3%) *Endolimax nana* (6.2%), *Cryptosporidium parvum* (5.3%), *Entamoeba histolityca/dispar* (3.6%), *Chilomastix mesnili* (3.5%) and *Iodomoeba bustchlii* (3.0%). Of these positive identifications, 57% were from asymptomatic controls as opposed to 43% from symptomatic cases (p value <0.0001) except for *C. parvum and I. bustchili*, which were detected significantly more in cases than in controls (p-value <0.0001). *A. lumbricoides* and *G. lamblia* were also detected more in cases than in controls though the difference was not significant (p value = 0.748, p value = 0.6288 respectively). Most parasites were identified more in female subjects than in male subjects (55% vs 45%, p value <0.0001). Parasites were detected in 51% subjects over 5 years and 49% in those under 5 years (p value <0.0001). Co-infections were 13% with bacterial-parasite (43% and 57%), 15% two parasites (58% and 42%) and 11% viral-parasite (66% and 34%) among controls and cases respectively. This information will add to the public health knowledge on intestinal parasites circulating in Kenya, help in placing mitigation measures to curb infection and reduce disease burden.

589

COMPARISON OF CONVENTIONAL AND IT MOLECULAR METHODS OF DETECTION OF HAEMOPARASITES FROM NIGERIAN CATTLE

Anise Nkenjop Happi[1], Olawale Osifade[1], Paul E. Oluniyi[2], Bamidele N. Ogunro[1]

[1]*University of Ibadan, Ibadan, Nigeria,* [2]*Redeemer's University, Ede, Nigeria*

Current diagnostic practices for haemoparasites are restricted to light microscopy and clinical examinations in most sub-Saharan African countries. This study was designed to investigate the haemoparasites of cattle in Ibadan, Nigeria with a comparative evaluation of both LM and PCR methods. Blood samples from 100 cattle slaughtered at Ibadan abattoirs, revealed a total infection rate of 34% including *Hemoplasma spp* (17%), *Anaplasma spp* (16%), microfilaria (5%) and *Trypanosoma spp* (12 %) by LM. While, 86% positivity was recorded with PCR amplification targeting the 16S and 18S rRNA genes of selected haemoparasites DNA, such as *Hemoplasma spp* (64%), *Babesia/Theleiria spp* (46%) and *Anaplasma/Ehrlichia spp* (5%). Comparison of LM and PCR analyses showed that no LM *Anaplasma spp* positive samples and 7 out of the 17 LM hemoplasma positive cows were confirmed by PCR. In addition, LM led to misdiagnosis of 46 *Babesia/Theleiria spp* positive samples. Amplicon sequencing with phylogenetic analysis of *Babesia/Theileria spp* positive samples revealed *Theileria velifera Theileria annulata* and for the first time in Nigerian cattle, *Theileria lestoquardi*. While in the *Anaplasma/Ehrlichia spp* positive samples, only *Anaplasma marginale* was characterized. *Mycoplasma wenyonii,* and for the first time, "*Candidatus* Mycoplasma haemobos" and *Pseudomonas fluorescens* were chracterized among the hemoplasma-infected cattle. The first report of "*Candidatus* Mycoplasma haemobos", *Pseudomonas fluorescens* and *Theileria lestoquardi* in Nigerian cattle is herewith documented. The alarming LM misdiagnosis of haemoparaites during this study shows its limitations as it fails to identify many parasites and emphasizes the need for inclusion of molecular techniques in their detection. The study also shows for the first time the high prevalence of haemotropic mycoplasma in Nigerian cattle via molecular diagnostic techniques.

590

USE OF A NEW TRICHROME STAIN FOR RAPID IDENTIFICATION OF CYSTS AND TROPHOZOITES OF *COLPODELLA* SP. (APICOMPLEXA)

Tobili Y. Sam-Yellowe, Kush Addepalli

Cleveland State University, Cleveland, OH, United States

Colpodella sp. are free-living protists, closely related to parasites of the apicomplexan phylum. Recently, *Colpodella*-like parasites infecting human red blood cells were reported in a patient with low natural killer cells and anemia. An additional tick borne *Colpodella* sp. human infection was reported in a patient with neurological symptoms. *Colpodella* sp. DNA was identified in the patient's cerebrospinal fluid (CSF) and in "host-seeking" *Ixodes persulcatus* ticks. *Colpodella* sp. although free-living may have the potential to be an opportunistic human pathogen transmissible by different routes. Clear differentiation of cysts belonging to each protist could not be achieved in previous studies using Giemsa staining. The life cycle stage initiating infection in humans is unknown. In this study, we developed a trichrome staining technique that differentiates cysts of both *Colpodella* sp. (ATCC 50594) and its prey *B. caudatus*. Mature *Colpodella* sp. cysts with developing trophozoites were identified by staining, revealing encystation steps in the life cycle not previously described. Morphological features of the different stages of the encystment process were identified by staining. Mitotic processes resulting in two-stage and four-stage juveniles within cysts were identified in *Colpodella* sp. Developing cysts of *B. caudatus* possessd small cytoplasmic vesicles unlike in *Colpodella* cysts. Calcofluor White staining also showed cyst differentiation between *Colpodella* sp. and *B. caudatus*. Based on the appearance of the internal and external features of the cysts, we investigated actin distribution in both predator and prey using a fluorescent actin probe and found that actin localized diffusely over the cell bodies of trophozoites and cysts of both *Colpodella* sp. and *B. caudatus.* Long filaments of actin were not observed. However, in some developmental stages, short rows of filaments were observed on trophozoites. Staining and fluorescence protocols used in combination can provide important insights regarding the life cycle of *Colpodella* species and allow for rapid detection and verification of *Colpodella* sp. in human infections.

591

AN UPDATE ON THE ROLE OF IMAGING IN THE CARE OF PATIENTS WITH SCHISTOSOMIASIS

Celine Lecce[1], Leila Makhani[1], Shveta Bhasker[1], Christian Lecce[1], Jason Kwan[1], Michael Klowak[1], Priyanka Challa[1], Anjola Ogunsina[1], Osaru Omoruna[1], Kimberley Marks-Beaubrun[1], Zachary Corso[1], Rachel Lau[2], Andrea Boggild[1]

[1]*Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada,* [2]*Public Health Ontario, Toronto, ON, Canada*

Schistosomiasis leads to significant morbidity and mortality worldwide. Infection with *Schistosoma mansoni* and *S. japonicum* can lead to severe hepatic disease including periportal liver fibrosis and portal hypertension. Previous studies recommend the use of abdominal imaging to detect early hepatic changes and improve disease outcome. However, there are no recently published or authoritative resources to guide the use of imaging in the initial diagnosis of schistosomiasis. We searched available literature regarding the role of imaging in the evaluation of patients with schistosomiasis and aim to synthesize clinical recommendations. Eight electronic databases were searched: Ovid Medline, EMBASE, Cochrane Library of Systematic Reviews, Epistemonikos, Global Health, NICE, TRIP and LILACS with the following search terms: [Schistosomiasis OR (Schisto* AND (mansoni OR japonicum))] AND [CT OR (computed AND tomography) OR Ultraso* OR Sonogr* OR MRI OR (Magnetic AND resonance AND Imaging) OR Echo OR Imaging] AND [Liver OR periportal OR peri-portal OR fibrosis OR hepat* OR echogenic* OR (portal AND hypertension)] from database inception to February 28, 2019. A total of 2977 articles were identified: 691 articles on Ovid Medline, 30 Cochrane, 1035 Embase, 10 Epistemonikos, 516 Global Health, 34 NICE, 529 TRIP, and 132 LILACS. A total of 1933 articles remained for title screening after de-duplication. Titles, abstracts and full-texts were systematically double-screened by two reviewers and a tertiary arbitrator. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) was employed. Two reviewers performed data extraction and quality of the studies was assessed with the Grading of Recommendations Assessment, Development and Evaluation (GRADE). Data were summarized using qualitative and quantitative measures to evaluate the role of imaging in the clinical management of schistosomiasis. Synthesizing the current literature on abdominal imaging in the evaluation of schistosomiasis can translate into clinical recommendations for improved risk stratification and overall management of schistosomiasis.

592

SCHISTODETECT™: DEVELOPMENT OF A RELIABLE AND SENSITIVE RAPID DIAGNOSTIC TEST FOR *SCHISTOSOMA JAPONICUM* INFECTION IN HUMANS

Jose Ma. M. Angeles[1], Yasuyuki Goto[2], Lydia R. Leonardo[1], Dindo Reyes[3], Kharleezelle J. Moendeg[4], Minh Anh Danh Trinh[4], Elena A. Villacorte[1], Pilarita T. Rivera[1], Masashi Kirinoki[5], Yuichi Chigusa[5], Raymond L. Houghton[3], Shin-ichiro Kawazu[4]

[1]*Department of Parasitology, College of Public Health, University of the Philippines Manila, Manila, Philippines,* [2]*Laboratory of Molecular Immunology, Department of Animal Resource Sciences, Graduate School of Agricultural and Life Sciences, The University of Tokyo, Tokyo, Japan,* [3]*InBios International Inc., Seattle, WA, United States,* [4]*National Research Center for Protozoan Diseases, Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Hokkaido, Japan,* [5]*Department of Tropical Medicine and Parasitology, Dokkyo Medical University School of Medicine, Mibu, Tochigi, Japan*

Zoonotic schistosomiasis continues to be a public health problem in Asian countries including China, the Philippines and Indonesia. Improving the diagnostic tools for surveillance in areas which have reached elimination level will help hasten the possible elimination of this disease. There is a critical need therefore for a rapid, low cost and highly sensitive point-of-care test (POCT) for the detection of specific antibodies in individuals infected with *Schistosoma japonicum*. For the development of the POCT, several schistosome proteins were screened for their antigenicity using different serum panels (negative non-endemic and endemic samples, microscopy/PCR positive samples). ELISA results showed that 5 antigens, thioredoxin peroxidase SjTPx-1, phytochelatin synthase SjPCS, major egg protein fragment Sjp40M tandem repeats Sj7 and Sj11, provided above 70% detection rate. SjTPx-1 and Sj7 showed the highest sensitivity and specificity. Analyses on responses of schistosome-infected individuals to these antigens suggested that SjTPx-1, the best antigen, can be complemented by other antigens for better diagnostic performance. Out of these antigens, 6 fusion proteins were constructed and produced for serological evaluation. ELISA results showed that SjTP7 (SjTPx-1, SjPCS and Sj7 fusion) and SjT47 (SjTPx-1, Sjp40M and Sj7 fusion) have the highest diagnostic potentials among the fusion proteins. However, as compared to the single antigens, SjTPx-1 remained to be the best antigen for the diagnosis of human schistosomiasis. Optimization of different formats of the rapid test kit was done using sera obtained from screening in an endemic municipality in the Philippines. It was concluded that the best working format for the rapid test involves SjTPx-1 antigen. Overall, it was concluded that SjTPx-1 alone is not effective in rendering the rapid test sensitive. Future efforts should focus on generating recombinant fusion proteins with improved yields and robust performance in the rapid test format.

593

DEVELOPMENT OF A SENSITIVE, QUANTITATIVE PCR ASSAY FOR THE DETECTION OF *SCHISTOSOMA MANSONI* TO AUGMENT STOOL SURVEYS FOR STH

Kareen Seignon, Jessica R. Grant, Nils Pilotte, Steven A. Williams

Smith College, Northampton, MA, United States

Schistosomiasis is a neglected tropical disease (NTD) that affects more than 200 million people globally. The causative agents of this infection in humans are the parasitic nematodes *Schistosoma mansoni*, *Schistosoma haematobium* and *Schistosoma japonicum*. Among other factors, the success of MDA relies on good diagnostic tests to identify endemic regions and to monitor the progress of MDA campaigns. Since we have already developed a series of qPCR tests that are exquisitely sensitive and species-specific for all of the soil-transmitted helminth (STH) parasites using a novel bioinformatics pipeline, it was logical for us to use the same approach to develop a quantitative, real-time PCR diagnostic assay for *S. mansoni* to add to our STH battery of tests for use in the large-scale stool surveys in which we participate. This bioinformatics pipeline uses a novel tool, RepeatExplorer, to identify highly repetitive DNA elements in the genome of any eukaryote. We have already used this approach to successfully develop qPCR assays for *Necator americanus*, *Ancylostoma duodenale*, *Ancylostoma ceylanicum*, *Trichuris trichiura*, *Ascaris lumbricoides* and others. The same method was applied to both *S. mansoni* and *S. haematobium* to design primers and probes to target these important parasites. Using DNA isolated from *S. mansoni* and *S. haematobium* specimens obtained from the Natural History Museum (London, UK), two new qPCR tests were designed and optimized. In addition to testing the assays on purified DNA, a spiking study was also performed to demonstrate the sensitivity and specificity of the assays on human stool samples with *S.mansoni* and *S. haematobium* eggs added in various concentrations. Next steps include a field study in Uganda to assess the use of these assays in parallel with our existing STH tests.

594

ACCEPTABILITY AND FEASIBILITY OF HOME-BASED GENITAL SELF-SWAB SAMPLING FOR THE DIAGNOSIS OF FEMALE GENITAL SCHISTOSOMIASIS IN ZAMBIA: LESSONS LEARNT FROM THE BILHARZIA AND HIV (BILHIV) STUDY

Comfort Rutty Phiri[1], Amy Sturt[2], Emily Webb[2], Isaiah Hansingo[3], Kwame Shanaube[1], Richard Hayes[2], Helen Ayles[1], Amaya L. Bustinduy[2]

[1]*Zambart, Lusaka, Zambia,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*Livingstone Central Hospital, Livingstone, Zambia*

The Bilharzia and HIV (BILHIV) study recruited women from two sites in Zambia from the Population Cohort of the HIV prevention trial HPTN071. The aims of the study were to assess the validity, acceptability and feasibility of self-sampling collection methods for the diagnosis of female genital schistosomiasis (FGS). BILHIV Community Workers (BCWs) delivered household based study activities for all sexually–active, non-pregnant women aged 18-31, including home-based education for urine, vaginal and cervical swabs self-collection. Vaginal lavage was performed at the cervical cancer clinic by a midwife and urine microscopy was performed onsite. Egg-patent infections were treated with praziquantel. From January to August 2018, 603 women were enrolled and 527 completed clinic follow up (87.4%). Median age was 24 years (range 22-28). Over half of participants (60.4%, 364/603) completed secondary school education. The majority of participants indicated that self-collection of specimens was "easy" or "very easy" on a 5 point Likert scale: urine 96.2% (580/603), vaginal swab 94.9% (572/603), cervical swab 86.6% (522/603). High proportions of women would be willing to self-collect the following specimens again in future: urine 96.2% (580/603), vaginal swab 96.7% (583/603), cervical swab 96.5% (582/603). The majority reported that vaginal specimen self-collection (93.0%, 561/603) and cervical sampling was not painful (83.6%, 504/603) and would recommend self-sampling to a friend (95.7%, 577/603). Self-sampling at home was preferred over provider-based sampling in the clinic due to: greater privacy (58.5%, 353/603), convenience (46.3%, 279/603) and lack of transport (15.9%, 96/603). Home based self-specimen collection for FGS diagnosis in women ages 18 - 31 years was highly acceptable, with the majority of participants reporting specimen self-collection to be easy/very easy with high willingness to participate in future home-based self-sampling. Results can inform future efforts for community-based diagnosis of FGS.

595

SPECIFIC NUCLEIC ACIDS LIGATION FOR DETECTION OF SCHISTOSOMES: SNAILS

Alexander J. Webb[1], Toby Landeryou[2], Richard Kelwick[1], Fiona Allan[2], Aidan Emery[2], Kirsten Jensen[1], Michael Templeton[1], Paul S. Freemont[1]

[1]*Imperial College London, London, United Kingdom,* [2]*Natural History Museum, London, United Kingdom*

Over 200 million people worldwide are affected by the parasitic infection Schistosomiasis. Fluke worms of the *Schistosoma* genus are the causative agents, with infection only occurring when the cercarial larvae penetrate the hosts' skin barrier. Transmission of the fluke worms occurs via contact with water that is contaminated by infected faeces or urine, where snails, which act as the parasites intermediate host, are also present. To help break the infective cycle of this parasite, point-of-care diagnostics are desirable to help identify infection hot spots as well as monitor and survey sites undergoing control measures. Using a synthetic biology approach, we have systematically designed and developed a new DNA-based biosensor to detect for schistosomes. Our recently developed technology is a DNA-specific molecular probe-based biosensor that can distinguish between schistosome species by targeting specific regions in mitochondrial genomes. Here, we report on the specificity and sensitivity of the biosensors, and show how we envision this biosensor could be used *in situ*.

596

PATHOLOGICAL EFFECT OF URINARY SCHISTOSOMIASIS AMONG SCHOOL CHILDREN IN AN ENDEMIC COMMUNITY OF SOUTHWESTERN NIGERIA

Adeyinka Samuel Adedokun[1], Olusola Ojurongbe[1], Akeem Akindele[1], Segun Akindokun[2], Temitope Bello[1], Victor Oyedepo[2], Johnson Ojo[1]

[1]*Ladoke Akintola University of Technology, Nigeria, Ogbomoso, Nigeria,* [2]*Ladoke Akintola University of Teaching Hospital, Nigeria, Osogbo, Nigeria*

Urinary schistosomiasis continues to thrive in most endemic countries of Africa despite continued drug intervention. Organ pathological changes are rarely investigated during intervention due to the fact that the current and proposed control strategies in endemic communities exclude investigation of pathological effect of the disease. Several association studies have infact linked the disease with debilitating medical conditions. This study therefore determines the prevalence and investigates organ pathological effect of the disease in Nigerian children. Urine specimens were collected from 625 children and examined using the filtration technique. Organ pathological changes were investigated using a portable ultrasound machine, and the World Health Organization method was used for lesions classification scoring. The prevalence of urinary schistosomiasis was 41.8% (261/625), a higher prevalence was recorded in males (52.7%) compared to females (47.3%). Age group 11-15 years recorded the highest prevalence of 48.6%. The pathologic effects recorded in the studied population include, bladder shape distortion (6.7%), bladder wall irregularity (24.3%), bladder wall thickening(41.4%), pseudopolyp of the bladder wall (1.3%) and massing of the bladder wall (2.9%). Moderate dilation of the right and left pelvis of the kidney was recorded in 25 (10.5%) of children. Pathological effects were more commonly seen among males than female, and among children within 11-15yrs old. In conclusion, prevalence of urinary schistosomiasis in this study was high. The pathological changes observed were focal and the affected schistosomiasis positive children were few. Deliberate and targeted intervention must be ensured to limit morbidities/mortalities due to the disease by ensuring continued drug intervention. Ultrasonography should be included as part diagnostic tool in endemic communities.

597

SCHISTOSOMIASIS ASSOCIATED WITH ADVANCED STAGE DUODENAL ADENOCARCINOMA

Daniel A. Welder, Clare McCormick-Baw, Megan Wachsmann, Zhikai Chi, Dominick Cavuoti

UT Southwestern Medical Center, Dallas, TX, United States

Here, we report a case of schistosomiasis associated with stage IV primary duodenal adenocarcinoma. A 41-year-old African American male presented to the ED with complaints of abdominal pain, weight loss, and decreased appetite over one month. He immigrated from Zimbabwe 10 years prior, and most recently visited 4 months ago. His past medical history is non-contributory. He was found to have microcytic anemia (Hgb 9.3, MCV 77.0), pneumonia, and focal small bowel dilation with thickening and inflammatory changes on abdominal CT. Endoscopy revealed a large, villous, infiltrative mass in the third portion of the duodenum. On histologic examination of the biopsy specimen, viable *Schistosoma* eggs were seen within the lamina propria of the duodenal mucosa and associated with adenocarcinoma. *Schistosoma mansoni* eggs were identified on stool ova and parasite exam, and serology was positive for *Schistosoma* IgG antibody. This case is an unusual presentation in the US in that viable ova are typically not seen, and *S. mansoni* is more likely to involve the colon rather than the small bowel. Identifying the parasite has important implications. Although this may be an indolent infection in immunocompetent hosts, in this case immune suppression is impending due to concomitant malignancy. Furthermore, there is evidence that *Schistosoma* infection may down-regulate the immune response by inducing M2 differentiation of macrophages, which has been associated

with a microenvironment favorable to malignancy. It has also been shown that *S. mansoni* is a risk factor for hepatocellular carcinoma and colonic adenocarcinoma, possibly by altering p53 activation.

598

EVALUATION OF OCCUPATIONAL RISK FOR *SCHISTOSOMA MANSONI* AND CHANGING PARASITE POPULATION STRUCTURE IN AGRICULTURAL WORKERS IN SALVADOR, BAHIA

Pedro Santos-Muccillo[1], João R. Cruz[2], Luciano K. Silva[1], Ronald E. Blanton[3], Mitermayer G. Reis[1], Lúcio M. Barbosa[2]

[1]*Oswaldo Cruz Foundation, Salvador, Brazil,* [2]*Bahiana School of Medicine and Public Health, Salvador, Brazil,* [3]*Case Western Reserve University, Cleveland, OH, United States*

In 2011, we described a group of local agricultural workers who showed a higher risk of infection and parasite load than the general population, suggesting an occupational risk. This study aims to evaluate the distribution, prevalence and intensity of Schistosoma mansoni infection in all local agricultural workers. All known urban gardens identified in 2013 were revisited in 2019, and all workers were invited to answer a questionnaire and provide stools. One stool was examined by Kato-Katz test on 2 slides. Participants positive for schistosomiasis were treated with praziquantel and other helminths were treated with albendazole. Of the 43 existing gardens in 2013, 18 remain active in 2019. They are distributed in 4 of 12 sanitary districts and scattered among 6 neighborhoods. Thirty-five agricultural workers were interviewed. S. mansoni infection was found in 22% (4/18) the workers. The majority were male (82.8%) with a mean age of 49.9 ± 15.1 years. Most (77.1%) were born outside of Salvador and lived 58.2 ± 22.9 % of their lives in the city. About 40% indicated a history of schistosomiasis, and of these, only one (7.1%) reported never being treated. Almost 70% were illiterate or did not finished elementary school. All reported having contact with surface water during work. Among workers, 33 were in the parasitological survey, with schistosomiasis prevalence of 18.2% (6/33) and mean parasite load of 224 ±149 eggs per gram of feces. A higher prevalence than the municipal average (2%). Our results indicate an occupational risk for some of the gardens in Salvador. To evaluate the local risk level, these sites will be studied and treated longitudinally every 3 months for 6 months. The parasite´s population structure, pre- and post-treatment, will soon be evaluated to better understand local transmission.

599

INCREASED SERUM CONCENTRATION OF IL-5 AND IL-17 DURING ACUTE FASCIOLIASIS IN CHILDREN LIVING IN HIGHLY ENDEMIC AREA IN CUSCO, PERU

Catalina Aron[1], Martin Montes[1], Maria L. Morales[1], Martha Lopez[1], Miguel Cabada[2]

[1]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [2]*University of Texas Medical Branch at Galveston, Galveston, TX, United States*

Fasciolasis is an infection caused by the trematode *Fasciola hepatica* with a worldwide distribution, with high burden in the highlands of Peru. Children under 15 years of age usually represent the population with the highest rate of infection. There is limited information regarding the immune response to *Fasciola hepatica* in children. The purpose of this study is to describe the cytokines involved during fascioliasis infection in children living in endemic areas during different states of the infection. We used stored serum samples from 33 children who lived in communities in Cusco region of Peru. 18 were male and 15 female, with ages ranging from 4 to 15 years old. Children were selected from a previous cross-sectional study of socioeconomic factors associated with *Fasciola hepatica* among children from 26 communities of the Cusco region of Peru. Subjects were classified into three groups, according to stage of disease: acute fasciolasis defined as eosinofilia, positive Fas2 EIA and absence of fasciola eggs in stool; chronic fasciolasis with high egg burden (over 100 eggs per Kato Katz sedimentation test), and a control group with no evidence of disease. We used a cytometric bead array assay to measure TNF-a, IFN-g, IL-2, IL-4, IL-6, IL-10 and IL-17 protein levels. We also determined IL-5 concentrations by EIA method. There was no significant difference in the levels of IL-2, IL-4, IL-6, IL-10, TNF-a and IFN-g between groups ($p > 0.05$, Kruskall-Wallis). However, children with acute infection had higher levels of IL-5 compared with children with chronic infection (median 1.77 vs 0.06 pg/ml, $p < 0.01$, Mann-Whitney). Furthermore, children with acute infection also had higher levels of IL-17 compared to children with chronic infection (median 1.51 vs 0 pg/ml, $p=0.04$, Mann-Whitney). This is the first study of the immune response to fasciolasis in children, comparing acute vs chronic infection. Previos studies in rat model showed mixed cytokine responses during reinfection, or attenuation of Th17 response. Further studies are needed looking for antigen-specific T-cell responses to elucidate the role of Th17 during human fasciolasis.

TROPICAL DISEASES RELATED TO WATER AND SANITARY RESILIENCE IN THE MUNICIPALITIES OF ATHIEME AND GRAND-POPO IN SOUTHWEST OF BENIN

Anselme Kpominanon Sede

UAC/LACEEDE, Abomey-Calavi, Benin

The observation in the Athieme-Grand-Popo study area shows the presence of the Mono river, the sea, the marigots and the lowlands, which make these neighboring communities a wetland. Populations often use river water, ponds and backwaters to meet a variety of human concerns. That is not without consequences on their state of health. Therefore, they develop coping strategies (water treatment by elaborate techniques, traditional treatment of diseases) to fight against pathologies related to water. According to health statistics, malaria, schistosomiasis and gastroenteritis are respectively the dominant waterborne diseases in the study area. The objective of this study is to analyze the effectiveness of the control strategies developed by the populations against the waterborne and aquatic diseases, for the reinforcement of the health security measures of the local populations. This makes it possible to understand the level of resilience of population health in relation to the adaptation strategies they develop in their biotope. The climatological (1985-2015), physico-chemical and bacteriological (2019) data obtained before and after the water treatment were used. These data are supplemented by those from the field surveys. The Hazard Analysis Critical Control Point (HACCP) method has identified, assessed the hazards and risks involved in surface water consumption and determined the levels of control through defined strategies. The tools used are observation grids, questionnaires and maintenance guides. The results showed that the techniques used by the populations for the treatment of water do not make it drinkable. Thus, treated water continues to remain a source of disease for human health. It also emerges from this analysis that the traditional treatment of water-related diseases has reliable measurement deficiencies. The availability of drinking water and adequate health centers, the consumption of drinking water, the effective use of health centers in case of illness, the formalization of traditional medicine, are the possible strategies for a better security health.

601

SEASONAL VARIATIONS IN NUTRIENT INTAKE AND DIETARY DIVERSITY AMONG ELECTRONIC WASTE WORKERS, GHANA

Sylvia Akpene Takyi[1], Julius N. Fobil[1], Niladri Basu[2], John Arko-Mensah[1]

[1]*University of Ghana, Accra, Ghana,* [2]*McGill University, Montreal, QC, Canada*

Whereas seasonality on nutrient intake and dietary diversity has been studied in children and female adults, particularly pregnant women; to the best of our knowledge, no dietary assessments have been conducted among electronic waste (e-waste) workers who are widely believed to be exposed to complex mixtures of trace, essential and rare earth elements that are likely to influence nutrient mobilization and their ultimate

metabolism. This study examined the seasonal variations in nutrient intake and dietary diversity among e-waste workers and a control population to inform of their nutritional status. E-waste workers (142) and controls (64) aged between 18 to 55 years were prospectively enrolled. Nutrient intake and diversity were assessed during two distinct seasons: dry and wet seasons, using a 2-day 24-hour recall and dietary diversity questionnaire. Data were analyzed using STATA 15.0, whereas Mann-Whitney and t-tests were used to examine seasonal differences in nutrient intake and diversity. Overall, median energy intake was higher in the e-waste workers (1949(1630-2299) kcal)) than in controls (1823(1507-2259)kcal) (p<0.05). Additionally, there were variations in the amount of nutrients consumed: e-waste workers consumed higher amounts of magnesium (mg), potassium (mg), vitamin A (RE) and B12 (mcg) than controls. However, these did not meet the recommended daily allowance. Furthermore, energy intake, carbohydrates, saturated fats, monounsaturated fats, omega-3 fatty-acids, cholesterol, vitamin C, potassium and phosphorous were higher in the dry compared to the wet season. Although dietary diversity scores were higher in the wet (5.08±1.13), than dry season (4.29±1.00), and higher in e-waste workers(4.93±1.22) than controls (4.67±1.44), they still did not meet the globally accepted requirements. In conclusion, seasonality exists in nutrient intake and dietary diversity of e-waste workers and may affect their nutritional status. Thus, food-based strategies are required to increase nutrient intake and diversity to improve nutritional status of e-waste workers.

602

DRINKING WATER USE BY INFANTS IN A LOW-INCOME COMMUNITY IN THE DOMINICAN REPUBLIC

John D. McLennan[1], Maria Mosquea[2]

[1]*Children's Hospital of Eastern Ontario - Research Institute, Ottawa, ON, Canada,* [2]*Servicio Nacional de Salud, Santo Domingo, Dominican Republic*

Drinking water is not required by infants who are adequately breastfed in the first months of life, however, water may be commonly given to infants, despite ongoing breastfeeding. This practice undermines exclusive breastfeeding and may expose infants to unnecessary health risks. The key objective of this study was to determine the extent of drinking water use, as well as it sources, among infants living in a low-income community in the Dominican Republic. Mothers (or alternative caregivers) of infants attending a well-baby clinic serving the studied community were systematically interviewed with a structured survey about child health practices at each check-up throughout infancy (0-12 months). The survey included questions about the frequency of use of six water sources and preparations pre-identified as the most common in the community. Data were available for 117 infants with 509 surveys (multiple surveys/infant as questions asked at each well-baby check-up). Water use from one or more sources was reported for 74% of one-month old infants and this increased with age, reaching 100% by six months of age. Five gallon bottles, exchanged for refills from local stores, were the most common water source overall and their use increased with infant age. A "special" bottled water marketed for infants was the next most common source overall and its use decreased with increasing infant age. A distant third was boiling water, which dropped as a practice with increasing infant age. Less than 5% used other sources. Greater than 75% of infants were being breastfed at each time point. Childhood diarrhea was reported at 18% of interviews and was significantly related to bottled water use, while controlling for age. Focused initiatives may be needed to encourage less early water use which may increase the extent of exclusive breastfeeding. Examining the quality of bottled water in this setting may also be needed given its extensive use in infancy and possible relationship to diarrhea.

603

FIELD TRIAL OF AN AUTOMATED BATCH CHLORINATOR SYSTEM AT SHARED SHALLOW TUBEWELLS AMONG THE MOST VULNERABLE FORCIBLY DISPLACED MYANMAR NATIONALS (FDMN) IN COX'S BAZAR, BANGLADESH

Nuhu Amin[1], Mahbubur Rahman[1], Anika Tasneem[2], Mahbub Ul Alam[1], Abul Kasham Shoab[1], Tarique Mohammad Nurul Huda[1], Md. Kawsar Alome[3], Maksudul Amin[3], Leanne Unicomb[1]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*North South University, Dhaka, Bangladesh,* [3]*Action Against Hunger, Dhaka, Bangladesh*

Point-of-use water treatments with chlorine are widely used in emergency responses because of chlorine availability, ease of use, cost-effectiveness, and residual protection in stored water. Despite considerable benefits, chlorination programmes in emergencies remain challenging because of no/lack of standard recommendation for dosing/residual chlorine levels, lack of appropriate chlorine delivery technologies, and limited research in emergencies. We conducted a small-scale field-trial to assess accuracy, and consistency of an automated chlorinator named "Zimba" in a Rohingya camp, Cox's Bazar. From August-September 2018, we selected 2 shallow tubewells, and enrolled 20 households (10 accessing each tubewell) to participate in household surveys. At baseline, field-team tested iron, turbidity, free and total chlorine from tubewell and household stored water using digital field-test kits. The Zimba was installed at the two tubewells dosing with~2.62% NaOCl. During follow-up visits, field-team tested free and total chlorine, turbidity, and iron concentration from Zimba water immediately after chlorination (N=337), household stored water (N=133), and chlorinated stored-water that the field-team placed in households in safe storage containers (N=33). At baseline, mean turbidity was 2.5 NTU, chlorine residual=0.10 ppm, and iron concentration=2.0 mg/L in household stored water. After introducing Zimba, free chlorine >0.2 mg/L was detected in all Zimba water samples (100%) collected immediately after chlorination (mean=2.12 mg/L, SD=1.12), in 24% of household stored water (mean=0.39, SD=0.90), and in 94% household stored safe storage container water (mean=1.4, SD=0.9). Zimba provided water with free chlorine >0.2 mg/L immediately after treatment and when kept in a safe storage container, but not when stored in the household's own containers. Our study suggested that Zimba has potential as a water treatment technology for humanitarian settings. Future research should explore the reasons for low chlorine concentration in the household stored water for effective water treatment, and impact on water contamination.

604

ESTABLISHING AN EFFECTIVE ENVIRONMENTAL SURVEILLANCE FOR POLIOVIRUS IN A DENSELY POPULATED URBAN LOW-INCOME AREA IN DHAKA, BANGLADESH

Md Ohedul Islam[1], Yoann Mira[2], Philippe Veltsos[2], Md Masud Alam[1], Ashraful Islam Khan[1], Sultan Uz Zaman[1], Tahmina Ahmed[1], Md Abdul Karim[1], Tania Ferdousi[1], Tuhinar Arju[1], Rashidul Haque[1], Firdausi Qadri[1], Mami Taniuchi[3]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Novel-T Sàrl, Geneva, Switzerland,* [3]*University of Virginia, Charlottesville, VA, United States*

Environmental surveillance (ES) for polio virus (PV) will play an important role in during the polio endgame as a supplement to acute flaccid paralysis surveillance to detect PV. In low income countries such as Bangladesh, there are many challenges to setting up an effective ES due to frequent migration of people, lack of accurate census and under-developed sewer network. In this study, we established ES in a densely populated urban low-income area of Mirpur (approximately 8.6 sq km), Dhaka to track Sabin 1 and 3 viruses after a supplemental immunization activity with bOPV for children under 5. Access to recent census and sewage/drainage system maps were limited. We developed Open Data Kit (ODK) Collect based forms for smart phones to digitally collect data for blue lines of the sewage/drainage lines and household demographic surveillance system

(HDSS). Close clustering of buildings resulted in interferences and limited line-of-sight for the smart phone GPS to access enough satellites for accurate readings. Subsequently, we replaced digital blue line tracing to physically walking and tracing the sewage/drainage lines throughout our study area using a physical paper map followed by manual digitization using QGIS tool. Forty field workers utilized the HDSS ODK forms to collect GPS location of the household, building and household information, children under 5 years of age and their vaccination status. HDSS data captured a total population of 209,637 of which 19,156 are children under 5 years of age. Novel-T developed an interactive map of the study area using the blue lines and the HDSS data along with other available layers of geographic information such as elevation, roads, schools, hospitals, water lines and buildings. Using this map along with its built-in watershed tool and population selector, we were able to determine candidate ES sites with accurate location and catchment area.

605

KNOWLEDGE, ATTITUDES AND PRACTICES OF MOTHERS REGARDING CHILDREN'S DIARRHEA, UNIVERSITY HOSPITAL OF MIREBALAIS, HAITI, MAY-JUNE 2018

Emmanuel Fabrice Julceus, **Tania Gessie Ramilus**, Raymonde Pinchinat, Emmanuel Mathieu, Ben Bechir Beaubrun, Renault Louis

Zanmi Lasante, Mirebalais, Haiti

Worldwide, diarrhea is the second leading cause of death among children under five years of age. In Haiti, 41% of children under one year of age are affected. WHO believes that improved health behavior could reduce diarrheal disease by 35% and advocates a targeted fight against diarrhea. The objective of this study was to evaluate the knowledge, attitudes and practices of mothers attending the community health department of the University Hospital of Mirebalais (CHDHUM) on prevention and treatment of diarrhea. This study was an exploratory sequential mixed methods. Three focus group were conducted with nurses and community health workers of the CHDHUM about usual attitudes and practices of Mirebalais' mothers. A survey of mothers aged 18 and over, living in Mirebalais area, with at least one child aged two and under, attending the CHDHUM was done from May to June 2018. Questionnaires were made according to five themes from WHO recommendations on diarrhea education (vaccination, hygiene, feeding, treatment, danger signs). Transcripts were analyzed by hand with predetermined codes, quantitative data were analyzed on Epi Info using proportion and chi square test. The results of the qualitative part helped to complete the perceptions (dentition causes diarrhea) and the practices (rice water to treat diarrhea) in the questionnaire. 268 mothers participated in the quantitative part. Knowledge was insufficient or bad for 42.6% of them, worse for those who were illiterate, aged less than 30, living in rural area, or who didn't receive information about diarrhea ($p<0.05$). Attitude was right for 90.7% of the mothers, better for those who attended secondary school or university ($p<0.0001$). Practice was inadequate or harmful for 76.5% of them, worse for those who were illiterate or aged less than 30 ($p<0.05$). A wide part of the mothers had inadequate or harmful practices and insufficient or bad knowledge. Young age, illiteracy, rural area were found as risk factors. These findings can help Haitian public health authorities to better target education initiatives and adapt them to the actual knowledge, attitudes and practices of the mothers.

606

THE USE OF DIGITAL TECHNOLOGY TO IMPROVE AND MONITOR HANDWASHING AMONG CHILDREN 12 YEARS OR YOUNGER IN EDUCATIONAL SETTINGS: A SYSTEMATIC REVIEW

Sylvia K. Ofori[1], Yuen Wai Hung[2], Kamalich Muniz-Rodriguez[1], Reece J. Kakau[1], Sunmisola E. Alade[1], Kadiatou Diallo[1], Kelly L. Sullivan[1], Jessica S. Schwind[1], Benjamin J. Cowling[3], Isaac Chun-Hai Fung[1]

[1]*Georgia Southern University, Statesboro, GA, United States,* [2]*Wilfrid Laurier University, Waterloo, ON, Canada,* [3]*The University of Hong Kong, Hong Kong, China*

Hand hygiene practices are one of the most effective non-pharmaceutical interventions in reducing the incidence, morbidity, and mortality from infectious diseases, especially among children. Digital technologies are used in health-related settings to advance health and wellbeing. Systematic reviews on the use of digital technologies in hand hygiene studies have focused on healthcare workers and community-based applications. The aim of our systematic review was to identify and describe the application of digital technology utilized in hand hygiene research among children in educational settings. We searched PubMed, IEEE Xplore and Web of Science for articles in the English language in January 2019. Titles and abstracts were independently screened for articles that met our inclusion criteria. Eleven articles were found to be eligible. The outcomes measured in the studies included absenteeism, the incidence of diarrhea or respiratory infections, and handwashing frequency. Nine studies used digital technology as an intervention tool and two for monitoring purposes. Three main digital technologies were identified including computer games (n=2), videos (n=7), and video cameras (n=2). Computer games and videos were used as educational tools while video cameras were used for monitoring handwashing behavior. Studies that used computer games focused on improving the self-efficacy of children and for increasing knowledge. Videos were used mostly as a component of a package to teach children about effective hand hygiene to reduce absenteeism or illness. Video cameras were compared with in-person observation in observing students reactivity to being monitored and to observe handwashing after toilet use. The types of digital technologies found in our systematic review proved to be effective in hand hygiene studies, especially when combined with other methods over a short period of time. However, long-term effectiveness remains to be demonstrated. Novel digital technologies adopted in educational environments may aid in helping children develop sustainable handwashing behavior across a multitude of settings.

607

CLEAN WATER ACCESS IN HAITI: IMPACT OF SOURCE TYPE AND MANAGEMENT STRATEGY ON FUNCTIONALITY AND WATER QUALITY

Declan Joseph Devine[1], Neil Van Dine[2], Brian Jensen[2], Mustafa Sikder[1], Daniele Lantagne[1]

[1]*Tufts University, Medfrod, MA, United States,* [2]*Haiti Outreach, Pignon, Haiti*

Access to safe water sources is critical to reducing the rates of waterborne diseases. In 2015, only 64.2% of Haiti had access to improved sources. Additionally, improved sources are often contaminated with *E. coli*. Understanding drivers of functionality and water quality will aid decision makers to identify water source intervention priorities. Between 2016 and 2018, Haiti Outreach collected data at water sources from six departments in Haiti; including type of source, functionality, management type, and presence of *E. coli*. We completed logistic regressions to study how source type and management are associated with functionality and *E. coli*. Data were collected from 12,875 public access water sources and *E. coli* was tested at 7,137 sources. Functionality was higher among unimproved sources (97.9% functional) compared to 65.0% in improved sources. Specifically, 71.2% of protected dug wells were functional, compared to

69.2% of boreholes and 49.4% of public piped systems. Summarizing water quality results, 42.1% of improved sources and 5.5% of unimproved sources met the standard of <1 *E. coli* CFU/100mL. Specifically, over 70% of borehole samples had <1 *E. coli* CFU/100 mL, compared with 25.9% of public piped systems and 23.4% of protected dug wells. Water sources managed by government water and sanitation supply committees (CAEPA) (OR 1.67, 95% CI 1.39-2.01), unsigned community committees (OR 1.48, 95% CI 1.26-1.74), and privately managed (OR 3.52, 95% CI 2.05 - 6.53) were more likely to be functional than those with no management structure. Sources managed by CAEPA (OR 2.05, 95% CI 1.53-2.74) were more likely to have <1 *E. coli* CFU/100 mL than those with no management. More engineered sources delivered safe water but were less likely to be functioning. Sources managed by accountable management structures were more likely to be functioning and produce safe water compared to public and community-based committees. These results inform: the source types and management structures that are most effective in improving access to safe drinking water in Haiti; and, the improvements in source functionality and safety needed to meet the SDGs in Haiti.

ZIKA VIRUS RNA PERSISTENCE IN SEWAGE: A NOVEL SURVEILLANCE TOOL

Aaron Muirhead[1], Kevin J. Zhu[2], Joe Brown[2], Margo A. Brinton[1], Federico Costa[3], Matthew J. Hayat[1], Christine E. Stauber[1]

[1]*Georgia State University, Atlanta, GA, United States,* [2]*Georgia Institute of Technology, Atlanta, GA, United States,* [3]*Universidade Federal da Bahia, Salvador, Brazil*

Zika virus (ZIKV) has emerged as one of the most challenging and concerning viral infections in this decade due to its association with congenital brain abnormalities and Guillain-Barré syndrome. An estimated 80% of cases of ZIKV infection are asymptomatic and symptomatic cases are difficult to detect based on symptoms alone as symptoms are shared with many other illnesses. Despite substantial advances in knowledge and understanding about ZIKV, diagnostic challenges remain in resource-limited settings where ZIKV is endemic, highlighting the need for novel and innovative diagnostic tools. The Global Polio Eradication Initiative exemplifies the critical role that environmental surveillance of waters and wastewaters has played in the eradication of a vaccine preventable disease, especially in the absence of clinically detectable cases. Limited research has explored sewage to measure transmission of non-enteric infections of global concern and no one has systematically explored the potential to use sewage to detect and analyze the spread of arboviruses such as ZIKV. To demonstrate the feasibility of ZIKV RNA detection in sewage, we examined ZIKV RNA persistence in sewage from a local wastewater treatment plant. In triplicate, we added ZIKV (MEX 1-44) (10^5/ml) to unpasteurized primary influent and stored the samples at 4°C, 25°C and 35°C for one month. We periodically extracted nucleic acids from the mixture using the QiaAmp Minelute Virus Spin Kit and measured ZIKV RNA as genomic copies via the Taqpath Zika Virus Kit. We found no appreciable decline in ZIKV RNA concentration at 4°C during the month. Based on our analysis, we estimated that 90% degradation or 1-log10 reduction of ZIKA RNA occurred after 14 days at 25°C and after 6 days at 35°C. Our preliminary work suggests that under a range of temperatures and over time, ZIKV RNA will remain stable in sewage. The evidence suggests that detection of ZIKV RNA in sewage may provide a cost-effective, community diagnostic tool that deserves further investigation as a novel surveillance approach.

WATER TREATMENT PROCESSES FOR PREVENTING TRANSMISSION OF SCHISTOSOMIASIS

Laura Braun, Lucinda Hazell, Michael R. Templeton

Imperial College London, London, United Kingdom

Schistosomiasis infection occurs through contact with cercaria-infested freshwater. While chemotherapy with praziquantel can have immediate beneficial effects, reinfection can occur rapidly if people are re-exposed to contaminated water. As schistosomiasis control targets become more ambitious and we move towards elimination, interest is increasing in the potentially complementary roles of water, sanitation, and hygiene (WASH) interventions. These may disrupt transmission of the parasite, thereby reducing the likelihood of reinfection following treatment. Water treatment for schistosomiasis control seeks to eliminate viable cercariae from water but the information available to-date about the effectiveness of water treatment processes against cercariae is limited and incomplete. As part of the WISER: Water Infrastructure for Schistosomiasis Endemic Regions project (www.wiserschisto.com), experiments were conducted in the UK, Ethiopia and Tanzania to test the effectiveness of chlorination, sand filtration, and ultraviolet disinfection against schistosome cercariae. *Schistosoma mansoni* cercariae cultured in the Natural History Museum, London were used as well as cercariae and water samples collected from the environment. The effectiveness of each of the treatment processes was examined individually. Guidelines have been produced to enable the design of household and community scale water treatment infrastructure that will help minimise re-exposure to unsafe water by providing safe facilities for water contact activities. This work is very timely considering the recent publication of the World Health Organization's toolkit for WASH and Neglected Tropical Disease (NTDs) programmes, as these two communities come together to find lasting solutions for combating schistosomiasis.

610

ULTRAVIOLET DISINFECTION OF SCHISTOSOME CERCARIAE IN WATER USING ULTRAVIOLET LIGHT EMITTING DIODES

Lucinda Hazell, Michael R. Templeton

Imperial College London, London, United Kingdom

Schistosomiasis is transmitted through skin contact with water containing cercariae, the human infectious stage of the parasitic helminth *Schistosoma spp*. The disease can be treated with a single dose of praziquantel and preventative chemotherapy has been successful at reducing the global health burden. However reinfection is common and hotspots, where prevalence remains high in spite of chemotherapy, persist. Treating water so that it is free from cercariae and can be safely used for contact activities such as laundry and bathing may help to prevent reinfection, but there are no formal guidelines for household or community scale water treatment for inactivating schistosome cercariae. Ultraviolet (UV) light is widely used for water disinfection in Europe, Asia, and the United States, but it is often seen as incompatible with low income settings due to the input energy requirements of conventional mercury source UV lamps. However, the emerging technology of UV light emitting diodes (UV-LEDs), which have considerably lower energy requirements and can be powered by battery or solar cells, may make UV disinfection a realistic option for remote communities in the near future. The literature suggests a relatively low UV fluence of 5-27 mJ/cm^2 is required to achieve a 1-2 log reduction. However, the majority of studies were carried out before the standard protocol for calculating fluence was introduced in 2003, and the data is insufficient to provide robust recommendations for practice. In this research, the UV sensitivity of schistosome cercariae was examined in accordance with the established fluence measurement protocol, using a bench scale UV-LED collimated beam device at three different wavelengths: 255 nm, 265 nm, and 285 nm. Experiments were carried out using *Schistosoma mansoni* cercariae cultured in the Natural History Museum, London along with cercariae and water samples collected from the environment in Mwanza, Tanzania and

the minimum recommended fluence to inactivate cercariae in water was determined. These results are timely, as we look towards inter-sectoral approaches for eliminating schistosomiasis as a public health problem.

611

WATER, SANITATION, AND HYGIENE (WASH) AS AGENTS OF IMPROVED SANITATION IN RURAL LIBERIA ENTREPRENEURS

Alex B. Keimbe[1], Isaac Mwase[1], Marcy Sallor[1], Jannie H. Horace[2]

[1]*Partnership for Advancing Community-Based Services (PACS), Monrovia, Liberia,* [2]*U.S. Agency for International Development (USAID), Monrovia, Liberia*

During the civil war in Liberia, much of the water and sanitation infrastructure was destroyed and has not yet been repaired or replaced. In 2017, about 42% of Liberians practiced open defecation according to the Joint Monitoring Programme. Less than 10% of the population has access to safely managed drinking water and sanitation services. In 2015, the Partnership for Advancing Community based Services (PACS) targeted 1490 rural communities in Bong, Lofa and Nimba Counties with the goal of increasing access to improved sanitation and achieving Open Defecation Free (ODF) status. A group of 280 WASH Entrepreneurs (WEs) were selected and trained to support this initiative. From 2015 to 2018, the WEs built or upgraded 19,460 individual household latrines including hand washing facilities serving an estimated 442,609 people. Additionally, the WEs installed 38,511 dish racks, 48,787 cloth lines, and 4,155 compost fences in the communities. They also constructed 90 hand-dug wells fitted with hand pumps to provide clean water to 22,500 community residents. After four years of PACS support, 82% (1225/1490) of the targeted communities were verified ODF. The ODF community members have access to improved low cost household latrines and handwashing stations. They also contribute money on a monthly basis through Village Savings and Loan (VSL) scheme set up for operation and maintenance of WASH facilities in order to ensure long term sustainability and ownership. PACS support helped rural communities build clean and healthy environments which are expected to reduce the burden of water borne diseases especially among children in these communities. As part of ongoing local capacity development, WEs will receive further training in hand pump installations, fabrication of low cost sanitation improvement products to continue the scale up and promotion of improved sanitation and clean water.

SPATIAL PROXIMITY TO WASTEWATER USED FOR IRRIGATION AND CHILDHOOD DIARRHEA IN THE MEZQUITAL VALLEY, MEXICO

Jesse D. Contreras[1], Rob Trangucci[1], Eunice E. Felix-Arellano[2], Sandra Rodríguez-Dozal[2], Horacio Riojas-Rodríguez[2], Rafael Meza[1], Jon Zelner[1], Joseph N.S. Eisenberg[1]

[1]*University of Michigan, Ann Arbor, MI, United States,* [2]*Instituto Nacional de Salud Pública, Cuernavaca, Mexico*

Wastewater reuse for agriculture is a common practice worldwide with important benefits to climate resilience and water conservation. Associations between local presence of wastewater reuse and negative health outcomes have been found in past research across the globe, but little information exists on the relevant routes of exposure between wastewater reuse and poor health. The Mexico City-Mezquital Valley system is one of the largest wastewater reuse systems in the world and has been the site of key epidemiological studies on wastewater and health. To understand the potential importance of environmental routes of exposure, we assessed the relationship between diarrheal disease in children and spatial proximity to wastewater canals using data from a longitudinal cohort study. We enrolled 581 households from communities in the Mezquital Valley that use wastewater for irrigation. A total of 1,705 surveys were completed during three rounds of interviews. Interviewers collected GPS coordinates of participating households, and local authorities provided digital maps of the wastewater canal system. The shortest distance between a study household and a wastewater canal was calculated in meters (m) using GIS software. The association between distance to a canal and diarrheal disease in children under five was estimated in a hierarchical Bayesian logistic regression model accounting for repeated observations and residual spatial correlations. To account for a non-linear association, household distance was transformed to its natural log. After adjusting for relevant covariates, living farther from a wastewater canal was associated with decreased diarrheal disease in children (100m vs. 10m OR = 0.54, 95% CI 0.37, 0.78; *e*-fold increase OR = 0.76, 95% CI 0.65, 0.90). These results suggest occupational and foodborne exposures are not the only important routes of exposure between wastewater and health, and community exposures may be driving negative health effects. Instead of only targeting specific groups, interventions should focus on whole communities to improve health where wastewater is reused.

613

MODELLING THE IMPACT OF PYRETHROID RESISTANCE ON PERSONAL PROTECTION AND THE MASS COMMUNITY EFFECT OF LONG-LASTING INSECTICIDE TREATED NETS

H. Juliette T. Unwin, Ellie Sherrard-Smith, Thomas S. Churcher, Azra C. Ghani

Imperial College, London, United Kingdom

Long-lasting insecticidal bed nets (LLIN) provide protection against malaria. Direct personal protection, which reduces exposure of users to infectious bites, is conferred by both its physical barrier and the killing and repellency action of the insecticide. Indirect mass protection for the whole community occurs due to the reduction in local mosquito population and the impact that this has on onward transmission. Standard LLIN contain a pyrethroid insecticide, but widespread resistance to this chemistry in mosquitoes may diminish both the direct and indirect impact. Piperonyl butoxide (PBO) synergises with pyrethroid insecticide to restore killing effects and are combined in PBO LLIN. We aimed to quantify the direct versus indirect effects of LLIN, and how these change as mosquito pyrethroid resistance increases. A mathematical model of *Plasmodium falciparum* transmission is used to estimate the reduction of parasite prevalence. Parametrisation of the LLIN model uses data from a systematic review of hut studies. LLIN efficacy wanes as pyrethroid resistance in local mosquitoes, measured using mosquito survival in discriminatory dose bioassays, increases. LLIN users are consistently predicted to have lower levels of malaria prevalence than non-LLIN users irrespective of the level of pyrethroid resistance. In the absence of resistance, in areas of high transmission (pre-intervention EIR of 100, 0-59 month year old parasite prevalence 56%) with 50% LLIN usage, we estimate the absolute reduction in prevalence attributed to the barrier to be 4%, the additional benefit of the insecticide to be 10% and the indirect protection to the user to be 17% (a total reduction of 31%). In non-users, the indirect reduction in prevalence is estimated to be 18%. However, when resistance is 50% the direct protection of the insecticide reduces to 8% and the indirect protection for the users and non-users reduce to 14% and 15% respectively. When PBO nets are simulated, the protection returns to pre-resistance levels. This study shows that pyrethroid resistance may diminish the protection gained from LLIN but PBO LLIN mitigate for this loss of protection.

WHOSE ARCHETYPE IS IT, ANYWAY? A MACHINE LEARNING APPROACH FOR CHARACTERIZING MALARIA TRANSMISSION SETTINGS

Amelia Bertozzi-Villa[1], Joshua L. Proctor[1], Jaline Gerardin[2], Caitlin Bever[1], Samir Bhatt[3], Peter Gething[4]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*Northwestern University, Chicago, IL, United States,* [3]*Imperial College, London, United Kingdom,* [4]*Oxford University, Oxford, United Kingdom*

Mechanistic malaria models are proving increasingly valuable to policy decision-making and assessment of new tools. Model performance

is often showcased in a range of "archetypal" transmission settings comparing low vs high seasonality, baseline transmission, and indoor biting. These archetypes are used in sensitivity analyses, to demonstrate model versatility, or to highlight varying intervention efficacy. Archetypal sites tend to be selected by convenience or represented by hypothetical locations that possess the desired properties. Each of these heuristic approaches faces a classification challenge when predicting outcomes for a new site: it is difficult to determine which archetype that new site should belong to. We present an alternative method for determining transmission archetypes *a priori* by harnessing the strength of geospatial data. Using the Malaria Atlas Project's covariate library, we assemble a database of malaria-related rasters detailing monthly climate indicators, vector species proportions, and historical ITN, IRS, and ACT coverages, all at 5km^2 pixel resolution for the continent of Africa. We apply singular value decomposition and *k*-means clustering to classify pixels into transmission archetypes. Our method identifies ten data-driven transmission archetypes, capturing a range of vector mixes and seasonality patterns across the continent. Using the agent-based model EMOD, we show that the same intervention can have drastically different effects across archetypes. A three-year intervention of moderate (40%) ITN, IRS, and ACT coverage is sufficient to eliminate in 62.1% of pixels in an archetype with high indoor biting and dual peaked seasonality, whereas that same strategy eliminates in only 48.1% of pixels in a Sahelian setting with low indoor biting and intense seasonality. We also explore novel intervention impact across settings, showing e.g. that ATSBs require a higher kill rate in some archetypes than others to be effective. This methodology is extensible to any mechanistic modeling framework across a range of diseases, and can aid in rapid outcome prediction for novel sites of interest worldwide.

MBITES: A MODELLING FRAMEWORK FOR THE STUDY OF MOSQUITO BIONOMICS AND VECTORIAL CAPACITY AS EMERGENT PATTERNS

Sean Wu[1], Héctor M. Sánchez C.[1], Biyonka Liang[1], Daniel T. Citron[2], John Henry[2], David L. Smith[2]

[1]*University of California Berkeley, Berkeley, CA, United States,* [2]*IHME, Seattle, WA, United States*

Mathematical models of malaria transmission by vectors are based on a model for the sporozoite rate first developed by George Macdonald, from which the concept of vectorial capacity (VC) was derived. VC is a parsimonious formula that maps various entomological parameters onto a metric which describes the intensity of transmission. While a useful metric, the mathematical elegance of VC obscures a large degree of uncertainty in how ecology and entomology interact in any specific setting to produce the bionomic parameters that become inputs to the formula for VC. To this end, we developed two models describing mosquito behaviors and behavioral state transitions related to malaria transmission: an individual-based model, and a system of differential equations. By partitioning the complexity of mosquito behavior into atomic units called flight bouts, each of which is taken with a specific behavioral intent (blood feeding, mating, oviposition, etc.), we arrive at a useful mechanistic description of mosquito behavior well-suited to simulation and extension. Using these models, we show how critical parameters, such as mosquito lifespan, feeding rate, and others are not just entomological constants, instead depending upon the local ecology and distribution of resources required for the mosquito life-cycle. In order to facilitate collaboration, critique, and dialogue, MBITES is being developed as an open-source R package to facilitate ease of use and understanding of code, with computationally heavy elements implemented in object-oriented C++.

616

SHAPESHIFTER: A NOVEL MODEL FRAMEWORK FOR SIMULATING INDIVIDUAL-LEVEL MALARIA INFECTION AND IMMUNE DYNAMICS

Jonathan Russell[1], Dan Goes[1], Andre Lin Ouedraogo[1], Chris Lorton[1], Isabel Rodriguez-Barraquer[2], Bryan Greenhouse[2], Edward Wenger[1], Jaline Gerardin[3], Caitlin Bever[1]

[1]*Institute for Disease Modeling, Bellevue, WA, United States,* [2]*University of California San Francisco, San Francisco, CA, United States,* [3]*Northwestern University, Chicago, IL, United States*

Targeted interventions used to interrupt malaria transmission in an endemic population depend on an accurate description of the parasite burden: who is at risk for infection, who is infectious, and what is the appropriate response given data from both active and passive surveillance measures. Sampling of parasite densities in malaria-endemic settings gives limited information on the infection and immune status of individuals. Mathematical modeling can help predict what immunological forces underly these sparse measurements. We have developed a novel mathematical model for malaria infection and immune development that functions within the context of EMOD - a highly detailed individual based stochastic model of infectious disease dynamics. Within this model framework, we represent an individual's immune status as a stochastic transition matrix from which infection trajectories are drawn. We then parametrized functions that modify this immune status using a combination of continuous, discrete, and categorical variables that characterize an individual. Next, we calibrated this model to fit both individual-level longitudinal measurements and population-level patterns as measured by cross-sectional surveys. Finally, we tested the robustness of this model in capturing malaria incidence and prevalence metrics as published in studies across a range of geographies and transmission intensities. We demonstrate the utility of this new model in addressing previously intractable epidemiological and programmatic questions in a setting with historically high endemic malaria transmission.

617

MODELING OF HEMATOLOGICAL INDICES DURING SEVERE AND UNCOMPLICATED MALARIA USING ARTIFICIAL NEURAL NETWORKS

Collins Misita Morang'a[1], Thomas D. Otto[2], Saikou Y. Bah[3], Vincent Appiah[1], Gordon A. Awandare[1], Lucas Amenga–Etego[1]

[1]*West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana,* [2]*Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom,* [3]*Vaccine and Immunity Theme, Medical Research Council Unit The Gambia at London School of Hygiene & Tropical Medicine, Banjul, Gambia*

Hematological indices alone cannot be used to classify severe and uncomplicated malaria, but their accurate interpretation could complement clinical assessments. Our objective was to use hematological indices from 2,691 samples obtained in Ghana, including non-malarial fevers (n=1135), uncomplicated malaria (n=688), and severe malaria (n=868), to identify correlates between clinical malaria outcomes and hematological indices using an artificial neural network (ANN). The data was randomly split (80:20%) to training and test data sets. For training, we used the multi-layer perceptron (a type of ANN used for artificial intelligence on big data) with two hidden layers of rectified linear units. The ANN was compiled and back-propagated using Adam optimizer in 1000 training epochs with cross-validation. Performance on the test data was inspected using accuracy and area under the curve (AUC). The predictions were further investigated by multiple comparisons between groups (P=0.05).We successfully developed three deep learning prediction models. The test accuracy of the first model was 97% (AUC 0.99) and the indices that were predicted to distinguish severe malaria from non-malarial fevers include red blood cell counts (RBC), hematocrit, platelet counts (PLT), monocyte counts, mean cell hemoglobin, and RBC distribution width (RDW) ($P < 0.0001$). Accuracy of the second model was 85% (AUC

0.928) and only PLT and RDW were predicted to distinguish uncomplicated malaria from non-malarial fevers (P < 0.001). The accuracy of the last model was 94% (AUC 0.98) and the levels of lymphocyte counts, white blood cell counts, platelet distribution width, and mean cell hemoglobin concentration (P < 0.001) can be used to distinguish between severe from uncomplicated malaria. We developed an artificial intelligence network that generates accurate classifications of hematological indices between uncomplicated and severe malaria as well as non-malaria fevers. In the future, these deep learning models will be incorporated to a tool/app to support clinical assessment during diagnosis and management of malaria cases.

618

ACCOUNTING FOR HUMAN MOBILITY IN MALARIA ELIMINATION PROGRAMS WITH HETEROGENEOUS TRAVEL DATA

Hsiao-Han Chang[1], Ayesha Mahmud[1], Daniel T. Citron[2], Caroline O. Buckee[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Institute for Health Metrics and Evaluation, Seattle, WA, United States*

Understanding the effect of human movement on malaria transmission is critical for malaria control and elimination. The movement of people between low and high risk regions has consequences for the spread and maintenance of infectious disease transmission, and modifies prospects for disease elimination. In previous work, we used mobile phone calling data, travel survey data, and parasite genetic data to infer parasite flow between populations in Bangladesh and identified the locations with high proportion of imported infections. However, we were unable to consider all the locations in the malaria endemic regions due to the lack of travel data in some areas, hindering our ability to evaluate specific intervention strategies. Here, we build a statistical model based on demographic factors to infer travel for locations that previously had missing data. We use this to parameterize a multi-patch malaria transmission model and infer vectorial capacity by fitting the model to observed incidence data. We highlight the heterogeneity in vectorial capacity across the Chittagong Hill Tract region, which has implications for control strategies. Using our model results, we assess and compare the effectiveness of different malaria elimination strategies, including vector control, mass drug administration, and focal screening and treatment. Our model results allow us to prioritize resource allocation for control efforts and identify the conditions necessary for malaria elimination in the region.

619

IMPLICATION OF SULFADOXINE-PYRIMETHAMINE RESISTANCE-ASSOCIATED MUTATIONS ON THE PROTECTIVE EFFICACY OF SEASONAL MALARIA CHEMOPREVENTION: A PHARMACOKINETIC-PHARMACODYNAMIC ANALYSIS

Gina Maria Cuomo-Dannenburg[1], Patrick Walker[1], Robert Verity[1], Matthew Cairns[2], Paul Milligan[2], Lucy Okell[1]

[1]*Imperial College London, London, United Kingdom,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

The Sahel sub-region of Africa has widely utilised seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine plus amodiaquine (SP+AQ) since the World Health Organisation recommended its use in 2012. Mutations in the *dhfr* and *dhps* genes are well documented to confer resistance to sulfadoxine-pyrimethamine (SP). In Eastern and Southern Africa, quintuple and sextuple mutations in *dhfr* and *dhps* spread during the use of sulfadoxine-pyrimethamine as a first-line treatment for malaria. Development of these mutations in the Sahel would significantly threaten the efficacy of SMC as an intervention. We are using existing population pharmacokinetic models of SP, amodiaquine and desethylamodiaquine, alongside clinical trial data to determine the relationship between resistance markers and SMC efficacy. We define the protective efficacy to be the probability of SMC preventing an infection when challenged with an infectious bite. This protective efficacy wanes with the drug concentration and we define PC50 to be the concentration achieving 50% protective efficacy. Our initial results show that in a setting with established quadruple mutation, PC50 is 1.365mg/ml and 0.131μg/ml for sulfadoxine and pyrimethamine respectively. This drug concentration occurs at approximately day 35 dependent upon pharmacokinetic factors. The analysis is being extended to include data on resistant parasites which will allow us to estimate how duration of protection will vary with age and level of resistance markers in the population. This model provides for the first time an understanding of SMC efficacy with SP+AQ informed by population pharmacokinetics and a predictive tool for protection provided based upon prevalence of resistance markers. We will determine appropriate thresholds for resistance markers below which SMC retains sufficient protective efficacy with good adherence to the regimen. This work highlights the need for ongoing surveillance of resistance markers and development of a new drug with a similar pharmacokinetic profile to replace SP+AQ as the chosen SMC drug regimen once highly resistant strains become established.

620

THE POWER OF NEXT GENERATION *PLASMODIUM FALCIPARUM* GENETIC CROSSES IN HUMAN LIVER-CHIMERIC MICE

Katrina A. Button-Simons[1], Sudhir Kumar[2], Lisa A. Checkley[1], Meseret Haile[2], Nelly Carmago[2], Catherine Jett[3], Shalini Nair[3], Marina M. White[3], Xue Li[3], François H. Nosten[4], Stefan H. Kappe[2], Timothy J. Anderson[3], Jeanne Romero-Severson[5], Michael T. Ferdig[1], Scott J. Emrich[6], Ashley M. Vaughan[2], Ian H. Cheeseman[3]

[1]*Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States,* [2]*Seattle Children's Research Institute, Seattle, WA, United States,* [3]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [4]*Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Mae Sot, Thailand,* [5]*Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States,* [6]*University of Tennessee, Knoxville, TN, United States*

Understanding the genetic architecture of complex phenotypes such as drug resistance is critical to developing effective interventions. Resistance to the anti-malarial artemisinin has been primarily associated with mutations in the *Plasmodium falciparum k13* gene and has emerged and spread in Southeast Asia. However, there is growing evidence that additional genetic mutations are involved in artemisinin resistance. Real-time, powerful genetic mapping is needed to understand this complex genetic architecture. Genetic crosses between *P. falciparum* strains are a powerful tool for mapping, but the historical requirement of a splenectomized chimpanzee to complete the *P. falciparum* lifecycle limited the isolation of unique recombinant progeny from crosses of long term culture-adapted malaria parasites. Utilizing the human liver-chimeric FRG huHep mouse infused with human red blood cells has revitalized *P. falciparum* genetic crossing experiments and quantitative genetic analysis. We demonstrate that a genetic cross can now be carried out in less than four months with lab adapted field-derived parasites isolated directly from patients. Over the past year we generated deep sequencing data for the parents and progeny of three novel genetic crosses and developed a bioinformatic pipeline to identify more than 140 unique recombinant progeny. Unlike previous crosses, our field-derived cross shows bi-parental plastid inheritance, contains minimal segregation distortion and exhibits a uniform recombination rate providing consistently high power to detect effects genome-wide. Through detailed simulations we show the increased power and improved mapping resolution that this panel of recombinant progeny will provide. We demonstrate how segregation distortion can decrease power even for qtl with large effect sizes by mapping chloroquine IC_{50} in two independent crosses, one of which includes significant segregation distortion surrounding causal mutations in the *pfcrt* gene. This innovative resource enables rapid dissection of the genetic architecture of emerging anti-malarial drug resistance with unprecedented power and accuracy.

621

UNRAVELING THE EPIGENOME OF THE HUMAN MALARIA PARASITE *PLASMODIUM FALCIPARUM*

Chengqi Wang, Samir Jahangiri, Justin Gibbons, Swamy Adapa, Jenna Oberstaller, Xiangyun Liao, Min Zhang, Rays Jiang, John Adams

University of South Florida, Tampa, FL, United States

During malarial blood infections, a hardwired regulatory program secures proper timing of gene transcription and production of functionally relevant proteins, for *Plasmodium* development and pathogenicity. Here, we reveal the critical role of epigenome in malarial development from three aspects in fundamental genome configuration, essential gene regulation and 3D genome architechture. Firstly, we discovered that *P. falciparum* genes are organized in co-expressed linear epigenetic units. We developed a hidden markov model to capture the regulatory cluster formed by adjacent genes during intra-erythrocyte development. We find more genes involved in red blood cell invasion located in same regulatory module with PfAP2-I transcription factor, demonstrating that AP2-I is responsible for regulating RBC invasion. Secondly, we have discovered the underlying epigenetic structures for essential genes in *P. falciparum*. We systematically investigated gene expression, epigenetic markers, and 3D genome configuration of *P. falciparum* essential genes by integrating genomics data with our recently published large-scale mutagenesis data. We found that essential genes form 'hubs' in the regulation network. And we used robust statistical methods to show that the euchromatin is significantly distributed along essential genes, whereas heterochromatin is associated with dispensable genes. Interestingly, we found that the repressive marker H3K36me2 is associated with lowered expression levels in certain sets of essential genes. Finally, we used higher resolution transcriptional data and chromatin conformation capture data to show essential genes tend to be co-regulated and require physical contact in 3D genome space.

622

SELECTION FOR GROUP A *VAR* GENES DOES NOT OCCUR DURING EARLY BLOOD-STAGE INFECTION IN MALARIA-NAÏVE HUMAN VOLUNTEERS

Kathryn Milne[1], Adam Reid[2], Ruth Payne[3], Navin Venkatraman[3], Mandy Sanders[3], Matt Berriman[2], Simon Draper[3], Phil Spence[1], **J. Alexandra Rowe**[1]

[1]*University of Edinburgh, Edinburgh, United Kingdom,* [2]*Wellcome Sanger Institute, Cambridge, United Kingdom,* [3]*University of Oxford, Oxford, United Kingdom*

The *Plasmodium falciparum var* gene family plays a key role in the pathogenesis of severe malaria. Parasites collected from children with severe disease in sub-Saharan Africa show predominant transcription of group A *var* genes, encoding PfEMP1 variants that bind to brain endothelial cells and form rosettes with uninfected erythrocytes. It is hypothesized that parasites expressing group A variants dominate infections in naïve hosts because they promote effective sequestration and confer a growth-advantage compared to parasites expressing group B and C variants. This hypothesis is widely accepted, but is not supported by direct evidence. Previous work using mosquito-infected human volunteers showed expression of a range of mostly group B *var* genes *in vivo*, measured 2-3 cycles after liver egress. Rapid switching or selection in favour of group A *var* genes must then occur if they are a major determinant of severe malaria. We used controlled human malaria infection (CHMI) with blood stage challenge to investigate changes in *var* gene transcription over time *in vivo*. 14 malaria-naïve human volunteers were infected with *P. falciparum* 3D7 by direct intravenous inoculation of infected red blood cells. Volunteers were followed for 7.5-10.5 days until thick smear positivity. Parasite gene expression on the day of diagnosis was assessed by RNA sequencing, and *var* gene transcription was compared to that in the starting inoculum. The inoculum showed transcription of a range of group B *var* genes, with the group A *var* gene Pf3D7_0400400/PFD00020c also detected. Surprisingly, after 4-6 cycles of growth *in vivo*, *var* gene transcription patterns were highly similar to the starting inoculum in all volunteers, with no increase in group A transcripts. The brain endothelial cell-binding group A variant Pf3D7_0400400 detected in the inoculum was not selected for in any of the volunteers, nor was there any evidence for switching towards other group A *var* genes. These data provide direct evidence against the prevailing hypothesis that group A variants dominate infections in naïve individuals because they have a growth advantage *in vivo*.

623

DEVELOPMENT OF AN *EX VIVO* HUMAN BRAIN ORGANOID MODEL TO STUDY SEVERE MALARIA PATHOGENESIS

Adriana Harbuzariu[1], Sidney A. Pitts[1], Andrew P. Shaw[2], Juan C. Cespedes[1], Keri Harp[1], Annette Nti[1], Mingli Liu[1], Jonathan K. Stiles[1]

[1]*Morehouse School of Medicine, Atlanta, GA, United States,* [2]*Georgia Institute of Technology, Atlanta, GA, United States*

Human cerebral malaria (HCM) is a severe neurological manifestation of infection with *Plasmodium* species, with high mortality occurring especially in children. We have previously demonstrated that increased intravascular erythrocyte hemolysis during parasite multiplication releases free heme, leading to blood-brain barrier leakage and neuronal injury in cerebral malaria and placental disfunction during pregnancy. Current experimental models limit translationally relevant studies of malaria pathogenesis at the level of the brain *in utero* or postnatally. Recently, human induced pluripotent stem cells (iPSC) have shown great promise as models for studying neuronal development and diseases in humans. Using iPSC approach, we have generated 3D *ex vivo* human cortical organoids to recreate a developmental heme-induced brain injury model. Our hypothesis is that heme induces human iPSCs and brain cortical organoid injury that can be attenuated by a neuroprotective factor, neuregulin (NRG-1). To test this hypothesis, we employed flow cytometry, western blot, multiplexed immunoassay procedures and immunohistochemistry to assess pluripotency, confirm neuronal and astrocyte markers including NRG-1, its receptor ErbB4, tight junction proteins, matrix metalloproteinases and apoptosis markers at various time points during cortical organoid development. Our results show that iPSCs and cortical organoids express NRG-1 and ErbB4, consistent with observations in the human brain. Heme induced iPSCs apoptosis and differentiation of iPSC at ~30 M concentration and beyond. In addition, heme reduced organoids growth and altered their architecture and structural integrity. NRG-1 attenuated the heme-induced iPSC and cortical organoid injury via ErbB4 mediated pathway. In conclusion, we demonstrate that cortical organoids can be used as a model for studying heme-induced brain injury in CM and can be used to test NRG-1 and other drugs as neuroprotective agents. This innovative model allows for investigation of CM pathogenesis, other brain disorders and hemolytic diseases and will offer new avenues for intervention.

A NOVEL *IN VITRO* MODEL OF *PLASMODIUM VIVAX* HYPNOZOITES

Araya Jivapetthai[1], Yongyut Pewkliang[1], Paviga Limudompon[1], Sreekanth Kokkonda[2], Wanlapa Roobsoong[1], Suradej Hongeng[1], Pradipsinh K. Rathod[2], Osamu Kaneko[3], **Rapatbhorn Patrapuvich**[1]

[1]*Mahidol University, Bangkok, Thailand,* [2]*University of Washington, Seattle, WA, United States,* [3]*Nagasaki University, Nagasaki, Japan*

Eradication of *Plasmodium vivax* malaria is difficult because of the ability of the parasites to form dormant liver-stage forms (hypnozoites) that tolerate most drugs and can reactivate after drug pressure dissipates. Research efforts to better understand the biology of *P. vivax* hypnozoites and design relapse prevention strategies have been hampered by the lack of a robust and reliable model for *in vitro* culture of liver-stage parasites. Here, we demonstrate an *in vitro* culture of *P. vivax* hypnozoites in a novel immortalized hepatocyte-like cell line (imHC). We also describe

the establishment of a system to quickly obtain hypnozoites by using DSM265, a chemical compound that efficiently kills only large growing liver stage parasites, not hypnozoites. The enriched hypnozoites exhibit biological characteristics of hypnozoites *in vivo*, including their reactivation from dormancy. Our *in vitro* hypnozoites model offers a significant breakthrough in the characterization of hypnozoite biology, and will facilitate the discovery of anti-relapse interventions.

625

SINGLE-CELL RNA-SEQ REVEALS TIGHTLY REGULATED CHANGES IN GENE EXPRESSION DURING THE INTRAERYTHROCYTIC LIFE CYCLE OF *P. VIVAX* PARASITES

David Serre[1], Matthew V. Cannon[1], Ramon L. Caleon[2], Thomas E. Wellems[2], Juliana M. Sa[2]

[1]*University of Maryland, Baltimore, MD, United States,* [2]*National Institutes of Health, Rockville, MD, United States*

Studies of gene expression in *Plasmodium* are complicated by the continuous developmental changes of the parasites. As a consequence, most studies of blood stage parasites have relied on synchronized *in vitro* cultures of *P. falciparum*. Since *P. vivax* cannot be continuously propagated *in vitro*, this parasite remains poorly studied and our understanding of its biology primarily derives from *P. falciparum,* without accounting for their divergence and differences (e.g., gametocytogenesis, red blood cell (RBC) preference and sequestration). Recently, single-cell RNA-seq has been applied to *P. falciparum* and rodent malaria parasites but viability requirements have precluded such studies in other *Plasmodium* species, including *P. vivax*. Here, we describe the gene expression profiles of 8,172 individual *P. vivax* parasites obtained from infections of 10 splenectomized non-human primates with four *P. vivax* strains. Our data provide, on average, information on 15,251 mRNA molecules from 1,149 genes per individual parasite, allowing evaluations of even weakly expressed genes. Our analyses confirm that multiple stages, including male and female gametocytes, are circulating in each infection, though their relative proportions vary among infections. Our findings highlight the highly specific and tightly regulated expression of most genes during the intraerythrocytic cycle (IEC): many genes are expressed only during a short developmental period and very few genes, if any, are expressed consistently. Transcripts for proteins used in RDTs show strikingly heterogeneous patterns of expression, suggesting that the presence of particular *P. vivax* stages is important for sensitive RDT detection. Stage-specific gene expression regulation is also noticeable for AP2 genes, raising the intriguing possibility that these master controllers of transcription play a key role in regulating the entire IEC. Finally, our analyses revealed that late schizonts expressed a significantly higher proportion of genes without *P. falciparum* orthologs, highlighting the differences in RBC invasion in these species and the need to specifically study *P. vivax*.

626

DEVELOPMENT OF DRUG CANDIDATES FOR CHAGAS DISEASE TARGETING THE *TRYPANOSOMA CRUZI* METHIONYL-TRNA SYNTHETASE

Frederick S. Buckner, John R. Gillespie, Nora R. Molasky, Zhongsheng Zhang, Wenlin Huang, Sayaka Shibata, Yi Liu, Erkang Fan

University of Washington, Seattle, WA, United States

Better drugs are needed to treat Chagas disease, a protozoan infection afflicting 6-8 million people primarily in Latin America. The disease is caused by *Trypanosoma cruzi* which establishes chronic infection lasting decades. The resulting cardiomyopathy (or enteropathy) is fatal in 20-30% of victims. The current antiparasitic drugs are fraught with side effects and have questionable efficacy for treating chronically infected patients. The *T. cruzi* genome contains a single methionyl-tRNA synthetase (MetRS) that is essential for protein synthesis. This enzyme is being targeted with novel inhibitors to develop leads for anti-*T. cruzi* drug development. The MetRS inhibitors were developed against the *Trypanosoma brucei* MetRS assisted by crystal structure of that enzyme bound to inhibitors. Approximately 400 compounds from a library of MetRS inhibitors have been screened against mammalian-stage *T. cruzi* cultures establishing structure activity relationships. Twenty-five compounds have been identified with EC_{50} values between 1-10 nM and another 54 in the range of 11-100 nM. These compounds are highly selective with cytotoxicity (CC_{50}) values on mammalian cells of greater than 10,000 nM in the large majority. An exemplary compound was tested in an *in vitro* washout assay (16-day exposure at 25X the EC50) and shown to have trypanocidal activity (with no outgrowth in the 60 day observation period), comparable to the clinical drug, benznidazole. The active compounds represent several distinct scaffolds within the MetRS inhibitor series and are associated with different physicochemical (e.g. LogP, solubility) and pharmacological properties. A subset of compounds has been tested in the murine acute *T. cruzi* infection model, demonstrating strong suppression of *T. cruzi* growth and 100% survival of the mice. New compounds have been synthesized with low plasma clearance and high volume of distribution (feature that are believed to be favorable for treating this tissue parasite) and will be tested in the *in vivo* efficacy model. The MetRS inhibitors represent a promising class of compounds to be developed as potential novel drugs for Chagas disease.

627

XENODIAGNOSIS OF DOGS VERTICALLY INFECTED WITH *LEISHMANIA INFANTUM* REVEALS SKIN PARASITE BURDEN AS STRONGEST CORRELATE OF CANINE INFECTIOUSNESS TO SAND FLY VECTOR

Breanna M. Scorza[1], Kurayi Mahachi[1], Erin C. Cox[1], Angela J. Toepp[1], Adam Lima[1], Anurag Kushwaha[2], Patrick Kelly[1], Claudio Meneses[3], Katherine N. Gibson-Corley[1], Lyric Bartholomay[4], Shaden Kamhawi[3], Christine A. Petersen[1]

[1]*University of Iowa, Iowa City, IA, United States,* [2]*Banaras Hindu University, Varanasi, India,* [3]*National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States,* [4]*University of Wisconsin, Madison, WI, United States*

Dogs are the primary reservoir for human visceral leishmaniasis due to *Leishmania infantum*. Phlebotomine sand flies maintain the zoonotic disease by transmitting parasites among dogs and to humans. A subset of dogs is infected during gestation, but the extent to which they contribute to the infected sand fly pool is unknown. We examined infectiousness of dogs naturally infected with *L. infantum* via vertical transmission (n=16) to the vector *Lutzomyia longipalpis* using xenodiagnosis. We also examined transmission correlates including dog age, clinical status, serostatus, and parasite burden in skin, spleen, and blood. Sand flies fed on two sites/animal for 30 min. 48 hrs post feeding, blood fed female flies were separated, DNA extracted and subject to Real Time-qPCR for detection of *Leishmania* DNA. A standard curve allowed quantification of equivalents taken up by individual sand flies. Clinical status was staged according to LeishVet guidelines based on physical exam and serum chemistry panel. We found vertically infected dogs are infectious to sand flies. Further, sand fly parasite uptake did not correlate with clinical status where dogs with moderate disease (stage 2-3) showed significantly higher transmission to the vector than dogs with mild (stage 1) or severe (stage 4) disease. Interestingly, we documented a substantial parasite burden in the skin of vertically infected dogs by RT-qPCR, despite never receiving intradermal parasites via sand flies. There was a significant correlation between skin parasite burden at the feeding site and sand fly parasite uptake ($p<0.01$), while positive xenodiagnosis did not correlate with parasitemia ($p=0.23$). This suggests dogs with high skin parasite burden contribute more to the infected sand fly pool. Although skin parasite load and parasitemia correlated with one another ($p<0.01$), the average parasite number detected in skin was higher compared to blood in all dogs tested. Thus, dogs without detectable parasitemia may already be infectious to the vector. Together, our data implicate skin parasite burden as a strong indicator of outward transmission potential.

628

TESTING FOR CHAGAS CARDIAC DISEASE AT A LARGE SAFETY-NET HOSPITAL IN NEW ENGLAND

Alyse Wheelock[1], Sukhmeet Sandhu[1], Davidson Hamer[2], Rachel Marcus[3], Deepa Gopal[4], Natasha Hochberg[5]

[1]*Internal Medicine Residency Program, Department of Medicine, Boston Medical Center, Boston, MA, United States,* [2]*Department of Global Health, Boston University School of Public Health; Section of Infectious Disease, Department of Medicine, Boston University School of Medicine, Boston, MA, United States,* [3]*MedStar Heart and Vascular Institute, Medstar Union Memorial Hospital, Baltimore, MD, United States,* [4]*Department of Medicine, Cardiovascular Division, Boston University Medical Center, Boston, MA, United States,* [5]*Section of Infectious Disease, Department of Medicine, Boston University School of Medicine, Boston, MA, United States*

Prior research suggests that Chagas disease, caused by the parasite *Trypanosoma cruzi*, is an important etiology of non-ischemic cardiomyopathy and cardiac arrhythmias among people who originate from Mexico, Central America, and South America. Less than 1% of the estimated 300,000 people living with Chagas disease in the United States have been diagnosed and treated, however. This study aims to determine the frequency of Chagas disease testing among individuals from endemic regions who display signs consistent with Chagas heart disease. Retrospective chart review was performed of electronic medical records from 2012-2017 at an academic safety net hospital in Boston. Inclusion criteria were patients born in Mexico, Central America, and South America with non-ischemic cardiomyopathy, conduction abnormalities (including bundle branch blocks or atrioventricular blocks), or arrhythmias (including sinus bradycardia, frequent premature ventricular complexes, or ventricular tachycardias). Data on demographics, electrocardiograms (EKG), echocardiography, Chagas disease diagnostics, and treatment were collected. Descriptive statistics were performed. 3099 patients met the inclusion criteria during the study period, including 1494 women and 1605 men. The most frequent countries of origin were El Salvador (n=755), Colombia (n=546) and Brazil (n=494). Only 42/3099 (1.4%) patients had Chagas serologies ordered. Of these patients, 8/42 (19.0%) tested positive for Chagas disease, 33/42 (78.6%) tested negative, and 1/42 (2.4%) had indeterminate results. Rates of Chagas disease testing were very low among this cohort of patients from endemic countries with EKG and echocardiographic findings consistent with Chagas cardiac complications. Among those patients tested, a significant proportion tested positive. Further analyses will be targeted towards determining factors associated with Chagas disease test ordering to explore opportunities for expanded testing. The initial findings of our study show a need to expand diagnosis and treatment of Chagas cardiac disease among Latin American immigrants in North America.

COMPARISON OF CHAGAS DISEASE SEROLOGY TEST PERFORMANCE IN THE UNITED STATES

Jeffrey D. Whitman[1], Christina A. Bulman[1], Emma L. Gunderson[1], Rebecca L. Townsend[2], Susan L. Stramer[2], Judy A. Sakanari[1], Caryn Bern[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*American Red Cross, Gaithersburg, MD, United States*

Chagas disease affects an estimated 300,000 individuals in the US. Diagnosis in the chronic phase requires positive results by two IgG serological tests. Three ELISAs (Hemagen, Ortho, Wiener Recombinante 3.0) and one lateral flow assay (InBios ChagasDetectPlus) are FDA-cleared. Comparative data in US populations are sparse. We evaluated plasma samples from 800 blood donors tested by the American Red Cross, 500 classified as seropositive by >2 blood bank tests (Ortho, RIPA, Abbott PRISM, Abbott ESA) and 300 classified as seronegative (by Ortho or PRISM). Country of birth was known for 255 seropositive specimens: 94 Mexico, 88 Central America and 73 South America. Seronegative samples were selected randomly, frequency-matched with seropositive samples by region of donation. Specimens were tested by the four FDA-cleared tests. We compared test performance to two references, blood bank classification (BB) and positive results by >2 FDA-cleared tests (consensus). A latent class analysis is planned. Compared to BB, sensitivity/specificity were 88.0%/100% for Hemagen, 92.4%/100% for Ortho, 94.0%/99.3% for Wiener and 97.4%/91.7% for InBios. Compared to consensus, sensitivity/specificity were Hemagen 90.7%/99.7%, Ortho 95.3%/99.7%, Wiener 96.3%/98.1% and InBios 99.2%/89.9%. Compared to BB status, sensitivity was lowest for those born in Mexico (83.0%, 85.1%, 91.5% and 97.9%) and highest for South America (93.2%, 97.3%, 98.6% and 98.6% for Hemagen, Ortho, Wiener and InBios). Some specimens positive by BB testing were negative or discordant in this evaluation, presumably due to antibody degradation. In conclusion, no test used alone had optimal performance. InBios was the most sensitive FDA-cleared test, detecting 97% of BB positives, but with specificity of 90-91%. Hemagen showed lower sensitivity in both analyses (88-91%) but high specificity. Ortho and Wiener had intermediate sensitivity and high specificity. Improved availability of the FDA-cleared tests and their combined use would facilitate laboratory diagnosis of Chagas disease in the US.

630

ADDRESSING EARLY DIAGNOSIS OF CONGENITAL CHAGAS DISEASE IN THE TIME OF THE ELIMINATION GOAL OF MOTHER-TO-CHILD TRANSMISSION IN THE AMERICAS

Yagahira E. Castro[1], Freddy Tinajeros[1], Caryn Bern[2], Gerson Galdos-Cardenas[1], Edith S. Malaga[3], Edward Valencia Ayala[3], Syamal Raychaudhuri[4], Kathryn Hjerrild[4], Steven J. Clipman[1], Andrés G. Lescano[3], Tabitha Bayangos[1], Walter Castillo[5], María Carmen Menduiña[6], Kawsar R. Talaat[1], Robert H. Gilman[1]

[1]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [2]*University of California, San Francisco, CA, United States,* [3]*Universidad Peruana Cayetano Heredia, Lima, Peru,* [4]*InBios International, Inc., Seattle, WA, United States,* [5]*Asociación Benéfica PRISMA, Lima, Peru,* [6]*Percy Boland Maternity Hospital, Santa Cruz, Plurinational State of Bolivia*

Early diagnosis of congenital Chagas disease (CChD) represents a good opportunity for early treatment. We evaluated factors of maternal adherence to the 6- or 9-month follow-up program (FP) and the ability IgM Shed Acute Phase Antigen (SAPA) ELISA in the early diagnosis of CChaD). Methods: Two prospective studies (consisting of a training and a validation cohort) were conducted in three hospitals in Santa Cruz, Bolivia. Pregnant women were screen for Chagas disease, and infants from seropositive mothers were examined to determine vertical transmission at birth and 1-month by microscopy, qPCR, and IgM TESA-blot (trypomastigote excreted-secreted antigens), and at 6- or 9-months for anti-*Trypanosoma cruzi* IgG antibodies. An IgM SAPA ELISA was optimized using a recombinant SAPA and camelid antibodies for IgM detection. Findings: A total of 5318 women were evaluated, overall maternal seroprevalence was 25.49% (95% CI: 24.33%-26.69%) and adherence to FP was 37.24% (95% CI: 34.66%-39.88%), respectively. Lower maternal education (adjusted OR: 0.75, p=0.049), owning a computer (adjOR: 1.97, p=0.002), and living in a house with more than three persons per room (adjOR: 0.73, p=0.022) impacted the odds of maternal adherence. When only one infant sample obtained at birth was evaluated in the validation cohort, the qPCR and the IgM SAPA ELISA have similar accuracy and were both higher than microscopy (sensitivity: 86.49%, 32/37; 81.58%, 31/38; 57.58%, 19/33, respectively, and specificity: 99.53%, 212/213; 96.15%, 209/217; 99.47%, 189/190, respectively). Interpretation: Socioeconomic factors were mainly determinants of maternal adherence. None of the early diagnostic tests achieved sensitivities higher than 90%, likely because of the biology of the infection. The IgM SAPA ELISA has the potential to be implemented in the short-term as an early diagnostic tool.

631

EVALUATING COMMUNITY-BASED SCREENING CAMPAIGNS FOR SEROLOGICAL DIAGNOSIS OF *TRYPANOSOMA CRUZI* AND *STRONGYLOIDES STERCORALIS* IN MADRID, SPAIN

Maria Delmans Flores-Chavez[1], Olvido Bocos[2], Francisca Vivas[3], Briggitte Jordan[4], Javier Nieto[5], Emilia Garcia[5], Belen Garcia[4], Ignacio Peña[6], Cristina Arcas[6], Carmen LLanos Aguilar[2], Ana Orellana[2], Jose Saugar[5], Juan Jose De Los Santos[4]

[1]*Fundación Mundo Sano / Centro Nacional de Microbiología, Madrid, Spain,* [2]*Centro Municipal de Salud Comunitaria de Usera, Madrid, Spain,* [3]*Ayuntamiento de Madrid, Madrid, Spain,* [4]*Fundación Mundo Sano, Madrid, Spain,* [5]*Centro Nacional de Microbiología-ISCIII, Madrid, Spain,* [6]*Salud Entre Culturas, Madrid, Spain*

Chagas disease (CD) and Strongyloidiasis (SS) are two parasitic infections which have poor visibility due to the absence or scarce presence of symptoms. The causative agents of these pathologies are the protozoan *Trypanosoma cruzi* and the nematode *Strongyloides stercoralis*, respectively. Both infections are diagnosed several years after having acquired them, in fact, most of those affected are unaware of their infection and, therefore, they did not receive a specific treatment at the appropriate time. In order to access to the diagnosis CD and SS, three strategies of community-based screening campaigns were evaluated: two Thursday afternoons each month (Thursday's screening), the first Saturday of each month (Saturday's screening) and one Sunday per semester (Sunday's screening). The population was included by the active action of health workers prior to the day of sampling in the Thursday's screening and Sunday's screening, while on Saturday's screening people were included at the same day of the activity when they were conducting an administrative process at the Bolivia Consulate. The management of samples and results was performed through the Municipal Community Health Centre of Usera. Subsequently all positive cases were referred to their reference hospitals according to the preference of each participant. CD was detected by three serological tests and SS by IgG detection of anti-*Strongyloides* antibodies. From April to December 2018, 522 samples were analyzed. The overall prevalence of CD and SS were 20% and 11% respectively, 99% of CD cases came from Bolivia, whereas SS was detected in people from different countries of Latin America. The combined search of both parasites facilitates the appropriate use of resources. Considering the economic costs of each strategy, Saturday screening is the most profitable system. Community-based screening campaigns allowed the detection of CD and SS outside the primary health care system, at time intervals according to the time availability of the population at-risk. Knowledge of the needs of the affected population will improve the efficiency of intervention strategies.

632

IMPROVED BIOMARKERS AND IMAGE ANALYSIS FOR CHARACTERIZING PROGRESSIVE CARDIAC FIBROSIS IN A MOUSE MODEL OF CHRONIC CHAGASIC CARDIOMYOPATHY

Kristyn Hoffman, Peter Hotez, Maria Bottazzi, Kathryn Jones

Baylor College of Medicine, Houston, TX, United States

Chronic Chagasic cardiomyopathy (CCC), caused by *Trypanosoma cruzi* infection, is an important public health problem due to progressive cardiomyopathy in patients, for which there is no curative treatment. CCC is characterized by myocarditis and cardiac fibrosis, which leads to life-threatening arrhythmogenic and circulatory abnormalities. This study aimed to identify non-invasive markers of cardiac fibrosis to monitor disease progression in a mouse model of CCC. Adult Balb/c cardiac cells were infected with *T. cruzi* H1 trypomastigotes (Tc1) or exposed to parasite lysate and concentrations of TGF-β, CTGF, ET-1 and PDGF-D were significantly elevated in the infected cell group supernatants. Female Balb/c mice were chronically infected with *T. cruzi* H1 and compared to an uninfected control group. Cardiac fibrosis, inflammation, mRNA expression of pro-fibrotic genes, and serum levels of pro-fibrotic biomarkers were measured. TGF-β genes, and other TGF-β superfamily genes, CTGF, ET-1 and PDGF were upregulated in the infected mouse heart. Serum concentrations of TGF-β, CTGF and PDGF-D, were significantly higher in infected mice and significantly correlated to cardiac fibrosis progression. Strain analysis was performed on MR images at 111 and 140 days post infection (DPI) and echocardiography images at 212 DPI. Chronic infection induced significantly elevated LV strain and concomitantly significantly decreased cardiac output at each time point. LV strain was significantly correlated to decline in cardiac output and increase in cardiac fibrosis. TGF-β, CTGF and PDGF-D can be used as biomarkers of fibrosis in CCC, as they positively correlated with levels of fibrosis measured on histopathology. Strain analysis of both MRI and echocardiography is a sensitive method to acquire longitudinal measurements in the same animal, which is not possible with the traditional method of measuring fibrosis on histopathology. Fibrosis biomarkers and strain analysis can be applied as longitudinal, non-invasive tools to study the effects of interventions and/or therapeutics on cardiac fibrosis development when using a mouse model of CCC.

633

CHILD MOUTHING OF CONTAMINATED FOMITES AND ANIMAL CONTACT IS ASSOCIATED WITH DIARRHEA AND STUNTING (REDUCE PROGRAM)

Christine Marie George[1], Ronald Saxton[1], Jennifer Kuhl[1], Jamie Perin[1], Nicole Coglianese[2], Elizabeth Thomas[1], Sarah Bauler[2], Anthony Koomson[2], Phil Moses[2], Geoffrey A. Nyakuni[3], Amagana Togo[3], Ruthly Francois[1], Patrick Mirindi[3], Lucien Bisimwa[3]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Food for the Hungry, Phoenix, AZ, United States,* [3]*Food for the Hungry, Bukavu, Democratic Republic of the Congo*

Exploratory play behavior is important for motor and cognitive development in young children. However this behavior also presents an exposure route to fecal pathogens for susceptible pediatric populations. In our prospective cohort study of 515 children under 5 years of age in South Kivu, Democratic Republic of the Congo, we are investigating the association between child play behaviors, diarrheal disease, and child growth. Child mouthing of soil and objects is assessed by five hour structured observation, and contact with domestic animals is assessed by caregiver reports. Spot checks of signs of open defecation or flying toilets on the household compound are also performed. In this abstract we report our baseline findings. Fifty percent of children were observed putting soil in their mouth, and 90% of children were observed mouthing a visibly dirty object during structured observation. Caregivers reported that 42% of children touched chickens, 36% touched guinea pigs, and 20% touched rabbits in the last week. Children observed putting soil in their mouth had a significantly higher odds of stunting (Odds Ratio (OR): 1.72 (95% Confidence Interval (CI): 1.06, 2.82)). Children observed putting a visibly dirty object in their mouth had a significantly higher odds of diarrhea (OR: 4.97 (95% CI: 1.17, 21.04)). Children that were reported to have touched chickens had a significantly higher odds of diarrhea (OR: 1.76 (95% CI: 1.06, 2.92)). In addition, children in households with signs of open defecation or flying toilets were at significantly higher odds of being wasted (OR: 2.87 (95% CI: 1.02, 8.04). Child mouthing of soil and visibly dirty objects and contact with chickens was associated with stunting and diarrhea in rural Democratic Republic of the Congo. These findings are being used to design an evidence-based Baby water, sanitation, and hygiene intervention to target these identified risk factors in the upcoming REDUCE trial. Interventions that focus on clean child play spaces are urgently needed to reduce pediatric exposure to fecal pathogens. This study is funded by the USAID Office of Food for Peace.

HAND CONTAMINATION WITH PATHOGENIC, ZOONOTIC AND ANTIMICROBIAL RESISTANT BACTERIA AMONG CAREGIVERS RESIDING WITH DOMESTIC ANIMALS IN INDIA

Marlene K. Wolfe[1], Karin Gallandat[2], Daniele Lantagne[1], Amy Pickering[1]

[1]*Tufts University, Medford, MA, United States,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Exposure to zoonotic pathogens and antibiotic resistant bacteria is an increasing concern in low-income domestic settings. Antibiotics in animal feed is expected to increase by 82% in India by 2030, likely intensifying environmental transmission of antimicrobial resistant bacteria. This study's goal was to identify whether hands are an exposure pathway for pathogenic, zoonotic, and antimicrobial resistant bacteria among caregivers living in close proximity to animals in India. We conducted a survey on animal care and collected hand rinse samples from 108 caregivers of young children in India. We cultured *E. coli* and total coliform from hand rinsate and extracted and analyzed DNA from cultured biomass to identify *E. coli* virulence genes (ECVG) by multiplex PCR and bacterial pathogens and antimicrobial resistance genes (ARG) by untargeted long-read genomic sequencing. We used quantitative PCR to identify a host-associated genetic marker (BacCow) specific to animal feces. Ruminants were present in 67% of compounds and poultry in 44%. *E. coli*, ECVG, and BacCow were identified in 78%, 29%, and 97% of samples respectively. Providing animal care was positively associated with cultured *E. coli* and presence of any ECVG, animal presence was positively associated with BacCow, and number of animals was negatively associated with ECVG. We identified 28 species of pathogenic bacteria (including zoonotic species such as enterotoxigenic *E. coli* and *Campylobacter spp.*), and 106 distinct ARGs, the majority conferring ß-lactam resistance. Animal fecal contamination on hands was highly prevalent. Caregivers providing animal care had increased ECVG on hands, suggesting a link between animal contact and diarrheagenic *E. coli* on hands. Results suggest hands are carriers of important pathogens and ARGs in this setting where animals are in close contact with humans. To our knowledge, this is the first study to conduct long-read sequencing of viable bacteria from caregiver hand samples in a low-income context. This untargeted, flexible approach is capable of identifying hundreds of pathogens at once and could be a valuable addition to models of risk assessment.

635

A PROSPECTIVE COHORT STUDY INVESTIGATING THE RELATIONSHIP BETWEEN THE GUT MICROBIOTA, ENVIRONMENTAL ENTEROPATHY AND IMPAIRED GROWTH IN RURAL BANGLADESH

Jamie Perin[1], Mathieu Almeida[2], Vanessa Burrowes[1], Shahnawaz Ahmed[3], Rashidul Haque[3], Tahmina Parvin[3], Shwapon Biswas[3], Ishrat J. Azmi[3], Md. Sazzadul Islam Bhuyian[3], Kaiser A. Talukder[3], Abu G. Faruque[3], O. Colin Stine[2], Christine Marie George[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*University of Maryland, Baltimore, MD, United States,* [3]*International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh*

There is a growing body of literature demonstrating an association between environmental enteropathy (EE) and stunting in young children. This condition is defined by reduced intestinal barrier function, and increased inflammation resulting in low nutrient absorption. Microbial communities in the child gut are thought to play an important role in this condition, although the relationship is poorly understood. In this study we investigated the associations between gut microbial communities, EE, and prospective child growth among children in rural Mirzapur, Bangladesh. We examined four fecal markers of EE (alpha-1-antitrypsin, calprotectin, myeloperoxidase, and neopterin) and anthropometric measures from a cohort of 68 children. We sequenced the 16S rRNA gene of bacterial DNA from stool, and used the resulting sequences to estimate amplicon sequence variants (ASV). We then age-matched children with poor growth to children with normal growth within one month based on the WHO child growth standards, and compared the change in abundance and diversity of ASV over time. Children had a mean baseline age of 17 months and there was a stool sample from each child at baseline and the 18 month follow-up. Using tertiles of standardized anthropometry and the four fecal markers of EE, we compiled child pairs to compare ASV identity and diversity by child growth. We observed increases in *Streptococcus* and *Escherichia/Shigella* among children with elevated alpha-1-antitrypsin compared to controls (3% increase versus 12% decrease, p=0.008 and 4% increase versus no change, p=0.042, respectively). There was higher *Proteobacteria* among children with poor growth (bottom tertile of height for age z-scores) than among controls, (31% versus 12%, p=0.015). We observed increased *Proteobacteria* presence among calprotectin defined EE cases than controls (15% increase versus 13% decrease, p=0.007). Diversity in ASV was lower among children with poor growth at study enrollment. Further research is necessary to determine the attributes of gut microbial communities most likely to promote or inhibit growth among young children in low- and middle-income countries.

636

PTM202, A BOVINE COLOSTRUM BASED NUTRITIONAL SUPPLEMENT, DECREASES THE ENTERIC INFLAMMATION OF ENVIRONMENTAL ENTERIC DYSFUNCTION IN BANGLADESHI INFANTS

Jeffrey Donowitz[1], Masud Alam[2], Mamun Kabir[2], Tahsin Ferdous[2], Aysha Zerin[2], Uma Nayak[3], Rashidul Haque[2], William A. Petri[3]

[1]*Virginia Commonwealth University, Richmond, VA, United States,* [2]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [3]*University of Virginia, Charlottesville, VA, United States*

PTM202 is a nutritional supplement composed of a combination of bovine colostrum and whole egg. Both the cows and hens are specifically vaccinated to induce antibodies in colostrum and eggs which provide passive immunity against human enteric pathogens. PTM202 has been shown to decrease the duration of diarrhea in Guatemalan and Filipino children. We conducted a randomized placebo-controlled trial to determine the effect of PTM202 on environmental enteric dysfunction (EED). Healthy 6 to 9-month-old Bangladeshi infants were randomized to receive either 7g of PTM202 plus micronutrient sprinkles (intervention arm [IA]) or micronutrient sprinkles alone (control arm [CA]), twice a day for 30 days via directly observed therapy. Biomarkers of EED (fecal myeloperoxidase [MPO], fecal Reg 1B, serum C-reactive protein [CRP], serum sCD14, and lactulose:mannitol ratio [L:M]) were measured on days 0 and 30. Compliance was 96.5% (193/200 took their respective supplement for 30 days). No significant differences in enrollment characteristics was found between the intervention and control arms. None of the EED biomarkers differed significantly between groups on day 0 other than CRP (IA 7.5 vs CA 16.5 mg/L, p = 0.05). At 30 days, children in the intervention arm had significantly lower MPO (IA 5972.1 vs. CA 7849.2 ng/ml, p = 0.05) and Reg 1B (IA 121.8 vs CA 145.3 ug/ml, p= 0.04) compared to children in the control arm. No difference was noted for CRP, sCD14, or L:M between arms at 30 days. In conclusion, 7g of PTM202 given twice a day decreases EED associated enteric inflammation and epithelial cell damage in Bangladeshi infants.

637

MODIFYING TOILETS TO MAKE THEM CHILD FRIENDLY IN RURAL BANGLADESH

Tarique Mohammad Huda[1], Ruhul Amin[1], Abdullah Al Masud[1], Elli Leontsini[2], Mahbubur Rahman[1], Tania Jahir[1], Jyoti Bhushan Das[1], Farzana Yeasmin[1], Fosiul Alam Nizame[1], Abul Kasham Shoab[1], Laura Kwong[3], Stephen P. Luby[3], Peter J. Winch[2]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Stanford University, Stanford, CA, United States*

In low income countries, child feces are often not collected nor disposed safely. Most toilets have dimensions and features most appropriate for adults. We aimed to understand how to modify existing latrines to make them child friendly. Our objectives were a) to identify barriers to young children using existing latrines and b) develop enabling technologies and behavioral recommendations to increase toilet use by 3 to 7 years old children. The study was part of a pilot trial to improve child development in rural Bangladesh. We conducted 4 Focus Groups with mothers of children 3 to 7 years old to explore the barriers of toilet use. The barriers to children using toilets included fear of darkness, long distance from the main house, discomfort to sit given large size of pan, and fear of falling due to slippery floor. We enrolled 20 households to try out the following enabling technologies: ring attached with rope for child to hold onto while squatting, wooden board with smaller hole placed on pan, transparent fiberglass tile on the roof, picture of a cartoon character with handwashing messages, and wooden step stool at the toilet entrance. Two to three weeks after installing the enabling technologies, we conducted 19 in-depth interviews with the caregivers to explore the acceptance and feasibility of the installed technologies. The holding ring was well liked by the children. Caregivers considered it affordable and available. The wooden board with hole reduced the fear of falling and the discomfort of sitting on pan. However, it was inconvenient for mothers to handle and maintain due to its heavy weight. Mothers felt disgust when the time came to clean it. The transparent fiberglass roof tile, an affordable and available technology, reduced the darkness during the day time, and kept the latrine floor dry as sunshine could come through it. The picture in the toilet was interesting to the children but only for the first few days. In conclusion, the fiberglass roof tile holding ring and step stool can make the toilets more child friendly in rural Bangladesh. Further studies could provide insight on the prospect for sustained use and willingness of beneficiaries to purchase.

638

EVALUATING A COMPLEMENTARY FOOD HYGIENE BEHAVIOR CHANGE INTERVENTION IN RURAL MALAWI

Kondwani R. Chidziwisano[1], Save Kumwenda[1], Jurgita Slekiene[2], Joachim H. Mosler[2], Tracy Morse[3]

[1]*University of Malawi, Blantyre, Malawi,* [2]*Eawag aquatic research, Zurich, Switzerland,* [3]*University of Strathclyde, Glasgow, United Kingdom*

Globally, diarrheal disease accounted for over 90% of foodborne illness in 2010, with over 70% of this burden in Sub-Saharan Africa. However, traditional diarrheal prevention interventions focused on water, sanitation, and handwashing (WASH), with little integration of food hygiene. We designed and implemented a theory-based complementary food hygiene and WASH intervention in rural Malawi and evaluated its impact on food hygiene behaviors. Formative research and intervention development was grounded in the RANAS (Risk, Attitude, Norms, Ability and Self – regulation) Model and targeted five key behaviors: 1) cleaning of feeding and cooking utensils, 2) safe utensil storage, 3) reheating of left-over food, 4) child self feeding, and 5) handwashing with soap at critical times. The intervention was delivered for 9 months through village meetings and household visits. Formative research indicated that norms, ability and self-regulation factors were the primary determinants of selected behaviors. Intervention activities were linked to Behavior Change Techniques of the RANAS model. We randomly assigned villages to a control or intervention group and targeted caregivers of children aged six months to two years. Food hygiene behaviors were measured through randomized before after study in the intervention and control villages and changes assessed through difference in the group level proportions of caregivers observed practicing the key behaviors. At endline, four behaviors showed a significant difference: cleaning utensils (95% vs 70%, *P*=0.008); keeping utensils in an elevated place (98% vs 16%, *P*=0.000), reheating of food (24% vs 4%, *P*=0.024) and handwashing with soap (46% vs 6%, *P*=0.000). Significant changes in perceived norms and perceived ability (*P*=0.000) related to the four behaviors among the intervention participants indicates an effective influence of the intervention on targeted behavioral determinants. The study suggests that theory driven behavior change initiatives using contextual and psychosocial factors effectively improved food hygiene behaviors in rural Malawi.

639

DOES A SCHOOL BASED INTERVENTION TO ENGAGE PARENTS CHANGE OPPORTUNITY FOR HANDWASHING WITH SOAP AT HOME? PRACTICAL EXPERIENCE FROM AN ON-GOING RANDOMIZED TRIAL IN NORTHWEST TANZANIA

Elialilia S. Okello[1], Heiner Grosskurth[2], Kenneth Makata[1], Onike Mcharo[1], Safari Kinungh'i[3], Saidi Kapiga[1], Belen Torondel[2], Robert Dreibelbis[2]

[1]*Mwanza Intervention Trials Unit, Mwanza, United Republic of Tanzania,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [3]*National Institute for Medical Research, Mwanza Centre, United Republic of Tanzania*

School-based deworming campaigns are a common approach to control of ascariasis and trichuriasis infections. However, preventing reinfection requires an integrative approach that combines de-worming with sustainable hygiene behaviour change at schools and homes. There is limited data on how school-based water, sanitation, and hygiene interventions can influence behaviour in the home. This sub-study examined the influence of the parental engagement sessions on access to handwashing materials and clean latrines at home. This longitudinal qualitative study included three rounds of household spot checks and interviews with 20 parents of children in 4 schools in northwest Tanzania participating in the Mikono Safi trial. At each school, parental engagement sessions were completed where parents were provided information on their own child's infection levels and information on STH prevention followed by a group discussion. Baseline data were collected before parental engagement sessions were implemented. Subsequent data collection occurred at 4 and 8 months following the intervention. At baseline, 19 out of 20 households had toilets but most of them were in poor condition and unsafe for children and no household had handwashing facilities near the toilet. All participating households participated in the parental engagement activities. Discussions regarding transmission of STHs evoked feeling of disgust and motivated parents to improve sanitation and access to handwashing at home. At the 4 months follow-up, 13 out of 20 households had made some repairs on the existing toilets or built new toilets and 12 built handwashing facilities next to the toilet. However, only 4 included soap at the handwashing facility. At 8 months, 16 households had installed handwashing facilities but only 8 had water and soap at handwashing facilities. Our strategy for engaging parents was effective in generating the intended emotional drivers of household behaviours. This resulted in substantial sustained structural hygiene. However, success was limited with regards to the provision of water and soap.

640

OPTIMIZING THE NUMBER OF CHILD DEATHS AVERTED WITH MASS AZITHROMYCIN DISTRIBUTION

Catherine Oldenburg[1], Ahmed Arzika[2], Ramatou Maliki[2], Ying Lin[1], Kieran O'Brien[1], Jeremy Keenan[1], Thomas Lietman[1]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*The Carter Center Niger, Niamey, Niger*

The MORDOR trial demonstrated a 14% reduction in all-cause child mortality with biannual mass azithromycin distribution compared to placebo. The largest observed reduction in mortality was in children aged 1-5 months. With the greatest absolute risk of mortality, these children may have the most to gain from interventions that reduce child mortality. Some implementation strategies may target younger ages, such as during infancy. We estimated the number of deaths averted by targeting different age groups versus 1-59 month-old children in the Niger site of MORDOR. Communities were randomized to 24 months of biannual mass azithromycin or matching placebo distribution to all children aged 1-59 months in the community. Mortality was measured via door-to-door census. Analyses were restricted to the Niger site only as any implementation of azithromycin for reduction of child mortality may be limited to settings with higher under-5 mortality. We calculated incidence rate differences (IRDs) for all-cause mortality in communities randomized to biannual azithromycin versus biannual placebo in children aged 1-5, 1-11, and 1-59 months at the time of treatment to estimate the absolute number of deaths averted per person-year based on the person-time observed in MORDOR-Niger. In 594 communities in Boboye and Loga, Niger, 3,615 deaths were observed over 145,694 person-years. Mortality in the placebo arm decreased with increasing age. IRDs for azithromycin versus placebo were -5.0 (95% confidence interval, CI, -6.6 to -3.4), -11.5 (95% CI -16.0 to -5.4), and -11.7 (95% CI -19.4 to -3.9) deaths per 1,000 person-years in the 1-59 month, 1-11 month, and 1-5 month age groups. This corresponded to 729 (95% CI 492 to 966), 297 (95% CI 168 to 427), and 126 (95% CI 43 to 209) deaths averted in each age group over the course of the trial. In conclusion, Although targeting higher risk groups is tempting, this may constitute a "paradox of prevention"—a far greater number of deaths may be averted by treating all preschool children than by targeting specific high-risk individuals or subgroups, thus maximizing the number of deaths averted.

641

PROJECTED IMPACT AND COST-EFFECTIVENESS OF HIGH-RISK TARGETED VERSUS COMMUNITY-BASED ADMINISTRATION OF AZITHROMYCIN FOR REDUCING CHILD MORTALITY IN SUB-SAHARAN AFRICA

Rebecca Brander[1], Marcia Weaver[1], Benson Singa[2], Grace John-Stewart[1], Patricia Pavlinac[1], Judd Walson[1]

[1]*University of Washington, Seattle, WA, United States,* [2]*Kenya Medical Research Institute, Nairobi, Kenya*

Mass drug administration (MDA) of azithromycin (AZM) is being considered to reduce child mortality in Sub-Saharan Africa (SSA). Targeted AZM administered to high-risk children is also being tested. To illustrate the health impact and resource implications of targeted vs population-based strategies, we modeled the cost effectiveness (CE) of MDA vs AZM administered at hospital discharge, an accessible population at high risk of death. CE was modeled from the payer's perspective with a 6-month time horizon. The model included AZM-related adverse events, growth faltering, and mortality as health effects, and the cost of AZM delivery and healthcare utilization. Model parameters were sourced from published literature when possible. In estimates with a base-case 1.65% mortality risk and 1.9% hospitalization risk in the population and 4.5% mortality risk and 17.7% re-hospitalization risk post-discharge, and a mortality reduction of 13.5% based on recent trial results, we found post-discharge AZM averted ~2800 deaths and ~170000 DALYs and would be cost-saving, whereas MDA would avert ~15000 deaths and ~860000 DALYs at a cost of $147/DALY averted. In sensitivity analyses, results were most affected by parameters for hospitalization and mortality rates, effects of AZM on hospitalization rates, and the costs of drug delivery in MDA. Targeted AZM was cost-saving in any scenario in which AZM reduced hospitalization rates, and was more cost-effective than MDA when mortality was >2% higher or hospitalization was >10% higher in the targeted vs general population, or when post-discharge delivery costs were <500% of MDA costs. Both post-discharge AZM and MDA costs per DALY doubled with each 50% increase in macrolide resistance prevalence. Targeting AZM to children at highest risk of death may be an antibiotic-sparing and cost-effective, or even cost-saving, strategy to reduce child mortality if trials of targeted AZM demonstrate a similar effect as MDA trials. However, targeted AZM averts fewer absolute deaths and DALYs and may not reach all children who would benefit. Any AZM administration decision must consider implications for antibiotic resistance.

"HE'S CONSIDERING HIS INVESTMENT, NOT HIS HEALTH": ECONOMIC DETERMINANTS OF RISK, PREVENTION AND RESPONSE BEHAVIORS RELATED TO THE FIVE PRIORITY DISEASE GROUPS IN COTE D'IVOIRE

Danielle Naugle[1], Natalie Tibbels[1], Abdul Dosso[2], William Benié[2], Walter Kra[3], Corinne Fordham[1], Mieko McKay[2], Valère Konan[4], Jeanne Brou[5], Jocelyne Nebre[5], Adaman Kouadio[4], Zandra Andre[6], Diarra Kamara[2], Stella Babalola[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Johns Hopkins University, Abidjan, Côte D'Ivoire,* [3]*Alassane Ouattara University, Bouaké, Côte D'Ivoire,* [4]*Department of Veterinarian Services Ministry of Animal Resources and Fisheries, Abidjan, Côte D'Ivoire,* [5]*National Institute of Public Hygiene, Abidjan, Côte D'Ivoire,* [6]*U.S. Agency for International Development, Abidjan, Côte D'Ivoire*

After the 2014-2016 Ebola outbreak in West Africa, countries are mobilizing to strengthen preparedness for future threats. To support that effort, this qualitative study explored individual, social, and cultural determinants of risk, prevention, and response behaviors related to the five priority zoonotic disease groups in Côte d'Ivoire (rabies, mycobacterium, bacterial and parasitic diseases, viral hemorrhagic fevers, and respiratory zoonotic diseases). Data were collected through 32 focus group discussions, 33 interviews, 20 observations, and 20 community maps engaging 234 adult men and women across four urban sites. Participants were purposively sampled from populations that interact regularly with animals like farmers, hunters, and butchers. The interviews were recorded, transcribed, coded and analyzed. The findings highlight the role of economic factors in shaping behavior. First, many risk, prevention and response behaviors around zoonotic diseases are inextricably linked to the actors' primary means of subsistence; as a result, decisions are made based on careful calculations to maximize financial gain and minimize loss. Second, an underlying economic precariousness favors close co-habitation with animals, curative rather than preventative approaches to health, self-medication of both animals and people, and the consumption and sale of sick and dead animals. Third, echoes of past experiences and fear of financial loss generate reluctance to inform authorities of potential outbreaks. Without overlooking other important behavioral determinants (including structural factors, lack of information, low perceived risk, and cultural/religious beliefs and practices), this presentation seeks to underscore the pervasiveness of economic determinants of key risk, prevention, and response behaviors in Côte d'Ivoire. Social and behavior change communication programs seeking to reduce the public health burden of zoonotic diseases might benefit from aligning prevention and response behaviors with the expressed priorities of the actors: maximizing financial gains and minimizing financial losses.

643

AN INVESTMENT CASE FOR MATERNAL NEONATAL TETANUSELIMINATION

Sarah K. Laing[1], Ulla Griffiths[2], Sophia Bessias[1], Sachiko Ozawa[1]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*UNICEF, New York City, NY, United States*

Maternal neonatal tetanus elimination (MNTE) has been a global public health goal since 1989. To date, 14 countries have yet to reach elimination targets of less than one case per 1000 live births per district. Many of the remaining districts are hard to reach, facing implementation challenges that require novel implementation strategies. The Strategic Advisory Group of Experts at the World Health Organization (WHO) proposed five strategies to achieve MNTE by 2020: 1) vaccination campaigns using standard tetanus-toxoid containing vaccines with regular syringes as well as single-dose, pre-filled, auto-disposable syringes (TT-Uniject^{TM}), 2) increased routine immunization of pregnant women, 3) promotion of clean delivery and umbilical cord care, 4) neonatal tetanus surveillance, and 5) conducting elimination validation activities. We estimated the costs, averted deaths, and cost-effectiveness of achieving MNTE between 2018 and 2020. We used data from the WHO-Maternal Child Epidemiology Estimation Group, the United Nations Development Program, and UNICEF for our analysis. We estimated that it will cost US $199.6 million to eliminate maternal neonatal tetanus by 2020. These costs include $162.3 million for vaccination campaigns, $6.2 million for routine immunization of pregnant women at antenatal care clinics, $23.8 million for promotion of clean delivery, $4.2 for surveillance, and $3.1 for elimination validation activities. Achieving and sustaining elimination through 2030 will avert over 74,000 neonatal deaths and 4.6 million life years. MNTE in the remaining 14 countries will cost $2,696 per death averted and $43 per life year gained. Maternal neonatal tetanus can be eliminated with significant investment and high prioritization. While reaching hard-to-reach populations require substantial costs, MNTE can bring about broader benefits through health systems strengthening and improved access to care. Achieving MNTE by the current target of 2020 will require financial commitment and strong political will.

644

DIRECT AND INDIRECT COSTS TO THE DOD FOR MILITARY BENEFICIARIES PROVIDED CARE IN THE MILITARY HEALTH SYSTEM FOR DENGUE FEVER, 2012 - 2017

Bria Graham-Glover[1], Lanna Forrest[1], Calli Rooney[2], Stephen Barnes[1], Stefan Fernandez[3], Emily Cisney[4], Jacob Ball[5], John Ambrose[1]

[1]*DHA US Army Satellite, Aberdeen Proving Ground, MD, United States,* [2]*U.S. Army Medical Materiel Development Activity (USAMMDA), Ft. Detrick, MD, United States,* [3]*Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand,* [4]*DoD JPEO CBRND, Ft. Detrick, MD, United States,* [5]*Army Public Health Center, Department of Defense, Aberdeen Proving Ground, MD, United States*

Dengue virus (DENV) is the mosquito-borne pathogen, causative of dengue fever (DF) and endemic in most of the world's tropical and sub-tropical regions. DF is a threat to troops deployed in these areas. While DF is known or suspected to have cause disease among US troops as early as the 1898 Spanish-American War, to-date the burden of dengue infections among U.S. Service Members (SMs) is largely unknown. No specific treatment or vaccine is licensed in the US and treatment is limited to supportive care. Further, there is little consensus of the true cost of DF among DoD service personnel and other MHS beneficiaries. To facilitate DoD funding prioritization and support decisions around dengue vaccines and therapeutics development, this study provided DoD estimates of dengue direct medical and lost productivity (as available) costs. Military Health System (MHS) beneficiaries (e.g., Active duty (AD) SMs and non-AD military beneficiaries) from all components and Services, meeting the case definition for DF between 2012 and 2017 were included (n=1,346). Dengue cases were identified by querying DoD paid hospitalizations and outpatient medical encounters for dengue associated diagnosis codes; and from reviews of reportable medical events of confirmed dengue cases. Each individual was included in the analysis only once per calendar year. The cost of an encounter was determined separately for outpatient and inpatient care and reported in 2018 dollars. Lost productivity costs were calculated for AD SMs only and included (1) lost duty time where a SM is not able to perform his duties (e.g., number of inpatient hospital days); and (2) limited duty time where a SM performs his duty following dengue care, but is considered to be at diminished capacity (e.g., working while sick). Treatment of DF in the MHS is costly to the DoD, totaling almost $2 million over a five year period in direct medical costs. Additionally, the DoD experienced approximately $1 million in lost productivity costs for SMs. These findings, in light of the global health agenda, suggest that the dengue vaccine should remain a priority.

645

EVALUATION OF A SAVINGS LED FAMILY-BASED ECONOMIC EMPOWERMENT INTERVENTION FOR AIDS-AFFECTED ADOLESCENTS IN UGANDA WITH HEALTH ECONOMIC EVALUATION: A FOUR-YEAR FOLLOW-UP

Yesim Tozan[1], Ariadna Capasso[1], Sicong Sun[2], Julia Sh Wang[3], Ozge S. Bahar[2], Christopher Damulira[2], Fred M. Ssewamala[2]

[1]*College of Global Public Health, New York University, New York, NY, United States,* [2]*International Center for Child Health and Development, Brown School of Social Work, Washington University, St. Louis, MO, United States,* [3]*Department of Social Work and Social Administration, The University of Hong Kong, Hong Kong, Hong Kong*

In Uganda, 660,000 children have lost a parent to HIV/AIDS. Family economic empowerment interventions can improve health and developmental outcomes among children in communities impacted by AIDS and mitigate the risks they face. In resource-limited settings, it is important to identify cost-effective, scalable and sustainable interventions to inform allocation of resources given competing health priorities. Yet, evidence is limited on the cost-effectiveness (CE) of interventions aimed at improving adolescents' physical and mental health. We present a CE analysis of *Bridges*, a NIH-funded savings-led economic empowerment intervention among children and adolescents impacted by AIDS in Uganda. We use longitudinal data corrected at 4 time-points: 12, 24, 36 and 48 month-follow-up (2012-2016). Intent-to-treat analyses using multi-level difference-in-differences models compared the effects on self-rated health, mental health functioning, and sexual health of the two treatment arms: 1:1 (*Bridges) and 2:1 (BridgesPLUS)* incentivized savings match to usual care over the 48 months. Per-participant costs for each arm were calculated using the treatment-on-the-treated sample. Intervention effects and per-participant costs were used to calculate the incremental CE ratios (ICERs). At 48-months, *BridgesPLUS* significantly improved self-rated health, (0.25, 95% CI 0.06–0.43), HIV knowledge (0.21, 95% CI 0.01–0.41), self-concept (0.26, 95% CI 0.09–0.44) and self-efficacy (0.26, 95% CI 0.09–0.43) and lowered hopelessness scores (-0.28, 95% CI -0.43–0.125); whereas Bridges improved self-rated health (0.26, 95% CI 0.08–0.43) and HIV knowledge (0.22, 95% CI 0.05–0.39) compared to usual care. ICERs ranged from $224 for hopelessness to $298 for HIV knowledge. Intervention effects were measurable two years post-intervention, with higher savings match (2:1) positively impacting more outcomes than lower savings match (1:1). Our findings support the incorporation of economic empowerment interventions for poor AIDS-impacted children and communities within national social protection frameworks in low- and middle-income countries.

645A

EVALUATION OF THE IMPACT OF THE CERTIFIED OPHTHALMIC PARAMEDIC PROGRAM AT A LARGE CHARITY EYE HOSPITAL IN DELHI, INDIA

Vimal Konduri[1], Ishaana Sood[2], Shalinder Sabherwal[2], Sunita Arora[2], Parul Datta[2], Kyle McDaniel[1], Suresh R. Chandra[1], Cat N. Burkat[1]

[1]*University of Wisconsin School of Medicine and Public Health, Madison, WI, United States,* [2]*Dr. Shroff's Charity Eye Hospital, Delhi, India*

Vision loss is a major healthcare issue in India, driven by lack of access to care. In 2014, the Certified Ophthalmic Paramedic (COP) Program based at Dr. Shroff's Charity Eye Hospital (SCEH) in Delhi, supported by Combat Blindness International, began training young women from Delhi and rural North India to become paramedics (COPs) through a free 2-year program. Afterwards, COPs work at SCEH facilities in their communities. The program aims to improve SCEH's reach and quality of care and advance COPs' socioeconomic mobility and gender equity. This mixed-methods study examined the program's impact on graduates, their families, and delivery of care. Program graduates from Delhi and 5 SCEH secondary centers (located in outlying rural areas) who completed training at least 1 year prior were considered. All answered "before" and "after" questionnaires with over 200 total questions, reflecting previous and current socioeconomic status (SES), gender equity, healthcare choices, and confidence. Qualitative interviews were administered to some subjects and their family members. The program's impact on care was assessed using hospital data on procedures and screenings. 53 of 69 eligible graduates were included in the study. 18 family members of 16 COP subjects were interviewed. Questionnaire responses showed that COP program participation was associated with a significant ($p=1.037x10^{-5}$) increase in participants' SES, measured by principal component analysis of household asset ownership, with a greater increase at secondary centers ($p=7.508x10^{-5}$) than in Delhi (p=0.03094). Program graduates also reported a significant ($p=2.152x10^{-5}$) increase in their contribution to family economic decision-making. Interviewed graduates and their families had positive opinions of the program, also offering some suggestions for improvement. At secondary centers, surgery volume increased by 164% and outpatient visits increased by 109% between 2013 and 2017. Overall surgery volume at SCEH increased by 62% and number of patients screened increased by 64% over same period, indicating a substantial increase in patient volumes since the COP program began.

646

ASSOCIATION OF PRE-CONTROL INFECTION PREVALENCE OF LYMPHATIC FILARIASIS WITH CLINICAL MORBIDITY

Natalie V. Vinkeles Melchers[1], Wilma A. Stolk[1], Belén Pedrique[2], Joost W. Vanhommerig[1], Luc E. Coffeng[1], Sake J. de Vlas[1]

[1]*Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands,* [2]*Drugs for Neglected Diseases initiative (DNDi), Geneva, Switzerland*

Lymphatic filariasis (LF), commonly known as elephantiasis, is a neglected tropical disease targeted for elimination through mass drug administration (MDA). Affected persons can experience painful and severely disfiguring clinical manifestations, which can lead to permanent disability and economic loss. We assess the statistical association between the prevalence of LF infection and morbidity before the initiation of MDA. A systematic review was performed by two independent researchers to collect population-based data on the pre-control prevalence of microfilariae (mf) and morbidity (lymphoedema/elephantiasis and hydrocele). Diagnostic techniques for the detection of mf prevalence were standardised by calculating a transformation factor, such that mf prevalence was standardised to thick blood smear (mf/20 μl). We quantified the association between pre-control prevalence of infection and morbidity using a logistic regression curve, with stratifications by geographical region, LF parasite species, age and sex. Model parameters were estimated using a maximum likelihood. The pre-control prevalence of mf was non-linearly associated with the prevalence of lymphoedema/elephantiasis. Pre-control prevalence of lymphoedema/elephantiasis was higher in South-East Asia (SEA) than in Africa, given similar pre-control mf prevalence in areas with low pre-control mf prevalence. The association between the prevalence of community infection and hydrocele was approximately linearly related, with higher hydrocele prevalence rates in Africa than in SEA or the Western-Pacific region. The associations were then applied to published data on pixel-level pre-control mf prevalence in Africa to estimate the prevalence of lymphoedema/elephantiasis and hydrocele at baseline. These pre-control associations can assist policy-makers, programme managers, drug developers, and mathematical modellers to better predict the baseline occurrence of disease in specific geographical areas with specific population distributions. In addition, these associations can be used to re-calculate the Global Burden of Disease due to LF.

647

THE EFFICACY OF TRIPLE DRUG THERAPY IN MASS DRUG ADMINISTRATION TO REDUCE LYMPHATIC FILARIASIS IN HAITI

Marisa A. Hast[1], Christine L. Dubray[1], Anita D. Sircar[1], Madsen Beau De Rochars[2], Joshua Bogus[3], Abdel N. Direny[4], Jean Romuald Ernest[5], Carl Fayette[5], Katiuscia O'Brian[3], Charles W. Goss[3], Daniel Frantz Sabin[5], Ryan Wiegand[1], Jean Frantz Lemoine[6]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*University of Florida, Gainesville, FL, United States,* [3]*Washington University in St. Louis, St. Louis, MO, United States,* [4]*RTI International, Washington, DC, United States,* [5]*IMA World Health, Port-au-Prince, Haiti,* [6]*Ministere de la Sante et de la Population, Port-au-Prince, Haiti*

In Haiti, transmission of *Wucheria bancrofti* lymphatic filariasis (LF) persists in several regions of the country despite a decade of annual mass drug administration (MDA). Recently, studies have shown that annual "IDA" triple drug MDA using ivermectin , diethylcarbamazine (DEC), and albendazole is more effective in eliminating microfilaria (Mf) than "DA" double drug MDA using DEC and albendazole alone. To further determine the efficacy of IDA MDA in Haiti, a longitudinal study was conducted within a community-randomized trial in Quartier Morin commune from November 2016 to January 2018. As part of the community trial, ten localities were randomized to receive either IDA or DA MDA. Participants were tested at baseline for LF antigenemia using filariasis test strips (FTS), and FTS positive participants were also tested for Mf positivity and Mf count per milliliter. FTS positivity at baseline was 8.0% (239/3004) in the IDA arm and 11.5% (344/2994) in the DA arm. Mf positivity was 1.4% (42/3004) and 2.4% (72/2994), respectively. Male sex, older age, locality, and presence of LF complications were significantly associated with both FTS and Mf positivity before treatment. Participants who were FTS positive were followed-up 12 months later for repeat FTS and Mf testing, and 84% successfully completed a second visit. Among FTS positive participants retained at follow-up, 20.5% became FTS negative in the IDA arm compared with 25.6% in the DA arm (P=0.3). Among retained participants who were Mf positive at baseline, 94.4% were free of Mf at 12 months in the IDA arm compared with 75.9% in the DA arm (P=0.02). Conversion to Mf or FTS negativity was not modified by age or sex in the IDA arm. In the DA arm, participants aged 5-9 years were more likely to become FTS negative compared with older age groups (P=0.001). Among FTS positives at 12 months, FTS score was significantly lower than at baseline in both arms, and median Mf count per ml was lower in the IDA arm (P=0.04). Overall, MDA using IDA was more effective than DA in reducing microfilaremia in Haiti. Adopting a three-drug regimen for yearly MDA may accelerate the elimination of LF as a public health problem in this region.

648

COMMUNITY-LEVEL EFFECTIVENESS OF MASS DRUG ADMINISTRATION OF IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE VERSUS DIETHYLCARBAMAZINE AND ALBENDAZOLE FOR ELIMINATION OF LYMPHATIC FILARIASIS IN PAPUA NEW GUINEA

Moses Laman[1], Livingstone Tavul[1], Stephan Karl[1], Bethuel Kotty[1], Zebedee Kerry[1], Steven Kumai[2], Anna Samuel[1], Lina Lorry[1], Lincoln Timinao[1], Samuel C. Howard[3], James Wangi[4], Leo Makita[5], Lucy John[6], Sibauk Bieb[6], Charles W. Goss[7], Katiuscia O'Brian[7], Gary J. Weil[7], James W. Kazura[3], Daniel J. Tisch[3], Catherine Bjerum[3], Christopher L. King[3], Leanne J. Robinson[8]

[1]*PNG Institute of Medical Research, Madang, Papua New Guinea,* [2]*Bogia District Health Office, Madang, Papua New Guinea,* [3]*Case Western Reserve University, Cleveland, OH, United States,* [4]*World Health Organisation PNG, Port Moresby, Papua New Guinea,* [5]*VBD Control Program, PNG National Department of Health, Port Moresby, Papua New Guinea,* [6]*PNG National Department of Health, Port Moresby, Papua New Guinea,* [7]*Washington University, St Louis, MO, United States,* [8]*Burnet Institute, Melbourne, Australia*

Evidence from Papua New Guinea (PNG) and elsewhere, has shown that a co-administered dose of Ivermectin, Diethylcarbamazine (DEC), and Albendazole (IDA) is more effective for clearing *W. bancrofti* microfilaremia (Mf) than treatment with the standard therapy of DEC plus ALB (DA). However, the number of rounds of IDA required to interrupt LF transmission is unknown. A large open-label, parallel group, cluster randomized trial conducted in PNG from 2016-2019 confirmed IDA has an acceptable safety profile in a moderate transmission region and superior individual-level efficacy (96% IDA versus 83% DA; p=0.038). To investigate the effectiveness of one round of IDA versus DA on the community-level prevalence of microfilaremia and antigenemia, all consenting community members were re-tested one year after MDA. Compared to baseline, communities that received a single dose of IDA showed a greater reduction in Mf prevalence with IDA (4.4%, N=2388 to 0.4%, N=2299) compared to communities that received DA (4.2%, N=2189 to 1.5%, N=1945). After controlling for MDA coverage and average bednet usage, the odds of Mf infection were 3.8 times greater in DA vs IDA villages 1 year after MDA (p=0.0005). MDA coverage was a significant predictor of village Mf prevalence decrease (p=0.032), but bednet usage was not (p=0.509). Filarial Strip Test positivity significantly decreased slightly after MDA (p<0.001) but to a similar degree in IDA villages (from 22% to 16%) and DA villages (23% to 18%; p=0.506). Xenomonitoring for LF in four villages was conducted at baseline and four to six weeks following MDA and 6 villages 12 months later, divided equally among the two treatment arms. Four to six weeks following MDA there was a >10-fold reduction in LF infected mosquitoes, equivalent between treatment arms. The 1-year data are pending. Data showing the effect of a second year of MDA with the same regimens will be available for presentation at the meeting. IDA has a greater impact than DA on community Mf prevalence after a single round of MDA and has the potential to significantly accelerate LF elimination in settings such as PNG by requiring fewer rounds of MDA to interrupt transmission.

649

EFFICACY AND EFFECTIVENESS OF A 3 DRUG REGIMEN AGAINST A STANDARD 2 DRUG REGIMEN FOR LYMPHATIC FILARIASIS: RESULTS OF AN OPEN-LABELLED CLUSTER RANDOMIZED TRIAL

Jambulingam Purushothaman[1], Subramanian Swaminathan[1], Gary J. Weil[2], Vijesh K. Sreedhar[1], Srividya Adinarayanan[1], Krishnamoorthy Kalianna Gounder[1]

[1]*Vector Control Research Centre (ICMR), Puducherry, India,* [2]*Washington University School of Medicine, St. Louis, MO, United States*

An open labelled cluster randomized trial was carried out to assess the efficacy and effectiveness of a 3-drugs (ivermectin, DEC, albendazole IDA) vs standard 2-drugs (DEC, albendazole, DA) for lymphatic filariasis (LF). Filarial infections were detected with the FTS test for filarial antigenemia. Participants with positive antigen tests were tested for microfilaremia (Mf) with 60 μl thick night blood smears. Clusters (villages) were block randomized by population and infection prevalence to receive either IDA or DA. Participants were treated with a single oral dose of 3-drug (ivermectin, 200 μg/kg; diethylcarbamazine, 6 mg/kg; albendazole, a fixed dose of 400 mg) or with DA alone. Treatment was offered to residents who were >5 years of age and not pregnant. Approximately 70% of the population consumed the drugs. Separate surveys were conducted 12 mo after treatment to compare the efficacy and effectiveness of the two drug regimens. For the efficacy study, a cohort of individuals with filarial infections at baseline were followed. 80% of 591 persons with Mf at baseline were re-examined for Mf at 12 mo. Mf prevalence after DA and IDA were 38% and 16%, respectively. Reductions in Mf counts were 71.1% and 86.5% after DA and IDA. The reductions were significantly better after IDA than after DA (P<0.05). Repeat cross-sectional surveys were performed to assess the overall effectiveness of a single dose of the two treatments at the community level. 4272 and 3549 persons were tested during pre- and post-treatment surveys in the 2-drug treatment villages. The corresponding figures in the 3-drug arm were 4782 and 3584. Mf prevalence decreased from 6.2 to 5.4% (by 13%) after DA and from 6.8 to 3.5% (by 48%) after IDA. Mf density was reduced by 18.8% after DA and by 52.6% after IDA. A single dose of DA or IDA were not effective for clearing CFA. Results from this study suggest that IDA is superior to DA regarding efficacy for treatment of individuals and regarding effectiveness at the community level for reducing the Mf prevalence and intensity in endemic communities. IDA has the potential to accelerate LF elimination if it is used for MDA in areas that currently receive DA.

Steer[13], Josaia Samuela[14], Ken B. Schechtman[2], Peter U. Fischer[2], Christopher L. King[10], Gary J. Weil[2]

[1]*Bruyere Research Institute, Ottawa, ON, Canada,* [2]*Washington University, St. Louis, MO, United States,* [3]*University of Ottawa, Ottawa, ON, Canada,* [4]*Vector Control Research Centre, Pondicherry, India,* [5]*University of Florida, Gainesville, FL, United States,* [6]*RTI Envision, Washington, DC, United States,* [7]*Ministère de la Santé Publique et de la Population (MSPP), Port au Prince, Haiti,* [8]*Planning Department in East Nusa Tenggara Provincial Government, Kupang, Indonesia,* [9]*Universitas Indonesia, Jakarta, Indonesia,* [10]*Case Western Reserve University, Cleveland, OH, United States,* [11]*Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea,* [12]*University of Melbourne, Melbourne, Australia,* [13]*Department of General Medicine, Royal Children's Hospital, Melbourne, Australia,* [14]*Ministry of Health and Medical Services Fiji, Suva, Fiji*

A multicenter community-based safety trial compared a standard two-drug treatment (DEC and albendazole, DA) with a three-drug treatment (ivermectin and DA, IDA) for lymphatic filariasis (LF). Treatment acceptability was measured using mixed methods. In each country, acceptability was assessed with a survey of 400 randomly selected participants (≥14 yrs) within four months of treatment. Focus group discussions were conducted in each country in communities where IDA was administered. 1919 participants were surveyed across 5 countries. 27 focus group discussions were analyzed for emergent themes. Survey data was linked to clinical data on adverse events (AE) collected by the safety trial teams. 17.4% (325/1870) of the sample had clinically assessed AE during the 7 day post-treatment monitoring period. When

surveyed, 43.7% (142/325) of these participants reported that they did not experience any AE. Survey data showed women reported AE more than men (71.7% vs 64.4%; p=0.01), including more frequent nausea (p=0.0015) and headache (p=0.0001). Men felt better more often after treatment than women did (10.1% vs 5.1%; p<0.0001). Participants reporting no AE in the day following treatment varied across sites: Fiji (68.9%), Haiti (55.2%), India (88.7%), Indonesia (52.9%) and PNG (72.6%) (p<0.0001). Indonesian participants reported a higher rate of passing intestinal worms following treatment (22.4%) as compared to the other sites (p<0.001). Qualitative data confirmed that participants were sometimes hesitant to take medication because of possible AE. Access to telephone numbers, presence of health staff, free treatment for AE and seeing family members whose AE cleared reassured community members about AE. Results showed that perceptions of AE varied between countries and between genders. Active AE management has the potential to reduce the perceived severity of AE as people are reassured about where to seek care following treatment. These results indicate that AE management must be an integral component of mass drug administration beforehand to reassure community and afterwards to care for AE. Gender-specific approaches to AE may be needed.

651

USE OF REAL-TIME DAILY REPORTING TO IMPROVE MASS DRUG ADMINISTRATION IN AN URBAN SETTING

Abdel N. Direny[1], Alain Javel[2], Jean F. Lemoine[3], Franck Monestime[2], Wenser Estime[2], Eurica Denis[2], Carl R. Fayette[2], Scott Torres[1], Ellen Knowles[1], Nancy Stroupe[1], Caitlin Worrell[4], Tara Brant[4]

[1]*IMA World Health, Washington, DC, United States,* [2]*IMA World Health, Port au Prince, Haiti,* [3]*Ministere de la Sante Publique et de la Population, Port au Prince, Haiti,* [4]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

Haiti is approaching elimination of lymphatic filariasis, with 84% of the 140 endemic communes under post-treatment surveillance in 2019. Achieving effective mass drug administration (MDA) in five communes of the Port-au-Prince metropolitan area remains a challenge, with MDA coverage steadily declining from 2012 to 2017 (79% to 41%). In 2017, the Ministry of Health (MOH) and partners adopted a new strategy to improve MDA coverage in urban settings. The investigators hypothesized that the use of mobile phones could improve MDA coverage through real-time daily reporting and staff feedback. A network of 750 community promoters (CPs) were trained to collect and submit data daily through an interactive voice response (IVR) using simple mobile phones. Data were cleaned, and daily reports generated with projected epidemiological coverage. Daily update reports were presented during next day morning briefings with the MOH and its partners, allowing reallocation of resources and focused efforts to strengthen areas of low performance. A total of 9,147 (81%) distribution post reports were received, including 7,830 (69%) received before the close of the MDA day. Reports were most commonly missing due to delay of submission of register forms from all posts and poor network connections. Based on analysis of the collected data, CPs provided feedback to community drug distributors to make improvements in the MDA process. Before using the mobile data collection system, it took months for the MOH and partners to obtain MDA performance data; with the new system, the program could estimate expected coverage before concluding MDA and make adjustments as needed. This strategy contributed to substantially improved data quality and MDA coverage (from 41% in 2017 to 80% in 2018) in the Port-au-Prince area at relatively low program cost ($USD 6000 for over 2 million people treated). For 2019 MDA, improvements will be made to resolve the issue of poor network connections by moving from an IVR platform to a short message service (SMS) platform.

652

PERSISTENT LYMPHATIC FILARIASIS TRANSMISSION IN HOTSPOT COASTAL COMMUNITIES DESPITE 10 OR MORE ROUNDS OF IVERMECTIN + ALBENDAZOLE MASS DRUG ADMINISTRATION. HOW CAN PROGRAMS ACCELERATE ELIMINATION TOWARDS THE 2020 TARGET?

Andreas Nshala[1], Abdel N. Direny[2], Kerry Dobies[2], Nancy Stroupe[2], Katie Crowley[3], Upendo J. Mwingira[4]

[1]*IMA World Health, Dar es Salaam, United Republic of Tanzania,* [2]*IMA World Health, Washington, DC, United States,* [3]*RTI International, Washington, DC, United States,* [4]*NTD Control Program and National Institute for Medical Research, Dar es Salaam, United Republic of Tanzania*

Fifty-five million Tanzanians are at risk of lymphatic filariasis (LF) infection. Two communities along the eastern coast of the Indian Ocean in Tanzania, Mafia and Lindi districts, had a baseline antigen prevalence of 46% and 53% respectively. Annual district-wide mass drug administration (MDA) started in 2001 in Mafia and 2003 in Lindi using Ivermectin (IVM) + Albendazole (ALB). After over 10 rounds of MDA in which epidemiological coverage varied from 44% to 87% in Mafia (12/13 rounds were effective) and from 29% to 90% in Lindi (7/10 were effective), with a steady trend of increased coverage through 2018, these coastal communities have not yet met the WHO criteria for stopping MDA. Sentinel and spot check sites assessments conducted in 2003, 2006, 2013, and 2016 revealed an average LF antigen of 28%, 27%, 4%, and 4% in Mafia, and 5%, and 7% in Lindi in 2013 and 2016. These results provided evidence that active transmission was ongoing in both districts. The program target is to reach below 2% LF antigen before conducting the transmission assessment survey (TAS) and eventually stopping MDA. In 2018, instead of once per year MDA as done in previous rounds, the program provided IVM+ALB twice per year targeting the eligible population, and reached 81% and 75% epidemiological coverage respectively in both MDA rounds. Sentinel and spot check sites reassessed in December 2018 after one round of MDA in 2017 and two rounds of MDA in 2018 revealed a remarkable reduction of LF antigenemia levels per site ranging from 100% (i.e. 0% prevalence) to 38% (i.e. over one thirds of infections reduced). It is demonstrated that LF antigenemia in hotspots could be reduced at an even faster rate than previously thought. Twice a year MDA with effective coverage for LF is feasible and acceptable, despite the challenge of perceived MDA fatigue from volunteers and the population at large. This approach may be key to reducing LF transmission in hotspots to achieve the elimination goal.

653

ANTIBODIES TO PEPTIDES REPRESENTING *PLASMODIUM FALCIPARUM* CIRCUMSPOROZOITE PROTEIN REFLECT ACQUISITION OF NATURALLY ACQUIRED IMMUNITY IN MALIAN ADULTS AND CHILDREN

Plowe[7], Andrea A. Berry[1]

[1]*University of Maryland School of Medicine, Baltimore, MD, United States,* [2]*U.S. Food and Drug Administration, Silver Spring, MD, United States,* [3]*Emmes Corporation, Rockville, MD, United States,* [4]*Malaria Research and Training Center, University of Sciences, Techniques and Technologies, Bamako, Mali,* [5]*Roche Sequencing Solutions, Madison, WI, United States,* [6]*Vaccine Research and Development Center, Department of Physiology and Biophysics, School of Medicine, University of California Irvine, Irvine, CA, United States,* [7]*Duke Global Health Institute, Duke University, Durham, NC, United States*

Plasmodium falciparum circumsporozoite protein (CSP) is the most studied malaria subunit vaccine antigen. CSP epitopes include the conserved

junction between the N-terminal and central repeat region (CRR), the immunodominant NANP CRR, and C-terminal polymorphic T and B cell epitopes. To investigate acquired CSP immunity, we probed sera from ten adults and ten children from Bandiagara, Mali, on a peptide microarray. 73 CSP variants from reference genomes and field-derived genomic data were represented as 16 amino acid (aa) peptides with 12 aa overlap. This resulted in 98 peptide positions with 1-23 variants at each position, totaling 251 peptide sequences. Log_2 transformed fluorescence intensities (FI) and serorecognition, defined as individual FI >2.5 standard deviations above FI for five U.S. malaria naïve controls, were compared. Adult sera had higher FI to 160 CSP peptides than children. Adult sera recognized more variant peptides than children (median adult 207.5 (range 157-241) and median children 86.5 (range 58-196), p=0.0001, Mann Whitney test). 60 CSP peptides were serorecognized by more adults than children and were located throughout the CSP ectodomain. In a longitudinal analysis of sera from children over three time points during the malaria season, overall FI was higher post- than pre-season (p<0.0001, Wilcoxon Signed Rank (WSR) test), and lower post- than mid-season (p< 0.0001, WSR test). Sera from children recognized a median (range) of 86.5 (58-196), 148 (75-84), and 115.5 (76-179) peptide variants pre, mid, and post season (pre to mid comparison p = 0.02, and mid to post comparison p = 0.08, WSR test). FI and serorecognition comparisons suggest that children develop antibody responses to diverse CSP epitopes during a malaria season, but responses wane. Overall, we described responses to CSP epitopes and their variants, and observed differential responses to the immunodominant NANP region, and other regions previously identified as potential markers of protective immunity. Next steps will be to differentiate immunodominant from protective responses in a larger study with longitudinal infection surveillance data.

IDENTIFYING ANTIBODY AND MONOCYTE RESPONSES ASSOCIATED WITH PROTECTION FROM MALARIA IN PREGNANT WOMEN

Amaya Ortega[1], Elizabeth Aitken[1], Wina Hasang[1], Holger Unger[2], Maria Ome-Kaius[3], Amy Chung[1], Stephen Rogerson[1]

[1]*The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia,* [2]*Victoria Hospital Kirkcaldy, Kirkcaldy, United Kingdom,* [3]*Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea*

Antibodies to VAR2CSA, member of the PfEMP1 family, have been associated with protection from placental malaria. Most studies have focused on the neutralising antibody that blocks placental sequestration, by inhibiting the adhesion of infected erythrocytes to chondroitin sulphate A, mediated by VAR2CSA. Placental malaria is frequently accompanied by accumulation of monocytes, and studies using promonocytic THP-1 cells demonstrate the importance of antibodies that promote phagocytosis of infected erythrocytes. To produce a more physiological model of how functional antibody can clear IgG-opsonised infected erythrocytes, we developed a novel phagocytosis assay using purified human primary monocytes. Results from intra-donor assays were highly correlated (r=0.70), inter-donor assays were less so (r=0.31). To investigate the role of antibody which promotes phagocytosis, monocytes isolated from Australian donors (n=3) and plasma samples from Papua New Guinean women were used. Women were categorized as non-infected with *Pf* (n = 50), infected with *Pf* placental malaria (n = 50) or infected with *Pf* but no placental malaria (n = 27). Phagocytosis assays measured antibody in sera to infected erythrocytes expressing VAR2CSA. Compared to women with placental malaria, pregnant women infected with *Pf* with no placental malaria were more commonly positive for (Chi-square test, p = 0.02) and had higher levels of (Mann-Whitney U test, p = 0.001) opsonising antibodies which promote monocyte phagocytosis infected erythrocytes. The assay has been further optimised to use beads coated with VAR2CSA domains, to examine domain specific responses, and we are characterising monocyte populations involved in phagocytosis (CD14, CD16, CD32 and CD64 markers). Primary human monocytes can reliably be used to measure opsonising antibody to parasite proteins on infected erythrocytes or coated on fluorescent beads, and opsonizing antibodies measured using these cells are associated with protection from placental malaria. Characterisation of functional immunity to VAR2CSA is an important complement to assays of adhesion blocking activity of antibody.

655

REPEATED MALARIA EXPOSURES SKEW MONOCYTES/ MACROPHAGES TOWARDS A REGULATORY PHENOTYPE

Rajan Guha[1], Anna Mathioudaki[2], Gunjan Arora[1], Shangping Li[1], Shafiuddin Siddiqui[3], Jeff Skinner[1], Didier Doumtabe[4], Safiatou Doumbo[4], Kassoum Kayentao[4], Aissata Ongoiba[4], Boubacar Traore[4], Judith Zaugg[2], Peter Crompton[1]

[1]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Rockville, MD, United States,* [2]*EMBL, Heidelberg, Germany,* [3]*NCI/National Institutes of Health, Bethesda, MD, United States,* [4]*Mali International Center of Excellence in Research, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali*

In malaria-naïve individuals, *Plasmodium falciparum* (*Pf*) infection results in high levels of *Pf*-infected red blood cells (iRBCs) that trigger systemic inflammation and fever. Conversely, individuals in endemic areas who are repeatedly infected are often asymptomatic and have low levels of iRBCs, even children who have yet to acquire fully protective antibodies. The molecular mechanisms underlying these clinical observations remain unclear. We previously showed that PBMCs collected from healthy Malian children before the malaria season responded to iRBCs by producing pyrogenic, pro-inflammatory mediators such as IL-1β, IL-6 and TNF. However, following febrile malaria there was a marked shift in the response to iRBCs with the same children's PBMCs producing lower levels of pro-inflammatory cytokines and higher levels of anti-inflammatory cytokines (IL-10, TGF-β). Moreover, genome-wide expression analysis showed that molecules involved in phagocytosis and intracellular killing were upregulated in PBMCs after malaria as compared to before. Together, these data suggested that malaria-induced epigenetic reprogramming of innate immune cells might play a role in immunity to malaria. In follow-up studies, age-stratified analysis of monocytes collected before the malaria season showed an inverse relationship between age and pro-inflammatory cytokine production capacity. Accordingly, monocytes of Malian adults expressed higher levels of CD163, CD206 and arginase 1, known molecules associated with a regulatory phenotype. These observations were recapitulated with an *in vitro* system of monocyte-macrophage differentiation whereby re-exposure to iRBCs was associated with diminished expression of pro-inflammatory mediators and a corresponding decrease in epigenetic markers of active gene transcription (i.e. H3K4me3) at the TSS/promoter regions of the same pro-inflammatory mediators. Together these data support the hypothesis that epigenetic reprogramming of monocytes/macrophages toward a regulatory phenotype contributes to the acquisition of clinical immunity to malaria.

656

CLEARANCE OF *PLASMODIUM FALCIPARUM*-INFECTED RED BLOOD CELLS BY NK CELLS AND MONOCYTES

Padmapriya Sekar, Gunjan Arora, Eric O. Long

National Institutes of Health, Rockville, MD, United States

Antibodies naturally acquired during repeated exposure to the parasite *Plasmodium falciparum* are essential for control of blood-stage malaria. NK cells are innate immune cells with an important role in containing viral infections and tumor growth, mainly by direct cytotoxicity and inflammatory cytokine production. Recently, we reported that primary human NK cells lyse *P. falciparum*-infected red blood cells (iRBCs) via antibody-dependent cellular cytotoxicity (ADCC) in presence of IgG isolated from adults living in a malaria-endemic region. This NK-mediated lysis results in inhibition of parasite growth *in vitro*. Live imaging showed release of parasitophorous vacuoles (PV) from iRBCs after incubation with NK cells. Many of these PVs gave propidium iodide-positive signals, suggesting loss of viability of *P. falciparum* inside the PVs after NK-mediated iRBC lysis. We are interested to know whether and how PVs

are eliminated from circulation and postulate that monocytes play a role in clearance of PVs, thereby preventing inflammatory responses by the innate immune system. Preliminary live imaging experiments suggest that monocytes phagocytose PVs that have been released from iRBCs after incubation with NK cells. We are testing plasma samples of individuals from malaria-endemic regions for antibodies reactive to *P. falciparum* antigens at the surface of PVs, and the contribution of Fc receptors on monocytes to phagocytosis of PVs.

MALARIA SPECIFIC GENE EXPRESSION SIGNATURE IN B CELLS FROM PAPUA NEW GUINEAN CHILDREN

Arlene E. Dent[1], Grace Weber[1], Bruce Rosa[2], Adam Pelletier[1], Paula Embury[1], Daisy Mantila[3], Moses Laman[3], Benishar Kombut[3], Maria Ome-Kaius[3], Christopher L. King[1], Leanne Robinson[4], Rafick-Pierre Sekaly[1], Makedonka Mitreva[2], James Kazura[1]

[1]*Case University, Cleveland, OH, United States,* [2]*Washington University, St. Louis, MO, United States,* [3]*PNG IMR, Madang, Papua New Guinea,* [4]*Burnet Institute, Melbourne, Australia*

Naturally acquired immunity to malaria develops slowly with age and is largely mediated by antibodies that protect against blood stage infection and malaria illness. Long-lived humoral immunity depends on the activation of T follicular help (Tfh) cells that support the differentiation of naïve B cells into long-lived plasma cells and memory B cells (MBC) in the germinal center reaction. The objective of this study was to advance understanding of the molecular pathways regulated in B cells and T cells of children with acute malaria and their specificity with respect to other acute febrile non-malaria illnesses. Papua New Guinean children aged 1-10 yrs old presenting with fever were enrolled in a prospective cohort study in which venous blood samples were collected at presentation and ~9 weeks later upon recovery. Children with fever were diagnosed with acute *Plasmodium falciparum* (Pf) malaria or acute febrile non malaria (Pf PCR negative) illness, e.g., pneumonia. We characterized B and T cell subsets by flow cytometry and performed RNA-Seq. Children with acute malaria had increased frequencies of classical, activated, and non-class switched MBC compared to children with acute febrile non malaria illness. Additionally, children with acute malaria had increased frequencies of quiescent Tfh subsets whereas children with acute febrile non malaria illness had increased frequencies of activated Tfh subsets. Using RNA-Seq, we found that total B cells from children with acute malaria had 272 upregulated genes compared to their recovery B cells and acute febrile non malaria B cells. These upregulated genes unique to malaria were significantly over-represented among 5 KEGG pathways: Protein processing endoplasmic reticulum, Parkinson's disease (mitochondrial function), Base excision repair, B cell receptor signaling, and Oxidative phosphorylation. We conclude that acute malaria B cells may have a unique immunometabolic signature that may reveal specific pathways useful for adjunct therapies. We are currently validating these findings with alternative methods and acute malaria B cells from other geographically distinct populations.

ENHANCING ATTENUATED SPOROZOITE VACCINES AGAINST MALARIA WITH A GLYCOLIPID ADJUVANT

Sumana Chakravarty[1], Charles Anderson[2], Moriya Tsuji[3], Andrew Ishizuka[4], Robert A. Seder[4], Stephen L. Hoffman[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States,* [3]*Aaron Diamond AIDS Research Center, New York, NY, United States,* [4]*Laboratory of Cellular Immunology, VRC, National Institutes of Health, Rockville, MD, United States*

A highly effective malaria vaccine is urgently needed. In clinical trials, Sanaria® PfSPZ-based vaccines, composed of aseptic, purified, cryopreserved, radiation attenuated PfSPZ Vaccine, or non-attenuated PfSPZ with chloroquine (PfSPZ-CVac) were safe and have been highly protective. Because PfSPZ Vaccine is based on eliciting long-lived tissue resident responses in the liver, novel approaches to improving its immunogenicity should be evaluated. Accordingly, we have been working on the effects of a novel glycolipid, 7DW8-5 that binds CD1d, and stimulates iNKT cells, as a rare immune stimulant in a mouse malaria model involving irradiated (irr) *P. yoelii* (Py) sporozoites (irrPySPZ). 7DW8-5 enabled reduction in number of doses from 3 to 1 for 75% protection with irrPySPZ by direct venous inoculation (DVI) and from 4 to 2 doses intradermally (ID), facilitated a contracted 1-week dosage regimen by DVI; and enhanced splenic CD8+ and CD4+ T cells responses with PfSPZ Vaccine in NHPs. In informal safety assessments, Balb/C and CD-1 mice injected with 10 μg (dose used in NHPs) of 7DW8-5 by DVI developed no signs of illness and doses of up to 100 μg 7DW8-5 administered intramuscularly (IM) with a recombinant adenovirus have been shown to be well tolerated in NHPs. These findings provided strong rationale for clinical development of 7DW8-5, and we are manufacturing 7DW8-5 under cGMPs, while refining preclinical regimens. Mice were durably protected at 16 weeks when immunized (DVI) with either 4 doses of 2×10^3 irrPySPZ (days 1, 3, 5, 8) or 2 doses of 2.5×10^4 (days 1,8) mixed with adjuvant. Durable protection declined when 7DW8-5 was omitted. Despite early studies showing efficacy by ID routes, irrPySPZ administered by non-DVI SC and ID routes resulted in 70-80% protection only with four doses of 1.5×10^5 irrPySPZ at two weeks after the last dose. Protection declined to 50% by 16 weeks, and two doses were not effective even at early challenge time points. Details of GMP 7DW8-5 testing *in vitro*, and immunogenicity in NHPs will be reported. Future use of this adjuvant is expected to vastly improve commercial, clinical, and public health benefits of PfSPZ vaccines.

Malaria still causes significant morbidity worldwide. However, a safe and effective vaccine remains elusive. Vaccines that showed promising results in the early phase of trials, which was usually conducted in malaria-naive areas, eventually proved suboptimal when tested in the endemic areas. Coinfections and pre-exposure to malaria are known to dysregulate immune system considerably, which might contribute to the differences in the efficacy of vaccines tested. To address this, we recruited five malaria-naïve Europeans and 20 malaria-preexposed Gabonese for a controlled human malaria infection (CHMI) with *Plasmodium falciparum* sporozoites (PfSPZ) Challenge (SanariaTM) via direct venous inoculation (DVI). Following the CHMI, all Europeans developed parasitaemia, whereas 8/20 (40%) African volunteers did not for the whole study period. This outcome enables the comparison of groups with a varying degree of antimalarial immunity. We analysed PBMCs from baseline, five and eleven days after DVI and stimulated them with *P. falciparum*-infected red blood cells (PfRBC) and controls to analyse antigen-specific cytokine response by flow cytometry. We demonstrate that the Gabonese who were able to control their parasitaemia (TBS-) had a higher percentage of IFN-g-producing CD4 T cells compared to TBS- Africans, who in turn had higher frequencies of these cells compared to the malaria-naïve Europeans. Additionally, we observed higher baseline frequency of PfRBC specific CM CD4 T cells in TBS- Africans, whereas TBS+ Africans have a higher frequency of TNF-producing CD8 NKT cells. Distinct patterns of immune responses over time associated with parasite control were also observed, which when supplemented with targeted gene set enrichment analyses, suggests migration of cells into the peripheral tissues to exert antimalarial responses. Our data provide information on the geographic differences in the immune response against malaria as well as the underlying mechanism of naturally-acquired immunity that lead to parasite control.

659A

IN VITRO AND *IN VIVO* ASSAYS TO ESTABLISH THE INFECTIVITY OF *IN VITRO*-PRODUCED *PLASMODIUM FALCIPARUM* SPOROZOITES

Abraham G. Eappen[1], Hashani Hettiarachchi[1], Tao Li[1], Sumana Chakravarty[1], Christiane Urgena[1], Benjamin U. Hoffman[2], McWilliams Ian[1], Patricia De La Vega[1], Ayyappan Rathakrishnan[1], Lixin Gao[3], MingLin Li[3], Peter F. Billingsley[1], B. Kim Lee Sim[1], Stephen L. Hoffman[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Columbia University Irving Medical Center, New York, NY, United States,* [3]*Protein Potential LLC, Rockville, MD, United States*

We are developing *in-vitro*-produced *Plasmodium falciparum* (Pf) sporozoites (SPZ) (iPfSPZ) to substitute for mosquito-produced PfSPZ (mPfSPZ) in controlled human malaria infections, vaccines, and biology studies. During the past 2 years we produced >10^8 iPfSPZ, and systematically studied iPfSPZ *in vitro* in HC-04 cells (hepatocyte line) and cryopreserved primary human hepatocytes (PHH), and *in vivo* in immunocompromised and fumarylacetoacetate hydrolase-deficient mouse (Fah-/-, Rag2-/-, Il2rg-/-, termed the FRG mouse) engrafted with human hepatocytes (FRG huHep) that has been shown to be an excellent model for *Plasmodium falciparum* (Pf) liver stage development. In HC-04 cells and PHH we added 5x10^4 iPfSPZ or mPfSPZ and after 6 days in culture assessed numbers of parasites > 10 μM expressing PfMSP1, PfLSA1, or PfHSP70 per well. In multiple experiments there were more parasites after adding iPfSPZ than mPfSPZ. Results of one set of assays comparing parasites/well expressing PfMSP1 after adding iPfSPZ vs PfSPZ were respectively 44±18 vs 36±8 in HC-04 cells and 116±35 vs 43±8 in PHH. We injected 0.8-2x10^6 iPfSPZ into FRG mice then 6 and 7 days later we infused the mice with human erythrocytes, and 6 hours after last infusion sacrificed the mice, processed the livers for immunohistochemistry (IHC) and cultured the blood to identify Pf. In two consecutive experiments, we successfully infected FRG mice with iPfSPZ and mPfSPZ producing asexual erythrocytic stage infection. In livers from FRG mice, by IHC there were qualitatively similar numbers of mature liver stage parasites 7 days after infection with iPfSPZ or mPfSPZ. In contrast to the *in vitro* assays and IHC of mice livers, the levels of asexual erythrocytic stage infection in the mice injected with iPfSPZ were substantially lower than in mice injected with mPfSPZ. Development of iPfSPZ and mPfSPZ to late liver stage parasites (*in vitro* and *in vivo*) were morphologically and quantitatively similar. We are now working to increase the efficiency of conversion from late liver stage to highly infectious erythrocytic stage parasites.

CHARACTERIZATION OF SUBSTANCE P DURING WEST NILE VIRUS INFECTION

Shannon E. Ronca, Sarah M. Gunter, Rebecca B. Kairis, R. Elias Alvarado, Allison Lino, Rodion Gorchakov, Kristy O. Murray

Baylor College of Medicine, Houston, TX, United States

In the United States, West Nile virus (WNV) has infected more than 7 million individuals since its introduction in 1999. Up to 40% of patients with symptomatic WNV infections will develop long-term, severe neurological complications. We must identify viable therapeutic options to prevent death and poor clinical outcomes, as no preventive vaccines have yet been licensed. A key player in neuroinflammation, substance P (SP), and its receptor neurokinin-1(NK1R) may play a valuable role in the progression of WNV infection. We previously conducted a study in the wild-type BL6 mouse model of WNV neuroinvasive disease using a highly selective NK1R antagonist and observed increased survival and modulation of SP that correlated with survival outcomes. Treatment successfully lowered levels of SP RNA in brains of treated mice, but did not alter levels of WNV RNA, suggesting a role for SP in modulating WNV infection. We aimed to characterize the levels of SP in the same mouse model during infection in the absence of treatment. When compared to uninfected controls, increased levels of SP are obvious within 1 day post infection (DPI) in whole blood and 5DPI in brains and levels correlate to survival. Additionally, we used flow cytometry to characterize the immune cell types present in brain and spleen during infection to identify which are key players to the exacerbating role of SP to WNV infection, including astrocytes and microglia, which have been previously identified to play roles in WNV infection and neuroinflammation of other diseases. This study provides evidence that SP is, at minimum, a valuable marker to detecting the severity of WNV infection, and further supports that treatment with an NK1R antagonist has potential as a treatment for WNV during acute infection.

THE RE-EMERGENCE OF YELLOW FEVER EPIDEMICS IN NIGERIA MAY CONTINUE DESPITE THE INCLUSION OF ITS VACCINE IN NATIONAL PROGRAM ON IMMUNIZATION. THE LOW POPULATION IMMUNITY SPEAKS

Marycelin M. Baba[1], Bamidele Soji Oderinde[1], Erick Mora Cardenas[2], Alessandro Marcello[2]

[1]*University of Maiduguri, Maiduguri, Nigeria,* [2]*International Centre for Genetic Engineering and Biotechnology, Trieste, Italy*

Globally, YF is a re-emerging disease with approximately 200,000 cases and 30,000 deaths occurring annually, with 90% of them in Africa. In 2016, 32 African countries with a total population of 610 million people were at the risk of YF. Nigeria is one of 37 countries in Africa with high risks of YF epidemics. YF epidemics in Nigeria were presumptively diagnosed in 1946, 1951, 1952, 1953 1957 but was confirmed in 1969 and it reoccurred in 1970. The estimated and laboratory confirmed cases from these epidemics (1946-1970) ranged from several thousands and 124 respectively. Among estimated cases, death claimed more than 1000 lives and 118 from confirmed cases. After 21 years of silence, YF epidemic hit Kwara State in September 2017 and extended to six other states and twelve Local Government Areas (LGAs) in January, 2018. These epidemics involved 358 suspected, 33 (51.6%) confirmed cases with 45 deaths (CFR :21.1% and 28.1% among suspected and confirmed respectively). Within this period, sporadic YF epidemics were reported in 16 states and 62 LGAs. In November 2018, another YF epidemics were reported in six states and FCT involving 11,140 confirmed cases. To assess the possibility of the persistence of these epidemics in the country, the population immunity studies were conducted in three states in northeastern Nigeria using micro-neutralization (MN), IgM/IgG ELISA and plaque reduction neutralization tests (PRNT). While other tests (ELISA and PRNT) are on ongoing, the MN which denotes the ability of the protective antibody to inhibit the infectivity of the virus shows that only 68 (9.2%) of 738 patients tested, had YF neutralizing antibody with a titre of 8 and above. Thirty –six of the 68 patients (52.9%) had antibody titre of 1:8 while 670 (90.8%) had no neutralizing antibody to this virus. The huge population immunity gap is a pointer to the possibility that YF epidemics will persist in Nigeria. It also implies that inclusion of YF vaccination in NPI is not sufficient to yield the desired herd immunity and the occurrence of these epidemics in Nigeria poses serious global threats.

662

SYNDECAN-1 AS A BIOMARKER OF SEVERITY IN ACUTE YELLOW FEVER

Francielle Tramontini Gomes de Sousa[1], Erika R. Manuli[2], Luiz G. Zanella[3], Yeh-Li Ho[3], Lucas Chaves Netto[3], Mariana P. Marmorato[3], Juliana Z. Dias[3], Mateus V. Thomazella[3], Carolina A. Correia[3], Cássia G. Silveira[3], Priscilla R. Costa[3], Geovana M. Pereira[3], Midiã S. Ferreira[3], Camila M. Romano[2], Esper G. Kallas[3], Eva Harris[1], Ester C. Sabino[4]

HCFMUSP, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil, [4]Department of Infectious and Parasitic Diseases, Institute of Tropical Medicine, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil

Symptomatic infections by yellow fever virus (YFV) are characterized by intense vasculopathy and organ impairment, especially liver, kidneys, lungs, intestine, and brain, leading to high mortality rates (~30%). The aim of this study was to evaluate clinical and laboratorial factors related to endothelial damage, such as syndecan-1 serum levels and Transendothelial Electric Resistance (TEER), in individuals with acute yellow fever (YF). Blood samples of patients with suspected YF were collected after informed consent was obtained, when individuals were admitted to Hospital das Clínicas, University of São Paulo, Brazil. YF cases were confirmed by detection of YFV in blood and/or autopsy tissues by RT-PCR. Cases were classified in three groups as follows: i) non-severe (N=11): individuals who recovered and presented neutrophil count <4000/mL, indirect bilirubin (IB) <0.6 mg/dL, and aspartate aminotransferase (AST) <1500 U/L; ii) severe (N=37): individuals who presented one or more of the following criteria: neutrophil >4000/mL, IB >0.6 mg/dL, AST <1500, and/or death; iii) control (N=11): healthy individuals. Serum levels of syndecan-1 (a transmembrane protein that is shed during vascular disruption) were significantly (p<0.001) higher in the severe group (mean 170.5 ng/ml) when compared to the non-severe (mean 50.6 ng/ml) or control groups (mean 2.3 ng/ml). Moreover, syndecan-1 serum levels strongly correlated with AST (Pearson R=0.469, p=0.001) and creatinine levels (Pearson R=0.512, p<0.001), as well as with death (Pearson R=0.469, p=0.001). Syndecan-1 serum levels were also significantly (p=0.0048) higher in YFV-infected individuals who died (mean 215.9 ng/ml) than in patients who recovered (mean 106.7 ng/ml). Notably, TEER values of human umbilical vein endothelial cells (HUVECs) treated with serum from the three different groups correlated with circulating levels of syndecan-1 (Pearson R=-0.493, p=0.044). In summary, these results indicate that syndecan-1 is associated with vascular impairment and yellow fever severity and therefore may be used as a biomarker of disease outcome.

AVIAN SUSCEPTIBILITY TO AFRICAN AND EUROPEAN USUTU VIRUS STRAINS

Sarah Kuchinsky[1], Francesca Frere[1], Eric Mossel[2], **Nisha Duggal**[1]

[1]*Virginia Tech, Blacksburg, VA, United States,* [2]*Centers for Disease Control and Prevention, Fort Collins, CO, United States*

Usutu virus (USUV; *Flaviviridae*) is an emerging mosquito-borne virus closely related to West Nile virus (WNV). USUV is likely maintained in an enzootic cycle between birds and *Culex* spp. mosquitoes and can cause severe neuroinvasive disease in humans. USUV was initially discovered in South Africa in 1959, with detection in additional African countries in subsequent years. In the past two decades, USUV has been introduced into Europe multiple times, with increasing geographic spread across the continent. Large-scale bird die-offs have accompanied the spread of USUV in Europe, particularly in Eurasian blackbirds (*Turdus merula*). However, no avian models have been developed for USUV, and whether the virus has become more transmissible or pathogenic during emergence is unknown. To determine whether USUV has evolved during emergence in Europe, we sequenced several African isolates and compared sequences to circulating European strains. We found evidence of positive selection in the USUV NS3 gene, with derived mutations occurring in European isolates. To test whether USUV may have become more pathogenic in birds during emergence, we selected two low-passage European and two low-passage African USUV strains to evaluate (Netherlands 2016, Spain 2009, Uganda 2010, and South Africa 1959). All strains replicated to high titers in chicken, duck, goose, and quail cell lines. Next, locally hatched two-day-old chickens were inoculated subcutaneously with the USUV strains. All chicks developed viremia between days 1 and 4 post-inoculation, with no morbidity or mortality in any group and a trend towards higher viremia in birds inoculated with European strains compared to African strains. In an *ex vivo* model using chicken PBMCs, the European isolates reached significantly higher titers than the Uganda 2010 isolate. Further comparisons will be performed in a susceptible mouse model and in wild birds to determine whether differences in viremia are species-specific.

Genotype I (GI) virus has replaced genotype III (GIII) virus as the dominant Japanese encephalitis virus (JEV) in the epidemic area of Asia. The mechanism underlying the genotype replacement has remained unclear. We focus our current study to investigate the role of mosquito vector and amplifying host(s) in JEV genotype replacement by comparing the replication ability of GI to GIII viruses *in vitro* and *in vivo*. GI and GIII viruses had similar infection rate and replicated the similar viral titers by blood meal feeding in *Culex tritaeniorhynchus*. But GI virus yielded a higher viral titer in amplifying host-derived cells, especially at the elevated temperature, and produced an earlier and higher viremia in experimentally inoculated amplifying hosts (pigs, ducklings, and young chicken). The amplifying advantage of viral genetic determinants of GI viruses was subsequently identified by utilizing chimeric and recombinant JEVs (rJEVs). As comparing to the recombinant GIII virus (rGIII virus), we observed a higher replication ability of the recombinant GI virus as well as the chimeric rJEVs encoding GI virus-derived NS1-3 genes in the amplifying hosts. The replication advantage of the chimeric rJEV abolished after the introduction of a single substitution of GIII viral mutation (NS2B-L99V, NS3-S78A, or NS3-D177E). In addition, the gain-of function assay further supported that rGIII virus encoding GI virus NS2B-V99L/NS3-A78S/E177E substitutions re-gained the enhanced replication ability. Thus, we conclude that the replication advantage of GI virus in the pigs and poultries is the result of three critical NS2B/NS3 substitutions. This may lead to more efficient transmission of GI virus than GIII virus in the amplifying hosts-mosquitoes cycle.

665

PROTECTIVE EFFICACY OF JAPANESE ENCEPHALITIS VIRUS MONOCLONAL ANTIBODIES DERIVED FROM VACCINATION IN A MINIATURE SWINE MODEL

Christian L. Cook[1], Victoria B. Ayers[1], Amy C. Lyons[1], So Lee Park[1], Ashley N. Doerfler[1], Susan M. Hettenbach[2], Ashley M. Zelenka[1], Konner R. Cool[1], Gregory J. Peterson[3], Stephen Higgs[2], Dana L. Vanlandingham[1], Yan-Jang S. Huang[1]

[1]*Department of Diagnostic Medicine/Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan, KS, United States,* [2]*Biosecurity Research Institute, Kansas State University, Manhattan, KS, United States,* [3]*University Research Compliance Office Kansas State University, Manhattan, KS, United States*

Japanese encephalitis virus (JEV) is a mosquito-borne flavivirus which causes neurotropic disease in humans and is maintained in swine and avian species which serve as amplification hosts. Current vaccines derived from a genotype III (GIII) isolates have significantly reduced the number of pediatric encephalitis cases. However, there has been increasing concern of potential vaccine failure and immune breakthrough due to the rapid emergence of genotype I (GI) throughout the Asia Pacific region. In this study, heterologous protective efficacy of two mouse anti-JEV monoclonal antibodies (mAbs), derived from immunization with GIII isolates, was

evaluated through the passive immunization and experimental challenge of pigs with a representative strain of the emerging GI. Prophylactic treatment of JEV-31 and JEV-169 mAbs, which target domain III and domain I of the envelope (E) protein, respectively, conferred protection against challenge of GI JE-91 strain based on the delayed onset of fever and viremia. Overall, our results demonstrated that anti-E mAbs derived from vaccination are capable of protecting against the infection with heterologous JEV genotypes and provide the basis for our understanding of the breadth of humoral immune responses induced by JEV vaccines in susceptible vertebrate hosts.

666

DISEASE SURVEILLANCE AND VIROME ANALYSIS STUDY OF JAPANESE ENCEPHALITIS VECTOR, *CULEX TRITAENIORHYNCHUS*, COLLECTED FROM THREE PREFECTURES IN JAPAN

Astri Nur Faizah[1], Daisuke Kobayashi[2], Michael Amoa-Bosompem[3], Haruhiko Isawa[2], Kyeong Soon Kim[4], Mamoru Watanabe[2], Kozue Miura[1], Kazuhiro Hirayama[1], Kyoko Sawabe[2]

[1]*The University of Tokyo, Tokyo, Japan,* [2]*National Institute of Infectious Diseases, Tokyo, Japan,* [3]*Tokyo Medical and Dental University, Tokyo, Japan,* [4]*Tottori University, Tottori, Japan*

Japanese encephalitis (JE) is the leading cause of viral encephalitis with over 60,000 cases annually and is endemic in many Asian countries, including Japan. Japanese encephalitis virus (JEV) is mainly transmitted by *Culex tritaeniorhynchus*. Knowledge on the paddy-breeding mosquitoes' nature is vital in understanding the transmission cycle of JEV. A lot of effort has been put into virome determination of virus-transmitted mosquitoes. Mosquito viruses, based on host range, are divided into arbovirus (which infect vertebrates) and insect-specific virus (ISV). Recent studies have indicated the ability of ISVs in affecting vector competence to transmit arboviruses. Using an extensive approach of high-throughput RNA-sequencing, JE surveillance together with virome analysis has become practicable. Therefore the aim of this study was to combine JE surveillance and determination of the JE vector's virome. In this study, we collected *Cx. tritaeniorhynchus* mosquitoes in three prefectures (Ishikawa, Tottori, and Nagasaki) in 2017. RNA viromes were processed using metagenomic sequencing. Subsequently, the results were verified by PCR and followed by phylogenetic analysis. We successfully identified eight novel viruses out of eighteen viral genomes, including one JEV detected in only Ishikawa prefecture. Novel viruses belonged to divergent families, notably *Flaviviridae* and Iflaviridae. The JEV identified belonged to Genotype I based on its envelope (E) gene sequences, and was closely related to JEV isolated from cattle in Miyazaki prefecture in 2009. We are currently comparing virome of mosquitoes from different prefectures and determining the correlation with JEV, if any. This study not only adds up the knowledge pool of ISVs in Culex mosquitoes, but it also reveals continuous amplification and active transmission cycle of JEV and highlights the need for constant national surveillance and vaccination. Japan is one of the countries in Asia to implement regular JE vaccination since 1930, however, the JEV circulation shows no sign of a halt, thus alerting other endemic countries where vaccination has never been applied.

667

EXPLANTS OF HUMAN AND RUMINANT PLACENTAS ARE TARGETED BY MEMBERS OF THE *BUNYAVIRALES* ORDER DIFFERENTLY: COMPARING CELLULAR AND MOLECULAR MECHANISMS OF INFECTION TO UNDERSTAND DISPARATE RATES OF MISCARRIAGE BETWEEN SPECIES

Cynthia M. McMillen, Devin A. Boyles, Joseph R. Albe, Amy L. Hartman

University of Pittsburgh, Pittsburgh, PA, United States

Rift Valley fever virus (RVFV) is an arbovirus that causes disease in livestock and humans in Africa and the Middle East. Ruminants are highly susceptible to RVFV infection resulting in synchronous miscarriages, or "abortion storms". Abortogenic rates reach as high as 100% within a given outbreak. In pregnant women, there have only been two confirmed cases of vertical transmission and infection increases the risk of late-term miscarriage. To understand the disparate ability of RVFV to infect placentas from ruminant livestock and women, we compared tissue permissivity and tropism of RVFV infected ruminant and human placentas. Secondly, because other phylogenetically similar viruses may have conserved mechanisms of infection, tropism, and pathogenicity, we sought to understand whether other *Bunyavirales* target reproductive tissues similar to RVFV. The decidua, chorioallantoic membrane, and villi from sheep, cattle, or human mid- or term-gestation placentas were infected with arboviruses from the *Bunyavirales* order (Heartland, Jamestown Canyon, La Crosse) or Zika virus for comparison. RVFV cell-tropism was visualized by confocal fluorescent microscopy and viral titer was quantitated by qRT-PCR and plaque assay. RVFV replicated in sheep and cow placenta; infection was more efficient in the chorioallontoic membrane compared to separate cultures of the chorion and allontoic membranes. Highest viral yields occurred in the chrioallontoic membrane of ruminants, whereas highest replication occurred in the chorionic villus of humans. Heartland, Jamestown Canyon, and La crosse viruses also replicated in ruminant tissue. These results incidate a previously unrecognized potential for Heartland, Jamestown Canyon and La crosse viruses to target placental tissue. This is the first example of *Bunyavirales* such as Heartland and La crosse viruses to infect tissues from species other than their natural hosts. Further comparison of the permissive nature of *Bunyavirales* to structurally different placenta structures will help pinpoint the viral and cellular components needed for viral entry into reproductive organs and induction abortions.

668

INVESTIGATION OF AIM2 LOSS IN BATS REVEALS FUNCTIONAL DAMPENING OF THE INFLAMMASOME PATHWAY

Geraldine X. Goh, Matae Ahn, Aaron T. Irving, Zhu Feng, Lin-Fa Wang

Duke-NUS Medical School, Singapore, Singapore

in the co-evolution between hosts and their commensal infectious agents, bats have emerged as mammals which appear to harbor a range of highly lethal zoonotic viruses such as filoviruses, lyssaviruses, henipaviruses, and coronaviruses. We previously reported a complete loss of the PYHIN gene family, including the mammalian AIM2 gene, a cytosolic dsDNa sensor capable of activating the inflammasome. AIM2 recruits its adaptor ASC and triggers formation of the multi-protein inflammasome complex, activating caspase-1 to cleave key cytokines such as IL-1β for secretion, and mediating a pro-inflammatory cell death program called pyroptosis. While AIM2 mediates an essential role in sensing and alerting mammalian cells to invasion by foreign pathogens, over-activation can trigger detrimental cell death and tissue injury in the host. We observed that wild-type bat immortalized kidney and primary bone marrow derived macrophages (BMDMs) indeed lack AIM2 inflammasome signaling and ASC-speck formation in response to cytosolic dsDNA. AIM2 reconstitution restored adaptor recruitment of ASC *in vitro*, with dose-wise increase of ASC-speck formation in response to treatment with cytosolic dsDNA.

Intriguingly, cytokine release and cell death remained relatively dampened in spite of AIM2 inflammasome reconstitution. in comparison to human caspase-1, bat caspase-1 exhibited decreased activity and was identified as responsible for the lack of IL-1β secretion. Taken together, our data indicates that loss of AIM2 in bats results in diminished ability to respond to cytosolic dsDNA, augmented by further dampening of the downstream inflammasome pathway. Thus bats may have evolved to protect against inflammasome hyperactivation during metabolic or oxidative stress, in part conferring them the ability to harbor zoonotic agents without immune-mediated pathogenesis.

669

PATHOGENIC *E. COLI* IN DRINKING WATER: ARE THEY HUMAN OR ANIMAL IN ORIGIN?

Jannatul Ferdous[1], Ridwan Bin Rashid[1], Rebeca Sultana[2], Sabera Saima[1], Musharrat Jahan[1], Anowara Begum[1], Peter Kjær Jensen[2]

[1]*University of Dhaka, Dhaka, Bangladesh,* [2]*University of Copenhagen, Copenhagen, Denmark*

The occurrence of pathogenic bacteria in drinking water is a global health concern. The aim of this study was to investigate the presence of diverse pathotypes of *E. coli* isolates in piped-to-plot 'improved' communal source water and in point-of-consumption of drinking water (point-of-drinking) and, to identify their origin of fecal contamination. The study was conducted from September 2014 to October 2015 in a low-income urban community of Bangladesh. PCR was performed for characterization of pathogenic *E. coli* and phylogenetic grouping. a total of 229 *E. coli* isolates were randomly collected where 125 isolates were from 108 point-of-drinking and 104 were from 76 communal source water samples. Diverse pathotypes were identified where ETEC was the most prevalent pathotype found in point-of-drinking water (37%, 46/125) and communal source water (46%, 48/104). Phylogenetic grouping showed substantial presence of subgroup B1 (most prevalent in animals feces) in both of point-of-drinking (50%, 91/181) and source water (50%, 90/181) isolates followed by the presence of B2-3 (most prevalent human feces) in (65%, 13/20) point-of-drinking and (35%, 7/20) source water. Our findings suggest that both communal sources and point-of-drinking water of the study area were mostly contaminated by the feces from animals (181/229) and to a lesser extent by human feces (20/229). The non-human mammals and birds played a vital role in fecal contamination of the water and require priority attention in future intervention effort of water quality improvement. Our results indicate that addressing human sanitation without consideration of fecal contamination from livestock sources may not be enough to prevent drinking water contamination and thus will persist as a greater contributor of diarrheal pathogens in low-income urban communities.

670

ANTIBODIES AGAINST *TREPONEMA PALLIDUM* SHOW THAT YAWS IS ENDEMIC IN NONHUMAN PRIMATES IN KENYA

Emily H. Hardgrove[1], Dawn M. Zimmerman[2], Michael E. von Fricken[3], Graham A. Matulisb[3], Joseph Kamau[4], Daniel Chai[4], Samson Mutura[4], Velma Kivali[5], Fatima Hussein[4], Peris Ambala[4], Andrea Surmat[6], Sascha Knauf[7]

[1]*Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA, United States,* [2]*Global Health Program, Smithsonian Conservation Biology Institute, Washington, DC, United States,* [3]*George Mason University, Fairfax, VA, United States,* [4]*Institute of Primate Research, Karen-Nairobi, Kenya,* [5]*International Livestock Research Institute, Nairobi, Kenya,* [6]*Mpala Research Centre and Wildlife Foundation, Laikipia, Kenya,* [7]*German Primate Center, Goettingen, Germany*

Yaws is a disease caused by the bacterium *Treponema pallidum* subsp. *pertenue* (*TPE*), believed to be a solely human pathogen. *TPE* has recently been identified in African nonhuman primates (NHP) raising concerns about a possible zoonotic reservoir. Kenya is one of 76 countries the World Health Organization (WHO) categorizes as previously endemic for yaws, but there are no current data on presence or absence. Sustainable yaws eradication will, however, rely on information about transmission dynamics and potential links between human and NHP *TPE* strains. in October of 2016, 65 olive baboons (*Papio anubis*) and two vervet monkeys (*Chlorocebus pygerythrus*) were sampled in Laikipia County, Kenya. As no skin lesions were observed, a preliminary serological screening was performed using the immunochromatographic Dual Path Platform (DPP) HIV-Syphilis Assay (Chembio Diagnostic Systems, Inc.) and the *T. pallidum* Particle Agglutination Assay (SERODIa ® TP-PA). The DPP test found antibodies in one of the two vervet monkeys and in 73.8% (48/65) of the baboons. Of the 37 baboon samples with definitive *TP-Pa* results, 31 were positive, including four that tested negative with the DPP assay, yielding a combined seropositivity of 54% (34/63). Based on the DPP assay, males (84.4%, 38/45) had a relative risk of 1.77 (p=.003, 95% [1.205, 3.015]) compared to females (47.62%, 10/21). Adult male baboons exhibited 100% (20/20) seropositivity compared to adult females, at 81.8% seropositivity (9/11). Infants exhibited the lowest seroprevalence rates (25%, 1/4), followed by juveniles (50%, 11/22), subadults (85.7%, 6/7), and adults (88.23%, 30/34). The propensity towards sexually mature animals is suggestive for a sexual transmission mode. Our data contribute evidence that in East Africa, *T. pallidum* infection is endemic in NHPs and multiple NHP taxa contain antibodies indicating latent infection. Providing reliable information on the epidemiology of treponematoses in both humans and NHPs, especially in regions where both co-exist, has important programmatic implications for yaws eradication.

671

HIGH INCIDENCE OF HUMAN BRUCELLOSIS IN A RURAL PASTORALIST COMMUNITY IN KENYA, 2016

Peninah M. Munyua[1], Eric Osoro[2], Elizabeth Hunsperger[1], Mathew Muturi[3], Athman Mwatondo[4], Doris Marwanga[5], Philip Ngere[6], Rebekkah Tiller[7], Clayton Onyango[1], Kariuki Njenga[2], Marc-Alain Widdowson[1]

[1]*US Centers for Disease Control and Prevention - Kenya, Nairobi, Kenya,* [2]*Washington State University Global Health Program, Nairobi, Kenya,* [3]*Kenya Ministry of Agriculture Livestock and Fisheries, Zoonotic Disease Unit, Nairobi, Kenya,* [4]*Kenya Ministry of Health, Zoonotic Disease Unit, Nairobi, Kenya,* [5]*Center for Global Health Research, Kenya Medical Research Institute, Nairobi, Kenya,* [6]*Kajiado county Department of Health, Nairobi, Kenya,* [7]*Bacterial Special Pathogens Branch, Centers for Disease Control and Prevention Atlanta, Nairobi, Kenya*

Brucellosis is a zoonotic infection of ruminants. Humans are generally infected through unpasteurized milk or contact with infected animals. Globally, incidence is higher in the Middle East and Asia, but data in sub-Saharan Africa are scarce. We estimated the incidence of human brucellosis in a pastoralist community with high brucellosis sero-prevalence from a previous study. We enrolled all household members of randomly selected households in Kajiado County. Between February 2015 and January 2016, any household member who fell ill was asked to visit any of three study health facilities. Those who met the clinical case definition for suspect brucellosis (fever and at least one of night sweats, joint or muscle pains, headache, fatigue and anorexia) provided a blood sample. Samples were tested by Rose Bengal test (RBT) for agglutination antibodies and TaqMan Array Card (TAC) for *Brucella* DNA. Positive tests by TAC or RBT constituted the laboratory-confirmed brucellosis cases. Data on demographics, clinical presentation and risk factors were collected using a standardized questionnaire. Estimated crude cumulative incidence, by age and sex, was the number of brucellosis cases in one year per total population in enrolled households. Of 4,746 enrolled persons in 804 households, 52% were males and median age was 18 (range, 1-99) years. We enrolled 236 suspect brucellosis cases at the health facilities; 64% were females and median age was 41 (range, 1-97 years). Of the 236 suspect cases, four (2%) tested positive by RBT and of 217 tested, 23 (11%) positive by TAC. Laboratory-confirmed acute brucellosis cases were 24 (10%), yielding a crude cumulative annual incidence of 506/100,000 persons (95% confidence interval; 441 - 580). Incidence among females was two times higher than males (662 vs 362) and two to eight times

higher in the 41-60 age compared to other age groups. Education on risk factors for *Brucella* transmission and animal vaccination would help reduce the high incidence of brucellosis in this pastoralist community.

672

SEASONALITY OF AGRICULTURAL EXPOSURE MORE IMPORTANT THAN SEASONALITY OF CLIMATE FOR PREDICTING YELLOW FEVER TRANSMISSION IN BRAZIL

Arran Hamlet[1], Daniel G. Ramos[2], Katy Gaythorpe[1], Alessandro P. Romano[2], Tini Garske[1], Neil Ferguson[1]

[1]*MRC Centre for Outbreak Analysis and Modelling, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom,* [2]*Secretariat for Health Surveillance, Brazilian Ministry of Health, Brasilia, Brazil*

Yellow fever virus (YFV) is a zoonotic arbovirus affecting both humans and non-human primates (NHP's) in Africa and South America. In South America since 1942 almost all cases have arisen from sylvatic spillover. Previous descriptions of YF's highly seasonal nature have relied on climatic explanations, with the role of the seasonality in exposure neglected - despite the high proportion of cases occurring in those involved in agriculture. This study investigates the role of seasonality in agriculture, as well as climate, in YF reporting for humans and non-human primates (NHP's). We fit a series of random forest models to yellow fever (YF) occurrence in both human and NHP's (2003-2018) at the 2nd administrative division against covariates accounting for the seasonality of climate, the seasonality of agriculture (planting, harvesting), agricultural output and host dynamics. An exhaustive combination of covariate groupings to produce 15 models which were assessed for accuracy and predictability. Models fit to human reports performed better than NHP with an average area under the curve (AUC) value of 0.924 (95% CI: 0.914 - 0.933) vs 0.893 (0.882 - 0.905). Models fit to covariates including the seasonality of agriculture, but not the seasonality of climate, fit better than the inverse, in humans 0.948 (0.941 - 0.955) vs 0.903 (0.891 - 0.916) and NHP's, 0.908 (0.897 - 0.918) vs 0.859 (0.845 - 0.873). Models also highlighted the influence of planting and harvesting corn, beans and soya as predictors of human YF reporting. These findings illustrate the importance of the seasonality of exposure and that it is not necessarily just an increased viral transmission in zoonotic reservoirs which leads to spillover, but also an increased interaction with the sylvatic cycle. Direct application of these findings in a public health setting is possible, with 45% of YF cases in Brazil occurring in those involved in agriculture. By highlighting both the crop types involved, and the temporal window, vaccination activities and public health outreach could effectively, and pro-actively, educate and vaccinate those at greatest risk of YF.

673

FARMERS AND FECES: A ONE HEALTH APPROACH TO EMERGING SWINE ZOONOSES

Emily Bailey[1], Vida Ahyong[2], Cristina Tato[2], Maria Phelps[2], Norma Jeff[2], Michelle Tan[2], Rene Sit[2], Joseph DeRisi[3], Gregory Gray[1]

[1]*Duke University, Durham, NC, United States,* [2]*Chan-Zuckerberg Biohub, San Francisco, CA, United States,* [3]*University of California at San Franscisco, San Franscisco, CA, United States*

North Carolina is the second largest producer of pork in the United States. Disease outbreaks, such as those from porcine epidemic diarrheal virus (PEDV), highly pathogenic porcine reproductive and respiratory syndrome virus (PRRSV), porcine circovirus 2 (PCV2), can readily threaten swine production operations sometimes resulting in large economic losses. Pathogen surveillance within swine farms can be an effective approach for the early identification of new disease threats and the mitigation of transmission before broad dissemination among a herd occurs. However, standard surveillance practices might not always be feasible as they may disrupt normal production operations. Additionally, the cost of conducting surveillance, particularly in large-scale settings, may also be a barrier to its routine implementation. The focus of this study was to describe a non-invasive swine slurry sampling method as an alternative approach for conducting routine surveillance in farms, providing an additional tool for farmers to protect their animals and themselves from new disease threats. Our preliminary molecular analysis of viruses detected in fecal slurry indicates that non-swine origin viruses are present these samples. These findings were then further validated using a metagenomic sequencing approach in partnership with the Chan-Zuckerberg Biohub and the Chan-Zuckerberg Initiative and their new bioinformatic pipeline, IDseq. The results of our preliminary analysis likely reflect the effects of virus recombination as well as close interaction between livestock and wildlife. This work also indicates the need for additional work further understand the impact of zoonotic viral pathogens on swine exposed workers particularly in areas where zoonotic disease transmission is known to occur, such as on large scale swine farms.

MALARIA MORBIDITY IN VENEZUELA 1995-2018: AN OBSERVATIONAL ANALYSIS OVER 1.7 MILLION CASES

Leopoldo Villegas[1], Leonor Pocaterra[2], Luis F. Chavez[3], Jorge Moreno[4], Elia Sanchez[5], Melfran Herrera[5], Angela Martinez[6], Gustavo Bretas[7], Anderson Martinez[7], Maria M. Villegas[7], Mary Ann Torres[8], Maria E. Guevara[7], Jose Oletta[9]

[1]*ASOCIS, Tumeremo, Bolivar, Bolivarian Republic of Venezuela,* [2]*Universidad Central de Venezuela, Caracas, Bolivarian Republic of Venezuela,* [3]*INCIENSA, San Jose, Costa Rica,* [4]*Centro de Investogacion de Campo Dr. Francesco Vitanza, Tumeremo, Bolivar, Bolivarian Republic of Venezuela,* [5]*Fundasalud Sucre, Cumana, Bolivarian Republic of Venezuela,* [6]*Instituto de Salud Publica, Ciudad Bolivar, Bolivarian Republic of Venezuela,* [7]*Global Development One, Silver Spring, MD, United States,* [8]*International Council Of Aids Service Organizations (ICASO), Montreal, ON, Canada,* [9]*Alianza Venezolana por la Salud, Caracas, Bolivarian Republic of Venezuela*

Venezuela is facing a complex humanitarian emergency with the worst malaria resurgence in the Americas. The national malaria information system (MIS) collects weekly malaria cases since 1955. This is an observational study based on national surveillance data as part of long-term (25 y) epidemiological studies on the dynamics of malaria transmission. Individual-level data on all malaria cases between 1995-2006 (nationwide) and 2007-2018 (84% of the national caseload) were obtained from the national/state information systems. Malaria cases (reported and estimated) were triangulated with publicly available datasets. Case notification forms contained basic information on demographics (age, sex), case classification (indigenous, imported), and the reporting location (municipality, State). From 2008 onwards new variables were added: key dates (symptom onset, diagnosis, and treatment), and reporting unit location (health facility, parish) and occupation, residence and, ethnicity. Between 1995-2018, data from 1.74 M (out of 2.1 M cases reported) were consolidated. Annual malaria cases showed marked heterogeneity in time and space. *Plasmodium vivax* was the most important parasite involved in the transmission nationwide (>70%). Over the study period, *P. falciparum* and *P.malariae* infections were clustered in hotspots in Bolivar and Amazonas States while most cases in Sucre state, are due to *P.vivax* (99%). Consistent with the increase in transmission over the years, local transmission occurred in 23/24 states (2018); mixed infections rose significantly (7 times). Key populations affected by malaria include miners, plantation workers, indigenous groups, pregnant women, adolescents, and young adults. Malaria resurgence has been driven by internal migration to mining areas, stock out of antimalarial drugs and limited control activities. Venezuela offers a unique opportunity to better understand the epidemiological characteristics of malaria resurgence in a humanitarian emergency context. Data-driven approaches to target interventions are required to curtail the negative effects on this malaria epidemic in Venezuela.

675

ESTIMATING CONTRIBUTIONS TO MALARIA TRANSMISSION BY MEASURING INDIVIDUAL HUMAN-TO-MOSQUITO *PLASMODIUM FALCIPARUM* TRANSMISSION EVENTS IN A NATURAL SETTING USING PARASITE GENOTYPING AND LONGITUDINAL HOST SAMPLING

Kelsey M. Sumner[1], Elizabeth Freedman[2], Lucy Abel[3], Andrew Obala[3], Steven Meshnick[1], Steven Taylor[2], Wendy Prudhomme-O'Meara[2]

[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [2]*Duke University, Durham, NC, United States,* [3]*Moi University, Eldoret, Kenya*

Despite increased malaria reduction efforts, *Plasmodium falciparum* prevalence has remained high in Western Kenya where parasites are found in up to 80% of residents. This malaria persistence highlights the need to identify the region's malaria reservoirs. Asymptomatic malaria could be a reservoir, but the amount asymptomatically-infected humans transmit malaria to mosquitoes remains unresolved. We estimated the relative contributions of asymptomatic and symptomatic *P. falciparum* human infections to successful mosquito transmission events in a high transmission area. We hypothesized that asymptomatic compared to symptomatic humans contributed more to mosquito transmission. For a 14-month longitudinal cohort of 243 participants across 3 villages in Webuye, Western Kenya, we collected blood samples from human participants asymptomatic (monthly) and symptomatic (as suspected) for malaria as well as mosquitoes from participant households (weekly). Using these human and mosquito samples, we sequenced 2 *P. falciparum* gene targets: (1) circumsporozoite protein and (2) apical membrane antigen 1. For every *P. falciparum*-infected mosquito, we counted the number of shared parasite haplotypes between a human infection and mosquito abdomen collected in the participant's household within 7 days following infection detection in humans. a shared parasite haplotype indicated a successful human-to-mosquito transmission event. Using a multi-level Poisson regression model, we compared asymptomatic vs. symptomatic human infections to the number of parasite haplotypes shared between the infected humans and mosquito abdomens. Across humans, we identified 895 asymptomatic and 153 symptomatic infections. Across mosquitoes, we identified 199 abdomens infected with *P. falciparum*. We found asymptomatic infections in humans were transmitted to mosquitoes more often than symptomatic ones, establishing that asymptomatic malaria highly contributes to mosquito infection and onward transmission. These findings inform the utility of targeted active test and treat strategies for finding asymptomatic malaria in endemic regions.

676

PERFORMANCE OF A CASE-BASED MALARIA SURVEILLANCE SYSTEM TO SUPPORT MALARIA ELIMINATION IN HAITI

Wilmar Belizaire[1], Reginald Joseph[2], Samson Marseille[3], Kenold Rendel[3], Jean Frantz Lemoine[4], Alyssa J. Young[1]

[1]*Clinton Health Access Initiative, Boston, MA, United States,* [2]*Ministère de la santé publique et de la population, Jeremie, Haiti,* [3]*Direction d'Epidémiologie des Laboratoires et de la Recherche, Port-au-prince, Haiti,* [4]*Ministère de la santé publique et de la population, Port-au-prince, Haiti*

Haiti has committed to eliminate malaria by 2025. Achieving this target requires a robust surveillance system that facilitates the timely reporting of high-quality individual case data. in December 2017 the Direction d'Epidémiologie des Laboratoires et de la Recherche (DELR) in collaboration with the Clinton Health Access Initiative (CHAI), and the National Malaria Program (PNCM) piloted a DHIS2 case-base surveillance system in 13 health facilities in the department of Grand-Anse, the region which reported 33.26% (n=2937) of confirmed cases in 2018. Benefits of using DHIS2 case-based reporting include an opportunity to conduct more in-depth analysis, leading to a better understanding of individual drivers of transmission. Demographic, diagnostic, geolocation and travel history data were collected for each confirmed malaria case by designated health facility personnel using DHIS2 through a mobile-based application. The performance of the case-base surveillance system evaluation process included monitoring four indicators a) proportion of forms with key indicator data fields completed, b) proportion of confirmed cases for which a paper notification form is completed, c) proportion of confirmed cases with a paper notification form completed that are also reported to DHIS2, and d) proportion of cases reported on a paper notification form that are reported in DHIS2 within one week of confirmation. Results from the 13-month DHIS2 case-based reporting pilot showed that form completeness, concordance, and electronic reporting rates remained high throughout the duration of the pilot, at 78.3%, 99.7%, and 93.9%, respectively. a large part of the success of the pilot was a result of weekly site supervision and data validation visits. Specific challenges to implementation included rapid diagnostic test stock-outs at health facilities, limited internet connectivity causing subsequent delays in data-server synchronization, and a lack of human and financial resources required to conduct weekly on-site data validation. These obstacles should be addressed before expansion to all health facilities and communities in Grand-Anse.

677

USE OF HEALTH FACILITY-BASED SEROLOGICAL SURVEILLANCE TO INVESTIGATE *PLASMODIUM FALCIPARUM* AND *P. VIVAX* TRANSMISSION DYNAMICS IN A PRE-ELIMINATION SETTING, INDONESIA

Henry Surendra[1], Supargiyono Supargiyono[2], Riris A. Ahmad[3], Rizqiani A. Kusumasari[2], Theodola B. Rahayujati[4], Siska Damayanti[4], Jackie Cook[5], Chris Drakeley[1]

[1]*Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Department of Parasitology, Faculty of Medicine-Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia,* [3]*Department of Biostatistics, Epidemiology and Population Health, Faculty of Medicine-Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia,* [4]*District Health Office of Kulon Progo, Wates, Indonesia,* [5]*MRC Tropical Epidemiology Group, Department of Infectious Disease Epidemiology, London School of Hygiene & Tropical Medicine, London, United Kingdom*

Measuring malaria burden in low transmission settings requires more sensitive tools, and more efficient sampling strategies. Here, we use serology and repeated health facility-based cross-sectional surveys including all clinical attendees and accompanying people to investigate *Plasmodium falciparum* and *P. vivax* transmission dynamics in a pre-elimination setting in Indonesia. The rolling surveys were conducted in 8 health facilities in Kulon Progo Regency, Indonesia, May 2017 to April 2018. Demographic data were collected from all participants and household coordinates were collected using participatory mapping methods. In addition to standard microscopy test, bead-based serological assays were performed on finger-prick bloodspot samples from 9453 people. Seroconversion rates (SCR) were estimated by fitting a simple reversible catalytic model to seroprevalence data. Mixed effect logistic regression was used to investigate factors associated with exposure and spatial analysis was performed to identify the clustering of higher values of antibody responses. Standard microscopy tests identified a parasite prevalence of 0.06% (95% CI: 0.03-0.14, n=6) and 0 for *P. vivax* and *P. falciparum,* respectively. The estimated seroconversion rate in the population was very low, SCR 0.003 (95% CI: 0.002-0.006) and 0.003 (95% CI: 0.002-0.004) for *P. falciparum* and *P. vivax*, respectively. Multivariate analysis revealed that adults and forest goers were more likely to have higher risk of exposure compared to their counterparts. Spatial analysis of antibody responses identified potential high-risk areas where a subsequent outbreak occurred. These findings suggest the use of health facility-based serological surveillance to supplement the existing surveillance systems to better understand malaria transmission dynamics in a pre-elimination setting. Findings from this study could be used by surveillance and control programmes to better target interventions. Further implementation research is needed to enable integration of these methods with existing surveillance systems.

678

MALARIA MORBIDITY AND MORTALITY FOLLOWING INTRODUCTION OF A UNIVERSAL POLICY OF ARTEMISININ-BASED TREATMENT FOR MALARIA IN PAPUA, INDONESIA: A RISING BURDEN OF *PLASMODIUM VIVAX* MALARIA

Jeanne Rini Poespoprodjo[1], Enny Kenangalem[2], Nicholas Douglas[3], Lenny Burdam[2], Ketut Gdeumana[4], Ferry Chalfien[2], Pak Prayoga[2], Fransciscus Thio[2], Angela Devine[3], Jutta Marfurt[3], Govert Waramori[4], Shunmay Yeung[5], Rintis Noviyanti[6], Pasi Penttinen[4], Michael J. Bangs[4], Paulus Sugiarto[7], Julie A. Simpson[8], Yati Soenarto[1], Nicholas M. Anstey[3], Ric N. Price[3]

[1]*Universitas Gadjah Mada, Yogyakarta, Indonesia,* [2]*Papuan Health and Community Development Foundation, Timika, Indonesia,* [3]*Menzies School of Health Research, Darwin, Australia,* [4]*PT Freeport Indonesia/International SOS, Timika, Indonesia,* [5]*The London School of Hygiene & Tropical Medicine, London, United Kingdom,* [6]*Eijkman Institute for Molecular Biology, Jakarta, Indonesia,* [7]*Rumah Sakit Mitra Masyarakat, Timika, Indonesia,* [8]*University of Melbourne, Melbourne, Australia*

Malaria control activities can have a disproportionately greater impact on *Plasmodium falciparum* than *P. vivax* in areas where both species are coendemic. We present the temporal trends in malaria-related morbidity and mortality in Papua, Indonesia before and after introduction of ACT for all *Plasmodium* species. a prospective, district-wide malariometric surveillance system was established in April 2004 to record all cases of malaria at community clinics and the regional hospital and maintained until December 2013. in March 2006, antimalarial treatment policy was changed to artemisinin combination therapy for uncomplicated malaria and intravenous artesunate for severe malaria due to any *Plasmodium* species. Over the study period a total of 418,238 patients presented to the surveillance facilities with malaria. The proportion of patients with malaria requiring admission to hospital fell from 26.9% (7,745/28,789) in the pre-policy change period (April 2004 to March 2006) to 14.0% (4,786/34,117) in the late transition period (April 2008 to December 2009). There was a significant fall in the mortality of patients presenting to the hospital with *P. falciparum* malaria (0.53% (100/18,965) versus 0.32% (57/17,691)), but this was less apparent for patients with *P. vivax* malaria (0.28% (21/7,545) versus 0.23% (28/12,397)). Between the same periods, the overall proportion of malaria due to *P. vivax* rose from 44.1% (30,444/69,098) to 53.3% (29,934/56,125) in the community clinics, and from 32.4% (9,325/28,789) to 44.1% (15,035/34,117) at the hospital. After controlling for population growth and changes in treatment seeking behaviour, the incidence rate ratio for the reduction of *P. falciparum* malaria was 0.40 (95%CI 0.40,0.41) and that *P. vivax* malaria was 0.60 (95%CI 0.59,0.60)). a universal policy of artemisinin-based blood schizontocidal treatments in Papua, Indonesia was associated with a greater decrease in the burden of *P. falciparum* compared to *P. vivax.* Widespread access of patients to safe and highly effective radical cure of *P. vivax* will be critical to malaria elimination efforts in co-endemic regions.

679

THE EPIDEMIOLOGY OF *PLASMODIUM VIVAX* AMONG ADULTS IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Nicholas F. Brazeau[1], Cedar Mitchell[2], Molly Deutsch-Feldman[2], OJ Watson[3], Andrew Morgan[1], Cory Keeler[4], Kyaw Thwai[2], Melchior Mwandagalirwa[5], Antoinette Tshefu[5], Joris Likwela[6], Robert Verity[3], Steven Meshnick[2], Jonathan Juliano[1]

[1]*University of North Carolina School of Medicine, Chapel Hill, NC, United States,* [2]*Gillings School of Global Public Health, Chapel Hill, NC, United States,* [3]*Imperial College London, London, United Kingdom,* [4]*Department of Geography, University of North Carolina, Chapel Hill, NC, United States,* [5]*Programme National de la Lutte contre le Paludisme, Kinshasa, Democratic Republic of the Congo,* [6]*Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo*

Although *Plasmodium vivax* has long been considered absent from Sub-Saharan Africa, recent reports of *P. vivax* infections among Duffy-negative hosts in Sub-Saharan Africa continue to accumulate. However, to date, no studies have performed a nationally representative survey of *P. vivax* in a Sub-Saharan African country. To overcome this critical gap, we used data collected from the 2013-2014 Standard Demographic Health Survey in the Democratic Republic of the Congo (*Study ID: DRC DHS-II*) to screen over 17,000 adults for *P. vivax*. Overall, we detected 472 cases of *P. vivax* (weighted prevalence: 2.96%, 95% CI: 2.28%, 3.65%). Among the 489 clusters that were sampled in the DRC DHS-II, the number of *P. vivax* cases ranged from 0 - 9 (weighted prevalence range: 0 - 46.15%). Among the 472 *P. vivax* cases, three infected hosts were Duffy-positive (0.64%) and 175 were co-infected with *P. falciparum* (31.70%). To identify the epidemiological and spatial risk factors associated with *P. vivax* infection, we evaluated over 30 covariates with generalized estimating equations. Among these covariates, individual-level wealth, access to health insurance, and precipitation were identified as significant predictors of *P. vivax* infection. However, *P. vivax* infections did not appear to cluster spatially (Moran's I: 0.02, $p > 0.05$), possibly due to interference by *P. falciparum* ($p < 0.05$). To evaluate the effect of scalable antimalarial interventions on *P. vivax* versus *P. falciparum*, we calculated the relative risks of bed-net use, housing materials, and health-insurance using inverse-probability weights with an ensemble supervised machine learning approach. Among these three interventions, only housing materials demonstrated a reduction in *P. vivax* cases [RR: 1.95 (1.11, 3.42)], while all three interventions reduced *P. falciparum* cases. Future work will include *P. vivax* phylogenetics and creating a Bayesian hierarchical spatial prediction model. The return of *P. vivax* to Sub-Saharan Africa is a renewed threat that complicates malaria elimination efforts. The results of this study will aid the DRC government in its efforts to halt the spread of *P. vivax.*

680

TRENDS IN OUTPATIENT MALARIA CASES AND THE EFFECTS OF MALARIA CONTROL IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Filippo Lechthaler[1], **Barbara Matthys**[2], Giulia Lechthaler-Felber[2], Joris Losimba Likwela[3], Hypolite Muhindo Mavoko[4], Junior Matangila Rika[4], Meschac Mutombo Mutombo[2], Laura Ruckstuhl[2], Joanna Barczyk[2], Estifanos Shargie[5], Helen Prytherch[2], Christian Lengeler[2]

[1]*Bern University of Applied Sciences, Bern, Switzerland,* [2]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [3]*Soins de Santé en Milieu Rural (non-profit organization SANRU), Kinshasa, Democratic Republic of the Congo,* [4]*University of Kinshasa, Kinshasa, Democratic Republic of the Congo,* [5]*The Globa Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland*

The Democratic Republic of the Congo (DRC) has the second highest case load from malaria in the world after Nigeria. Malaria control interventions have been strengthened in line with the Millenium Development Goals. We analyzed the effects of these interventions on malaria at health facility level using a retrospective trend analysis of malaria cases between 2005 and 2014, with data collected from outpatient and laboratory registers based on a representative sample of 175 health facilities across the country. We applied a time series analysis to assess trends of suspected and confirmed malaria cases by health province and for different age groups. a linear panel regression model controlled for non-malaria outpatient cases, rainfall, light intensity, health province and time fixed effects, to examine the relationship between the interventions and malaria case occurrences and positivity rates. Overall, recorded suspected and confirmed malaria cases in the DRC have increased. a sharp increase in confirmed cases from 2010 coincides with the introduction of the new treatment policy and the resulting scale-up of diagnostic testing. Controlling for confounding factors, the introduction of rapid diagnostic tests (RDTs) was significantly associated with the number of tested and confirmed cases. The evolution of the positivity rate does not indicate a downward trend in morbidity due to malaria. The sharp increase in confirmed malaria cases from 2010 is associated with improved diagnostic availability, mainly the introduction of RDTs. Before that, a great part of malaria cases were treated based on clinical suspicion. This finding points

to a better detection of cases that potentially contributed to improved case management. Furthermore, the expansion of diagnostic testing along with the increase in confirmed cases implies that before 2010, cases were underreported, and that the accuracy of routine data to describe malaria incidence has improved.

681

INTEGRATING GENETIC AND ENVIRONMENTAL DATA TO MODEL TRANSMISSION PARAMETERS (MOVEMENT AND HABITAT USE) IN THE MAJOR INSECT VECTOR OF SLEEPING SICKNESS IN UGANDA (*GLOSSINA FUSCIPES*)

Norah Saarman, Evlyn Pless, Anusha Bishop, Giuseppe Amatulli, Adalgisa Caccone

Yale University, New Haven, CT, United States

Tsetse flies (genus *Glossina*) are the obligate vectors of the trypanosome parasite that cause animal and human African trypanosomiasis (also known as nagana and sleeping sickness, respectively). One of the most effective strategies in controlling these dangerous and costly diseases is through vector control of tsetse flies. Establishing feasible programs that reduce on-the-ground disease risk require knowledge of vector movement and habitat use. Spatial modeling of these parameters using genetic and ecological data can fill this knowledge gap. However, integrating these two data types remains a challenge in spatial ecology. In this study, we build upon maximum likelihood methods developed by Bouyer et al (2015 in PLoS NTD) to predict movement and habitat use in the insect vector *Glossina fuscipes fuscipes* in Uganda. We use a novel strategy that applies a machine learning algorithm (random forest regression) to model both genetic and ecological parameters (gene flow and fly density, respectively) based on remotely-sensed environmental data (temperature, precipitation, isothermality, altitude, etc.). The final output integrates the two models into a single bivariate map that can identify areas (i) with the highest disease risk and greatest need for medical infrastructure, (ii) with marginal habitat that can be controlled at low cost but also require dedicated monitoring to prevent re-colonization, and (iii) likely to harbor isolated populations that can be effectively eradicated and/or use in the development of novel vector control strategies. To our knowledge, this is the first application of machine learning to integrate genetic and ecological data to predict these important disease transmission parameters (vector gene flow and habitat use). We also apply our approach to forecast future patterns of gene flow and habitat use under alternative global warming and solar geoengineered scenarios. Future forecasting will help to predict changes in parasite transmission dynamics, and can improve strategic planning to reduce human and animal African trypanosomiasis in a changing climate.

682

MUTUALISTIC BACTERIA-PROVISIONED RESOURCES IMPACT VECTOR COMPETENCY

Brian L. Weiss[1], Rita Rio[2]

[1]*Yale School of Public Health, New Haven, CT, United States,* [2]*Department of Biology, West Virginia University, Morgantown, WV, United States*

Many symbionts supplement their host's diet with essential nutrients. However, whether these nutrients also enhance parasitism is unknown. In this study, we investigated whether folate (B9) production by the tsetse fly (*Glossina* spp.) essential mutualist, *Wigglesworthia,* aids auxotrophic African trypanosomes in completing their lifecycle within this obligate vector. We show that the expression of *Wigglesworthia* folate biosynthesis genes changes with the progression of trypanosome infection within tsetse. The disruption of *Wigglesworthia* folate production caused a reduction in the percentage of flies that housed midgut (MG) trypanosome infections. However, decreased folate did not prevent MG trypanosomes from migrating to and establishing an infection in the fly's salivary glands, thus suggesting that nutrient requirements vary throughout the trypanosome life cycle. We further substantiated that trypanosomes rely on symbiont-generated folate by feeding this vitamin to *G. brevipalpis*, which exhibits a low trypanosome vector competency and houses *Wigglesworthia* incapable of producing folate. Folate supplemented *G. brevipalpis* were significantly more susceptible to trypanosome infection, further demonstrating that this vitamin facilitates parasite infection establishment. Our cumulative results provide evidence that *Wigglesworthia* provides a key metabolite (folate) that is 'hijacked' by trypanosomes to enhance their infectivity, thus indirectly impacting tsetse species vector competency. Parasite dependence on symbiont-derived micronutrients, which likely also occurs in other arthropod vectors, represents a relationship that may be exploited to reduce disease transmission.

PARATRANSGENIC MANIPULATION OF MICRORNA275 IN THE TSETSE FLY AND ITS DOWNSTREAM EFFECT ON TRYPANOSOME INFECTIONS

Liu Yang, Brian Weiss, Serap Aksoy

Yale University, New Haven, CT, United States

Tsetse flies (*Diptera Glossina*) are prominent vectors of African trypanosomes, which are the causative agents of "sleeping sickness" in humans and "Nagana" in domesticated animals throughout sub-Saharan Africa. As effective vaccines and affordable treatments for these diseases are still lacking, we investigated alternative methods, such as interfering with trypanosome infection progression in tsetse, as strategies to reduce disease. We discovered previously that trypanosomes manipulate the expression of a host microRNa 275 (*miR275*), which in turn regulates the structural integrity of tsetse's gut associated peritrophic matrix (PM). This outcome promotes the establishment of trypanosome infections in the fly's gut. To investigate the role of *miR275*in tsetse vector competence, we developed a novel system to constitutively manipulate the expression of tsetse *miR275*. We engineered a tsetse commensal endosymbiont, *Sodalis glossinidius,* to express antagomir-275, which binds to *miR275* thus reducing its expression. We subsequently recolonized flies with recombinant (rec)*Sodalis* and evaluated the downstream effects on tsetse midgut physiology as well as trypanosome infection traits. We found that flies colonized with rec*Sodalis*display impaired digestion phenotypes and are highly susceptible to infection with trypanosomes. Our study is a proof of concept that paratransgenic expression is an effective method to regulate microRNa expression levels for downstream functional studies.

TSETSE CONTROL IN G-HAT *FOCI*: FOR HOW LONG AND HOW TO STOP?

Jean Baptiste Rayaisse[1], Inaki Tirados[2], Dramane Kaba[3], Mahamat Hissène Mahamat[4], Moise Kagbadouno[5], Albert Mugenyi[6], Mallaye Peka[7], Fabrice Courtin[8], Mamadou Camara[5], Philippe Solano[9]

[1]*CIRDES, Bobo - Dioulasso, Burkina Faso,* [2]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [3]*IPR, Bouaké, Côte D'Ivoire,* [4]*IRED, Ndjaména, Chad,* [5]*PNLTHA, Conakry, Guinea,* [6]*COCTU, Kampala, Uganda,* [7]*PNLTHA, Moundou, Chad,* [8]*IRD, Bouaké, Côte D'Ivoire,* [9]*IRD, Montpellier, France*

With the development and the use of tiny targets, implementation of tsetse control in complement to the "screen and treat" strategy has significantly impacted gambiense Human African Trypanosomiasis (g-HAT) incidence in Guinea, Chad, Côte d'Ivoire and Uganda. This combination of methods, in addition to saving lives and reducing/eliminating transmission, is easily accepted by populations that are not anymore disturbed by tsetse bites and that are more protected against g-HAT. However, with the reduction of the tsetse densities together with decrease in disease incidence, and decrease in funding when the number of cases has gone down, the question of sustainability of vector control operations emerges. Tsetse eradication can be contemplated in potentially isolated areas (e.g. like the Mandoul in Chad), but in many HAT *foci* tsetse populations are not isolated, e.g. in areas like the mangrove in Guinea. In these areas, the

question becomes: until when should the vector control be maintained, and by who? If it has to be stopped, what are the conditions to be fulfilled in before stopping? We propose here an algorithm aiming at helping decision on tsetse control in g-HAT *foci* according to the incidence of HAT cases in the focus, which consists in: 1) maintaining vector control as long as new cases are still found, 2) decreasing vector control when number of new cases reaches zero, but keeping a capacity of reaction to be able to implement vector control in the vicinity of new cases, should they be found (« reactive vector control »), and 3) stopping vector control when no cases have been found during 5 consecutive years with similar medical effort. Parallel to these decisions, other tools (xenomonitoring in tsetse, monitoring in animals and tsetse densities surveillance) should be used to help for early response if necessary, using prediction models. Such an approach is useful and will give some common guidelines for decision making, depending on the context, provided stakeholders have the same understanding on the description/definition of the different situations.

685

AMBLYOMMA VARIEGATUM, VECTOR OF AFRICAN TICK-BITE FEVER, CONTAINS AN INTEGRATED *RICKETTSIA AFRICAE* CHROMOSOME IN ITS NUCLEAR GENOME

Alistair C. Darby[1], Alaa M. Al-Khafaji[1], Mark Whitehead[1], Catherine S. Hartley[1], Glen Robinson[1], Stuart D. Armstrong[1], Aleksandra Y. Beliavskaia[1], Germanus S. Bah[2], Naftaly Githaka[3], Lesley Bell-Sakyi[1], **Ben Makepeace**[1]

[1]*University of Liverpool, Liverpool, United Kingdom,* [2]*Institut de Recherche Agricole pour le Développement, Ngaoundéré, Cameroon,* [3]*International Livestock Research Institute, Nairobi, Kenya*

Amblyomma variegatum, the tropical bont tick, is one of the most important ticks involved in pathogen transmission to humans and livestock in sub-Saharan Africa and the Caribbean, and also has direct impacts on ruminant productivity. It is the primary vector of two bacteria in the Rickettisiales: *Ehrlichia ruminantium*, the aetiological agent of heartwater disease in ruminants, and *Rickettsia africae*, which causes African tick-bite fever in humans. Unusually for a pathogenic *Rickettsia* sp., the prevalence of *R. africae* in *A. variegatum* has been reported to be close to fixation. We confirmed this finding using specimens collected from the Adamawa Region of Cameroon, where 95.3% of ticks (*n* = 192) removed from cattle were positive by qPCR. However, the normalised density of rickettsial to tick single-copy genes was often low (rickettsia:tick ratio of ~0.5 - 5). The Tick Cell Biobank maintains two *A. variegatum* cell lines (AVL/CTVM13 and AVL/CTVM17) that were found to be positive by PCR for several rickettsial genes; Sanger sequencing confirmed that these genes were of *R. africae* origin. Unexpectedly, no microscopic or proteomic evidence of a bacterial infection in these cell lines was evident, and tetracycline treatment of cultures over two months, which was sufficient to eliminate *Rickettsia raoultii* from parallel tick cell cultures, had no significant effect on *R. africae* DNa signal in the *A. variegatum* lines. We extracted high molecular-weight DNa from AVL/CTVM17 cells and a single adult *A. variegatum* male from a colony maintained at the International Livestock Research Institute in Nairobi. Using Chromium 10x libraries, we sequenced these genomes on an Illumina NovaSeq and obtained assemblies of ~6 Gb, the first from an *Amblyomma* sp. The cell line and the tick genomes contained an integrated *R. africae* chromosome, although a large deletion representing ~10% of the rickettsial genome was present in both assemblies. This finding has significant implications for the epidemiology of *R. africae* and suggests that other tick genomes may contain integrated rickettsial DNA.

A NOVEL GROUP OF SCABIES MITE INACTIVE CYSTEINE PROTEASES WITH PRO-COAGULATORY FUNCTIONS

Deepani D. Fernando[1], Simone Renolds[2], Gunter Hartel[2], Bernard Cribier[3], Nicolas Ortonne[4], Katja Fischer[2]

[1]*Faculty of Veterinary Medicine and Animal Science, University of Peradeniya, Peradeniya, Sri Lanka,* [2]*QIMR Berghofer Medical Research Institute, Brisbane, Australia,* [3]*Universite de Strasbourg Faculte de Medecine, Strasbourg, France,* [4]*CHU Henri Mondor, Service d'Anatomo-Pathologie, Paris, France*

Scabies is an infectious skin disease caused by the burrowing mite *Sarcoptes scabiei* affecting an estimated 100-300 million people worldwide and various companion, farm and wild animals. There is no vaccine and the few available broad-spectrum anti-parasitic drugs fail to control the disease. Scabies is not simply an itch; its mechanical damage to the skin allows the entrance of *Staphylococcus aureus* and group a *Streptococcus* leading to serious secondary complications and mite essential secretory / excretory proteins contribute to this bacterial establishment. Scabies mite express cysteine proteases homologous to the group 1 allergen of house dust mites. However, in contrast to their free-living relatives scabies mites express multiple cysteine proteases comprised of 5 proteolytically active (Sars1a-e) and 5 inactive (SMIPP-Ca-e) members. Recombinant, soluble SMIPP-C proteins were successfully expressed and purified from *Escherichia coli*. Localisation studies using immune-histology demonstrated that SMIPP-Cs are present in the mite gut and excreted within the faeces. Gene expression analysis found that SMIPP-Cs are highly expressed in the adult female mite, and less in other life stages. Initial functional investigations showed that SMIPP-Cs bind to calcium ions and the skin protein Dermatopontin, a fibrin formation accelerator. Two SMIPP-Cs were found to accelerate blood coagulation, accelerate fibrin formation during fibrinogen polymerisation and delay plasmin induced fibrinolysis, hence maintaining the fibrin clot for a longer time. Scanning electron micrographs of SMIPP-C induced fibrin clots revealed a complex structure compared to normal fibrin clot structures, suggesting that SMIPP-C proteins are responsible for an aberrant fibrin formation. Immuno-histological localisation of SMIPP-C proteins in the microthrombi within skin biopsies from human scabies lesions further consolidate the SMIPP-C role in the host-pathogen interplay. We propose that scabies mite SMIPP-Cs cause the pathophysiology of the micro-thrombi formation commonly found in scabies infected skin histology.

687

RHODNIUS ECUADORIENSIS POPULATION GENOMICS IN SOUTHERN ECUADOR FOR GUIDING VECTOR CONTROL PROGRAMS

Luis E. Hernandez Castro[1], Anita G. Villacís[2], Björn Andersson[3], Jaime A. Costales[2], Sofía Ocaña-Mayorga[2], Erin L. Landguth[4], Cesar A. Yumiseva[2], Mario J. Grijalva[2], Martin S. Llewellyn[1]

[1]*University of Glasgow, Glasgow, United Kingdom,* [2]*Pontifical Catholic University in Ecuador, Quito, Ecuador,* [3]*Karolinska Institutet, Stockholm, Sweden,* [4]*University of Montana, Missoula, MT, United States*

Understanding triatomine population dynamics at a region scale is key for an effective vector control program. Here we aimed to investigate province-wide population structure and gene flow in the main Chagas disease vector in southern Ecuador, *Rhodnius ecuadoriensis*, and provide guidelines for vector control. To achieve this, we genotyped 2,552 SNP markers of 282 *R. ecuadoriensis* samples from 25 communities in Loja, Ecuador from 2004 to 2018. a strong signal of structuring (F_{ST} = 0.225, P-value = 0.001) was detected by our hierarchical analysis of molecular variance (AMOVA), which attributed most of the variation to regions (17.21 %) and individuals within populations (77.50%) as compared to populations within regions (domicile vs sylvatic populations – 5.29%). Interestingly, populations pairwise F_{ST} comparisons showed similar patterns of structure. After that, we identified 13 genomic clusters among samples using discriminant analysis of principal components (DAPC). Additionally, we explored phylogenetic relationship using a neighbour-joining tree of pairwise genetic distance from samples allele counts which clustered them by region, similarly to pairwise F_{ST} comparisons and DAPC results. Once genomic differentiation pattern was stablished, we tested isolation-by-distance (IBD) as null hypothesis using mantel test and correlograms which drew a significant correlation (mantel r = 0.55, P-value = 0.001). Finally, we tested the usability of our 2,552 SNPs to detect *loci* more differentiated than the expected of neutral *loci* and found 157 candidate F_{ST}-outlier

locus which can be the target of local adaptation. Our findings suggested little differentiation between domicile and sylvatic vector population exists and that vector migration among communities within a region is high. Although spatial correlation was strong, other processes may be shaping Loja vector populations as indicated by correlograms. Vector control design should account for the high vector population gene flow within in a region for successful eradication, although sylvatic population still represent a risk for recolonization.

688

THE GENETIC BASIS OF PRAZIQUANTEL RESISTANCE IN *SCHISTOSOMA MANSONI*

Winka Le Clec'h[1], Frederic D. Chevalier[1], Marina McDew-White[1], Robbie Diaz[1], Amanda Strickland[1], Meghan Guzman[2], Ana Carolina de Mattos[2], Philip T. LoVerde[2], **Tim Anderson**[1]

[1]*Texas Biomedical Research Institute, San Antonio, TX, United States,* [2]*University of Texas Health, San Antonio, TX, United States*

Praziquantel (PZQ) monotherapy is the basis for schistosome control. Mass treatment campaigns (2016-2021) aim to distribute 250 million PZQ tablets per year, constituting a 10-fold increase in tablet distribution, and intensifying selection for PZQ resistance. PZQ-resistant (PZQ-R) parasites have been reported from the field and can be selected in the laboratory, but the genetic basis of PZQ-R is unclear. We measured the *in vitro* dose-response of male worms from the laboratory selected SmLE-PZQ-R resistant population and SmLE PZQ-sensitive (PZQ-S) population and observed a 14-fold difference in IC_{50} (12.75 ± 4.49 (SE) μg/mL vs. 0.86 ± 0.14 (SE) μg/mL). We also demonstrated that SmLE-PZQ-R population contains individuals that are impervious to high dose PZQ. To determine the genetic basis of PZQ resistance in this SmLE-PZQ-R population, we used a pooled association approach. We phenotyped individual male worms 72h after PZQ treatment (24.3 μg/mL) using a quantitative metabolism-based assay (lactate production), which provides an excellent proxy for worm recovery. We then pooled male worms showing the lowest and highest lactate production, and illumina sequenced these pools. Comparison of allele frequencies between the two pools unambiguously ($p=10^{-20}$) identifies a single ~3 Mb region on chromosome 3 containing 72 genes, including several very promising candidate *loci*. To enrich PZQ-R or PZQ-S alleles, we genotyped larval parasites to identify those carrying SNPs in the QTL region associated with PZQ-R or PZQ-S and established infections with these two populations in hamsters. This "marker-assisted" selection approach resulted in two parasite populations differing by >368 fold in PZQ response. We conclude that PZQ resistance in this laboratory population has a single gene, recessive inheritance and results in a dramatic change in resistance. We are now using RNAi to knock down genes within the QTL region to identify the gene involved in PZQ-R. Our central aim is to identify the genetic basis of PZQ-R in order to understand the mechanism of action and to develop molecular markers for monitoring PZQ-R in schistosome control programs.

CAN CIRCULATING ANTIGENS BE PREDICTORS FOR FEMALE GENITAL SCHISTOSOMIASIS AS DIAGNOSED BY EXPERT REVIEW AND COMPUTER AUTOMATED IMAGE ANALYSIS

Sigve Holmen[1], Eyrun Kjetland[2], Bellington Vwalika[3], Isaiah Hansingo[4], Comfort Rutty Phiri[5], Maina Mudenda[6], Joyce Mapandi[6], Govert Van Dam[7], Paul Corstjens[7], Claudia de Dood[7], Emily Webb[8], Amy Sturt[8], **Amaya Lopez Bustinduy**[8]

[1]*Holmen Innovative Solutions, Oslo, Norway,* [2]*University of Oslo, Oslo, Norway,* [3]*University of Zambia, School of Medicine, Lusaka, Zambia,* [4]*Livingstone Central Hospital, Livingstone, Zambia,* [5]*Zambart, Lusaka, Zambia,* [6]*Livingstone Central Hospital, Lusaka, Zambia,* [7]*Leiden University Medical Center, Leiden, Netherlands,* [8]*London School of Hygiene &Tropical Medicine, London, United Kingdom*

Urogenital schistosomiasis (UGS) caused by *S. haematobium* is estimated to affect more that 200 million people, with the main burden of disease in Africa. Female Genital Schistosomiasis (FGS) presents with sandy patches (SP) and abnormal blood vessels (ABV) in the lower female genital tract. These lesions are associated with post-coital bleeding, dyspareunia, infertility and prevalent HIV. in a study of 603 females aged 18 – 31 years in Zambia, we investigated whether urine Circulating Anodic Antigen (CAA), can be used as a diagnostic indicator of FGS. CAa is regurgitated into the bloodstream by *Schistosoma* worms, and after rapid renal clearance it can be detected in urine. CAa detection was performed at Leiden University Medical Center in the Netherlands. FGS (SP and ABV) was diagnosed by expert review of digital colposcopic images and by computer automated image analysis (CAIA), using previously published algorithms detecting areas of the cervical mucosa that appear more yellow than the surrounding tissue. The reviewer was blinded to the clinician's original diagnoses and CAIA. ABVs were identified by circular template matching and mean distance between blood vessels. The prevalence of live *Schistosoma* worms, as determined by a positive CAA, was 15.1 % (91 / 601). FGS prevalence was 36.9 % (179 / 485) by expert review and 49.5 % (240 / 485) by CAIA, with a Cohen's Kappa of 0.25 ($p < 0.001$). FGS prevalence was 25.6 % (124 / 485) when the analysis was restricted to images positive for FGS by both expert review and CAIA. FGS positive images were associated with a positive CAa ($p < 0.001$). CAa had an FGS detection rate of 5.8 % and a positive predictive value of 35.1 %, indicating that CAa results alone fail to detect most cases of FGS in adults in a setting with a relatively low prevalence of current infection. This supports previous findings in which SP and ABV may appear in the absence of current infection with *S. haematobium.* The lesions in FGS are most likely late-stage, chronic manifestations of the disease, reinforcing the urgent need for visual diagnostics and early treatment. Further research is needed to explore if live worms influence FGS symptoms and HIV risk.

690

TREATMENT OUTCOMES OF *FASCIOLA HEPATICA* INFECTION IN PRE-SCHOOL AND SCHOOL AGE CHILDREN IN CUSCO, PERU

Melinda B. Tanabe[1], Camille M. Webb[1], Maria L. Morales[2], Marta Lopez[3], Miguel M. Cabada[1]

[1]*University of Texas Medical Branch, Galveston, TX, United States,* [2]*IMT - Universidad Peruana Cayetano Heredia, Cusco, Peru,* [3]*IMT - Universidad Peruana Cayetano Heredia, Galveston, TX, United States*

Fasciola hepatica is endemic in the Andes highlands with an infection prevalence reaching almost 70% among children in some communities. Triclabendazole (TCBZ) is the only recommended treatment for humans. Resistance to TCBZ is an emerging problem. Our aim was to evaluate treatment outcomes of TCBZ in children with chronic fascioliasis in the highlands of Cusco, Peru. a community-based study evaluated the impact of Fasciola among pre-school and school-age children in 26 communities in Cusco. We identified children with chronic fascioliasis defined as the presence of eggs in stool. Children were treated with one or two doses of TCBZ 10mg/kg given with a fatty meal. We evaluated stool samples for Fasciola eggs at least one month after treatment to assess response. Three stool samples per subject were tested with Kato Katz and rapid sedimentation each time. Of 2958 children included in the study, 166 had Fasciola eggs in stool (prevalence of 5.6%). The mean age of those infected was 10.6 years and 50.6% were male. The mean egg count was 56 eggs/gram of stool. 29 (17%) children had eosinophilia, 34 (20%) had anemia, and 52 (31%) had stunting at baseline. in total 162 children were treated, 157 with one dose and 5 with 2 doses of TCBZ. Follow up was within 90 days in half the cases (median 90 days, IQR 56 - 118). Of 86 children that followed up within 90 days, 33 (37.5%) had positive eggs in stool and 32 of these received a second course of treatment. Twenty (62.5%) continued to pass eggs in stool. Overall effectiveness was 62.5% with one dose and 77% after two doses of TCBZ. in the highlands of Cusco in Peru, a single dose TCBZ had a low effectiveness and almost one in four subjects failed to respond to a second dose of treatment. Research for alternative safe effective drugs for fasciolasis is urgently needed as the emergence of resistance threatens control programs.

691

POC-CCA PERFORMANCE FOR MAPPING LOW AND MODERATE ENDEMICITY AREAS FOR SCHISTOSOMIASIS MANSONI AND THERAPEUTIC EFFICACY EVALUATION FOLLOWING SCHOOL-BASED PRAZIQUANTEL ADMINISTRATION (60 MG/KG) IN BRAZIL

Agostinho Gonçalves Viana[1], Pedro Henrique Gazzinelli-Guimarães[2], Vanessa Normandio de Castro[1], Yvanna Louise Oliveira[3], Lílian Lacerda Bueno[1], Stefan Michael Geiger[1], Sílvio Santana Dolabella[3], Anna Phillips[4], Ricardo Toshio Fujiwara[1]

[1]*Universidade Federal de Minas Gerais, Belo Horizonte, Brazil,* [2]*Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, EUA, Bethesda, MD, United States,* [3]*Universidade Federal de Sergipe, Aracaju, Brazil,* [4]*Imperial College London, London, United Kingdom*

Current diagnostic methods for intestinal schistosomiasis (detection of eggs in stool by Kato-Katz (KK) are limited and may be particularly unreliable at low levels of infection. in order to overcome some of the pitfalls of the KK method, there has been interest in developing more sensitive tests for the diagnosis of schistosomiasis. The Point-Of-Care (POC) Circulating Cathodic Antigen (CCA) urine assay (POC-CCA) has been reported to be a sensitive and specific alternative to KK in different endemic settings. Specific data comparing the performance of microscopy and antigen detection tests in low Schistosomiasis prevalence settings and mainly, a good method for cure control, however, is currently not available. in this context, the aim of this work was to compare the performance of POC-CCa and KK in the urine and stool samples of school-aged children (SAC) (5-16 years-old) from low endemic area of Minas Gerais State, and in a moderate endemic area of Sergipe State Brazil as well as to test the performance of POC-CCa as a tool for therapeutic efficacy evaluation in areas under MDa programs. For the KK assay, three stool samples were collected, and 2 KK slides were prepared per sample. Up to the present moment, of the 1,285 SAC surveyed in the state of Minas Gerais, 32 (2.5%) of the samples were positive for KK (intensity mean, 20 eggs mg/stool). However, when evaluated the results of the POC-CCa test, 245 (19%) samples were positive in Minas Gerais state. Moreover, out of 542 SAC surveyed until the moment in Sergipe state, 130 (23.9%) of the samples were for KK (intensity mean, 43 eggs mg/stool), 183 (33.7%) samples were positive by the POC-CCa test, considering trace as positive. The results of the analysis 30 days after treatment (praziquantel 60mg/Kg) showed that out of the 210 and 197 POC-CCa positive and treated patients in both areas respectively, 31.5 (84%) and 29.5 (85%) turned out to negative by POC-CCA. Only 15.2% of the positive individuals in both areas remained positive 30 days after treatment by the rapid test. Taken together our preliminary results POC-CCa appears to be a good test to evaluate and monitor infection cure control after treatment.

692

VALIDATION OF HOME-BASED GENITAL SELF-SWABS FOR THE DIAGNOSIS OF FEMALE GENITAL SCHISTOSOMIASIS IN ZAMBIAN WOMEN FROM AN HIV-1 PREVENTION TRIAL

Amy Sturt[1], Comfort Rutty Phiri[2], Emily Webb[1], Isaiah Hansingo[3], Lisette Van Lieshout[4], Paul Corstjens[4], Govert Van Dam[4], Claudia de Dood[4], J. Russell Stothard[5], Richard Hayes[6], Helen Ayles[6], Amaya L. Bustinduy[6]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Zambart, Lusaka, Zambia,* [3]*Livingstone Central Hospital, Livingstone, Zambia,* [4]*Leiden University Medical Center, Leiden, Netherlands,* [5]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom,* [6]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

The diagnosis of Female Genital Schistosomiasis (FGS) is challenging as it relies on resources rarely available in low income settings. The BILHIV (bilharzia and HIV) study assessed the performance of two home-based self-collection methods (cervical and vaginal swabs) compared to cervicovaginal lavage (CVL) for the detection of *S. haematobium* DNa by real-time polymerase chain reaction (PCR). Between January and August 2018, participants from the Population Cohort of HPTN071 (PopART), an HIV prevention trial, were recruited if they were non-pregnant, sexually active, 18-31 years old and residents of two communities (Maramba and Dambwa) in Livingstone, Zambia. Genital self-swabs and a urine specimen were collected and a questionnaire administered at home visits. a midwife obtained a CVL at the cervical cancer clinic. 603 women were enrolled, 319 (53%) from Maramba and 284 (47%) from Dambwa, and 87.3% (527/603) completed CVL. The median age was 24 years (IQR 22 - 26) and 60.4% (364/603) had completed some secondary school. Overall prevalence of *Schistosoma* infection was 5.5% (33/603) based on urine microscopy and 15.1% (91/601) based on urine Circulating Anodic Antigen (CAA). Maramba had higher prevalence of microscopy 8.2% (26/319) and CAa positivity 20.5% (65/317) compared to Dambwa, 2.5% (7/284) and 9.2% (26/284) respectively. *Schistosoma* PCR was positive in: 3.1% (14/451) vaginal self-swabs (3.7% in Maramba and 2.8% in Dambwa), 3.5% (9/257) cervical self-swabs (4.8% in Maramba and 2.6% in Dambwa), and 2.7% (14/523) CVL (3.8% in Maramba and 1.2% in Dambwa). Sample processing is ongoing (CVL (523/527), vaginal swabs (452/603) and cervical swabs (257/603)). Preliminary analysis suggests that home-based genital self-sampling for the detection of *Schistosoma* DNa is comparable to clinic-based collection. Sensitivity and specificity analysis will be performed at completion of specimen processing. Genital self-sampling may provide a future option for FGS community diagnosis at scale.

693

POC-LAMP FOR HUMAN SCHISTOSOMES COMPARATIVE COST AND TIME ANALYSIS FOR VARIABLE ARRANGEMENTS

Brittany Pulkkila[1], Chummy S. Sikasunge[2], James Mwansa[2], **Nilanjan Lodh**[1]

[1]*Marquette University, Milwaukee, WI, United States,* [2]*University of Zambia, Lusaka, Zambia*

Schistosomiasis is one of the major Neglected Tropical Diseases (NTDs), with more than 200 million people infected and close to 800 million at risk, mostly in sub-Saharan African countries. It is caused by two major species, *Schistosoma mansoni* and *S. haematobium*. These often share the same location, raising the problem of accurate and specific diagnosis and can impact any control strategies based on targeted mass drug administration (MDA). World Health Organization has drawn attention to the need for field applicable tests with high specificity and improved sensitivity. To address the above-mentioned issues, we have evaluated the amplification of both *S. mansoni* and *S. haematobium* by loop-mediated isothermal amplification (LAMP), which can be used as a point-of-care (POC) test, from filtered urine samples collected from school children after treatment in Zambia by four different extraction techniques: Qiagen, LAMP-PURE (LP), Chelex and heating. The feasibility of POC-LAMP is also evaluated by determining comparative cost analysis and person-time involvement for each approach. DNa extraction by LP is the fastest (average 20 minutes) compared to the other three methods, although it is the most expensive including amplification ($9.35 compared to $4.90 for heating extraction and amplification). Chelex extraction is slower and simpler than LP and also detected 20% more positive infection than heating. Extraction by heating is also very fast, inexpensive and probably the simplest to perform. However, LAMP performed on heating-extracted samples resulted into many false-negative results, possibly indicating the presence of inhibitor(s). Qiagen and LP extraction both detected 100% of positive infections, but Qiagen extraction is more cost effective than LP. We have demonstrated the sensitivity, cost-effectiveness and time requirement of the LAMP method to detect both schistosome parasites from field collected urine samples. LAMP can be used as a POC test for surveillance and assessing success of control intervention in Zambia as part of their ongoing local schistosomiasis control program.

694

THE DIAGNOSTIC POTENTIAL OF GLYCAN SPECIFIC ANTIBODIES IN SCHISTOSOMIASIS ASSESSED BY GLYCAN MICROARRAYS

Anna O. Kildemoes[1], Angela van Diepen[1], Tom Veldhuizen[1], Linh Nguyen[1], Mio Tanaka[2], Govert J. van Dam[1], Meta Roestenberg[1], Shinjiro Hamano[2], Cornelis H. Hokke[1]

[1]*Leiden University Medical Center, Leiden, Netherlands,* [2]*Institute of Tropical Medicine (NEKKEN), Nagasaki, Japan*

During *Schistosoma* infections, antibodies specific for numerous antigens are induced by parasite larvae, adult worms and eggs. a large proportion of these antibodies are directed against antigenic glycans, which are part of the parasite's glycoprotein and glycolipid repertoire. It remains poorly understood whether these anti-glycan antibodies play a role in immunity to schistosomiasis or contribute to parasite immune evasion. Irrespective of the function of antibodies to defined schistosome glycans in infection, they may constitute a valuable sofar untapped potential in a diagnostic context. As animal experimental work has shown that these anti-glycan antibody responses are highly dynamic, we aim to identify specific glycan targets of the antibody response in schistosome infection. After glycomics analyses of *Schistosoma mansoni* life stages and other helminths, we have isolated and identified hundreds of glycans of which several are unique to blood flukes. These native *S. mansoni* glycans combined with synthetic glycans relevant to schistosomes and other helminths were used to construct a glycan microarray. As such the antigenic repertoire on the microarray represent targets uniquely present in schistosomes as well as targets cross-reactive with other organisms: helminths, other invertebrates, food stuff of plant origin or the mammalian host. We have used this microarray to screen sera from a controlled human *S. mansoni* infection model and from schistosomiasis cohorts from both low and high transmission endemic areas, pre- and post-treatment, in order to identify targets with diagnostic potential. We focus on elucidating anti-glycan antibody responses, which are not only specific to schistosomes but also provide grounds for distinction between current infection and prior exposure/infection. Additionally, we aim to identify differences between responses to *S. mansoni* and *S. haematobium* infection. Development of an antibody based diagnostic tool with such properties would be a useful addition to the diagnostic toolbox available for monitoring treatment efficacy and in schistosomiasis control/elimination programs.

695

PERSISTENCE OF AFEBRILE SUBMICROSCOPIC *PLASMODIUM* SPP. INFECTIONS IN AN ENDEMIC AREA FOR MALARIA IN COLOMBIA

Jehidys E. Montiel Ramos[1], Luisa F. Carbal Reyes[1], Lina M. Zuluaga Idarraga[1], Ana M. Vasquez Cardona[1], Daniel C. Aguirre Acevedo[1], Berlin Londoño Renteria[2], Alberto Tobon Castaño[1]

in malaria endemic regions, many of *Plasmodium* infections are below the level of detection by microscopy (submicroscopic) which is the standard test for malaria diagnosis. Submicroscopic infections (SI) persist undetectable and could contribute to malaria transmission. Understanding of dynamic and duration of SI is indispensable to develop control strategies. Afebrile and SI detected in an endemic Colombian population were longitudinally followed for 60 days. The clearance time of SI and associated factors were estimated. Inhabitants of 4 endemic villages in Tumaco (Pacific Coast) were enrolled between August/2017-March/2018. SI were defined as those detected by LAMP (Loop-mediated isothermal amplification) but no by microscopy with an axillary temperature lower than 37,5°C. An ELISa test was performed to evaluate Antiplasmodial IgG Antibody levels at cero day. SI people were followed up for two months by LAMP and microscopy in at least 6 measurements to estimate the parasite positivity in time. a survival analysis was performed to calculate the survival function and a log rank test to compare the survival distributions regarding malaria history. a cox regression model was done to identify risk factor associated to the persistence. SI in the community were detected in 64/958 individuals (6,7%), 67,2% were *P. falciparum* and 32,8% were *Plasmodium* spp. The median persistence was 53 days and 47,5% had at least three negative consecutive LAMP results with a clearance rate of 0,013/100 SI/day. The median survival was higher in individuals with history of malaria (58 days) compared to individuals without history of malaria (31 days) but there were not statistically significant differences (p 0,205). On the other hand, an increased in the antibody levels against Pf-msp was associated with a decrease in the clearance *Plasmodium* risk (HR 0,14; CI 95%: 0,043- 0,475). There is a high proportion of SI which can persists over time and this persist is related with antibody levels Pf-msp. It is suggested that a cumulative exposure to *Plasmodium* antigens is associated with protection from future clinical malaria episodes and therefore with SI.

696

FALCIPARUM BUT NOT VIVAX MALARIA DURING EARLY GESTATION IS ASSOCIATED WITH INCREASED RISK OF SUBSEQUENT HYPERTENSIVE DISORDERS OF PREGNANCY

Whitney E. Harrington[1], Aung Myat Min[2], Mary Ellen Gilder[2], Nay Win Tun[2], Kerryn Moore[3], Moo Kho Paw[2], Jacher Wiladphaingern[2], Kesinee Chotivanich[4], Nicholas J. White[5], Francois Nosten[2], Rose McGready[2]

[1]*Seattle Children's / University of Washington, Seattle, WA, United States,* [2]*Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand,* [3]*Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, The University of Melbourne, Melbourne, Australia,* [4]*Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand,* [5]*Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Old Road Campus, Oxford, United Kingdom*

Malaria and hypertensive disorders of pregnancy (HDoP) continue to affect millions of pregnancies world-wide, particularly those of young, first-time mothers. Prior research suggests a link between the two conditions, but to date, no large, prospective analysis has considered the effect of peripheral falciparum or vivax malaria on risk of HDoP, by gestational age of infection. Using data from the Thai-Myanmar border collected between 1986 and 2016, we evaluated the relationship between (1) any falciparum or vivax malaria and (2) gestational age of first falciparum or vivax infection and the risk of gestational hypertension (GH), pre-eclampsia (PRE-EC), and eclampsia (EC). 23,262 singleton, live-born pregnancies were considered, in which women were enrolled during first trimester and followed fortnightly with data recorded on blood smear positivity, blood pressure, and proteinuria. Logistic regression models were adjusted for maternal age, first trimester weight, weight gain, chronic hypertension, number of consultations, place of delivery, refugee status, and year of delivery. Among all women, any falciparum infection was associated with risk of any HDoP (AOR 1.63, 95%CI: 1.13-2.37), with strongest effect for GH (AOR 1.84, 95%CI: 1.18-2.87). When stratified by gravidity, falciparum malaria predicted risk of PRE-EC among primigravidae (AOR 4.11, 95%CI: 1.35-12.49) and risk of GH among multigravidae (AOR 2.16, 95%CI: 1.33-3.51). Falciparum infection between 0-11 weeks gestation (AOR 2.51, 95%CI: 1.40-4.50) or 12-21 weeks gestation (AOR 1.75, 95% CI:1.00-3.05) was associated with risk of HDoP. There was no association between vivax malaria and HDoP. In this large, prospectively followed cohort we observed a strong association between early peripheral falciparum malaria and HDoP. The data suggest that falciparum but not vivax malaria during a key period of placental development may result in chronic placental hypoxia, eventually progressing to clinical GH or PRE-EC. These data highlight the critical need to prevent malaria early in gestation, during a window when many women may not yet be aware of the pregnancy.

697

THE EFFECT OF DELAYED TREATMENT ON PROGRESSION TO SEVERE *PLASMODIUM FALCIPARUM* MALARIA: A POOLED MULTICENTRE INDIVIDUAL-PATIENT ANALYSIS

Delay in receiving treatment for uncomplicated malaria (UM) is often reported to increase the risk of developing severe disease, but findings are not consistent across all studies. Understanding which factors underpin progression to severe disease is important in quantifying the potential impact of improving access to treatment and identifying high-risk groups. We searched Ovid MEDLINE and Embase to identify studies on severe P.falciparum malaria with any information on treatment delay, such as duration of symptoms or fever, and contacted authors to obtain individual-patient data. To date, we have pooled data from seven studies in Uganda, The Gambia, Benin, Yemen and Malaysia of 1,377 patients with severe malaria and 2,273 UM controls. Definitions of severity phenotypes were standardised across the studies to compare treatment delay in UM patients with different severe disease manifestations using mixed-effects logistic regressions adjusted for age. An illness duration of ≥ 24 hours prior to arriving at the health facility in children was associated with increased odds of severe malarial anaemia (SMA) compared to UM controls; OR=4.50 (2.06-9.84). Arriving at the facility within 4 days of symptom onset is estimated to prevent 49% of SMa cases, whilst treatment within 24 hours could prevent 76% of SMa cases. Duration of illness was significantly shorter in those with cerebral malaria (CM), hyperlactatemia and hyperparasitaemia compared to controls, whilst no difference was observed for respiratory distress syndrome (p=0.23) or hypoglycaemia (p=0.12). Our results suggest improving rapid access to treatment would probably be highly effective at preventing SMA. CM, hyperlactatemia and hyperparasitaemia have a faster onset and trigger treatment seeking earlier, thus access to treatment would be required within a shorter time-frame to prevent these faster-developing phenotypes. We are continuing to gather additional datasets and explore the pathway to severe disease as well as the effects of accessibility, failure and source of initial treatment prior to the study, transmission intensity, seasonality and socioeconomic determinants.

MALARIA ATTRIBUTABLE FEVER IN LOW AND HIGH TRANSMISSION SETTINGS OF ZAMBIA: DIFFERENCES BETWEEN ACTIVE AND PASSIVE CASE DETECTION

Japhet M. Matoba[1], Philip Thuma[1], Jennifer C. Stevenson[2], Julia Pringle[3], Caison Sing'anga[1], Mukuma Lubinda[1], Amy Wesolowski[4], Tamaki Kobayashi[4], Douglas Norris[5], William J. Moss[6]

[1]*Macha Research Trust, Choma, Zambia,* [2]*Macha Research Trust & Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Choma, Zambia,* [3]*Johns Hopkins Bloomberg School of Public Health, Department of Molecular Microbiology and Immunology, Baltimore, MD, United States,* [4]*Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [5]*Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [6]*Department of Epidemiology, Department of Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Fever is a common symptom of malaria. It is also one of the main symptoms of many other illnesses such as diarrhea and pneumonia. For these diseases, diagnosis with a fever is usually the first point of entry into the health surveillance system. The Zambian government uses active and passive sampling strategies like the malaria indicator survey and rapid surveillance reporting systems for monitoring febrile illnesses and assessing their burden in the community. Understanding the characteristics of febrile illness obtained through these methods can help in adapting treatment guidelines suited to various malaria transmission settings, thereby helping to mitigate threats due to changes in the epidemiological profile as countries strive for malaria elimination. Towards this goal, we examined the correlation of fever and malaria between a cross-sectional analysis of 7,875 actively detected individuals and 513, 307 passively detected health seeking individuals from a health center rapid reporting surveillance system over the period of 2012 to 2015. The participants were drawn from low and high transmission areas in Choma and Nchelenge Districts in Southern and Luapula Provinces of Zambia. Choma and Nchelenge Districts have a malaria prevalence of 1% and 30% respectively. Fever was classified as having a body temperature above 37.5 ^{0} C, while malaria was assessed by a point-of-care rapid diagnostic test (RDT) for *Plasmodium falciparum*. From Choma District and the actively detected data, none of the febrile individuals yielded a positive RDT while 0.5% were RDT positive but afebrile. In Nchelenge District, 80% of the actively detected fevers were attributable to malaria. Among the passively sampled individuals, only 5% of those febrile were RDT positive in Choma District while 56% of fevers were attributable to malaria in Nchelenge. All fever cases were once considered as malaria but as transmission declines, there is need for more information on what is causing fever and how to address it. Our results suggest the need for rigorous integrated management of febrile illness and introduction of point of care diagnostics for non-malaria fever.

699

EPIDEMIOLOGY OF SUBPATENT *PLASMODIUM FALCIPARUM* INFECTIONS IDENTIFIED BY HIGH-SENSITIVITY REAL-TIME PCR DETECTION DURING COMMUNITY-BASED PROACTIVE AND REACTIVE CASE DETECTION IN WESTERN KENYA

Steve M. Taylor[1], Kelsey M. Sumner[2], Betsy Freedman[1], Judith Mangeni[3], Andrew A. Obala[3], Wendy P. O'Meara[1]

[1]*Duke University, Durham, NC, United States,* [2]*UNC Gillings School of Global Public Health, Chapel Hill, NC, United States,* [3]*Moi University, Eldoret, Kenya*

Low-level, asymptomatic *Plasmodium falciparum* infections are common in high-transmission settings, and the availability of conventional malaria

rapid diagnostic tests (cRDTs) for case detection enables community-based screening for these infections. These screening approaches include reactive case detection (RACD), wherein index cases of malaria trigger ring testing, and proactive case detection (PACD), wherein high-risk groups are tested in targeted fashion. We sought to measure the suitability and efficiency of a common cRDT that detects *P falciparum* HRP2 for these purposes by performing sensitive PCR-based parasite detection on specimens collected in 2013-14 in a high-transmission setting in Western Kenya. Over 3,500 participants were enrolled: index children were RDT-positive (cases) or matched RDT-negative controls, and they and all household members were tested with cRDT at enrollment and blood spots were archived. We designed, validated, and applied a TaqMan real-time PCR assay targeting a multi-copy motif *pfr364* in the *P. falciparum* genome that detects down to 0.1 parasite/uL of whole blood. Overall, the parasite prevalence was 22.9% by cRDT and 61.5% by PCR; compared to members of control households, Prevalence Ratios were higher for case household members by both cRDT (PR: 2.21; 95% CI 1.82 - 2.7) and PCR (PR: 1.74; 95% CI 1.58 - 1.92), indicating significant household infection clustering. The overall sensitivity of cRDT compared to PCR was 36%. Sensitivity was highest in infections > 100,000 p/uL (98.2%) and lowest in infections < 1p/uL (8.5%); using a conventional density cutoff of 100p/uL, the sensitivity above the limit was 84% and below was 21%. Based on cRDT prevalence in subgroups, we estimated that the number of household members needed to screen with a cRDT to identify one additional infection was 9.8 in a PACD program and 4.4 in an RACD program. In our site in Western Kenya, *P. falciparum* infections detected by cRDT or PCR were clustered within households of children with malaria; compared to a PACD approach, the RACD approach using cRDT to screen asymptomatic members of the community is twice as efficient at case detection.

ONGOING ASSESSMENT OF *PLASMODIUM FALCIPARUM* PARASITE PREVALENCE IN SOUTHERN PROVINCE ZAMBIA: RESULTS FROM A 2019 PARASITE SURVEY THREE YEARS AFTER A MASS DRUG ADMINISTRATION TRIAL

Brooke Mancuso[1], Travis Porter[1], Maya Fraser[2], Kafula Silumbe[2], Busiku Hamainza[3], Hawela Moonga[3], Adam Bennett[4], Josh Yukich[1], Caterina Guinovart[2], Kammerle Schneider[2], John M. Miller[2], Thomas P. Eisele[1]

[1]*Tulane University School of Public Health, New Orleans, LA, United States,* [2]*PATH, Seattle, WA, United States,* [3]*National Malaria Control Center, Lusaka, Zambia,* [4]*University of California San Francisco, San Francisco, CA, United States*

Between 2014-2016 10 districts along Lake Kariba in Southern Province, Zambia were the site of a community randomized controlled trial investigating the impact of mass drug administration (MDA) strategies. The study area received a continuous effort to maintain a fully scaled intervention package (SIP) of proven malaria interventions, including universal coverage of long-lasting insecticidal nets (LLINs), up to 50% targeted coverage of indoor residual spraying (IRS) with the highly effective Actellic-300cs, improved access to malaria diagnosis and treatment through community case management, improved supply chain and program management, high quality malaria surveillance using DHIS2, and targeted programmatic MDa in higher transmission areas after the initial MDa trial ended. Yearly parasite surveys in the study area during the peak transmission season (April-May) from 2014 - 2016 showed *Plasmodium falciparum* parasite prevalence (*Pf*PR) in children <5 years old to have declined by 87%, irrespective of trial arm, from a baseline of 31.3% in 2014 to 4.0% immediately following the MDa trial in 2016. Since the trial, the Zambian National Malaria Elimination Centre (NMEC) has maintained the full SIP across Southern Province. The decline in *Pf*PR was maintained (*Pf*PR = 3.7%) in the former trial area in 2017, 15 months after the MDa trial. Another parasite survey is currently underway (April-May 2019); we will report if the SIP has successfully maintained the large declines in malaria 3 years after the MDa trial. We will also report SIP components and other factors associated with *Pf*PR in 2019.

701

TARGETED SURVEILLANCE FOR FOREST-BASED MALARIA TRANSMISSION: RESULTS OF A CLUSTER RANDOMIZED CONTROLLED TRIAL IN SOUTHERN LAO PDR

Adam Bennett[1], Emily Dantzer[1], Bouasy Hongvanthong[2], Francois Rerolle[1], Sophia Hocini[1], Jennifer Smith[1], Jimee Hwang[3], Roland Gosling[1], Joshua Yukich[4], Bryan Greenhouse[1], Rattanaxay Phetsouvanh[5], Andrew A. Lover[6]

[1]*University of California San Francisco, San Francisco, CA, United States,* [2]*Center for Malariology, Parasitology, and Entomology, Vientiane, Lao People's Democratic Republic,* [3]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States,* [5]*Department of Communicable Disease Control, Vientiane, Lao People's Democratic Republic,* [6]*University of Massachusetts-Amherst, Amherst, MA, United States*

Lao PDR is targeting elimination of *Plasmodium falciparum* by 2025, and all species of malaria by 2030, but transmission due to forest exposure remains a challenge to these goals. We conducted a cluster randomized controlled trial in Champasak Province, Lao PDR to evaluate the role of village-level mass test and treat (MTAT) and forest worker peer navigator-led focal test and treat (FTAT) for reducing *Pf* prevalence and incidence. Testing included the use of ultra-sensitive rapid diagnostic tests (uRDTs). Using a split-plot design, 56 villages and 14 health facility catchment areas were randomized to receive either the MTAT or FTAT intervention. Two MTAT rounds were conducted in the intervention villages June-Sep 2018, and continuous FTAT implemented Mar-Nov 2018. Of 24,912 tests conducted during MTAT, only 8 were positive by uRDT/RDT for *Pf* (0.03%) and 9 for *P. vivax* (0.04%). PCR detected slightly higher *Pf* positivity (0.07%) and far higher *Pv* positivity (1.58%) than RDTs. During FTAT, 2,906 forest workers were tested at or near the forest fringe, and 67 positive for *Pf* by uRDT/RDT (2.31%). PCR detected 51 *Pf* infections (1.75%) and 116 *Pv* infections (4.04%). Across interventions, diagnostic sensitivity was similar for uRDT (70%) and RDT (68%) compared to PCR for *Pf,* but very low for *Pv* by RDT (8%). Mean monthly *Pf* incidence decreased in the FTAT areas from 0.16/1000 in 2017 to 0.12/1000 in 2018, and was constant in control areas, but this difference did not reach significance in a random effects negative binomial model (Incidence rate ratio (IRR): 0.62, 95% CI 0.23 - 1.64). End-line cross-sectional survey results including PCR will also be presented. The far higher positivity results in forest-worker based FTAT compared to village-based MTAT highlights the importance of targeting forest transmission through active surveillance, and the low sensitivity of RDTs for *Pv* highlights the need for more sensitive diagnostics to detect this reservoir. Engaging the forest worker community through peer navigators is a potentially effective and feasible approach and should be considered as part of a malaria elimination strategy in areas with continued forest transmission.

702

GENOME SEQUENCES OF THE FILARIAL PARASITES *MANSONELLA PERSTANS* AND *MANSONELLA OZZARDI*

Amit Sinha[1], Catherine B. Poole[1], Richard D. Morgan[1], Zhiru Li[1], Laurence Ettwiller[1], Nathalia F. Lima[2], Marcelo U. Ferreira[2], Samuel Wanji[3], Clotilde K. Carlow[1]

[1]*New England Biolabs, Ipswich, MA, United States,* [2]*University of Sao Paulo, Sao Paulo, Brazil,* [3]*University of Buea, Buea, Cameroon*

Mansonella perstans and *M. ozzardi* are filarial parasites that cause human mansonelliasis. *M. perstans* is highly prevalent in areas of sub-Saharan Africa and South America, whereas, *M. ozzardi* is found exclusively in the Americas and Caribbean islands. *Mansonella* parasites are severely understudied and little is known about their biology, epidemiology, or pathogenesis. Clinical symptoms following infection can be absent or non-distinct, and diagnostic as well as treatment options are lacking. We have obtained the first draft sequence of the genomes of *M. perstans* and *M. ozzardi*. Multiple isolates of both the species were sequenced,

using multiple sequencing platforms including Illumina, PacBio and 10X Genomics. These data were assembled to yield genome sizes of ~80Mb in ~1000 to ~5,000 contigs, encoding ~10,000 proteins in each genome. The completeness of these genomes was evaluated using BUSCO, a software that measures the fraction of Single Copy Orthologs expected to be conserved within a taxa. The BUSCO score for both *M. perstans* and *M. ozzardi* is > 85%, similar to the scores of other filaria with complete genome sequences, indicating the high quality of these *Mansonella* genomes. We performed orthology analysis and comparisons to other filarial parasites to identify shared as well as species-specific proteins. The availability of genomes sequences from *M. perstans* and *M. ozzardi* will provide further insight into the evolution and phylogenetic relationships between the *Mansonella* species from different continents. The genomes will also serve as an important resource for further biochemical, molecular and genetic studies, as well facilitate the development of new diagnostic biomarkers and therapeutic tools.

703

FILARIAL POPULATION GENOMICS AND ITS ROLE IN ELIMINATION PROGRAMS

Warwick Grant[1], Michel Boussinesq[2], Katie Crawford[1], Patricia Graves[3], Shannon Hedtke[1], Annette Kuesel[4], Colleen Lau[5]

[1]*La Trobe University, Bundoora, Australia,* [2]*IRD UMI* [233]*-INSERM U*[1175]*-Montpellier University, Montpellier, France,* [3]*James Cook University, Cairns, Australia,* [4]*WHO/TDR, Geneva, Switzerland,* [5]*Australian National University, Canberra, Australia*

Lymphatic filariasis and onchocerciasis have been targeted for elimination, primarily using mass drug administration at the community level, with global elimination as a public health problem the endpoint for lymphatic filariasis and elimination of transmission in 80% of affected sub-Saharan countries by 2025 as the current onchocerciasis target. Where duration, treatment coverage, and compliance are sufficiently high, it has been demonstrated that elimination is achievable for both parasites within defined geographic areas. However, transmission has re-emerged after apparent elimination in some areas, and in others has continued despite years of drug treatment. a critical question is whether this observed re-emergence and/or persistence of transmission is due to local parasites—i.e., the result of inadequate duration, drug coverage, poor response of the parasite to drugs, or inadequate methods of assessment and/or cutoffs for determining when to stop treatment—or due to parasites introduced to the area via human or vector movement from another endemic area. We review population genomics in *Onchocerca volvulus*, the filarial nematode that causes onchocerciasis, and *Wuchereria bancrofti*, the major pathogen for lymphatic filariasis. We focus in particular on the combination of genetic epidemiology and genome-wide associations to define transmission zones and distinguish between local and introduced parasites as the source of resurgence and to identify genetic markers associated with parasite response to chemotherapy. Our ultimate goal is to assist elimination efforts by developing easy-to-use tools that incorporate genetic information about transmission and drug response for more effective mass drug distribution and surveillance strategies.

704

ONCHOCERCA VOLVULUS SECRETOMES: A SOURCE OF POTENTIAL TARGETS FOR DETECTING VIABLE PARASITES

Sasisekhar Bennuru[1], Sara Lustigman[2], Thomas Nutman[1]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*New York Blood Center, New York, NY, United States*

As efforts shift from control to elimination of *Onchocerca volvulus (Ov)*, additional tools to identify those contributing to ongoing Ov transmission in low transmission settings will be needed to reliably detect viable adult female. Building on our previously identified targets for antigen detection, we did comparative proteomic analyses of the secretomes of adult male (AMES) and adult female (AFES) with previously published somatic proteomes of adult female (OvAF), adult male (OvAM), microfilariae (MF), embryonic stages (EMB), L3 and L4 larval stages. Compared to the AFES (650 proteins), the AMES had 7 times as many proteins (~4600) detected. Principal component analyses indicated a high degree of similarity between the OVAFES with the somatic proteomes of MF and embryonic stages. Multivariate analyses resulted in the identification of clusters of proteins that were commonly detected in the AFES, OvAF, MF and/or EMB. Functional analyses of the proteins suggest that the AMES were enriched for proteins involved in nuclear export, post-translational modifications, and peptidase activity. In contrast AFES was enriched for unspecified secreted class of proteins and those that had endopeptidase inhibitor activity. To evaluate if any of the proteins identified commonly between OvAF-AFES or OvAF-AFES-EMB/MF, could be detected in body fluids of infected individuals, we also performed proteomic profiles of serum, exosomes and urine, and compared these with uninfected control fluids. The intersection of these data show that there only a relatively few proteins commonly found in each of these developmental stages and/or anatomical compartments. Among these, however, are a number of potential targets that can be exploited for biomarker assessment in onchocerciasis.

705

THE ANTHELMINTIC PRAZIQUANTEL ACTIVATES A SCHISTOSOME TRANSIENT RECEPTOR POTENTIAL CHANNEL

Jonathan S. Marchant, Sang-Kyu Park

Medical College of Wisconsin, Milwaukee, WI, United States

Schistosomiasis (Bilharzia) is a parasitic worm infection that infects over 200 million people worldwide. No effective vaccine currently exists and the drug praziquantel (PZQ), discovered around 40 years ago, is the key clinical therapy. The clinical formulation of PZQ is a racemate (±PZQ) composed of the enantiomers (*R*)-PZQ and (*S*)-PZQ. (*R*)-PZQ causes Ca^{2+} influx and spastic paralysis of adult worms, with (*S*)-PZQ acting as a less active distomer. From a treatment perspective, it is problematic that despite decades of clinical use, as well as demonstration of PZQ resistance in both lab and field, the target of PZQ remains unknown. This lack of knowledge has proved a longstanding roadblock in schistosomiasis chemotherapy. Resolution of the target of PZQ action in schistosomes would facilitate discovery of new anthelmintics and novel vulnerabilities of parasitic flatworms to chemotherapy. Here, we demonstrate (*R*)-PZQ activates a Ca^{2+}-permeable schistosome transient receptor potential (TRP) channel in *Schistosoma mansoni*, christened *Sm*.$TRPM_{PZQ}$. *Sm*.$TRPM_{PZQ}$ was activated by ±PZQ with an EC_{50} of 1.08±0.14μM in a Ca^{2+} imaging assay and this activation was stereoselective, with the (*R*)-PZQ evoking Ca^{2+} signals over a considerably lower concentration range (EC_{50} of 597±10nM) than (*S*)-PZQ (EC_{50} of 27.9±3.1μM). At 37°C, (*R*)-PZQ activated *Sm*.$TRPM_{PZQ}$ over an even lower concentration range (EC_{50}=154±33nM, Figure 2E), corresponding to the concentration-dependency of (*R*)-PZQ evoked contractions of schistosome worms *in vitro*. Analysis of *Sm*.$TRPM_{PZQ}$ in transcriptomic datasets evidences expression across various schistosome life cycle stages, and analysis of flatworm genomes revealed expression of $TRPM_{PZQ}$ in both free-living and parasitic flatworms that exhibit sensitivity to PZQ. These data provide the first report of a schistosome target activated by PZQ, are consistent with *Sm*.$TRPM_{PZQ}$ being a target of this clinically important therapeutic

706

EVALUATION OF A PROTOTYPE DUAL ANTIGEN RAPID TEST TO DETECT EXPOSURE TO *ONCHOCERCA VOLVULUS*

Vitaliano A. Cama[1], Guilherme Maerschner Ogawa[1], Alison Golden[2], Austin Newsam[1], Sara Lustigman[3], Paul T. Cantey[1], Thomas B. Nutman[4], Sasisekhar Bennuru[4]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*PATH, Seattle, WA, United States,* [3]*New York Blood Center, New York, NY, United States,* [4]*National Institutes of Health, Bethesda, MD, United States*

Serological tools for onchocerciasis are currently limited to the OV-16 ELISa and rapid diagnostic test, with reported high specificity (>98%) but

sensitivities between 45-80%. Therefore, there is a need for improved assays to support elimination mapping. The novel recombinant antigen OVOC3261 was identified from >400 *O. volvulus* protein candidates spotted on a protein array and screened for IgG4 reactivity with sera samples of infected individuals. The performance of OVOC3261 (~82% sensitivity) alone and in conjunction with OV-16 to detect IgG4 antibodies in skin snip positive patients was assessed and validated by Enzyme Linked Immunosorbent Assay (ELISA), a multiplex bead assay (Luminex™) and luciferase immunoprecipitation systems (LIPS). a prototype dual antigen rapid test (DART) was developed; reactivity to either (or both) antigens was considered positive. Two well-characterized panels of serum (n=279) and dried blood spots (DBS, n=440) were assembled to evaluate the diagnostic performance of DART. Each test was read by 3 different people and scored band intensities relative to a semi-quantitative color intensity scale. DART had a combined sensitivity of 93.9% (OVOC3261 87.9%, OV-16 85.5%) and a specificity of 83.1% (OVOC3261 89.2%, OV-16 92.3%) when used with serum, and a 90% sensitivity (OVOC3261 81.4%, OV-16 73.3%) and 94.6% specificity (OVOC3261 95.3%, OV-16 99.2%) when tested with DBS. Data from 231 individuals tested in both panels showed lower band intensities with DBS when compared to serum ($p<0.01$, paired t-test). Overall, OVOC3261 added to the sensitivity of OV-16, although with some reduction in specificity. DART is simple to use and could support the ongoing efforts to eliminate the transmission of onchocerciasis.

707

IN SILICO IDENTIFICATION OF NEW BIOMARKERS AND DEVELOPMENT OF RAPID DIAGNOSTIC TESTS FOR THE FILARIAL PARASITES *MANSONELLA PERSTANS* AND *MANSONELLA OZZARDI*

Catherine B. Poole[1], Amit Sinha[1], Laurence Ettwiller[1], Lynne Apone[1], Karen McKay[1], Vaishnavi Panchapakesa[1], Nathália F. Lima[2], Marcelo U. Ferreira[2], Samuel Wanji[3], Clotilde K. Carlow[1]

[1]*New England Biolabs, Ipswich, MA, United States,* [2]*University of São Paulo, São Paulo, Brazil,* [3]*University of Buea, Buea, Cameroon*

Mansonelliasis is a widespread yet neglected tropical infection of humans caused by any of three species of filarial nematodes, *Mansonella perstans*, *M. ozzardi* and *M. streptocerca*. *M. perstans* is found throughout Saharan Africa and in South America, whereas *M. ozzardi* and *M. streptocerca* are localized to certain areas of Latin America or Africa, respectively. Clinical symptoms are nondistinct and diagnosis mainly relies on the detection of microfilariae in skin or blood. Species-specific DNA repeat sequences have been used as highly sensitive biomarkers for filarial nematodes such as *Brugia malayi*, *Loa loa* and *Onchocerca volvulus*. We have developed a bioinformatic pipeline to mine Illumina reads obtained from sequencing *M. perstans* and *M. ozzardi* genomic DNA for new biomarker candidates. This approach led to the discovery of species-specific, repeat-based biomarkers and the successful development of loop-mediated isothermal amplification (LAMP) diagnostic tests with remarkable levels of specificity and sensitivity for each *Mansonella* infection. The assays performed successfully on clinically defined human samples and experimentally infected *Culicoides milnei*. These new tools are field deployable and suitable for the reliable detection and differentiation of *M. perstans* and *M. ozzardi* from other co-endemic filarial species in human hosts and insect vectors.

708

LOA LOA: DETECTION OF CIRCULATING CELL-FREE DNA IN BODY FLUIDS

Frimpong Kodua[1], Sasisekhar Bennuru[1], Papa Drame[2], Eric Dahlstrom[3], Thomas Nutman[1]

[1]*National Institutes of Health, Bethesda, MD, United States,* [2]*Duke Global Health Institute, Duke University, Durham, NC, United States,* [3]*National Institutes of Health, Hamilton, MT, United States*

We have previously described the utility of qPCR-based detection of *Loa loa (Ll)*microfilariae (mf) that detected a single copy gene LLMF72. Using pipelines based on raw reads from next generation sequencing data and RepeatExplorer, we identified 15 high copy tandem repetitive elements in the *Ll*genome (with coverage across the genome ranging from 1000-20000x). Using custom primer-probe sets designed to amplify each of these 15 repeats we assessed their ability to amplify genomic DNA of *Loa*loa and not amplify the often co-endemic filarial species*Onchocerca volvulus*and *Wuchereria bancrofti*. Among all of the repeats, one LL2643 was found to be the most sensitive, though each primer probe set had 100% specificity. When compared to LLMF72, LL2643 was found to be the 256-fold more sensitive by qPCR with a limit of detection reliably shown to be 1fg/ul. Given the increased sensitivity of the assay to detect gDNA equivalent to $1/10^{th}$of a mf, we tested the utility of LL-2643 in detecting circulating cell-free DNA (ccfDNA) in Ll-infected individuals. Analyses of the ccfDNA extracted from serum/plasma of 32 mf+ Ll-infected individuals indicated a significant correlation between Ct values and mf counts ($r=-0.68$, $p<0.0001$). More importantly, in patients that were followed longitudinally following treatment, almost all of the patients' ccf DNA was undetectable. Interestingly, the kinetics of the disappearance of ccfDNA showed a marked reduction of Ll DNA at 1 month following diethylcarmbazine therapy ($p<0.001$) that continued to fall over to undetectable over time. Currently, the assay is being tested to evaluate if the ccfDNA can be detected in urine of infected individuals so that a non-invasive method of diagnosis and treatment can be developed.

709

CTL4 GENE-KNOCKOUT TO BLOCK *PLASMODIUM* INFECTION IN THE VECTOR MOSQUITO

Maria L Simoes, Yuemei Dong, Godfree Mlambo, George Dimopoulos

Johns Hopkins University, Baltimore, MD, United States

The development of genetically modified (GM) mosquitoes for malaria control has gained strength through the recent advances in gene-drive technology and an increased understanding of vector-parasite interactions. While most work aiming at the development of GM malaria resistant mosquitoes, suitable for population replacement, has focused on the over-expression of anti-parasitic genes, here we have explored a strategy relying on CRISPR/Cas9-based inactivation of mosquito encoded *Plasmodium* agonists. During its sexual cycle inside the mosquito vector, *Plasmodium* engages in intimate interactions and relies in numerous *Anopheles*-derived host factors, which act as facilitators of infection. The C-type lectin CTL4 has been identified as a *Plasmodium* agonist (Osta *et al*., 2004). in our recent work we showed that the C-type lectin-mediated protection against parasite melanization in the African vector *A. gambiae* is dependent on the intensity of infection, rather than the mosquito-parasite combination (Simões *et al*., 2017). RNa interference (RNAi)-based silencing of CTL4 resulted in melanization and reduction of live parasites, albeit RNAi results in only partial gene silencing. We hypothesized that the knockout (KO) of CTL4 would result in complete melanization of the parasites, and consequently a complete halt of *P. falciparum*'s development inside the mosquito. We are currently using CRISPR/Cas9 technology for targeted CTL4-KO in *A. gambiae*. We generated gRNa overexpressing *A. gambiae* transgenic lines that were crossed with the Vasa::Cas9 strain, to generate CTL4-KO *A. gambiae* mutants. These CTL4-KO GM mosquitoes are being evaluated for parasite blocking of total *Plasmodium*-agonist disruption. The effects of CTL4-KO on bacterial and fungal development inside the mosquito are also being screened.

Anopheles gambiae mosquitoes are the major African vectors of *Plasmodium falciparum*, the deadliest human malaria parasite. Transmission of this parasite occurs when a female mosquito takes a blood meal to produce eggs, but whether parasite development interacts with oogenesis in the initial phases after blood feeding remains largely unknown. Here we show that in the naturally occurring *An. gambiae-P. falciparum* association, parasite development is non-competitively linked to biological processes leading to egg development. We reveal that *An. gambiae* experience no reproductive costs of *P. falciparum* infection, such that there is a positive correlation between the number of eggs a female develops and the number of oocysts in her midgut. This interaction is regulated by the insect steroid hormone 20-hydroxyecdysone (20E) produced by the female post-blood meal, as impairing 20E signaling breaks the positive egg-oocyst correlation and leads to fewer oocysts—suggesting that 20E may regulate relative female investments in reproduction and immunity. Strikingly, females that invest less in reproduction support faster parasite development, via the accumulation of lipids carried by transporters involved in oogenesis. Faster growth in turn leads to earlier sporozoite infectivity, increasing the chances of parasite transmission. We observe similar phenomena in field infections with *P. falciparum* parasites from West Africa, where we additionally reveal that parasite genetic components affect the interaction of parasite growth with 20E-regulated mosquito metabolism. Overall, our results suggest that *Plasmodium* has adopted a developmental strategy in *Anopheles* that limits costs to the mosquito while also promoting its transmission. Moreover, by highlighting the ability of the parasite to rapidly adapt in response to changes in mosquito physiology, our findings have profound implications for currently proposed vector control tools targeting mosquito reproduction.

711

KNOCKOUT OF *ANOPHELES STEPHENSI* LRIM1 USING CRISPR-CAS9 REVEALS ITS CRUCIAL ROLE IN VECTOR COMPETENCE

Ehud Inbar[1], Abraham Eappen[1], Robert Alford[2], William Reid[1], Tao Li[1], Robert Harrel[2], Sumana Chakaravarty[1], Donald F. Ward[1], Kim Lee Sim[1], Stephen L. Hoffman[1], Peter F. Billingsley[1]

[1]*Sanaria Inc., Rockville, MD, United States,* [2]*Insect Transformation Facility, Institute for Bioscience and Biotechnology Research, University of Maryland, Rockville, MD, United States*

Sanaria® PfSPZ Vaccine and PfSPZ-CVac confer high protective efficacy against *Plasmodium falciparum* (Pf) infections. These vaccines are composed of aseptic, purified, cryopreserved Pf sporozoites (SPZ), and are manufactured using aseptically grown *Anopheles stephensi*. *Anopheles* immune genes such as Leucin-Rich Immune (LRIM) protein and Thioester-Containing Protein 1 (TEP1) inhibit *Plasmodium* sporogony by melanization and phagocytosis of the oocysts. Knocking out these genes should theoretically increase PfSPZ infection intensities and improve manufacturing efficiency of PfSPZ products. We generated an *A. stephensi* LRIM1 knockout line, Δ*aslrim1*, using CRISPR-Cas9. LRIM1 protein was undetectable in homozygous Δ*aslrim1* by western blot with anti-AsLRIM1 antibody. Knocking out LRIM1 profoundly affected the mosquito. The bacterial load increased overwhelmingly and the microbiome composition was altered. These alterations probably accounted for the increased adult mosquito mortality. There was also a reduction in the number of eggs oviposited, and the fertility of males decreased. Contrary to expectation, Δ*aslrim1* non-aseptic mosquitoes were unable to support growth and development of PfSPZ. Pf infection intensities were partially restored when adult mosquitoes were maintained on 10% sugar solution containing antibiotics, and fully restored when Δ*aslrim1* mosquitoes were produced aseptically. In summary, LRIM1 is crucial to *A. stephensi*, being essential for survival of mosquitoes (probably because of their reduced capacity to survive bacterial insult), affecting reproductive capacity. Reductions in Pf infections are probably due also to bacterial overload as the ability to support growth and development of Pf in aseptic mosquitoes is unaffected.

712

BACTERIAL SUPPRESSION OF MALARIA TRANSMISSION BY MOSQUITOES

Wei Huang[1], Janneth Rodrigue[2], Alfonso Mendoza-Losana[2], Marcelo Jacobs-Lorena[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*GlaxoSmithKline plc, Tres Cantos, Spain*

The intolerable burden of malaria demands the urgent development of novel approaches to fight this deadly disease. Previously, we have shown that engineered mosquito symbiotic bacteria can render mosquitoes resistant to the parasite. However, translation of these findings to the field faces major regulatory barriers. Here we describe two non-modified symbiotic bacteria - *Delftia* sp. and *Pseudomonas* sp. These bacteria were originally isolated from mosquitoes that had lost the ability to sustain the development of *Plasmodium falciparum* parasites. While *Pseudomonas* easily colonizes the mosquito and is transmitted vertically, it is a poor inhibitor of *Plasmodium* development. *Delftia* on the other hand, is a potent inhibitor of *Plasmodium* development in mosquitoes. This bacterium does not impose a fitness load: it does not affect mosquito survival, blood feeding behavior, fertility or fecundity. *Delftia* has promise for use in the control of malaria.

713

NUCLEASES IN THE MOSQUITO GUT REDUCE EFFICIENCY OF RNA INTERFERENCE

David J. Giesbrecht[1], David Boguski[2], Ian Wiens[1], Lisa Zhan[1], Daniel Heschuk[1], Steve Whyard[1]

[1]*University of Manitoba, Winnipeg, MB, Canada,* [2]*Fisheries and Oceans Canada, Winnipeg, MB, Canada*

Sterile insect technique (SIT) against mosquitoes suffers from high costs of sex-sorting and sterilization. RNa interference (RNAi) against transcripts essential for sex-determination and testis development has been proposed as a cost-effective means of producing sterile males for SIT. For this goal to be realized, optimization of dsRNa delivery is needed. Because endogenous nucleases can impede dsRNa delivery in some insects, we investigated the impacts of nucleases in mosquito guts. Ten putative nucleases were identified in the *Aedes aegypti* genome, with two highly expressed in the guts of larvae. Using an *ex-vivo* assay, we observed that dsRNa is rapidly degraded within the mosquito larva's gut. Double-stranded RNa targeting these two nucleases, when fed to the larvae, effectively reduced both the nuclease transcripts and gut nuclease activity. When these nuclease-specific dsRNAs were co-delivered with dsRNa targeting a reporter gene, improved knockdown of the reporter gene's transcripts was observed.

These results suggest that inhibiting nuclease activity could bring RNAi-based SIT within reach. Finally, we discuss several approaches to package dsRNa in mosquito food to avoid nuclease degradation.

714

INTERACTION BETWEEN PLASMODIUMAL PHATUBULIN AND *ANOPHELES* FREP1 ASSISTS MALARIA TRANSMISSION

Genwei Zhang[1], Guodong Niu[2], Manpreet Kaur[2], Luara Perez[2], Xiaohong Wang[2], **Jun Li**[2]

[1]*University of Oklahoma, Norman, OK, United States,* [2]*Florida International University, Miami, FL, United States*

Passage of *Plasmodium* through a mosquito is essential for malaria transmission. FREP1, a mosquito midgut peritrophic matrix protein, binds to the parasite and mediates *Plasmodium* infection in *Anopheles*. Notably, this FREP1-mediated *Plasmodium* invasion pathway is highly conserved across multiple species of *Plasmodium* and *Anopheles*. Previous experiments show that FREP1 binds to *P. falciparum*. FREP1 also binds to rodent malaria pathogen *P. berghei*. Furthermore, nine *P. berghei* proteins were co-precipitated with FREP1-conjugated beads. After cloning these nine genes and expressing them in insect cells, six of them were confirmed to interact with FREP1. Among them, α-tubulin and heat shock protein 70 (Hsp70) are highly conserved in *Plasmodium* species with >95% identity. Thus, antiserum against α-tubulin and Hsp70 were produced in mice to determine their effects on *Plasmodium* transmission. Our results show that anti-α-tubulin serum significantly inhibits *P. falciparum* transmission to *An. gambiae*, while anti-Hsp70 serum does not. In addition, purified rabbit polyclonal antibody against human α-tubulin blocks *P. falciparum* transmission to *An. gambiae*. Although α-tubulin is normally inside a cell, fluorescence microscope assays show that anti-α-tubulin Ab can access and bind to *Plasmodium* ookinete apical invasive apparatus. Therefore, we propose that the interaction between FREP1 and α-tubulin may direct the ookinete invasive apparatus towards midgut PM for efficient parasite invasion.

715

IMMUNITY AND MEMORY AGAINST MALARIA: AN ATLAS OF THE MOSQUITO IMMUNE SYSTEM AT SINGLE-CELL RESOLUTION

Gianmarco Raddi

University of Cambridge/Wellcome Sanger Institute, Cambridge, United Kingdom

Malaria is yearly responsible for 219 million cases and over 400,000 deaths. *Anopheles gambiae* mosquitoes are the main African vectors for the most virulent malaria parasite: *Plasmodium falciparum*. Mosquitos are not mere bystanders however, and rely on both humoral and cellular innate immune responses to defeat invading pathogens, including malaria. These efforts are coordinated by hemocytes, the insect equivalent to vertebrate's white blood cells. Yet, hemocyte biology is largely unknown, mainly due to their fragility and low numbers. in order to identify unknown cell types, their gene signatures, and their spatial-temporal localization in the mosquito we isolated *Anopheles* hemocytes and characterized them by single-cell RNa sequencing. a total of 5,218 individual *Anopheles* hemocytes were profiled 1,3 and 7 days after sugar-feeding, blood-feeding, or infection with *Plasmodium berghei*. Ten cell sub-types were identified, including novel effector, inhibitory, phagocytic, and secretor cells. Bulk RNAseq of *Anopheles* hemocytes, guts, and carcasses was also performed to identify selective marker genes. The putative cell types were validated with fluorescence in situ hybridization (RNA-FISH) in mosquito sections, whole guts and carcasses, and isolated hemocytes, showing an increase in active granulocytes and novel effector cells with malaria infection. After validation, challenged hemocytes' transcriptomic changes with time were investigated to understand hemocyte lineage and development. Both a rapidly dividing hemocyte progenitor pool and a more general trajectory of cell activation were identified, showing a progressive increase in immunity, signal transduction, spliceosome, and cell cycle genes from day 1 to 2 and 3, before returning to baseline at day 7.Finally, *Plasmodium* infection leads to a dramatic increase of the novel secretor cell type, as well as active granulocytes. Our results are the first comprehensive transcriptomic study of a whole invertebrate organism's immune system, demonstrating hemocytes' complexity far exceeds what is currently described in the literature

716

IMPLEMENTING MALARIA DIAGNOSTIC COMPETENCY ASSESSMENT COURSES IN NON-ENGLISH SPEAKING COUNTRIES OF AFRICA

Mamadou Alpha Diallo[1], Mame Cheikh Seck[1], Ibrahima Diallo[2], Khadim Diongue[1], Aida Sadikh Badiane[1], Mouhamadou Ndiaye[1], Daouda Ndiaye[1]

[1]*Cheikh Anta Diop University, Dakar, Senegal,* [2]*National Malaria Control Program, Dakar, Senegal*

Accurate malaria diagnosis is important for rational use of antimalarials and prevent drug resistance. Hence, a need to implement a comprehensive and regular malaria microscopy training and competency assessment program. Since 2016, Cheikh Anta Diop University (UCAD) is conducting External Competency Assessment in malaria microscopy (ECAMM) courses for non-English speaking countries in Africa. Here, we assess the outcomes of the first three years of this program. The audience was limited to 12 individuals per course. Each course was conducted over five consecutive days. On Day 1, a pre-assessment of participants in malaria theoretical knowledge and malaria microscopy was done. Days 2 through 4 comprised both learning units and assessment modules for malaria microscopy. Participants were assessed on parasite detection, species identification, and parasite quantitation. The slides sets were from the WHO Slide Bank. Only Level 1 and Level 2 microscopists were certified as WHO experts. Since 2011, twelve ECAMM courses have been conducted with 138 participants from 22 countries. Out of the 138, 96 (69.6%) were certified as experts either as level 1 or level 2. Eighteen countries had at least one microscopist certified. Out of the 138, 116 participants (84.1%) had both their sensitivity and specificity higher than 90%. The assessment results showed that accuracy in parasite detection ranged from 68% to 100%, with 60 out of 138 participants achieving 100%. Accurate results for species identification were variable, ranging from only 39% to 100%, with 55 out of 138 achieving more than 90%. The results for parasite counting were also variable, ranging from 14% to 100%, with 81 out of 138 achieving 50% or more of their counts within 25% of the true count. Significant improvements were reported in malaria microscopists after attending the program. Although all participants gained knowledge and awareness about the benefits of ECAMM courses, its implementation should be extended to more participants. We recommend that all higher officials and policymakers in the field of malaria to pay attention to it and allocate adequate budget on a continuous basis.

717

ENGAGING COMMUNITIES TO SUPPORT CONSENTING FOR MINIMALLY INVASIVE TISSUE SAMPLING (MITS) PROCEDURE: LESSONS LEARNED FROM BANGLADESH

Faruqe Hussain[1], Emily Gurley[2], Md. Saiful Islam[1], John Blevins[3], Ahoua Kone[3], Abdush Suban Mulla[1], Abu Uzayer[1], Afroz Zahan[1], Aziz Ahmed[1], Shikha Datta Gupta[1], Suruj Ali[1], Abdullah Al Masud[1], Mamunur Rashid[1], Ahmed Shahriar[1], Shams El Arifeen[1], Shahana Parveen[1]

[1]*International Centre for Diarrhoeal Disease Research, Bangladesh, Mohakhali, Dhaka, Bangladesh,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States,* [3]*Rollins School of Public Health, Emory University, Atlanta, GA, United States*

The Child Health and Mortality Prevention Surveillance (CHAMPS) Network is using community engagement platform to involve the community into the implementation of post-mortem minimally invasive tissue sampling (MITS) using needle, to identify the aetiology of death among <5 children

in Baliakandi sub district, Bangladesh. Communities could confuse MITS with full autopsy leading to refusal. We aimed to establish and sustain trust and partnership engaging community leaders and residents to facilitate decision making on MITS consent. We first conducted 50 institutional level consultations with community and religious leaders and then held meetings in the courtyards and tea stalls with general adult residents between May 2017 to March 2018, before and after inception of MITS in 3 different health facilities. We informed and educated ~28% adult populations (out of 146,601) through 810 meetings in 261 villages. Community meetings provided a useful platform responding to community queries and concerns related to MITS procedure. Almost all of the community and religious leaders consulted showed positive responses to determine cause of child death through MITS implementation. Cascading sharing information and consultation from community leaders to general community residents built trust and partnership. Communities appreciated the respect CHAMPS team showed to families of deceased children and team participation in funeral activities facilitated trust. Clarifying from the beginning the extent of what the program will offer effectively minimized community expectations to financial or medical care support beyond the program scope and reduced further queries and arguments. Greater than half (53%) of parents and relatives of deceased children who consented for MITS procedure were exposed to engagement activities. Engaging the residents who live remotely requires additional time and effort. It is important to actively engage community leaders and residents to develop and strengthen trust, increase acceptance and minimize expectations when implementing socio-culturally sensitive community-based public health programs.

718

HEALTH AND SAFETY OF UCLA INTERNAL MEDICINE RESIDENTS PARTICIPATING IN SHORT-TERM INTERNATIONAL CLINICAL ELECTIVES

Jesse E. Ross, Noah Kojima, Chris Tymchuk

University of California Los Angeles, Los Angeles, CA, United States

International clinical electives continue to be very popular among resident physicians; however, very little is known about their health and safety while on these electives. The UCLa Department of Medicine Global Health Pathway offers short-term international clinical electives to 25 residents each year to rotate at partner sites in Malawi, Peru and Thailand. All residents undergo a mandatory pre-departure orientation, which consists of lectures with Infectious Disease faculty and a pre-travel visit with a travel medicine physician. Residents are also directly supervised by a UCLa faculty member on site for the majority of their elective. We surveyed past participants of the electives to determine if there were any significant health or safety issues that they faced or were diagnosed with during or after their electives. We distributed an anonymous, online survey to 142 former participants and received 63 responses for a response rate of 44%. The majority of respondents rotated at our partner site in Lilongwe, Malawi (87%) and the remainder at partner sites in Iquitos, Peru (11%) and Bangkok, Thailand (2%). The results of our survey revealed the most common adverse health events were: diarrhea (45%), fever (17%), and vomiting or flu like symptoms (7%). None of the reported adverse health events led to hospitalization or early termination of the elective. Four participants (6%) reported a bodily fluid exposure, with two exposures necessitating the initiation of HIV post exposure prophylaxis. There were no reported HIV seroconversions among the respondents. While 19% of participants reported a concerning tuberculosis exposure, there were no reported PPD or IGRa conversions. Three participants reported concern for personal safety and one reported being a victim of robbery. While this study is limited by its retrospective nature and a relatively low response rate, the results suggest that short-term international clinical electives are safe if appropriate steps are taken to mitigate any potential health or safety risks of performing clinical work in international settings.

719

BUSINESS MODEL INITIATIVES TO IMPROVE ACCESS TO ESSENTIAL MEDICINES IN LIMITED RESOURCES COUNTRIES. A PHARMACEUTICAL COMPANY'S APPROACH

Harald Nusser, Tayyab Salimullah, Viviam Canon, Nadine Shecker, Rachel Hinder, Rebecca Stevens

Novartis Social Business, Basel, Switzerland

According to WHO ~2 billion people have no access to essential medicines. Pharmaceutical companies are requested to contribute to improving access for patients in limited resources settings. Novartis Social Business (NSB) is a unit based on a patient-centric model aiming to support under-resourced healthcare systems, placing equal weight on financial and social returns. NSB brings together different access to medicine programs; in addition to the well established Malaria initiative that by 2018 has delivered without profit more than 880m antimalarials, NSB includes "Healthy Family", "SMS for life" and "Novartis Access". Healthy Family has built local, sustainable capabilities for healthcare in India, Kenya and Vietnam, where local health educators teach their communities, host educational meetings and guide for seeking diagnosis and treatment from a qualified doctor. Only in 2018, ~7.8 million people attended health educational meetings; there were 15.123 health camps in place, providing medical care to more than 700.000 people. In addition, a pilot was conducted in Jigani, India to incorporate digital tools and test online doctor's support to trained nurses when they are with patients in the field. "SMS for life" was implemented initially in 2009 in Tanzania, and more recently in Zambia as a tool for surveilling availability of essential medicines and diagnostic tests for Malaria, HIV and TB in remote rural areas. "Novartis Access" includes a portfolio available to governments, NGOs and other public sector providers in low-income countries at a price of UDS1 per treatment per month, and covers treatments for key diseases including malaria, pneumonia, diabetes, hypertension, asthma, dyslipidemia and some types of cancer. The number of monthly treatment delivered went from 84.448 in 2016 to 2.274.700 in 2018, reaching more than 1.5 m patients the last year. The first year of Novartis Access in Kenya has been recently evaluated and suggests an initial positive impact on the availability of drugs for diabetes and hypertension at the healthcare facility level.

720

BURNOUT AND WELLBEING IN GLOBAL HEALTH: OBSERVATIONS FROM RECIPIENTS OF THE CONRAD N. HILTON HUMANITARIAN PRIZE

David G. Addiss[1], Leslie Leonard[2], Deirdre Guthrie[3]

[1]*Task Force for Global Health, Atlanta, GA, United States,* [2]*Emory University, Atlanta, GA, United States,* [3]*Spore Studios, Three Oaks, MI, United States*

Global health and humanitarian organizations attract highly motivated people who care deeply about social justice and alleviating suffering. They often work in conditions of deprivation, conflict, and chronic stress, which can contribute to burnout. Burnout leads to high staff turnover, decreased performance, and sub-optimal organizational effectiveness. To understand work-related burnout and the capacity of humanitarian organizations to recognize, manage, and prevent it, we invited recipients of the Conrad N. Hilton Humanitarian Prize - among the most influential humanitarian and global health organizations - to complete a survey and participate in interviews. Fourteen human resource (HR) directors completed surveys and 39 semi-structured interviews were completed with CEOs (10), HR directors (10), and up to three staff per organization (19). Factors identified by more than 50% of HR directors as contributing to burnout included: poor relationships with supervisors or other leaders (86%); long, unpredictable working hours (71%), ambiguous job expectations (64%), communication challenges (64%), and barriers to professional and personal growth (57%). HR directors identified significant deficiencies in the quality and effectiveness of resources available to manage employee stress. Perceived barriers to wellbeing included lack of time (86%), funding (64%) and expertise (57%). Interviews revealed four types of stressors:

structural dynamics, including internal (e.g., workload, supervision) and external (e.g., contracts, pressure to perform) factors; and safety, both physical (e.g. threat of violence) and psychological (e.g., lack of civility). Types of stressors differ by gender and setting (e.g., headquarters or "field"), and residency status ("national" or "expatriate"). Staff who over-identify with work find it difficult attend to their own wellbeing. These findings suggest that among elite humanitarian and global health organizations, stress is ubiquitous, burnout is not uncommon, self-care is often sub-optimal, and resources for wellbeing are inadequate.

721

RISK FACTORS FOR INFECTIOUS DISEASES IN URBAN ENVIRONMENTS IN SUB-SAHARAN AFRICA: A REVIEW

Matthew R. Boyce, Rebecca Katz, Claire J. Standley

Georgetown University, Washington, DC, United States

Our world is rapidly urbanizing. According to the United Nations, between 1990 and 2015, the percent of the world's population living in urban areas grew from 43% to 54%. Estimates suggest that this trend will continue and that over 68% of the world's population will call cities home by 2050, with the majority of urbanization occurring in African countries. This urbanization will have a profound effect on global health and could significantly impact the epidemiology of infectious diseases owing to the trade, travel, and migration inherent to cities. a better understanding of infectious disease risk factors specific to urban settings is needed to plan for and mitigate against these impacts. We conducted a systematic literature review of the Web of Science and PubMed databases to assesses the risk factors for infectious diseases in urban environments in sub-Saharan Africa. a search combining keywords associated with cities, migration, infectious disease, and risk were used to identify relevant studies. Original research and meta-analyses published between 2004 and 2019 investigating geographical and behavioral risk factors, changing disease distributions, or control programs were included in the study. The search yielded 414 papers, of which 37 met the criteria for inclusion in the analysis. Papers were categorized according to risk factor, geographic area, and study type. The papers covered 27 countries in sub-Saharan Africa with West Africa the most represented sub-region. Malaria and enteric diseases were the most frequent focus of the studies. The results of this work can inform public health policy as it relates to capacity building and health systems strengthening in rapidly urbanizing countries, as well as highlight knowledge gaps that warrant additional research.

722

COSTING ANALYSIS OF SEROLOGICAL SURVEILLANCE FOR MEASLES AND RUBELLA IMMUNITY IN ZAMBIA

Andrea Carcelen[1], Bryan Patenaude[1], William J. Moss[1], Phil Thuma[2], Simon Mutembo[3], Kyla Hayford[1]

[1]*Johns Hopkins University, Baltimore, MD, United States,* [2]*Macha Research Trust, Choma, Zambia,* [3]*Ministry of Health, Choma, Zambia*

Despite reportedly high vaccination coverage, measles and rubella outbreaks remain common. This is a product of the fact that vaccination coverage is only a proxy measure of population immunity. However, estimating immunity requires biological markers and laboratory testing through serological surveillance. a better understanding of the costs of serosurveys and the tradeoff of cost per information gained is needed to inform how serological surveillance can be optimally used to support immunization programs. There is limited systematically collected data on the actual cost of serosurveys. This study aims to assess the tradeoff between cost and precision of seroprevalence estimates obtained by collecting serological specimens during a household survey to estimate population immunity levels for measles and rubella using empiric data and simulation models. Costs were calculated with data from the Zambian post-campaign coverage evaluation survey using an ingredients-based approach from the government-funded healthcare perspective and were linked with seroprevalence results. To frame the collection of serosurvey data, a costing framework for integrated disease surveillance was adapted to capture the categories of implementation inputs across serosurvey functions. We estimated the total serosurvey cost in Southern province was US $88,382 to collect dried blood spots (DBS) from 658 participants in 16 clusters. Personnel was the largest contributing input (52%) followed by transportation (16%). Compared to a traditional vaccination coverage survey, collecting DBS for serological surveillance added $27,253 to the total survey costs. Cost and precision tradeoffs will be further investigated by simulating various sampling strategies for serological surveys and varying survey parameters. As more countries add specimen collection to their surveys, it is important to understand the costs and cost per information gained. This cost-precision model will allow policy makers to determine what the added cost of collecting specimens and argue the case for using serosurveys to identify potential pockets of susceptible individuals.

723

DEVELOPING GLOBAL HEALTH PRACTITIONERS: A NOVEL INTERNATIONAL HEALTH EXPERIENCE FOR US MEDICAL STUDENTS

Sara U. Schwanke Khilji, Justin Denny

Oregon Health & Science University, Portland, OR, United States

Student interest in global health is burgeoning (Khan 2013). As the number of students seeking international health experiences (IHE) increases, training programs are challenged to accommodate this demand with opportunities that prepare students for work in global health while providing professionally and culturally relevant learning experiences, embedded within an appropriate ethical framework (Melby 2016). The *OHSU Global Southeast Asia Clinical Field Experience* is a novel elective IHE offered through the Oregon Health & Science University (OHSU) School of Medicine. The four-week elective is structured as a hybrid immersion experience, integrating traditional clinical observership opportunities at an OHSU Global partner site in Thailand with interactive didactics led onsite by OHSU faculty, introducing learners to fundamental concepts in global health such as globalization of healthcare, global burden of disease, and ethics (Jogerst 2015). Broadly, the course aims to develop students› ability to conceptualize health as the result of macro-level influences on both individuals and populations - including historical, political, economic, and cultural - and to apply these concepts in a non-US setting. The course was developed in accordance with core OHSU Global programmatic principles, including long-term, bidirectional, and mutually beneficial relationships with partnering institutions in Southeast Asia. It is complemented by a reciprocal four-week observership experience at OHSU for Thai medical students from the OHSU Global partner site in Bangkok. Student narrative feedback has been highly positive, with the majority of students citing the beneficial impact of the experience on their perceptions of what constitutes global health; knowledge and ability to analyze the main drivers of disease globally; and recognition of the importance of cultural humility. Ethical approval for a post-course survey is under development to more fully analyze the impact of the elective on learner knowledge, attitudes, perceptions, and career decisions.

724

INEQUITIES IN THE BURDEN OF FEVER, DIARRHEA AND ACUTE RESPIRATORY INFECTION IN CHILDREN UNDER FIVE IN LOW- AND MIDDLE-INCOME COUNTRIES AND THE ROLE OF INTEGRATED COMMUNITY CASE MANAGEMENT IN TARGETING THOSE MOST AT RISK

Peter Winskill, Ben Lambert, Alexandra B. Hogan, Patrick G. Walker

Imperial College London, London, United Kingdom

Upon surviving the neonatal period, the biggest killers of children aged under five years in low- and middle-income settings are malaria, pneumonia and diarrhoea. The burden of all three diseases can be greatly reduced with prompt access to the effective treatments that are available. However, inequities in society and access to treatment affect both the

risk of acquiring one or more of these conditions as well as being able to access healthcare for appropriate treatment if infected. In an effort to address inequities, the WHO recommends integrated Community Case Management (iCCM) as an "equity-focused strategy that complements and extends the reach of public health services by providing timely and effective treatment of malaria, pneumonia and diarrhoea to populations with limited access to facility-based health care providers, and especially to children under 5". Here we present a multi-country, multivariate, multilevel, Bayesian logistic regression analysis of Demographic and Health Surveys (DHS) data quantifying the inequitable burden of fever, diarrhoea and acute respiratory infection (ARI) in children aged under five years and the relationship between burden and measures of inequity such as wealth, rurality and remoteness. The analysis evaluates international, national and subnational trends in over half a million children in twenty-six countries. We also assess the potential for iCCM to address these imbalances by targeting treatment to those most in need.

725

HEALTH SERVICES IN LONG-TERM REFUGEE CAMPS: IMPLICATIONS FOR INTEGRATION WITH NATIONAL SURVEILLANCE SYSTEMS

Aurelia Attal-Juncqua, Aashna Reddy, Erin M. Sorrell, Claire J. Standley

Georgetown University, Washington, DC, United States

The number of displaced persons today is estimated at over 65 million, the highest ever in history. Of these, 25 million are classified as refugees (over half of which are children), and 10 million are considered stateless. Millions more have been placed at risk of displacement or homelessness over the past decade due to natural disasters and other non-conflict emergencies. Displaced people therefore represent a major population in jeopardy of not receiving essential health services, sometimes over long durations of time. Establishing formal shelters or camps for displaced persons is the traditional approach to addressing their basic needs. However, there is a known risk of emergence and transmission of infectious diseases in crowded camp settings. Moreover, the countries who host displaced persons and refugees are usually low and middle income themselves, and vulnerable to added strains on their health systems, therefore large numbers of displaced persons can threaten national or even global health security. In prolonged resettlement, where camps persist for months, years, or even transition towards establishment as permanent settlements, there is no clear process for maintaining health services long-term or to whom that responsibility falls. In our study we selected three major refugee camps—Zaatari in Jordan, Dadaab in Kenya, and Cox's Bazaar in Bangladesh—as case studies to explore the extent to which health service provision is integrated with the host country's national health system, particularly with respect to surveillance for infectious diseases. Through examination of the literature, as well as key informant interviews, we note the challenges, opportunities, and lessons learned for supporting long-term health systems strengthening during the creation and management of displaced persons camps.

726

INFECTIOUS DISEASE SURVEILLANCE WITH MLAB - AN APP FOR AUTOMATED RAPID DIAGNOSTIC TEST ANALYSIS

Thomas F. Scherr[1], Carson Moore[1], Caison Sing'anga[2], Japhet Matoba[2], Ben Katowa[2], Philip Thuma[2], David Wright[1]

[1]*Vanderbilt University, Nashville, TN, United States,* [2]*Macha Research Trust, Macha, Zambia*

There is no doubt that malaria control strategies have made progress, noted by an estimated 274 million fewer cases and 1.1 million fewer malaria-related deaths reported in the last decade. Significant hurdles remain, however, including case identification, surveillance, and resource management, that must be addressed prior to countries embarking on elimination campaigns. It is implausible that a one-size-fits-all solution exists for malaria elimination, and an endemic nation's decision is based on available resources, geography, population, and current level of disease prevalence. a reactive case detection strategy used in and around Macha, Zambia has shown great success. in this approach, an index malaria case is identified at a health center and a response team travels to the home of the index case to screen and treat nearby individuals. While "test-and-treat" has been successful in localized areas of low transmission, concerns over scalability and sustainability keep the approach from being more widely accepted. Regardless of strategy, the international community agrees that all elimination strategies would benefit from improved surveillance, better information workflow, and data aggregation. There remains a need for a scalable surveillance solution that can be readily implemented by elimination-ready countries. To meet this need, we present mLab, a mobile application for analyzing point-of-care rapid diagnostic tests, as part of a mobile Health and Treat (mHAT) strategy. Together, these address the challenges that elimination campaigns currently face. mLab utilizes image-processing of diagnostic tests to provide an automated, semi-quantitative, rapid malaria diagnosis. This data serves as the gateway to improved surveillance, as the mHAT web platform will more quickly mobilize a reactive-case response team, provide near real-time RDT results reporting, and in-depth analytics. Ultimately, the mHAT approach will enable resource monitoring for improved supply chain management, data-driven decisions, and more targeted interventions for malaria elimination campaigns.

727

A NATIONAL SURVEY OF EMERGENCY MEDICINE PROVIDERS' KNOWLEDGE AND MANAGEMENT OF TROPICAL DISEASES IN THE RETURNING TRAVELER

Nelly Gonzalez-Lepage[1], Ashley Iannantone[1], Megan Rech[2], **Theresa Nguyen**[2]

[1]*Loyola University Medical Center - Stritch School of Medicine, Maywood, IL, United States,* [2]*Loyola University Medical Center - Department of Emergency Medicine, Maywood, IL, United States*

Due to a combination of socioeconomic, climate, and geographical factors, there has been an increased prevalence of tropical diseases within the United States (U.S.). An estimated 87 million U.S. travelers visit international destinations per year, and many of them may present to the Emergency Department (ED) for travel-related illnesses. The objective of this survey study was to assess the level of EM physicians' training and confidence in the diagnosis and management of tropical diseases. We developed a 30 question online survey to explore self-reported gaps in knowledge regarding tropical diseases and to determine the availability of institutional resources for assisting EM physicians in the clinical management of such diseases. This survey was developed, validated, and administered to 834 EM physicians nationwide via the Emergency Medicine Practice Research Network. Descriptive statistics were used to present survey results. a total of 204 responses (24% response rate) were received. Overall, 91.7% of physicians had received prior training specific to treating and/or managing tropical diseases (in medical school, residency, fellowship, or at their current institution). Despite this, 40.7% of EM physicians reported gaps in knowledge regarding which diagnostic tests were appropriate to order for different tropical diseases and 21% reported the absence of an established screening process for returning travelers at their home institution. Of seven tropical diseases (Dengue, Zika, Cholera, Typhoid, Chagas, Malaria and Schistosomiasis), the highest perceived knowledge gap was for Dengue, with 71.1% of physicians reporting a need for Continuing Medical Education (CME) training focused on diagnosis and management. This is the first national survey to date assessing general EM providers' knowledge and management of tropical diseases in the returning adult traveler. Our needs assessment has identified specific gaps in knowledge which can be filled by development of CME resources and guidelines for standardized screening processes within the ED.

728

DEVELOPMENT OF GLOBAL HEALTH CURRICULUM, TRAINING AND PARTNERSHIPS IN AN ACCREDITED MPH PROGRAM IN CLEVELAND, OHIO

Daniel J. Tisch, Ronald E. Blanton, Charles H. King, Peter A. Zimmerman

Case Western Reserve University, Cleveland, OH, United States

The Case Western Reserve University (CWRU) Master of Public Health (MPH) Program developed the Concentration in Global Health in 2008. This coincided with a University-wide NIH-funded framework to link global health training across 5 Schools and 9 departments. This CWRU Framework for Global Health provided the administrative and training environment to identify and develop integrated curricula, workshops, a certificate program, and mentored field experiences. These incorporated MPH students, faculty, and MPH-dual degree programs and partnerships. The MPH Global Health Concentration has recently undergone a systematic revision of global health competencies in order to address revised accreditation standards through the Council on Education for Public Health (CEPH). The program implemented a Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis utilizing surveys and feedback from meetings with students, faculty, internal partners, and external partners as part of a three year self study. The Global Health Concentration competencies were re-defined according to discipline standards, academic/training strength and opportunities, and the missions of the MPH program and University. The five new Global Health competencies were linked with curricula, training experiences, assessments, professional needs, outcomes, and partnerships. Alignment of these competencies to courses and learning experiences, as well as our institutional, regional, and global partnerships will be described. The lessons learned from our global health research and training history, self-study, and revised competencies/curriculum will be presented.

729

A QUALITATIVE ASSESSMENT OF VICO (VIGILANCIA INTEGRADA COLABORATIVA) IN GUATEMALA

Mariangeli Freitas Ning[1], Jahn Jaramillo[2], Michael Park[3], Terrence Q. Lo[3], Loren Cadena[4], Olga L. Henao[3], Andres Espinosa-Bode[4]

[1]*TEPHINET/Centers for Disease Control and Prevention, Guatemala City, Guatemala,* [2]*Public Health Institute/Centers for Disease Control and Prevention, Guatemala City, Guatemala,* [3]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [4]*Centers for Disease Control and Prevention, Guatemala City, Guatemala*

The collaborative integrated surveillance system (VICo) was implemented in 2007 to better understand and characterize the burden of diarrheal, respiratory and febrile illnesses in Guatemala. VICo is a collaboration of the Ministry of Health (MSPAS) of Guatemala, the Universidad del Valle de Guatemala (UVG), and the Centers for Disease Control and Prevention (CDC). To evaluate the usefulness of VICo and inform both the current redesign of the system and new surveillance activities in the Central American region, CDC personnel in Guatemala conducted semi-structured interviews with 39 key stakeholders responsible for the development and operationalization of VICo. Participants included local, regional, and national level staff from MSPAS, UVG, and CDC and were selected using purposive sampling methods. We used grounded theory to explore stakeholder perceptions of VICo and generate recommendations for improvement. Thematic analysis was conducted to identify and summarize emergent themes. Preliminary analysis identified five areas relevant to the usefulness of VICo: inter- and intra- agency communication and collaboration, policy and strategy, use and timeliness of data, simplicity of the surveillance system, and prioritization of activities. It also identified needed improvements in capacity building and workforce development. Further analysis of the usefulness groupings will develop specific themes that underscore the strengths and weaknesses of VICo from the perspectives of the stakeholders and the organizations they represent. The lessons learned will inform decision makers on needed improvements to activities in Guatemala and provide insights for new surveillance activities in the region. Finally, the qualitative assessment approach serves as a model that can be adapted for evaluation and assessment of impact of other surveillance activities. The ongoing evaluation of surveillance is essential to ensure activities are meeting the needs of countries and generating the data needed for the planning and implementation of effective public health policies and strategies.

AFRICAN CENTERS OF EXCELLENCE IN BIOINFORMATICS: AN EVIDENCED-BASED APPROACH TO BIOMEDICAL RESEARCH COLLABORATION IN AFRICA

Darrell E. Hurt[1], Christopher Whalen[1], Mamadou Wele[2], Daudi Jjingo[3], Michael Tartakovsky[1]

[1]*National Institute of Allergy and Infectious Diseases, North Potomac, MD, United States,* [2]*University of Sciences, Techniques, and Technologies of Bamako, Bamako, Mali,* [3]*Makerere University, Kampala, Uganda*

The African Centers of Excellence in Bioinformatics, or ACE, is a program established to increase bioinformatics research collaborations for US-sponsored research in a region deeply impacted by emerging and re-emerging pathogens. ACE attempts to overcome some of the fundamental challenges faced by computational researchers in Africa: the lack of access to the tools and cyberinfrastructure that keep skills and understanding current with global research efforts. The Centers are established and nurtured through a public-private partnership facilitated by the Foundation for the NIH between the NIH's National Institute of Allergy and Infectious Diseases and a consortium of research and educational institutions in Africa, their governments, and private sector companies. Their collaboration delivers in-kind contributions of high-performance computing infrastructure, bioinformatics tools, training, and mentoring to students and faculty. The first ACE Center opened its doors in April of 2015 in collaboration with the Republic of Mali and the University of Sciences, Techniques, and Technology of Bamako. The second ACE Center opened in March 2019 at the Infectious Diseases Institute on the Makerere University campus in Kampala, Uganda. This Center, the most advanced to date, includes a telelearning-capable classroom, a visualization lab featuring virtual reality-based training, and significant compute, storage, and network infrastructure, including special provisions for power and efficiency.

731

AN EXPLORATORY STUDY OF THE MIGRATORY PATTERNS OF NOMADIC FULANI OF NORTHEASTERN FOR HEALTH CARE DELIVERY

Oladele B. Akogun

The Health Programme, Common Heritage Foundation, Yola, Nigeria

In Africa, many minority groups such as the nomadic Fulani are often denied access to health because of their itinerant lifestyle. Few migrant communities benefited from the community-directed intervention strategy for increasing access to health service. An understanding of the drivers of migration is necessary for developing universal health coverage that will include the nomads. An 11-month exploratory study of the nomadic Fulani communities around the river Benue-Gongola confluence, Northeastern Nigeria was carried out using qualitative techniques. Three migratory routes were identified. During harmattan season (October-January), the nomads migrate occupy the Benue-Gongola river confluence while their livestock eats from an abundance of dry pasture, during the dry-hot season (February-April) they congregate in the valley taking advantage of the perennial river. The dry-hot season is the best season for implementing health interventions. We trained their volunteers to recognize, diagnose and distinguish between fevers using the rapid diagnostic test kit for malaria. The nomads desert the valley at the onset of the rain (May-June). During July-October when the rain becomes intense and the lowland is flooded large nomadic communities break into manageable units and disperse further uplands where the land is more visible. It is at this time

that nomads are farthest from health facilities. It is the time to apply the health education and skills as well as use the health supplies that they had obtained in previous locations. We identified the types of health activities in which the nomads could participate during each of the periods. While two clans completed a migratory cycle in approximately twelve months, another did so in 24 months and the fourth clan completed a cycle in about 32 months. The commonest diseases follow similar seasons and commodities can be delivered to fit the season's needs. Nomads have a highly effective communication system, revered leadership and organization structure which could be explored for extending the universal health coverage to them.

733

WORKING WITH THE COMMUNITY TO ESTABLISH A HEALTH PROMOTION PLAN IN THE KINDERGARTENS IN THE CONTEXT OF A CHILD MORTALITY SURVEILLANCE IN MANHIÇA, MOZAMBIQUE

Saquina Cossa[1], Maria Maixenchs[2], Felismina Tamele[1], Zubaida Manhenge[1], John Blevins[3], Inacio Mandomando[1], Quique Bassat[2], Khatia Munguambe[1]

[1]*Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique,* [2]*ISGlobal, Hospital Clinic, Universitat de Barcelona, Barcelona, Spain,* [3]*Emory Global Health Institute, CHAMPS Program Office, Emory University, Atlanta, GA, United States*

The ultimate goal of the Child Health and Mortality Prevention Surveillance Program (CHAMPS) is to implement activities focused on maternal and child health with input from the community in collaboration with existing, trusted community organizations and key leaders. Through a community engagement (CE) strategy and with the collaboration of the District's Health, Women and Social Welfare Services, kindergartens from Manhiça District, in Southern Mozambique, were identified as key stakeholders and approached to explore their views on the most prevalent diseases affecting pre-school children and currently prevention measures in order to jointly design a plan to improve children´s health in general. Kindergarten's educators and parents and caregivers of children attending kindergartens were involved in a series of participant meetings, which took place from April to July 2018 in the kindergartens. Reports and field notes were organized in a matrix for data analysis. Twenty-seven meetings were held (19 with parents and caregivers and 8 with kindergartens educators) involving a total of 456 participants. Malaria, fevers, cough and diarrhea were the most prevalent perceived diseases on pre-school children. The main factors affecting child mortality, according to participants, were the fact that the hospital is distant and poorly supplied, the cost of medicines in private pharmacies, the preference for the use of traditional medicine due to lack of access to health care, the poor condition of the kindergartens 'latrines and the fact that kindergartens do not provide lunch to children. Participants proposed health education campaigns on specific diseases, nutrition and hygiene; a mobile health care team to attend to those in distant areas, emergency kits available at the kindergartens; and training health workers to express empathy when providing assistance. a plan has been designed to provide education in nutrition, hygiene and first aid to parents, caregivers and educators and use them as disseminators of information to the wider community. Working with the people involved when designing strategies to improve their own health is crucial.

734

BUILDING TRUST, RESPECT, AND EMPATHY IN PUBLIC HEALTH INTERVENTIONS: AN ETHIOPIAN CASE STUDY

Caroline Ackley[1], Berhanu Damise[2], Ketema Degefa[2]

[1]*London School of Hygiene & Tropical Medicine, London, United Kingdom,* [2]*Haramaya University, Harar, Ethiopia*

In this paper we suggest approaches to community engagement activities that facilitate clinical public health interventions. In Eastern Hararghe, Ethiopia, children under-5 are dying from clinically unknown causes of death, and often buried with an inadequate or non-existent medical history. One reason for uncertainty into causes of death is that 55-60% of child deaths in the study sites are considered community-based according to Kersa Demographic and Health Surveillance.[KA1] The Child Health and Mortality Prevention Surveillance (CHAMPS) study aims to identify leading and underlying causes of death in children under-5 through multiple techniques, including minimally-invasive tissue sampling (MITS). We performed a 13-month qualitative study intended to elicit perspectives related to the community engagement approaches and strategies for conducting MITS, including 8 in-depth interviews, 2 semi-structured interviews, 2 focus groups discussions, and 5 instances of participant observation. Additionally, we analysed reports from 12 community advisory board meetings. We found that trust, respect, and empathy were the most important factors for the community in successful public health interventions. Prior to CHAMPS activities in Ethiopia, communities felt they knew what was causing under-5 child death; namely malnutrition, and poor sanitation and hygiene - each linked to the will of God. Given the lack of clinical data into causes of death, MITS presented an opportunity for the community to gain certainty in their convictions. However, MITS is highly contentious in the study site and the community demanded engagement activities to align study objectives with community priorities, while highlighting the themes of trust, respect and empathy. Based on the findings, we suggest that community engagement be a component in public health interventions to facilitate alignment between biomedical investigation and community perception. For interventions to be successful, socio-cultural and religious understandings of respect, trust, and empathy must first be qualitatively explored and then acted upon in study implementation.

735

MEASURING THE "KNOW-CAN GAP": DIFFERENCE IN KNOWLEDGE AND SKILLS FOR ASSESSING CHILDHOOD DIARRHEA AND PNEUMONIA AMONG PUBLIC AND PRIVATE FRONTLINE WORKERS IN UTTAR PRADESH, INDIA

Lopamudra Ray Saraswati, Ashutosh Mishra, Prince Bhandari, Animesh Rai, Ambrish Chandan

RTI International India, New Delhi, India

In India, frontline workers (FLWs) - public accredited social health activists (ASHAs) and private rural medical providers (RMPs) - play a pivotal role in the early detection and treatment of childhood diarrhea and pneumonia. This study measures *knowledge* and *skills*, and the gap between the two ('*know-can*' gap), related to assessment of childhood diarrhea with dehydration and pneumonia among public and private FLWs, and explores factors associated with them. We surveyed 473 ASHAs and 447 RMPs in six districts of Uttar Pradesh (UP) in India. Knowledge was assessed using face-to-face interviews and skills using video vignettes. While 'sunken eyes' and 'loss of skin turgor' were considered key signs of dehydration, 'fast breathing' and 'chest in-drawing' were considered for pneumonia. The '*know-can*' gap was defined as the lack of skills among those who had knowledge. We used logistic regression (separately for ASHAs and RMPs) to identify the correlates of knowledge (among all) and of skills (in a subset of FLWs that had correct knowledge). FLWs' knowledge related to signs of dehydration ranged from 23% to 48%, and that of pneumonia ranged from 27% to 37%. Their skills ranged from 3% to 42% for dehydration and 3% to 18% for pneumonia. There was a significant '*know-can'* gap in all the signs, except 'sunken eyes'. Regression analyses showed a strong association of training and supervisory support with better knowledge and skills related to diarrhea with dehydration, but only better knowledge related to pneumonia. Mass-media exposure, interpersonal communication with a health worker, and seeing a patient in the last week were other factors associated with correct knowledge and skills. This finding suggests that knowledge-focused trainings are ineffective. Programs should, instead, focus on hands-on trainings followed by refresher trainings. Given the important contribution of FLWs in the Indian health system, the quality of their services will be central to India's continued progress against under-five deaths, and the gap between their knowledge and skills warrants immediate attention.

736

A QUALITATIVE ASSESSMENT OF ACCEPTABILITY DETERMINANTS TO FACILITATE MINIMALLY INVASIVE TISSUE SAMPLING (MITS) IMPLEMENTATION IN QUELIMANE, MOZAMBIQUE

Amilcar Magaco[1], Edu Namarogolo[1], Saquina Cossa[1], Rui Anselmo[1], Dianna Blau[2], Mischka Garel[2], Robert Breiman[2], Jesuel Cassimo[3], Quique Bassat[4], Maria Maixenchs[4], Inácio Mandomando[1], Khátia Munguambe[1]

[1]*Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique,* [2]*Emory Global Health Institute, Atlanta, GA, United States,* [3]*Direção Provincial de Saúde da Zambézia, Quelimane, Mozambique,* [4]*Centro de Investigação em Saúde de Manhiça, Manhica, Mozambique*

The Countrywide Mortality Surveillance for Action (COMSA) aims to implement a child mortality surveillance program through strengthening vital registration event reporting (pregnancy, birth and death) and investigating causes of death (CoD) in sample Mozambique based in verbal autopsies. in Quelimane district (central Mozambique), Minimally Invasive Tissue Sampling (MITS) will be added to fine-tune the CoD determination approaches. Before MITS´ implementation, an evaluation of the feasibility (i.e. acceptability, practicality and implementation) and ethical considerations of child mortality surveillance was considered fundamental. a socio-anthropological study is being conducted at community level. a total of 26 semi-structured interviews (SSI) with health care providers and *nharrube (traditional authorities who washes the bodies before the funeral)* and 14 focus group discussions (FGD) with community leaders and midwives were completed to understand the local attitudes and perceptions related to the death of children. Audio materials were transcribed, systematically coded and analyzed using NVIVO12®. Participants desire to know the CoD influenced the initial discourse in favor of acceptability. However, some participants were skeptical about the procedure. Poor community mobilization, disagreement with Islamic religious practices, and with local traditional beliefs and practices were identified as potential barriers to MITS implementation. in contrast, desire to know the causes of child deaths, intention to clear the elders from accusations of witchcraft, involvement of leaders in the process of disseminating project information, and the provision of transport for bodies back to the community constitute potential facilitators for the implementation of MITS. Although MITS was considered an innovation to determine the CoD in children, community members remain skeptical about the procedure in lifeless bodies due to tensions with religion and tradition. However, this initiative in Quelimane should emphasize the importance of the high involvement of a variety of influential community and religious leaders.

737

BUILDING AN ACCESSIBLE EVIDENCE BASE FOR MEDICAL COUNTERMEASURE USE IN BIOEMERGENCIES - THE SPECIAL PATHOGEN RESEARCH NETWORK INITIATIVE

Lauren M. Sauer[1], Mark J. Kortepeter[2], Nahid Bhadelia[3], Theodore Cieslak[2], Richard Davey[4], Kerry Dierberg[5], Jared D. Evans[6], Maria G. Frank[7], Jonathan Grein[8], Colleen S. Kraft[9], Christopher J. kratochvil[2], Susan McLellan[10], Gregory T. Measer[11], Aneesh K. Mehta[9], Vanessa Raabe[9], George Risi[12], Erica Shenoy[13], Timothy M. Uyeki[14]

[1]*Johns Hopkins University School of Medicine, Baltimore, MD, United States,* [2]*University of Nebraska Medical Center, Omaha, NE, United States,* [3]*Boston University School of Medicine, Boston, MA, United States,* [4]*National Institute of Allergy and Infectious Diseases (NIH), Bethesda, MD, United States,* [5]*Bellevue Hospital, New York, NY, United States,* [6]*Johns Hopkins University Applied Physics Laboratory, Laurel, MD, United States,* [7]*Denver Health Medical Center, Denver, CO, United States,* [8]*Cedars Sinai Health System, Los Angeles, CA, United States,* [9]*Emory University, Atlanta, GA, United States,* [10]*University of Texas Medical Branch, Galveston, TX, United States,* [11]*United States Food and Drug Administration (FDA), White Oak, MD, United States,* [12]*Biomedical Advanced Research and Development Authority, Washington, DC, United States,* [13]*Massachusetts General Hospital, Boston, MA, United States,* [14]*Centers for Disease Control and Prevention, Atlanta, GA, United States*

During the 2014-2016 Ebola virus disease (EVD) outbreak, clinicians lacked a readily available resource cataloguing available medical countermeasures (MCMs) to treat EVD patients in West Africa and other regions. Some patients received investigational interventions under uncontrolled compassionate use protocols. Therefore, the Special Pathogens Research Network (SPRN) of the National Ebola Training and Education Center (NETEC) formed the MCMs Working Group (WG) with members from 10 Regional Ebola and other Special Pathogen Treatment Centers (RESPTC) and NETEC partners. The goal of the MCMs WG is to develop an evidence-informed, easily accessible, practical assessment of potential countermeasures for clinicians managing patients with selected highly hazardous communicable diseases. Pathogens were selected based on 1) ability to cause severe disease; 2) potential to cause large outbreaks; 3) paucity of currently available cleared MCMs; 4) occurrence of nosocomial spread to health care providers; and 5) transmissibility requiring specialized care in a biocontainment unit. After a standardized literature review is conducted, an assessment of potentially available countermeasures is performed by 2-4 subject matter experts, followed by peer review. Pathogens selected to date include Marburg, Lassa, Middle East Respiratory Syndrome Coronavirus (MERS-CoV), Crimean Congo Hemorrhagic Fever (CCHF), Nipah, Variola (and Monkeypox) and South American Hemorrhagic Fever (Junin, Machupo, etc.) viruses. The list overlaps with the World Health Organization's list of "Blueprint" priority diseases. Reviews on seven pathogens are in progress. In conclusion, the NETEC SPRN MCM WG was created to provide a preemptive compendium of systematic and clinically relevant summaries of available MCMs for selected pathogens based on pre-specified criteria. Challenges will include updating current documents as new scientific evidence becomes available. Plans are in place for regular review and updates, with the most up-to-date materials available on the NETEC website for open-source access.

738

INTEGRATING TRADITIONAL HEALERS INTO THE HEALTH CARE SYSTEM TO IMPROVE EARLY DIAGNOSIS OF EPIDEMIC PRONE DISEASES IN WEST NILE REGION, UGANDA, 2010-2019

Titus Apangu[1], Gordian Candini[1], Janet Abaru[1], Bosco Candia[1], Felix J. Okoth[1], Linda A. Atiku[1], Harriet Apio[1], Amy Schwartz[2], Paul Mead[2], Kiersten Kugeler[2]

[1]*Uganda Virus Research Institute, Entebbe, Uganda,* [2]*United States Centers for Disease Control and Prevention, Fort Collins, CO, United States*

In rural Uganda most patients consult traditional healers during times of illness before visiting allopathic health facilities. Traditional healers provide access to supportive care for common illnesses but their use can delay diagnosis and treatment for severe conditions and hinder early detection of epidemic-prone diseases. Because early antimicrobial treatment saves lives and stops plague outbreaks, the Uganda Plague Program has engaged traditional healers to improve recognition and referral in the plague-endemic West Nile region since 2010. Participating healers receive general health education, plague specific training, referral cards and record books. Healers refer patients they feel might have plague or other severe illnesses to nearby health facilities with a designated referral card. Presentation of this card at participating facilities allows the sick individual to bypass any queue. Plague Program personnel meet monthly with all participating healers to discuss facility referrals, verify arrival in facility registers and provide feedback on the discharge diagnoses and outcomes. During 2010-2019, 43 healers made 748 referrals to 21 facilities in the West Nile region. One plague case was identified as part of this program. Common discharge diagnoses among those referred to facilities included malaria (n=262), pneumonia and respiratory tract infections (n=182), gastrointestinal illness (n=41), parasitic infections (n=33), sexually transmitted infections (n=30) and peptic ulcer disease (28). Most patients

(724; 97%) improved after receiving care at a health clinic. This program was instituted during a time when the episodic nature of plague was on a decline. Nevertheless, patients with wide-ranging life-threatening conditions such as malaria and pneumonia received more appropriate therapy for their suspected condition than had they remained in the care of a healer alone. Traditional healers serve as a first line of detection for unusual illnesses, and improving trust and communication between traditional and allopathic health care systems may improve early detection of epidemic-prone diseases in rural Uganda.

739

HUMAN RESOURCE FOR HEALTH CHALLENGES IN SIERRA LEONE

Haja Abie Manasaray, Beah Joe Lebby, Ivan Macauley-Black, Julian Mattia

Njala University/Ministry of Health, Bo, Sierra Leone

Sierra Leone has some of the worst health indicators in the world. It was one of the three West African countries seriously heat by the deadly outbreak of Ebola in 2014 which left a total of 3,589 confirmed death according to the World Health Organization (WHO). The outbreak affected an already crippled health system where health care workers accounted for 307 cases with 221 deaths. Several efforts have been made in post-Ebola to improve the health workforce in the country. The current study conducted in July 2017, looks at health worker density in rural communities in Sierra Leone and the challenges they face in their work environment. a total of 84 peripheral health units (PHUs) were targeted in 7 health districts. Questionnaires were administered to the head of each PHU to track the human resource capacity at the facility level. Key questions included; the number of staff available, their cadre, whether they had received in-service training and number of villages covered by the facility. Overall, 70 PHUs were assessed in 7 health districts. These comprised 39 males and 31 females with an average age of 42 years. About 90% confirmed haven received at least 1 in-service training. The average number of staff at each facility was 5.4 with an average 3.7 trained professional staff. Furthermore, only 46% of the total staff are on payroll. The average number of population per PHU was 6,960 people. The density of trained health professional was 0.53 staff per 1,000 population. Each PHU administer health care to an average 19 villages with the nearest village being within an average 11 kilometers. Also, 37% and 26% of the PHU staff confirmed that they do outreach on a twice monthly and monthly basis respectively. The 0.53 trained health professionals per 1000 population is below the WHO recommended threshold of 4.5 skilled health professionals per 1000 population. This is an improvement to the 2013 ratio of 0.19 skilled health professional per 1000 population. These results shows that the health sector especially at the primary level is overburdened with limited motivation. It however shows an improvement but there is still very huge challenge in reaching the WHO threshold.

740

STILLBIRTH BURDEN AND CHALLENGES FOR REPORTING: INITIAL RESULTS FROM THE CHAMPS MAKENI SITE, SIERRA LEONE

Mary Claire Worrell[1], Carri Jo Cain[2], Solomon Samura[2], Erick Kaluma[3], Baindu Kosia[4], Michelle Dynes[1], Kevin Clarke[1], Navit Salzberg[5], Sorie I. Kamara[6], Foday Sesay[7], Mohammed Sheku[7], Amara Jambai[8], Robert F. Breiman[5], Reinhard Kaiser[9]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*World Hope International, Makeni, Sierra Leone,* [3]*Crown Agents, Makeni, Sierra Leone,* [4]*FOCUS* [1000]*, Makeni, Sierra Leone,* [5]*Emory Global Health Institute, Atlanta, GA, United States,* [6]*ICAP, Makeni, Sierra Leone,* [7]*Ministry of Health and Sanitation, Makeni, Sierra Leone,* [8]*Ministry of Health and Sanitation, Freetown, Sierra Leone,* [9]*Centers for Disease Control and Prevention, Freetown, Sierra Leone*

Sierra Leone has a stillbirth rate of 24.4 per 1000 total births [2015]. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network site in Makeni, Sierra Leone aims to improve understanding of stillbirth etiology through prospective surveillance and collection of comprehensive cause of death data, including advanced laboratory and histopathology diagnostics. Data will allow decision makers to develop interventions and national policies. We present initial results on stillbirth enumeration and assess misclassification. We used the World Health Organization definition for stillbirth: a baby born with no signs of life either ≥ 28 weeks of gestation or with birth weight ≥ 1000 grams. We assessed misclassification by reviewing the stillbirth status designation at eligibility screening and stillbirth criteria for each case and assessed concordance between data from clinical records and verbal autopsies. We consider clinical data to be the most reliable source of information. From July 2018 to February 2019, CHAMPS detected 79 stillbirths. Of these, 97% of caregivers provided consent for enrollment for clinical data collection and verbal autopsy. Seventy-four (96%) of the reported stillbirths were delivered at a health facility; six (8%) cases were misclassified when comparing eligibility stillbirth status to clinical records, including one miscarriage misclassified as stillbirth, three neonatal deaths misclassified as stillbirths, and two stillbirths misclassified as neonatal deaths. Clinical and verbal autopsy data yielded discordant status on 10 cases (14%). As nearly all stillbirths identified occurred in a health facility, we very likely missed community stillbirths, highlighting a need to improve community surveillance. We found evidence of stillbirth misclassification suggest the need to improve education of healthcare staff. Stillbirth status discordance between clinical and verbal autopsy data needs further investigation particularly to determine adherence to case definitions and validity of verbal autopsy data for classifying stillbirths in this context.

741

TWO STEPS FORWARD, ONE STEP BACK: THE IMPACT OF REDUCING PRIVATE SECTOR CO-PAYMENT MECHANISM SUBSIDIES ON THE AVAILABILITY, USAGE, AND PRICE OF QUALITY-ASSURED ACTS IN KENYA, NIGERIA, AND UGANDA

Tayo Olaleye[1], Luke Baertlein[1], Patricia Njiri[2], Alex Ogwal[3], Theodoor Visser[4], Abby Ward[4], Leslie Wentworth[4], Aaron Woolsey[4]

[1]*Clinton Health Access Initiative, Abuja, Nigeria,* [2]*Clinton Health Access Initiative, Nairobi, Kenya,* [3]*Clinton Health Access Initiative, Kampala, Uganda,* [4]*Clinton Health Access Initiative, Boston, MA, United States*

In 2010, the Global Fund launched the Affordable Medicines Facility for malaria (AMFm) to increase accessibility of WHO-quality-assured artemisinin combination therapies (QAACTs) through a manufacturer-level subsidy. Access to QAACTs in participant countries increased, on average with a four-fold expansion in the percent of private sector facilities stocking QAACTs. AMFm continued as the private sector Co-Payment Mechanism (CPM); however, in 2018, it was terminated in Nigeria (NG), and reduced in Kenya (KE) and Uganda (UG). Population representative samples of private medicine retailers were surveyed across these countries to assess the subsidy reduction impact on availability, price and market share of antimalarials at two time periods: during the CPM (2014-2016, n=2760) and after its reduction (2018-2019, n=1146). Comparing retail prices of antimalarials before and after the reduction of the CPM, the average retail price of QAACTs increased from $0.48 to $1.31 in NG and $0.99 to $1.23 in UG, but decreased from $1.11 to $0.80 in KE. The average price of non-quality assured ACTs remained stable at $1.45 in NG, but decreased from $3.64 to $2.05 in UG, and $4.25 to $0.86 in KE. Concurrently, the proportion of outlets with QAACTs in stock dropped from 72% to 49% in NG, 71% to 64% in UG, and 72% to 35 % in KE. Availability of non-quality assured ACTs increased from 13% to 56% in NG, 6% to 40% in UG, and 42% to 68% in KE. Non-ACT antimalarial availability increased in NG but decreased in UG and KE. The QAACT market share declined in each country relative to other ACTs, but non-ACT antimalarial market share remained constant or declined. Results suggest the retail price of QAACTs increased in 2 of 3 countries after the CPM reduction, coinciding with a decline in availability and market share of QAACTs. However, availability and market share of non-quality assured ACTs increased during this time, resulting in no net decline in ACT availability or market share. There was no indication that artemisinin

monotherapies gained market share following the subsidy reduction. The public health impact depends on the uncertain quality of ACTs that are not WHO-quality-assured.

742

SPIDER ENVENOMATIONS THERAPEUTICS AND ANTIVENOM ACCESSIBILITY: A SYSTEMATIC REVIEW

Christian Lecce, Avinash N. Mukkala, Aisha Khatib, Michael A. Klowak, Pryanka Challa, Eric Shao, Jason Kwan, Tianna Chong-Kit, Jamie Sookhoo, Emma Hagopian, Dylan Kain, Mofe Adeosun, Andrea K. Boggild

Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada

Spiders are a group of arthropods in the order *Araneae* and class *Arachnida* which have eight legs and fangs. Modern advancements in transportation allow increased human travel to areas which are endemic to spiders, increasing the possibility of envenomation. Physicians could select the optimal envenomation treatment using a clinical resource that compares efficacy statistics of antivenom versus other therapeutics. Our goal is to compile existing prevention and treatment data in the literature in order to synthesize this clinical resource. PubMed (NCBI), MEDLINE (OVID), EMBASE (OVID), Cochrane Database of Systematic Reviews (CIDR) and TOXLINE (TOXNET) were searched from inception to June 2018 using combinations of the search terms "spider," and "envenomation*. Iterative inclusion and exclusion of search terms was employed to maximize extraction. The GRADE approach will be used to assess quality of studies reporting therapeutic interventions. Evidence will be summarized using descriptive measures for each intervention type, as well as a qualitative synthesis. Meta-analysis will be planned if sufficient efficacy measures exist. 961 MEDLINE articles, 1053 PubMed, 1486 EMBASE, 0 CIDR and 149 TOXLINE records were retrieved for title and abstract screening; after a multi-step de-duplication pipeline, 1928 remained. Following abstract screening, 282 full-text records were eligible for inclusion. Upon initial review of these records, *Latrodectus hasseltii*, *Latrodectus mactans, Loxosceles reclusa,* and *Phoneutria spp.* were the most medically relevant. Data will be grouped and summarized by prevention, therapeutic strategies, geographic location and species. The recommended mode of treatment and management will be provided on an evidence-based, per-species basis. Increased transcontinental movement of people and tropical produce has facilitated importation of arachnids to non-endemic regions where clinicians lack familiarity with envenomation syndromes and appropriate therapeutics. Synthesizing the current evidence around therapeutic strategies can inform the development of treatment and prevention protocols.

743

A SYSTEMATIC REVIEW OF SCORPION ENVENOMATION THERAPEUTICS AND ANTIVENOM ACCESSIBILITY

Avinash N. Mukkala, Christian Lecce, Aisha Khatib, Michael A. Klowak, Priyanka Challa, Eric Shao, Jason Kwan, Tianna Chong-Kit, Jamie Sookhoo, Emma Hagopian, Dylan Kain, Mofe Adeosun, Andrea K. Boggild

Tropical Disease Unit, Toronto General Hospital and University of Toronto, Toronto, ON, Canada

Scorpions (Scorpiones) are eight-legged arthropods of the class Arachnida. With increased human migration and transcontinental shipment of produce from the tropics, the incidence of scorpion envenomations may increase in non-endemic areas. We aim to synthesize existing evidence around prevention and treatment of scorpion envenomations into a clinical resource, including provision of information on access to, and indications for, antivenom usage. PubMed (NCBI), MEDLINE (OVID), EMBASE (OVID), Cochrane Database of Systematic Reviews (CIDR) and TOXLINE (TOXNET) were searched from inception to June 2018 using combinations of the search terms "scorpion" and "envenomation". Iterative inclusion and exclusion of search terms was employed to maximize article extraction. The GRADE approach will be used to assess quality of studies reporting therapeutic interventions. Evidence will be summarized using descriptive measures for each intervention type, as well as a qualitative synthesis. Meta-analysis will be planned if sufficient efficacy measures exist. 961 MEDLINE articles, 1053 PubMed, 1486 EMBASE, 0 CIDR and 149 TOXLINE records were retrieved for title and abstract screening; after a multi-step deduplication pipeline, 1928 remained. After title and abstract screening, 422 studies were eligible for inclusion. Some of the main medically important species include: Mesobuthus tamulus, Androctonus australis, Hemiscorpius lepturus, Tityus serrulatus, and Centruroides sculpturatus. Data will be grouped and summarized for ease of clinician use by prevention, therapeutic strategies, geographic location and species. The recommended mode of treatment and management will be provided on an evidence-based, per-species basis. Increased transcontinental movement of people and tropical produce has facilitated importation of scorpions to non-endemic regions where clinicians lack familiarity with envenomation syndromes and appropriate therapeutics. Synthesizing the current evidence around therapeutic strategies for scorpion envenomations can inform the development of appropriate treatment and prevention protocols.

744

GEOGRAPHIC DISTRIBUTION UPDATE OF ARGENTINIAN TRIATOMINE SPECIES AS VECTORS OF CHAGAS DISEASE FRAMED IN A CITIZEN SCIENCE PROJECT

Soledad Ceccarelli[1], Agustin Balsalobre[1], Maria Eugenia Cano[1], Delmi Canale[2], Patricia Lobbia[2], Joaquín Cochero[3], Raúl Stariolo[2], María del Pilar Fernandez[4], Jorge E. Rabinovich[1], Gerardo A. Marti[1]

[1]*Centro de Estudios Parasitológicos y de Vectores, La Plata, Argentina,* [2]*Centro de Referencia de Vectores, Coordinación Nacional de Vectores, Ministerio de Salud de la Nación, Santa María de Punilla, Argentina,* [3]*Instituto de Limnología "Dr. Raúl A. Ringuelet", La Plata, Argentina,* [4]*Laboratory of Eco-epidemiology, Department of Ecology, Evolution and Environmental Biology, Columbia University, New York, NY, United States*

The Wallacean Shortfall phenomenon indicates that there is very little knowledge of the geographic distribution for the vast majority of the species described today, especially for invertebrates. in the case of insect vectors species and associated vector-borne pathogens, there are current initiatives that compile occurrence data, providing geographic information that enables policymakers to make evidence-based decisions. Other vector species are often sparsely recorded and there are few globally comprehensive sets of primary data compiled. Such is the case of triatomine species (Reduviidae: Triatominae), vector of *Trypanosoma cruzi* - Chagas disease etiological agent. Currently, there are about 150 species described worldwide for the Triatominae subfamily, 137 species distributed in the Americas, and 17 species cited for Argentina. Although all species are considered as potential vectors, around 70 species have been found naturally infected with this parasite. Beyond the ‹Atlas of the Tratominae› published by Carcavallo et al. (1998), no work carried out a full integration of the existing geographic information of Argentinian triatomine species, as some successful efforts completed in other Latin American countries. Recently, an updated and integrated occurrence database of 135 American triatomine species called 'DataTri' was published. Additionally, for the last 15 years, the National Vector Reference Center of Argentina (CeReVe) has been compiling occurrence data during their own fieldwork, which has remained unpublished. Finally, a citizen science project called 'GeoVin' was developed to gather occurrence data of Argentinian triatomine species through citizen participation using a mobile app. Here we report a multi-source database of distributional records for all Argentinian triatomine species. a total of 9593 occurrence data were collected between 1918-2019. We hope that this study helps and encourage colleagues and citizen to keep this information updated that can be used as basic information by public health agencies to guide surveillance actions and control of Chagas disease.

745

MOLECULAR DETECTION OF TICK-BORNE BACTERIA AND ARBOVIRUSES AT LIVESTOCK MARKETS AND SLAUGHTERHOUSES FROM WESTERN KENYA

Tatenda Chiuya[1], Daniel K. Masiga[1], Jandouwe Villinger[1], Eric M. Fevre[2], Amanda Bastos[3]

[1]*International Centre of Insect Physiology and Ecology, Nairobi, Kenya,* [2]*International Livestock Research Institute, Nairobi, Kenya,* [3]*University of Pretoria, Pretoria, South Africa*

Ticks are vectors of viral, bacterial, and protozoal pathogens of public health importance, including *Rickettsia*, *Ehrlichia*, *Anaplasma*, *Theileria*, and Crimean-Congo hemorrhagic fever (CCHF) virus, which can cause severe systemic illness and mortality. Active surveillance of tick-borne bacteria and viruses is necessary for intervention planning, and to detect novel pathogens or novel vector-pathogen associations. We collected 462 ticks from cattle, sheep, and goats at livestock markets and slaughterhouses in three neighboring counties in western Kenya over a period of 13 months. Livestock farming and trade in this region is characterized by peri-urban livestock markets and close association with humans in areas of high population density. We identified the ticks using both morphological and molecular techniques targeting the cytochrome oxidase 1 (COI), 16S rRNA, and internal transcribed spacer (ITS2) genes and pooled them (334 pools of 1-3 ticks) according to sex, species, and host of origin. We then screened the pools for zoonotic and livestock pathogens by PCR coupled with high-resolution melting (HRM) analysis using primers targeting bacterial 16S rRNA, 18S rRNA, and *omp*B genes and arboviral non-structural protein, RNa dependent RNa polymerase, and nucleoprotein genes. Amplicons with unique melting profiles were sequenced. The sampled ticks identified were from the genera *Amblyomma*, *Rhipicephalus*, and *Haemaphysalis*. *Rickettsia africae* was detected in 82 pools of *A. variegatum*, while 18 pools of *Rhipicephalus decoloratus* were positive for *Anaplasma platys.* Two pools of *R. decoloratus* were positive for CCHFV, while sindbis virus was detected in *A. variegatum* (1 pool) and *R. decoloratus* (1 pool). in addition, 201 pools of ticks were positive for *Coxiella* endosymbionts. Our findings demonstrate the presence of infected ticks on animals being traded, and translocated across the counties, which thus may disseminate these pathogens into disease free areas.

746

RESISTANCE MECHANISMS OF *PHLEBOTOMUS ARGENTIPES* THE VECTOR OF LEISHMANIASIS IN SRI LANKA

Ruwanika K. Pathirage[1], Karunaweera N. Karunaweera[1], Karunaratne S. Karunaratne[2]

[1]*Department of Parasitology, Faculty of Medicine, Colombo, Sri Lanka,* [2]*Department of Zoology, Faculty of Science, University of Peradeniya, Peradeniya, Sri Lanka*

Phlebotomus argentipes is the known vector of *Leishmania donovani,* the causative organism of leishmaniasis. a major challenge of an effective vector control program is the development of insecticide resistance in the vector. in order to develop an effective vector control programme it is important to identify the vector susceptibility to insecticides. Thalawa and Pannala and Mamadala and Mirigama sites were selected for sand fly collection. F1 progeny were exposed to different concentrations of DDT, malathion, deltamethrin and propoxur. Results were validated with the control mortalities using Abbott's formula. For biochemical analysis, esterase assay, glutathione S-transferase assay, oxidase assay, protein assay and acetylcholinesterase assay were performed with individually homogenized sand flies. DNa was isolated from individual sand flies using a method by Livak, 1984 followed by PCR to determine the insensitivity of the pyrethroid target site sodium channel regulatory proteins to identification of possible mutations of the gene. According to the susceptibility test, the colony population was susceptible to concentrations of >0.6% DDT and >0.7% Malathion, >0.007% Deltamethrin and >0.015% Propoxur. Biochemically proved that, the most of the flies had protein activity <0.3μmol min^{-1} mg^{-1}, esterase activity <1.00 μmol min^{-1} mg^{-1} and GST activity <0.4μmol min^{-1} mg^{-1}. All protein, esterase and GST activity were < 0.35 equivalent units of monooxygenase amounts. Over half of this population had <30% residual AChE activity in the presence of propoxur. However, 6.5% had >60% residual activity. Hence, the majority of the population may be considered susceptible to the insecticides used in this study. Furthermore, the kdr mutations were not seen hitherto in wild *P. argentipes* populations in this study. However, further studies are being conducted to ascertain the genetic variations related to the susceptibility patterns of Sri Lankan *P. argentipes* to synthetic insecticides.

747

UNUSUAL REACTIONS TO ARTHROPOD BITES: HORSE FLY, BED BUG, BROWN RECLUSE SPIDER AND TICK BITES

Don W. Kannangara, Dhyanesh Pandya

St Luke's University Health Network, Phillipsburg, NJ, United States

Arthropod bites affect human and animal health by envenomation, allergic reactions and disease transmission by acting as biological or mechanical vectors. Hematophagous arthropods also inject vasodilators, anticoagulants, platelet inhibitors, anti-itch and analgesic compounds that assist in blood feeding. Death may result from 1. potent toxins injected such as the paralytic toxin of *Ixodes holocyclus* 2. bacterial, viral and parasitic infections transmitted or 3. by allergic reactions resulting in anaphylactic shock. The compounds in arthropod saliva also may cause local reactions and skin necrosis. Arthropod salivary compounds play a key role in pathogen transmission and their establishment in a host by inhibition of host defenses. We present case examples of a horse fly bite acting as a mechanical vector resulting in a severe local reaction caused by a bacterial infection, eschar formation following bed bug bites and severe skin necrosis following "brown recluse spider bites". Brown recluse spiders are not native to New Jersey or Pennsylvania, but could be transported from endemic areas. We report one case each from these two states, highly likely to be brown-recluse bites with skin and deep tissue necrosis requiring debridement. We also present different examples of skin reactions after tick bites that include blistering, "vesiculo-pustular poison-ivy like rashes", eschar associated rashes and involvement of large areas of skin.

748

CDC'S INTERNATIONAL RESPONSE TO THE ZIKA VIRUS OUTBREAK: STRENGTHENING REGIONAL PUBLIC HEALTH ENTOMOLOGY NETWORKS

Rebecca Levine[1], Norma Padilla[2], Rajesh Ragoo[3], Daniel Impoinvil[1], Samuel Dadzie[4], Mamadou Coulibaly[5], Audrey Lenhart[1]

[1]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [2]*Universidad del Valle, Guatemala City, Guatemala,* [3]*Caribbean Public Health Agency, Port of Spain, Trinidad and Tobago,* [4]*Noguchi Memorial Institute for Medical Research, Legon, Ghana,* [5]*University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali*

The 2016 Zika virus outbreak highlighted capacity gaps in vector surveillance and control programs, particularly in smaller, resource-constrained countries. in addition, there were limited opportunities for countries to share expertise in public health entomology and few formal mechanisms for countries to work together to bring vector borne disease outbreaks under control. CDC supported a regional network-based strategy to improve the ability of countries to conduct vector surveillance and leverage resources for vector control. Regional networks were developed or strengthened to create frameworks for vector personnel from neighboring countries to share surveillance data, collaborate on vector control strategies, build capacity, and improve information exchange. Three entomological networks focusing on *Aedes* surveillance were supported in Central America, the Caribbean, and West Africa, improving capacity for preparedness and response to *Aedes*-borne diseases. As an example, by the end of 2017, a unified strategy was formalized for the island of Hispaniola, whereby both Haiti and the Dominican Republic

conducted joint cross-border *Aedes* surveillance activities, agreed to share entomological data, and adopted the same entomological surveillance platform. The networks were also used to provide trainings to personnel from over 40 countries on *Aedes* trapping methods, integrated vector management, insecticide resistance surveillance, mapping and use of GIS, digital surveillance platforms, and data management and analysis. a formal evaluation of the networks is being conducted in 2019, to assess their role in improving *Aedes*-borne disease surveillance, preparedness, and response capacity among the member countries. Network-based approaches in resource-constrained settings can empower countries to leverage resources in vector surveillance and control, which contributes to sustainable improvements in entomological capacity and outbreak response.

749

VENEREAL TRANSMISSION OF VESICULAR STOMATITIS VIRUS BY *CULICOIDES SONORENSIS* MIDGES

Paula Rozo-Lopez[1], Yoonseong Park[1], Berlin Londono[1], Barbara Drolet[2]

[1]*Kansas State University, Department of Entomology, Manhattan, KS, United States,* [2]*United States Department of Agriculture, Agricultural Research Service, Arthropod-Borne Animal Diseases Research Unit, Manhattan, KS, United States*

Culicoides sonorensis midges are well-known arbovirus vectors that play an important role in the spread of diseases such as vesicular stomatitis virus (VSV). VSV epidemiology has many complex variables to consider, including a broad range of vertebrate hosts, multiple routes of transmission, and extensive diversity of suspected vector species. Understanding non-conventional routes for VSV vector transmission might help explain viral maintenance during inter-epidemic periods and times of adverse conditions for horizontal (bite) transmission. To determine whether infected females, though intrathoracic and oral inoculation, can transmit VSV to uninfected naïve males. Our results showed the presence of viral RNa in 11.4% of males mated with injected females and 11.9% of the males mated with orally infected females during the third gonotrophic cycle. Additionally, we evaluated whether intrathoracically inoculated male midges can venereally transmit VSV to uninfected naïve females. a total of 41.7% of the females tested positive for the presence of viral RNa 7 days after copula. Lastly, we conducted ultrastructural studies with immunohistochemistry on reproductive organs of males and females and established relevant anatomical sites for virus location that results in transmission through copulation. Our research indicates that *Culicoides* midges are capable of efficient venereal transmission and may help explain ecological, temporal, and spatial aspects of VSV epidemiology.

750

SUBLETHAL ACOUSTIC TRACHEAL RUPTURE PROVIDES NOVEL INSIGHTS OF LARVAL MOSQUITO RESPIRATION, CONTRADICTING THE CLASSICAL THEORY OF OBLIGATE METABOLIC GAS EXCHANGE VIA THE SIPHON

Herbert Joseph Nyberg

New Mountain Innovations, Inc., Old Lyme, CT, United States

Acoustic larvicide occurs by exposing mosquito larvae to acoustic energy rupturing the dorsal tracheal trunks (DTTs) by the expulsion of gas bubbles into the body. In studying this we identified undescribed anatomical and physiological respiratory features. The classical theory of respiration is that the siphon and DTTs play an obligate role in respiration. In contrast, the results of the present study contradict the widely accepted theory that culicine larvae respire via atmospheric gas exchange. Gas exchange necessary for survival occurs in the absence of a tracheal connection to the atmosphere through the siphon. We identified an undescribed tracheal occlusion necessary for the acoustic larvicide rupture of the DTTs, this constriction prevents the escape of energized gas from the siphon as well as precluding the exchange of metabolic gas with the atmosphere. This contradiction of the classical theory of respiration will impact future efforts in controlling mosquito populations and the associated diseases they transmit.

751

CHARACTERIZATION OF THE REPRODUCTIVE BEHAVIOR OF THE NATURAL POPULATION OF *ANOPHELES COLUZZII* AND *ANOPHELES GAMBIAE* IN SENEGAL

Oumou K. Gueye[1], El Hadj A. Niang[1], Mouhamed B. Faye[1], Amblat A. Ahmad[1], Abdoulaye K. Dia[1], Frederic Tripet[2], Abdoulaye Diabate[3], Charles Wondj[4], Ibrahima Dia[5], Lassana Konate[1], Ousmane Faye[1], Oumar Gaye[1]

[1]*Universite Cheikh Anta Diop, Dakar, Senegal,* [2]*Keele University, Newcastle-under-Lyme, United Kingdom,* [3]*Institut de Recherche en Science de la Santé/Centre Muraz, Bobo-Dioulasso, Burkina Faso,* [4]*Centre for Research in Infectious diseases (CRID) and International Institute of Tropical Agriculture (IITA), Yaounde, Cameroon,* [5]*Unité d'Entomologie Médicale, Institut Pasteur de Dakar, Dakar, Senegal*

Anopheles gambiae s.s., the major malaria vector in Africa, has long been known to exist in nature as two distinct and sympatric populations. Initially described as M and S molecular forms, now formally named as *Anopheles coluzzii* Coetzee & Wilkerson while the S form retains the nominotypical species name, *Anopheles gambiae*. In most of their sympatric areas, the reproductive isolation between the incipient species is thought to be the main barrier to hybridization. However, in Senegal, the barrier to the gene flow seems to be porous in some areas with relatively high hybridization rates. Here, we studied the swarming behavior of these two species to investigate its impact on the hybridization.The study was carried out in the south and center of Senegal during the 2018 raining season. Swarms were surveyed at sunset towards the lightest part of the sky, about 0.5 - 4m above the ground. Once located, swarm were collected using a net. Indoor resting populations was also collected during the same period from each sentinel village by pyrethrum spray catch earlier the morning to estimate the frequency of the two species and their hybrids. All specimens collected were identified morphologically then by PCR. Results show that *An. gambiae* swarms mainly over bare ground whereas *An. coluzzii* swarms over various objects forming a dark-light contrast with the ground. The height of swarms varies between 0.5 to 2.5 meters and the swarming duration was about 10 minutes. Swarming was correlated with sunset and no mixed swarm were found in the sympatric area despite the high level of hybridization rate. Swarming behavior shows a pre-mating reproductive barrier between *An. coluzzii* and *An. gambiae* in Senegal. No link was found between swarming behavior and hybridization, but the lack of mixed swarm may be the result of low number of sample obtained in the sympatric area.

752

PREDICTION OF MICROCLIMATES USING MACHINE LEARNING

Rachel Sippy[1], Diego Herrera[2], David Gaus[2], Ronald Gangnon[3], Jonathan Patz[3], Jorge Osorio[3]

[1]*SUNY-Upstate Medical University, Syracuse, NY, United States,* [2]*Salud y Desarollo Andino, Pedro Vicente Maldonado, Ecuador,* [3]*University of Wisconsin - Madison, Madison, WI, United States*

Microclimates are an important component of our ecosystem and can impact human health through heat illnesses or by impacts on vector habitats. *Aedes aegypti*, the vector of dengue, chikungunya, and Zika, is a highly localized species and its abundance is impacted by microclimate conditions. Research on microclimates can be difficult, as precise on-the-ground measurements are required; our understanding microclimate stability is limited. Although we know microclimates affect human health, there have been no attempts to predict microclimates. HOBO Temperature/Relative Humidity Data Loggers were deployed in four sites per month for 24 to 576 continuous hours (1—24 days) each month from September 2016 to August 2017 in a community in rural Ecuador. Data

were summarized for each 24-hour period. We assessed the variability of summary microclimate variables across time and urban environments. We combined remotely-sensed and climate station weather data with urbanicity, elevation, and spatial components to predict summary microclimate variables across the entire community using machine learning approaches. Two-hundred and eighty-seven log-days of data were collected. We found that some microclimate variables were temporally stable, urban sites had warmer temperature variables and rural sites had higher relative humidity variables. For prediction, we found random forest algorithms were the best fit for many microclimate variables (temperature mean, median, minimum and relative humidity mean, median), with decent prediction (R^2: 0.61—0.65). Generalized boosting models fit temperature and relative humidity variance well, as well as minimum and maximum relative humidity, with good prediction (R^2: 0.61—0.72). The best fit model for maximum temperature was a support vector machine, though this yielded moderate prediction (R^2: 0.53). Our study was limited by a small sample size over time and space, and limited availability of prediction variables at fine spatial scales. Machine learning approaches are a promising option for microclimate prediction though additional research should be conducted with validation of model predictions.

753

STUDY ON RESERVOIRS OF CUTANEOUS LEISHMANIASIS IN AN ENDEMIC AREA IN MALI

Cheick Amadou Coulibaly

University Park, PA, State College, PA, United States

Cutaneous leishmaniasis (CL) remains a major public health problem in African nations, including Mali, where no information is available on the vertebrate reservoirs involved in parasites transmission cycles. This study was carried out to determine the natural infection rates of *Leishmania* parasites in rodents, and to assess exposure of both rodents and domestic animals to sand fly bites in a cryptic focus of CL in the district of Baroueli, Mali. in Baroueli, a high prevalence (31%, May 2006) of disease was detected through leishmanin surveys though active cases were never found despite active case detection over a period of two years. The sampling of rodents using Sherman traps was carried out. a total of 42 rodents were captured and identified as *Mastomys natalensis*, *Mus musculus*, *Mastomys sp*. *Mastomys natalensis* species with 64.3% was the predominant specie. PCR and Microscopy, used for infection detection, were negative. ELISA, used to assess exposure to bites, detected antibodies against *Phlebotomus duboscqi* saliva and possibly *Leishmania* in the rodent *Mastomys natalensis.* Bloodmeal analysis from humans and domestic animals by PCR targeting cytochrome B revealed that *P. duboscqi* fed on mostly on goats, chicken and humans. To the best of our knowledge, this is the first detection of anti-*Leishmania* antibodies in *Mastomys natalensis* in Baroueli, Mali. Successful parasite isolation from lesions need to be established to confirm these rodents are disease reservoirs.

754

GENETIC DIVERSITY OF ORIENTIA TSUTSUGAMUSHI IN NORTH INDIA

Manisha Biswal, Ryumzok Targain, Jasleen Kaur, Navneet Sharma, Arun Bansal

Postgraduate Institute of Medical Education and Research, Chandigarh, India

Scrub typhus has emerged as a major cause of acute febrile illness in India in recent years. The causative agent, *O. tsutsugamushi* has more than 20 antigenic types due to a variable 56-kDa outer membrane protein. It is crucial to know the prevailing antigenic types in India for the success of diagnostic immunoassays and prospective vaccine candidates. in north India, the principal antigenic types circulating are unknown. Our tertiary care hospital caters to a large area of north India (around 8 states with ten million population). Therefore, the current study was planned to identify the genotypes of *O. tsutsugamushi* circulating in this wide area of north India. a total of 590 adults and children with presenting with suspected scrub typhus between July 2017 and March 2018 were included in this study. DNa was extracted from whole blood and eschar (where available) and a nested PCR was used to amplify a 483-bp region of the 56-kDa antigen gene of *O. tsutsugamushi*. The PCR products were purified and DNa sequencing was performed and aligned using the CLUSTAL_V program. a phylogenetic tree was constructed using neighbour- joining algorithms and analyzed using the sequences obtained in this study and those obtained from the GenBank database.a total of 52 samples were positive for PCR and 48 amplicons were sequenced and analysed. Karp-like strains predominated in all states studied (72.9%) followed by Kawasaki-like (20.8 %). We found three amplicons which were very similar to Boryong and Kuroki reference strains. We did not find any Kato or Gilliam-like strains. *Orientia tsutsugamushi* shows a great diversity in its strains over a large geographical area of north India. This has implications for both diagnostic assays and vaccines for scrub typhus.

BIODIVERSITY OF MOSQUITOES IN MALARIA AND DENGUE CO-ENDEMIC AREAS IN KHANH HOA AND BINH PHUOC PROVINCES, VIETNAM

Nam Sinh Vu[1], Nicholas J. Martin[2], Jeffrey C. Hertz[2], Tu Cong Tran[1], Phong Vu Tran[1], Anh Duc Dang[1], Duong Nhu Tran[1], Maysa T. Motoki[3]

[1]*National Instititue of Hygiene and Epidemilogy, Hanoi, Vietnam,* [2]*Naval Medical Research Unit-2, Singapore, Singapore,* [3]*Vysnova Partners, Maryland, MD, United States*

A collaborative study to assess the distribution and behavior of mosquitoes, with a focus on those recognized as vectors of malaria and dengue was conducted, to determine if vectors of both diseases were present in the same areas within Khanh Hoa and Binh Phuoc Provinces, Vietnam. Adults and immature (larvae) mosquitoes were collected in Khanh Thanh and Cau Ban Communes, Khanh Hoa Province, and Bu Gia Map and Dac O Communes, Binh Phuoc Province. Adult mosquitoes were collected using cow-baited net trap, light trap and aspirator, while immatures were collected by standard larval dippers. Mosquito taxa were identified based on morphological characters, PCR-based identification methods were used to aid identification for *Anopheles* (*Celia*) *dirus s.l.*, *An*. (*Cel*.) *minimus s.l.*, and *An.* (*Cel*.) *maculatus s.l.*, and the internal transcribed spacer 2 (ITS2) region of ribosomal DNa (rDNA) was generated for overall species identification. a total of 4,492 specimens were collected in the first survey, representing 30 taxa from five genera: *Aedes*, *Anopheles*, *Armigeres*, *Culex* and *Mansonia*. Among them, the primary malaria vectors, *An*. (*Cel*.) *dirus s.s.*, *An*. (*Cel*.) *minimus s.s.*, and *An.* (*Cel*.) *maculatus s.s.,* and dengue vectors, *Aedes* (*Stg*.) *aegypti and Ae.* (*Stg*.) *albopictus*, were collected in almost all the studied locations. The PCR-based identification allowed us to discriminate *An. maculatus s.l.* into two species: *An. maculatus s.s.* and *An. sawadwongporni*. Voucher specimens will be deposited into the Smithsonian Institution, National Museum of Natural History (SI-NMNH), Washington DC, USA. The PCR-based identification method was critical to the identification of *Anopheles* cryptic species. This study provides additional information about the biodiversity and ecology of mosquito fauna in Vietnam. Results demonstrate that there is a risk of infection from either malaria and dengue in study areas within Khanh Hoa and Binh Phuoc Provinces.

756

THE EFFECTS OF LANDCOVER ON *ANOPHEL*ES POPULATION DYNAMICS IN ANN TOWNSHIP, RAKHINE STATE, MYANMAR

Christopher C. Hayes[1], Sai Zaw Min Oo[2], Yannaung M. Maung[2], Zayar Han[2], Maung M. Mya[2], Christopher V. Plowe[1], Myaing M. Nyunt[1]

[1]*Duke University, Durham, NC, United States,* [2]*Department of Medical Research, Yangon, Myanmar*

Over the past several decades, developing countries such as Myanmar have increased industrialization and use of natural resources. The

results of these trends are anthropogenic environmental impacts such as deforestation, strip-mining, and land re-purposing for agriculture or housing. The effects of these human-driven land-cover changes on vector species densities, distribution, ecology, and local malaria transmission within Myanmar are largely undocumented. The objective of this study was to assess the effects of variability in the land-cover on the species-specific density of major local malaria vectors. To accomplish this, we systematically collected mosquitoes at randomized locations, both indoor and outdoor, within varying land-cover types such as deep forest, rice paddy, and forest edge. Collections were performed across multiple villages, over a period of 3-5 days within each village. Villages were divided into sectors based on similar land-cover types, and within those sectors one trap was rotated to different randomized geographic positions for several twelve-hour day and night trapping sessions. The collected mosquitoes were identified by both morphology and polymerase chain reaction (PCR). The relative species-specific densities were determined based on village-specific levels of land-cover independent of vector-control measures used. The distribution of specific species of *Anopheles* in the studied land-covers will be presented, and potential factors affecting anthropogenic variability will be discussed. Data from this study will improve the current understanding of species-specific vector dynamics in the area, and will help guide further efforts for vector reduction and infection control.

757

MICROORGANISM-BASED LARVAL DIETS AFFECT MOSQUITO DEVELOPMENT, SIZE AND NUTRITIONAL RESERVES IN THE YELLOW FEVER MOSQUITO *AEDES AEGYPTI* (DIPTERA: CULICIDAE)

Raquel Souza[1], Flávia Vírginio[2], Thaís Riback[1], Lincoln Suesdek[2], José Barufi[3], Fernando Genta[1]

[1]*Fundação Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*Instituto Butantan, São Paulo, Brazil,* [3]*Universidade Federal de Santa Catarina, Santa Catarina, Brazil*

Mosquito larvae feed on organic detritus from the environment, particularly microorganisms comprising bacteria, protozoa, and algae. Little attention has been paid to nutritional studies in *Aedes aegypti* larvae. We investigated the effects of yeast, bacteria and microalgae diets on larval development, adult size, survivorship, lifespan and wing morphology. Microorganisms (or Tetramin® as control) were offered as the only source of food to recently hatched first instar larvae and their development was followed until the adult stage. The main macronutrients were analyzed in single larvae to correlate energetic reserve accumulation by larva with the developmental rates and nutritional content observed. FITC-labeled microorganisms were offered to fourth instar larvae, and its ingestion was recorded by fluorescence microscopy and quantitation. Larvae developed in all diets, however insects fed with bacteria and microalgae showed a severe delay in development rates and low survivorship. Diets with better nutritional quality resulted in adults with bigger wings. *Asaia* sp. and *Escherichia coli* resulted in better nutrition and developmental parameters and seemed to be the best bacterial candidates to future studies using symbiont-based control. The diet quality was measured and presented different protein and carbohydrate amounts. Bacteria had the lowest protein and carbohydrate rates, yeasts had the highest carbohydrate amount and microalgae showed the highest protein content. Larvae fed with microalgae seem not to be able to process and store these diets properly. Larvae were shown to be able to process yeast cells and store their energetic components efficiently. In conclusion. our results point that mosquito larvae show high plasticity to feed, being able to develop under different microorganism-based diets. The important role of *Ae. aegypti* in the spread of infectious diseases requires further biological studies in order to understand the vector physiology and thus to manage the larval natural breeding sites aiming a better mosquito control.

758

MATING INDUCED MRNA EXPRESSION CHANGES IN FEMALE SPERM STORAGE ORGANS OF THE YELLOW FEVER MOSQUITO *AEDES AEGYPTI*

Carolina Camargo[1], I. Alexandra Amaro[2], Laura C. Harrington[2], Frank W. Avila[1]

[1]*Universidad de Antioquia Max Planck Tandem Group, Medellin, Colombia,* [2]*Cornell University, Ithaca, NY, United States*

The yellow fever mosquito *Aedes aegypti* is the primary vector for numerous viruses that negatively impact human health, including dengue, chikungunya, and zika viruses. Manipulation of insect reproduction has been proposed as an alternative to suppress mosquito populations or replace them with mosquitoes that are resistant to viruses. To develop such control strategies, it is necessary to understand the biological processes that enable males and females to successfully reproduce. Female sperm storage is a crucial process in insect reproduction that requires the coordination of male and female-derived proteins that regulate post-mating process and allow sperm viability during storage. Studies in *Drosophila melanogaster* have shown that secretory cells of the sperm storage organs (spermathecal secretory cells, SSCs) produce proteins that function in ovulation, egg-laying and sperm storage, and several SSC genes are regulated by mating. While *Ae. aegypti* contain SSCs, the proteins they produce, and their transcriptional response to mating alone or a blood-meal is unknown. We conducted an RNAseq analysis on the spermathecae of *Ae.aegypti* in 4-6 day-old virgin females, mated females, and mated and blood fed females at 6, 24, and 72hrs post-mating. Our goals were to 1) identify female-specific proteins likely to be involved in reproduction and 2) determine gene expression profiles of the spermathecae in response to mating and blood ingestion in this important species. This study will allow us to identify genes likely to be required for fertility in *Ae. aegypti.*

759

A MOSQUITO TRIGLYCERIDE LIPASE IS CRITICAL FOR *ANOPHELES GAMBIAE* REPRODUCTION AND FOR *PLASMODIUM FALCIPARUM* DEVELOPMENT IN THE MOSQUITO

Maurice A. Itoe[1], Kristine Werling[1], Amy Deik[2], Kathleen A. Westervelt[1], Clary Clish[2], Flaminia Catteruccia[1]

[1]*Harvard T.H. Chan School of Public Health, Boston, MA, United States,* [2]*Broad Institute of Harvard and M.I.T, Cambridge, MA, United States*

When a female mosquito feeds on blood, dietary lipids are mobilized from the midgut epithelium and loaded onto lipid transporters for delivery to ovaries, fat body, and flight muscles where they are utilized for a number of physiological processes or can be stored and broken down. Despite the conservation of this process across blood feeding mosquito species, limited information is available on the role of lipolysis in the reproductive biology of female mosquitoes and in their interaction with the pathogens they transmit. To fill this knowledge gap, we have characterized putative key components of the lipolytic machinery in the main African malaria vector, *Anopheles gambiae,* for their role in the female's reproductive success and parasite development. An initial lipidomic time course analysis revealed a coordinated alteration of triacylglycerols (TAGs) and other neutral lipids in different mosquito tissues after blood feeding, suggesting lipid mobilization. Strikingly, RNa interference (RNAi) targeting the putative TAG lipase, *TL2* reduced the number of eggs developed by females and caused complete embryonic lethality. Moreover, depletion of *TL2* induced faster *Plasmodium falciparum* development, with parasites becoming infectious within a shorter time period. Similar results were also obtained upon RNAi knockdown of a putative lipid droplet surface protein 1(LDSP1), an orthologue of perilipin 1 in mammals known to regulate TAG lipase activity on the surface of lipid droplets for the breakdown of fat, suggesting conservation of lipolytic pathways between mosquitoes and mammals. Lipidomic analyses of female tissues after *TL2* silencing showed accumulation of TAGs, DAGs, PCs in midguts and cholesterol esters (CE)

in ovaries. Consistently, injection of candidate lipids into the hemolymph shortly after blood feeding partially rescued egg numbers and fertility in *TL2*-deficient females, highlighting the relevance of blood meal-derived fatty acid in the mosquito reproductive success. This study identifies TAG lipolysis as a critical step for the fertility of *An. gambiae* females and the development of *P. falciparum* parasites.

DETECTION OF ARBOVIRUSES AND PARASITES IN MOSQUITO VECTORS WITH A BEAM OF LIGHT

Maggy Sikulu-Lord[1], Gabriela A. Garcia[2], Lilha M. Santos[2], Jill N. Fernandes[3], Floyd E. Dowell[4], Rafael Maciel-De-Freitas[2]

[1]*The University of Queensland, Herston, Australia,* [2]*Instituto Oswald Cruz-Fiocruz, Rio de Janeiro, Brazil,* [3]*The University of Queensland, St Lucia, Australia,* [4]*U.S. Department of Agriculture, Kansas City, KS, United States*

To determine the effectiveness of mosquito control programs, decision-makers need timely, high throughput and cost-effective surveillance tools to determine mosquito survival, species identity or infection status prior to and after implementation of an intervention. This information is required to identify high risk areas in a timely fashion allowing for the prioritization of resources to communities most in need thus maximizing the efficiency of vector control interventions. To date, no technique has been shown practical, cost effective and rapid enough to be scaled up for surveillance of large mosquito control programs. In the last decade, our team has been applying the Near infrared spectroscopy (NIR) technique to characterise mosquito vectors that transmit human pathogens such as malaria, dengue Zika and Chikungunya. The main goal is to find a cheaper and rapid alternative technique for determining the efficacy of available control interventions and upcoming vector control tools and predict future disease outbreaks. We sought to determine the applicability of NIRS for rapid detection of a number of infections including Zika, dengue, Chikungunya and malaria. Infected and uninfected cohorts of mosquitoes were reared under controlled laboratory conditions and a Labspec NIR spectrometer (Malvern Panalytical Inc, Boulder, CO) was used to scan the mosquito samples. Machine learning algorithms were used to identify spectral signatures related to each infection in heads/thoraces and abdomens. Our collective results from a range of studies indicate that our light based technique could be used to predict mosquitoes infected with Zika, dengue, Chikungunya and malaria with accuracies ranging between 80-97% at a significantly lower cost and more rapidly than traditional techniques used for similar purposes.. Our next step is to expand the existing models for use in other regions and to apply the models in the field for predicting future disease outbreaks.

761

PYRUVATE KINASE ACTIVITY IS MODULATED IN THE FAT BODY OF *AEDES AEGYPTI* IN RESPONSE TO NUTRIENT CHANGES

Natthida Petchampai[1], Jun Isoe[2], Patricia Y. Scaraffia[1]

[1]*Tulane University, New Orleans, LA, United States,* [2]*The University of Arizona, Tucson, AZ, United States*

Glucose oxidation through glycolysis is important for ammonia detoxification in *Aedes aegypti*. Pyruvate kinase (PK) catalyzes the last step of the glycolytic pathway. Recently, two alternatively spliced mRNA variants (AaPK1 and AaPK2) that code for PKs were identified in the *A. aegypti* genome. Recombinant AaPK1 was found to be regulated by multiple allosteric effectors, including specific amino acids and phosphorylated sugars. Here, *in vivo* characterization of AaPKs was performed. First, we measured AaPK mRNA and protein expression in tissues dissected from sucrose- and blood-fed mosquitoes. Although transcriptional analysis showed differential mRNA expression patterns in mosquito tissues, the protein levels in most of the tissues remained unchanged throughout the time-course analyzed. Then, we examined AaPK enzymatic activity in fat body and flight muscles from mosquitoes maintained under four different nutritional conditions: (1) sucrose, (2) water (deprivation of sucrose), (3) blood/sucrose, and (4) blood/water. For non-blood-fed mosquitoes (conditions 1 and 2), the subtraction of sucrose increased AaPK activity in the fat body at 72 h after feeding. Moreover, western blotting revealed that AaPK protein expression was up-regulated in the fat body of non-blood fed mosquitoes that were given water for 72 h. In contrast, the AaPK activity declined in the fat body of blood-fed mosquitoes that were provided with water (condition 4) instead of sucrose (condition 3) for 96 and 120 h. The level of AaPK activity in the flight muscles was similar in all dietary conditions and time points. The results demonstrate that AaPK activity in mosquito fat body is regulated in response to specific nutritional changes. Our data also provide new insights into carbon and nitrogen metabolism in *A. aegypti* mosquitoes.

A RAPID SCREEN IDENTIFIES CLIPC9 AS A REGULATOR OF MELANIZATION IN THE MALARIA VECTOR *ANOPHELES GAMBIAE*

Gregory L. Sousa, Michael Povelones

University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA, United States

The mosquito melanization response is a crucial immune pathway that is regulated by a network of CLIP domain serine proteases (CLIPs). CLIP cascades link pattern recognition to melanin production by activating phenoloxidase (PO), which is the rate limiting melanization enzyme. Current methods to identify regulators of melanization in the malaria vector, *Anopheles gambiae*, include PO enzyme activity assays and microscopic evaluations following microbial infections. These approaches, while robust, require large mosquito cohorts and/or technically intensive hemolymph extractions. Here, we describe the development of a rapid screen, referred to as the melanization-associated spot assay (MelASA), that is capable of identifying novel melanization regulators with far fewer mosquitoes and without biochemical or microscopic analyses. The MelASA was based on an observation that mosquitoes injected with *E. coli* excreted a quantifiable amount of melanotic material. CLIPA8 is essential for immune challenge-induced melanization, and we demonstrated that the appearance of these excretions, like PO activity, required this serine protease homolog. Using MelASA, we then interrogated the CLIPC subfamily and identified CLIPC9 as a putative melanization regulator. Follow up analyses revealed CLIPC9 as a critical player in both the melanization of *E. coli* and *Plasmodium berghei* parasites. To facilitate biochemical and immunohistochemical analyses, we developed a polyclonal antibody against CLIPC9 and report its presence within the hemolymph. Work is on-going to understand the hierarchical position of CLIPC9 within the CLIP network and to determine its relationship with other immune pathways such as mosquito complement. This screen represents a streamlined approach for dissecting the contributions of multimember gene families such as the CLIPs in melanization. We report that CLIPC9 is the first CLIPC family member involved in the melanization immune response in any mosquito.

763

INSECT ARYL-HYDROCARBON RECEPTOR (AHR) MEDIATES A NEGATIVE LOOP OF IMMUNE MODULATION

Aditi Kulkarni, Wanqin Yu, Jennifer Curtiss, Jiannong Xu

New Mexico State University, Las Cruces, NM, United States

The immune homeostasis in insects is known to be well maintained by different negative feedback mechanisms. AhR is a xenobiotic sensor and ligand-dependent transcription factor. In this study, we examined the role of insect AhR signaling in immune regulation in parallel to the classical immune pathways using the mosquito *Anopheles gambiae* and fruit fly *Drosophila melanogaster* models. In the mosquito model, we pharmacologically manipulated AhR activation using AhR agonists or antagonists, and knocked down *AhR* gene via RNAi, and then the mosquitoes were challenged by injection with a bacterium *Serratia* sp. S1. When AhR was activated by feeding the agonist kynurenine, survival

rate was reduced from 58% (in control) to 38.7% (Chi square test, P<0.01). When AhR was inhibited by the antagonist CH233191, survival was increased from 58% to 80% (Chi square, P<0.01). In addition, *AhR* gene silencing resulted in higher survival upon the bacterial challenge. The chemical inhibition of AhR increased immunity against rodent malaria parasite *Plasmodium berghei,* less oocysts were present in the treated mosquitoes (t test, P<0.01). In *Drosophila*, AhR is encoded by gene *spineless, Ss.* Bacterium *Providencia* causes lethal infection in flies when ingested. The wild type flies were more sensitive to the intestinal infection, showing a higher mortality than the two loss-of-function mutant lines, *Ss1* and *Ssa* (Mantel-Cox, P<0.01). When wild type flies were treated with the AhR antagonist CH233191, the survival was improved (Mantel-Cox, P<0.05). Furthermore, the interrogation of transcriptome of before and after bacterial infections in AhR manipulated mosquitoes revealed that AhR controlled the transcription of genes with immune-suppressive function, including *ClipA14, Tieg, Srpn6, Srpn10* and *Socs*. However, AhR manipulation did not affect the transcription of immune genes regulated by Toll and IMD immune pathways. The data suggest that insect AhR mediates an independent negative loop of immune modulation in maintaining immune homeostasis.

764

CHEMICAL DEPLETION OF PHAGOCYTIC IMMUNE CELLS IN *ANOPHELES GAMBIAE* REVEALS DUAL ROLES OF MOSQUITO HEMOCYTES IN ANTI-*PLASMODIUM* IMMUNITY

Hyeogsun Kwon, **Ryan C. Smith**

Iowa State University, Ames, IA, United States

Mosquito immunity is comprised of both cellular and humoral factors that provide protection from invading pathogens. Immune cells known as hemocytes, have been intricately associated with phagocytosis and innate immune signaling. However, the lack of genetic tools has limited hemocyte study despite their importance in mosquito anti-*Plasmodium* immunity. To address these limitations, we employ the use of a chemical-based treatment to deplete phagocytic immune cells in *Anopheles gambiae,* demonstrating the role of phagocytes in complement recognition and prophenoloxidase production that respectively limit the ookinete and oocyst stages of malaria parasite development. Through these experiments, we also define specific sub-types of phagocytic immune cells in *An. gambiae*, providing new insights beyond the morphological characteristics that traditionally define mosquito hemocyte populations. Together, this study represents a significant advancement in our understanding of the roles of mosquito phagocytes in mosquito vector competence and demonstrates the utility of clodronate liposomes as an important new tool in the study of invertebrate immunity.

765

PYRETHROID AND ORGANOPHOSPHATE INSECTICIDE RESISTANCE IN *ANOPHELES ARABIENSIS* IN WESTERN KENYA

Pauline W. Orondo[1], Harryson Atieli[2], Steven G. Nyanjom[1], Alex L. MingChieh[3], Andrew K. Githeko[4], Guiyan Yan[3]

[1]*Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya,* [2]*International Center for Malaria Research, Homa Bay, Kenya,* [3]*University of California, California, CA, United States,* [4]*Kenya Medical Research Institute, Kisumu, Kenya*

Malaria control in Kenya primarily relies on insecticide treated nets, however, in 2018 indoor residual spraying (IRS) using Actellic®300SC an organophosphate was implemented. Malaria vector abundance has since been reduced significantly causing major shift in malaria vector species. Intensive use of insecticide based control measures may have further selected for increased insecticide resistance in the malaria vectors. The objective of the present study was to determine resistance to multiple classes of insecticide in Homa Bay, a county with mixed crop irrigation. This study determined the frequency of knock down resistance (kdr) and insecticide resistance mechanisms in *An. arabiensis* malaria vector. *Anopheles gambiae* s.l. larvae were collected in high and low transmission zones, which are approximately 15km apart. These were reared and subjected to standard WHO bioassay test against deltamethrin and melathion. Species identification (n=181) indicated 2.2% *An. gambiae* s.s. and 97.8% *An. arabiensis*. *An. arabiensis* recorded a mortality of 97.9% (n=324) in high transmission zone and 83.9% (n=114) in low transmission zone against deltamethrin, whereas both high (n=104) and low transmission zones (n=103) recorded 100% mortalities against melathion. The frequency of kdr-east was observed to be zero (0) and 0.16 (n=51) and (n=70) in high and low transmission zones respectively, while the frequency of kdr-west was 0.1 and 0.04 in the high and low transmission zones respectively. This suggests heterogeneous distribution of insecticide resistance. The frequency of ACE gene was observed to be zero (0) in both high (n=44) and low transmission zone (n=58). These findings provide important information for selecting appropriate insecticides for malaria vector control in an area with multiple classes of insecticide use.

766

IDENTIFICATION AND MOLECULAR CHARACTERIZATION OF PLANT EXTRACTS AS NOVEL LARVICIDAL AGENTS AGAINST *AEDES AEGYPTI* MOSQUITOES IN JAMAICA

Rhaheem N. Layne-Yarde, Simone L. Sandiford

The University of the West Indies Mona, Jamaica, Kingston, Jamaica

The *Aedes aegypti* mosquito is a vector for many arboviruses such as dengue, Zika and chikungunya which have all negatively impacted the tropical regions of the world. Current attempts to control mosquito populations in Jamaica have limited success because of inadequate funding of vector control agencies and lack of knowledge regarding the status of insecticide resistance in mosquitoes. Therefore, the discovery of novel agents which possess mosquitocidal activity is necessary in order to effectively assist in reducing the *Aedes aegypti* populations in the country. Essential oils of plant species from families such as Lamiaceae, Rutaceae and Verbanaceae have shown promise as potential mosquitocidal agents and the cytotoxic effects of local plant species from these families will be evaluated in this investigation. Insect cell lines have become a popular alternative cell-based research tool and are being used in this study for the initial screening of the plant extracts. Extracts that have prominent cytotoxic effects against the mosquito cells will be further analyzed using the *Aedes aegypti* larvicidal assay. To investigate the mechanism of action of the extracts, the expression of genes that have been shown to be involved in cell death and insect immunity will be investigated.

767

BACTERIAL COMPOSITION DIFFERS BETWEEN PERMETHRIN-SUSCEPTIBLE AND -RESISTANT *ANOPHELES GAMBIAE SENSU STRICTO* IN A SITE WITH INTENSE PYRETHROID RESISTANCE IN WESTERN KENYA

Diana N. Omoke[1], Ezekiel Mugendi[2], Eric Ochomo[1], Mathew Kipsum[1], Samson Otieno[1], Edward Esalimba[1], Mili Sheth[3], Audrey Lenhart[3], Nsa Dada[3]

[1]*Kenya Medical Research Institute, Kisumu, Kenya,* [2]*Kenyatta University, Nairobi, Kenya,* [3]*United States Centers for Disease Control and Prevention, Atlanta, GA, United States*

Insecticide resistance poses a growing challenge to malaria vector control. Following evidence of associations between the mosquito microbiota and insecticide resistance, we characterized the microbial composition of malaria vectors in relation to their insecticide resistance profiles, in different locations with high and low levels of pyrethroid resistance. Here, we report findings from our study on *Anopheles gambiae s.s.* in Turukuyi village, Bungoma County, where high levels of pyrethroid resistance were detected. F_1 non-blood fed female *An. gambiae s.s.* that were obtained from wild-caught mosquitoes were exposed to five times (107.5µg/ml) the discriminating dose of permethrin using the CDC bottle bioassay. The microbiota of mosquitoes that were alive (resistant, n=50) or dead (susceptible, n=50) following the bioassay were characterized using high throughput sequencing targeting the universal bacterial and archaeal 16S

rRNA gene. Results showed significant differences in bacterial composition between resistant and susceptible individuals (PERMANOVA, F=2.33, P=0.001), with *Sphingobacterium* and *Streptococcus*—both comprising pyrethroid-degrading species, and the radiotolerant *Rubrobacter,* being over three folds (P<0.05) more abundant in resistant compared to susceptible mosquitoes. This first report of association between the microbiota and pyrethroid resistance in *An. gambiae s.s.* corroborates results of previous studies conducted on *Anopheles albimanus* from Peru and Guatemala. Our findings form the basis of future work on the role of mosquito microbiota in insecticide resistance, and potentially the identification of novel microbial markers of insecticide resistance in mosquito populations.

768

HABITAT CHARACTERIZATION AND INSECTICIDE SUSCEPTIBILITY OF *AEDES AEGYPTI* MOSQUITOES IN IFAKARA TOWN AND SURROUNDING WARDS

Najat Feruzi Kahamba, Alex Limwagu, Salum Mapua, Halfan Ngowo, Emmanuel Kaindoa, Fredros O. Okumu

Ifakara Health Institute, Morogoro, United Republic of Tanzania

In past decades, significant progress has been made against malaria in Tanzania, but other mosquito-borne diseases such as dengue, yellow fever, chikungunya and zika which transmitted by *Aedes aegypti* remain neglected. The concern over these diseases in sub-Saharan Africa has risen in recent times due to outbreaks in various places and several detection of viruses in areas with no outbreak yet. *Ae. aegypti* is anthropophilic vector which breeds in artificial containers, but can be controlled by larval source management and personal protection. Though it is widely distributed in urban areas, its distribution and susceptibility to public health pesticides remain unknown in small towns and rural areas in Tanzania. This study aims to characterize aquatic habitats of *Ae. aegypti* in Ifakara and to assess the susceptibility against insecticides commonly used in public health. The study area was gridded (200m × 200m), grids with houses and buildings were randomly selected for search of aquatic habitats. Habitats were described by type, size, location, water clarity, presence of shades and surrounding environment. Larvae of *Aedes* were collected and reared in the insectary for insecticide susceptibility tests following standard WHO guidelines against pirimiphos-methyl 0.25%, deltamethrin 0.05%, permethrin 0.75%, dieldrin 4% and bendiocarb 0.1%. A total of 27541 larvae were collected, of which 63% (n=17245) were *Ae. aegypti* and 37% *Culex* mosquitoes. The most common *Aedes* habitats in the area were used tires, clay pots, flower pots, garage pits, tree holes and discarded containers. Habitats with clear water and shades were most commonly infested by *Aedes.* The *Aedes* mosquitoes were fully susceptible to all the insecticide classes in all wards except Mlabani, Viwanja sitini and Ifakara mjini where there were signs of resistance to bendiocarb, deltamethrin and permethrin but for which susceptibility was confirmed. These findings provide baseline data on habitat characteristics and insecticide susceptibility of *Ae. aegypti* in Ifakara. It also provides a basis for stronger vector surveillance against Aedes-borne infections in small towns

769

COPEPODS AS POTENTIAL BIO-CONTROLS AGAINST INVASIVE MOSQUITOES IN THE UK: A COMPARISON OF TWO LOCAL CYCLOPOID PREDATOR SPECIES

Marie C. Russell, Alima Qureshi, Chris G. Wilson, Lauren J. Cator

Imperial College London, Ascot, United Kingdom

The Asian Tiger Mosquito, *Aedes albopictus*, is a known vector of several diseases of public health importance including Chikungunya, Dengue, Yellow Fever, and Zika; and it is likely to successfully invade the UK in the coming years. We assessed the functional response and the predation efficiency of copepods *Macrocyclops albidus* and *Megacyclops viridis* from Surrey, South East England, UK against newly-hatched French *Ae. albopictus* larvae. Experimental replicates were all of a similar design with one cyclopoid copepod predator and varying numbers of mosquito larvae in 20 mL of spring water for a six-hour period of exposure to predation. The functional response experiments required varying the initial densities of mosquito larvae from a range of one to 32, and the assessment of predation efficiency was done at a prey density of 24. Predator-absent controls were included throughout the course of all experiments to account for background prey mortality. Both copepod species exhibit population-destabilizing type II functional responses that do not change significantly over temperatures likely to be experienced in UK larval mosquito habitats. The predation efficiency of *M. viridis* was approximately 7.5 percentage points higher than that of *M. albidus*. There is also a significant positive relationship between the body lengths of the copepods and their predation efficiencies. We suggest that *M. viridis* copepods have higher predation efficiency than *M. albidus* against French *Ae. albopictus* larvae, and that this difference is due in part to the fact that *M. viridis* copepods generally have longer body lengths than *M. albidus*. Our study suggests that in the event of an *Ae. albopictus* invasion in the UK, *M. viridis* would be a superior control agent to *M. albidus*.

770

A COMPARATIVE STUDY OF THE DENSITY, RESISTANCE STATUS AND SPOROZOITE RATES OF *ANOPHELES FUNESTUS* AND *AN. GAMBIAE* SPECIES COMPLEXES IN WESTERN KENYA

Rissy Makokha[1], Seline Omondi[2], Isaiah Debrah[2], Maxwell Machani[2], Bernard Abong'o[2], Jackline Kosgei[2], Silas Agumba[2], Duncan Athinya[3], Stephen Munga[2], Yaw Afrane[4], Carol Wangui Hunja[1], Eric Ochomo[2]

[1]*South Eastern Kenya University, Kitui, Kenya,* [2]*Kenya Medical Reserach Institute, Kisumu, Kenya,* [3]*University of Nairobi, Nairobi, Kenya,* [4]*West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana*

With the increasing use of insecticide-based vector control tools, two phenomena have occurred; one is a shift in populations of sympatric vectors and two, is the emergence and spread of insecticide resistance. We assessed the composition, *Plasmodium falciparum* sporozoite rates, resistance profiles and mechanisms, and the impact of the observed resistance on the commonly used Long Lasting Insecticidal Nets in *Anopheles* mosquitoes in western Kenya. Female mosquitoes resting indoors were randomly collected from houses in Ahero, Kisumu county and Asembo, Siaya county in western Kenya. The mosquitoes were exposed to 0.05% deltamethrin using WHO tube bioassays to determine resistance status. CDC bottle bioassay with escalating doses:1× (12.5µg/ml), 2× (25µg/ml), 5× (62.5µg/ml) and 10× (125µg/ml) was used to determine intensity of deltamethrin resistance. We also investigated the efficacy of locally available LLINs using WHO cone bioassay. Enzyme-linked Immunosorbent assay was used to determine *P. falciparum* sporozoite infection rates. *Anopheles funestus (s.s)* was the predominant mosquito species collected at both study sites. *An. gambiae (s.s)* was present in least proportions during the study period, accounting for 3.96% and 1.00% in Asembo and Ahero, respectively. Both WHO tube and CDC bottle bioassays implicated *An. funestus* as having the highest intensity of insecticide resistance to deltamethrin compared to *An. gambiae* complex. There was partial restoration of susceptibility in the resistant vectors when they were pre-exposed to PBO then to deltamethrin. *Anopheles funestus* also showed reduced bio-efficacy to the commonly used LLINs. *Plasmodium falciparum* sporozoite rates were highest in *An. funestus* sampled from Asembo and Ahero. Increasing insecticide resistance in *An. funestus* is alarming especially given the increasing densities and higher sporozoite rate compared to other malaria vectors existing in sympatry. This is a probable reason for the current increasing malaria incidence in many parts of Eastern and Southern Africa as reported in the most recent WHO malaria report.

771

SOCIO-CULTURAL AND COMMUNITY PERCEPTIONS ON PREGNANCY THAT INFLUENCE UTILIZATION OF MALARIA IN PREGNANCY INTERVENTIONS IN THE ASHANTI AND VOLTA REGIONS OF GHANA

Matilda Aberese-Ako[1], Harry K. Tagbor[1], Gifty D. Ampofo[1], Pascal Magnussen[2]

[1]*University of Health and Allied Sciences, Ho, Ghana,* [2]*University of Copenhagen, Copenhagen, Denmark*

Malaria in pregnancy (MiP) is a preventable and treatable infection. Despite efforts in sub-Sahara Africa to prevent and manage it, MiP exists with serious consequences. Ghana has implemented WHO recommended interventions such as insecticide treated bed nets, intermittent preventive treatment of malaria in pregnancy and testing and treating malaria in pregnancy, since 2005. This study sought to understand and describe how socio-cultural and community perceptions about pregnancy influence utilization of MiP interventions. We conducted 72 in-depth interviews with pregnant women, 30 opinion leaders, 10 herbalists, 10 pastors, 8 traditional birth attendants and 8 husbands in study communities. Focus group discussions were held with 28 pregnant women and 28 women who delivered recently. Observations and conversations were held with health providers and pregnant women in 8 health facilities. Ethical clearance was obtained from the University of Health and Allied Sciences' Research Ethics Committee and research participants' consent was sought. Nvivo 11 was used to support data coding. Data was triangulated and analyzed using grounded theory approach. Pregnant women favored cultural and community perceptions on prevention and treatment of maternal health diseases such as MiP, over health education and treatment options from health care facilities. Negative pregnancy outcomes such as miscarriages and still-birth from malaria and other biomedical causes, were interpreted as spiritual attacks from enemies. Pregnant women were encouraged by community members to seek physical and spiritual protection to prevent such outcomes. Thus pregnant women resorted to health shopping such as visiting hospitals, prayer centres, herbalists and self-medication with herbs. Some were not convinced of the efficacy of malaria in pregnancy interventions, so they focused more on pastors and traditional methods. Socio-cultural and community perceptions about pregnancy influence utilization of MiP interventions. MiP policy interventions should consider intensifying engagement with communities in order to ensure uptake of MiP interventions.

772

MODELING THE SPATIO-TEMPORAL SPREAD OF INSECTICIDE RESISTANCE AND ITS IMPACT ON MALARIA CONTROL

Prashanth Selvaraj, Caitlin Bever, Daniel Bridenbecker, Edward Wenger

Institute for Disease Modeling, Bellevue, WA, United States

Chemical insecticides are critical to the success of malaria control programs worldwide but increasing resistance threatens to undermine these efforts. Understanding the evolution and propagation of resistance is imperative to mitigating loss of intervention effectiveness. Here we present a multi-locus model of vector genetics that accounts for gene linkages and a many-to-many mapping of genotypes to phenotypes with which we model insecticide resistance in Anophelines. Using this model of vector genetics combined with an agent-based mathematical model of malaria transmission that simulates the interactions between human hosts and mosquitoes, we investigate deployment strategies and the choice of insecticides that are most likely to lead to the development of resistance in vector populations. From near elimination to high transmission settings in Africa, we predict the impact of resistance in Anophelines on malaria transmission and investigate various spatiotemporal deployment strategies of insecticides either sequentially or as mixtures to best manage resistance and ensure continued efficacy of ongoing control and elimination efforts.

773

SUSCEPTIBILITY OF *ANOPHELES GAMBIAE* S.L. TO INSECTICIDES IN SIERRA LEONE

Evelyne Sampe Alyko[1], Samuel Juana Smith[2], Yemane Yihdego[3], Rebecca Levine[4], Jenny Carlson[5], Stephen Karando Mansaray[1], David Schnabel[6], Ramlat Jose[7], Frederick Yamba[2], Miriam Mokuena[3]

[1]*PMI VectorLink project, Freetown, Sierra Leone,* [2]*National Malaria Control Program, Freetown, Sierra Leone,* [3]*Abt Associates, Rockville, MD, United States,* [4]*Centers for Disease Control and Prevention, Atlanta, GA, United States,* [5]*US Agency for International Development, Washington, DC, United States,* [6]*President's Malaria Initiative, Centers for Disease Control and Prevention, Sierra Leone, Freetown, Sierra Leone,* [7]*President's Malaria Initiative, US Agency for International Development, Sierra Leone, Freetown, Sierra Leone*

Long-lasting insecticide-treated nets (LLINs) are the primary tool for malaria vector control in Sierra Leone. Indoor residual spraying (IRS) is under consideration for future deployment. Insecticide resistance in *Anopheles* is a threat to the utility of any vector control tools that rely on insecticides, so obtaining information on the insecticide resistance status of these vectors is a basic requirement. We investigated the susceptibility status of the main malaria vector in Sierra Leone, *An. gambiae* s.l., to several insecticides. Larvae were collected and reared to adults from four districts in Sierra Leone (Bombali, Kono, Bo, and Western Rural), which represent the country's four regions. Females aged two to five days were exposed to various insecticides using the World Health Organization (WHO) tube test or Centers for Disease Control and Prevention (CDC) bottle bioassay protocols. Insecticides tested included the pyrethroids deltamethrin, permethrin, and alpha-cypermethrin, the organophosphate pirimiphos-methyl, the pyrrole chlorfenapyr, and the neonicotinoid clothianidin. Synergist assays with piperonyl butoxide (PBO) pre-exposure were also conducted using deltamethrin and alpha-cypermethrin. Results showed that mosquitoes were fully resistant to the pyrethroids, with mortality ranging between 7.3% and 65.3%, but fully susceptible to pirimiphos-methyl, chlorfenapyr, and clothianidin. After pre-exposure to PBO, the mortality rate observed for both deltamethrin and alpha-cypermethrin increased to between 58.9% and 82.5%, however, it still remained below the 90% cut-off point for confirmed resistance. These findings suggest that "next generation" LLINs impregnated with PBO or other non-pyrethroid insecticides should be considered for malaria vector control in Sierra Leone. Additionally, should IRS be used in the future, non-pyrethroid insecticides would be viable options. These findings are being used to make evidence-based decisions regarding the most appropriate vector control tools in Sierra Leone and form the basis for updating the country's insecticide resistance management plan.

774

YEAST-ENCAPSULATED ORANGE OIL EFFICIENCY AS LARVICIDE FOR *AEDES* MOSQUITOES

Bruno Gomes[1], Camila P. Jesus[1], Huarlen Ogélio[1], Fabiane Brant[1], Michael J. Workman[2], Monique Costa[1], Ademir Martins[1], Ivy Hurwitz[2], Mariana David[1], Fernando A. Genta[1]

[1]*Oswaldo Cruz Institute (IOC-FIOCRUZ), Rio de Janeiro, Brazil,* [2]*University of New Mexico, Albuquerque, NM, United States*

Aedes aegypti and *Aedes albopictus* are important vectors of arbovirus impacting human health in tropical and temperate regions. The control of larvae in aquatic environments is an important strategy for vector control programs. Essential oils have been considered as an environmental friendly alternative for chemical insecticides but they are vulnerable to rapid degradation by UV radiation. Here, we present a study that screen the larvicide activity of yeast-encapsulated orange oil in different strains of *Aedes* mosquitoes from Brazil. Larvicide activity was tested on three *A. aegypti* colonies (≈F10) originated from Macapá/AP, Oiapoque/AP and Caseara/TO, that present different resistance phenotypes for temephos (OP, RR_{50} = 0.8 - 21.8) and deltamethrin (PYR, RR_{50} = 1.6 - 143.9). For

A. albopictus, the activity was screened in two F1 colonies from Rio de Janeiro/RJ and Manaus/AM. For each strain, early L3 larvae were exposed to 10 concentrations of yeast-encapsulated essential oil in four subsets of 25 specimens per concentration. In all bioassays, the *A. aegypti* Rockefeller strain was adopted as positive control of essential oil larvicide activity and insecticide susceptible reference lineage. Dead yeast without essential oil was used as a negative control. Mortality was registered after 24h of exposure and lethal doses were calculated using the logit generalized linear model implemented in R. Bioassays were repeated at least three times on different days with mortality ranging between 10 and 95%. Preliminary results indicate that the yeast-encapsulated orange oil was effective (LD_{50} < 50 mg·L^{-1}) against all five mosquito colonies, regardless of their species, geographic origin or resistance phenotype for chemical insecticides. The LD_{50} values for *A. aegypti* (8.6 - 14.9 mg·L^{-1}) are consistently lower than those observed for *A. albopictus* (32.7 - 33.3 mg·L^{-1}). The low variation of larvicide activity among *A. aegypti* strains with different insecticide resistance phenotypes indicate a low probability of cross-resistance between the yeast-encapsulated orange oil and chemical insecticides, such as organophosphates and pyrethroids.

775

COMPARING THE ENTOMOLOGICAL IMPACT OF A NOVEL MALARIA VECTOR CONTROL INTERVENTION USING HUMAN LANDING CATCH VERSUS CDC LIGHT TRAPS

Welbeck A. Oumbouke[1], Eleanore D. Sternberg[2], Antoine M. Barrreaux[2], Alphonsine A. Koffi[3], Ludovic P. Alou[3], Jackie Cook[4], Matthew B. Thomas[2], Raphael N'Guessan[1]

[1]*Institut Pierre Richet/London School of Hygiene & Tropical Medicine, Bouake/Cote d'Ivoire, Côte D'Ivoire,* [2]*Department of Entomology and Center for Infectious Disease Dynamics, The Pennsylvania State University, University Park, PA, United States,* [3]*Institut Pierre Richet/Institut National de santé Publique (INSP), Bouake/Cote d'Ivoire, Côte D'Ivoire,* [4]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Human landing catches (HLCs) are currently the gold standard method to determine vector human biting rate (HBR), which is a key measure for assessing the impact of vector control efforts. However, a range of issues associated with the HLC method has led to the development of alternative methods, including the Centers for Disease Control and Prevention (CDC) light traps. Although this sampling method has been designed to perform comparably to HLC, evidence on whether this technique can be used as a proxy for HLC remains inconclusive. The current study utilizes data from a 40-village cluster randomized controlled trial in central Côte d'Ivoire to compare the performance of HLC vs CDC light traps. The trial has been evaluating the impact of household screening plus insecticide-treated eave tubes on mosquito density and malaria transmission, compared to a control arm in which the village clusters have LLINs alone. Exposure to mosquitoes was measured for two years in both study arms using HLC and CDC light traps. Indoor sampling by HLC was done every month for one night in four randomly selected houses per village. Indoor sampling by CDC traps was done every other month in 12 randomly selected houses per village. Mean indoor mosquito densities measured with each sampling method will be compared between study arms, and the correlation between both sampling methods for entomological indicators (mosquito density and entomological inoculation rate) will be assessed. Temporal changes in mosquito densities and species composition will also be estimated and compared for each sampling method. Findings from the study will provide evidence on whether CDC light traps can be used as a reliable surrogate for HLC in trials of new vector control tools.

776

RISK OF TRANSMISSION AND THE INSECTICIDE SUSCEPTIBILITY STATUS OF THE POTENTIAL VECTORS OF YELLOW FEVER IN THE NORTHERN, UPPER EAST AND UPPER WEST REGIONS OF GHANA

Millicent Captain-Esoah[1], Philip K. Baidoo[2], Samuel K. Dadzie[3], Joseph Chabi[4], Dorothy Obuobi[4], Godwin K. Amlalo[4], Chrysantus Kubio[5], Francis B. Veriegh[6], Martin N. Donkor[7], Sampson A. Abagale[7], Kwadwo K. Frempong[3], Daniel A. Boakye[3]

[1]*Department of Applied Biology, University for Development Studies, Navrongo, Ghana,* [2]*Department of Theoretical and Applied Biology, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana,* [3]*Department of Parasitology, Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Accra, Ghana,* [4]*Vestergaard NMIMR Vector Labs, Noguchi Memorial Institute for Medical Research, Legon, Accra, Ghana,* [5]*Ghana Health Service, Karaga District Health Directorate, Northern Region, Karaga, Ghana,* [6]*Center for Scientific and Industrial Research, Water Research, Accra, Ghana,* [7]*Department of Applied Chemistry and Biochemistry, University for Development Studies, Navrongo, Ghana*

Yellow fever (YF) is an arboviral disease transmitted by *Aedes* mosquitoes. Ghana reported YF cases in Northern part in 2011 and 2016 with twelve people infected and three deaths. This study is to assess the ecological and entomological risk in the transmission of YF within affected areas. Hundred houses were selected from Bolgatanga, Damongo, and Nadowli using stratified sampling. This was done both in the dry and wet seasons for 16 months in 2015 and 2016. Mosquito larvae were collected from indoor and outdoor containers within and around selected houses. The WHO transmission risk indices was used to assess the likelihood of transmission in study sites. Knockdown resistance gene mutation was identified in 200 *Ae. aegypti* mosquitoes using PCR. A total of 8,768 mosquitoes were collected from all the three study areas with *Aedes* spp being 6,630 (76 %). Out of the *Aedes* spp., *Aedes aegypti* formed 97 %, *Aedes vittatus* 2.8 %, and *Aedes simpsoni* 0.2 %. All the areas have been identified as high risk by larval indices and man-vector contact rates. The density of *Ae. aegypti* was conducive to promote an outbreak of YF if the virus is introduced. All the *Aedes aegypti* mosquitoes tested from Bolgatanga area showed a suspected resistance to deltamethrin, permethrin and propoxur with mortalities >90%. Out of 200 *Aedes aegypti*, 130 (65%) were found with *Kdr* gene mutation. Community-wide surveillance programmes should be implemented in all the study communities to monitor insecticide resistance and prevent future outbreaks.

777

EFFECT OF IVERMECTIN ON FERTILITY FECUNDITY AND MORTALITY OF *ANOPHELES ARABIENSIS* FED ON TREATED HUMANS

Wondemeneh Mekuriaw[1], Meshesha Balkew[2], Delenasaw Yewhalaw[3], Adugna Woyessa[1], Fekadu Massebo[4]

[1]*Ethiopian Public Health Institute, Addis Ababa, Ethiopia,* [2]*PMI/Abt, Addis Ababa, Ethiopia,* [3]*Tropical and Infectious Disease Research Center, Jimma University, Jimma, Ethiopia,* [4]*Department of Biological Sciences, Arba Minch University, Arba Minch, Ethiopia*

Malaria is a disease transmitted by female *Anopheles* mosquitoes. The control program mainly relay on vector control using insecticides. However, insecticide resistance is widely spreading in vector populations, which might affect control programs. Ivermectin based vector control approaches are getting attention to control the resistant malaria vectors either by targeting humans or animals. Hence, the aim of this study was to assess the residual or delayed effect of administering a single oral dose of ivermectin to humans on survival, fecundity and fertility of *Anopheles arabiensis*. Six volunteer males with age range between 25-40 years and weight ranges 64-72 Kg were recruited after receiving informed consent. Volunteers were assigned randomly either treatment or control using lottery method. Four of them received a recommended single oral dose

of 12mg ivermectin and the other two individual did not receive the drug and were used as control. There was no significant variation in mortality rate of *An. arabisensis* fed on ivermectin group between day 1 and day 4 (P = 0.73). More *An. arabiensis* were died on day one post ingestion of ivermectin compared to day 7, 10, and 13 feedings (P < 0.001). The mean mortality of mosquitoes fed on treatment group at day 4 was significantly higher compared day 7, day 10, day 13 and control (P < 0.01). The mean survival day of mosquitoes fed on day 1 was 2.1 days, while those fed on day 4 survived 4.0 days. Anopheles mosquitoes fed on treatment group at day 7 produced lower number of eggs than those fed on day 10, day 13 and control. However, the difference was no significant between day 10, day 13 and control. The significant effect of ivermectin on fertility of mosquitoes was observed on day 7 post ivermectin treatment. In conclusion, a single oral dose of ivermectin induced significant mortality for seven days and reduced fecundity and fertility of *An. arabiensis* even after day 7 of administration. And it is recommended to conduct study on the effect of ivermectin on insecticide resistant mosquito population before public use for malaria control.

778

POTENTIAL DISTRIBUTION OF *ANOPHELES ARABIENSIS* IN THE AMERICAN NEOTROPICS

Juan C. Hernandez, Mariano Altamiranda-Saavedra, Margarita M. Correa

Grupo de Microbiología Molecular, Escuela de Microbiología, Universidad de Antioquia, Medellin, Colombia

Mosquitoes are well-known biological invaders able to colonize areas with environmental suitability for survival. One of the most important invasions in the context of malaria epidemiology was that of *Anopheles arabiensis* in Brazil. Therefore, this work estimated the fundamental niche of *An. arabiensis* to determine its potential distribution in the American Neotropics. Records of species occurrence and bioclimatic layers (WorldClim v2.0 ~5Km) were used. Bioclimatic layers were delimited to the area accessible to the species (M), corresponding to natural ecoregions. A potential distribution model was designed using maximum entropy algorithm in MaxEnt, defining the parameters of the model with the Akaike information criterion (AIC). The result was validated by applying the partial ROC test in Nichetoolbox and the model was reclassified in a binary map. In general, the results indicate a wide potential distribution of *An. arabiensis* in the American neotropics, with exception of Sierra Madre in Mexico and the Andean mountain range in western South America. These results are in accordance with the wide range distribution, adaptability and invasion capacity, characteristic of this species. Knowledge of suitable areas for *An. arabiensis* provides the information for the design of preventive measures in the possible event of reemergence and propagation of this vector in the Americas.

779

PRELIMINARY ENTOMOLOGICAL FINDINGS FROM ROUTINE MONITORING OF MALARIA VECTOR POPULATION IN FOUR SENTINEL SITES IN LIBERIA, WEST AFRICA

Ibrahima Baber[1], Agnes Nador[2], Chrispin Williams[2], Tuwuyor Belleh[1], Paye Nyansaiye[2], Julius Teahton[3], Harris Momo[4], Mamadou O. Diallo[5], Jessica Kafuko[6], Tiffany Clark[7], Aklilu Seyoum[7], Peter Obenauer[8], Yemane Yihdego[9], Jennifer Armistead[10]

[1]*U.S. President's Malaria Initiative (PMI) VectorLink (VL) Project, Abt Associates Inc., Monrovia, Liberia,* [2]*National Malaria Control Program, Ministry of Health, Monrovia, Liberia,* [3]*National Public Health Institute of Liberia (NPHIL), Ministry of Health, Monrovia, Liberia,* [4]*University of Liberia, Faculty of Sciences, Monrovia, Liberia,* [5]*U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States,* [6]*U.S. President's Malaria Initiative, U.S. Agency for International Development (USAID), Monrovia, Liberia,* [7]*PMI VectorLink (VL) Project, Abt Associates Inc., Rockville, MD, United States,* [8]*PMI, Navy and Marine Corps Public Health Center Detachment, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States,* [9]*PMI VectorLink (VL) Project, Abt Associates Inc., Accra, Ghana,* [10]*PMI, United States Agency for International Development, Washington, DC, United States*

Mosquito surveillance was conducted from 2015 to 2018 to investigate malaria vectors in different zones in Liberia. Data were collected monthly (pyrethrum spray catches [PSC] and Centers for Disease Control and Prevention light traps) or bimonthly (human landing catches [HLC]) from four sentinel sites: Tomato Camp (Northern hinterland), Jeneta (Central hinterland), Frank Town and Bokay Town (coastal area). All are rural and non-irrigated areas with malaria prevalence of 52% - 62%. *Anopheles gambiae* s.l. was the predominant species collected across all sites (95%; 9525/10017), with *An. funestus* comprising 5% (492/10017) of the total collection. A total of 5758 *An. gambiae* s.l. were collected using PSC with the following site distribution: Frank Town (35%), Jeneta (30%), Tomato Camp (33%), and Bokay Town (2%). A greater proportion of *An. gambiae* s.l. were collected indoors (79%; 1535/1943) compared to outdoors (21%; 408/1943) using CDC light traps, however the outdoor traps were not baited. Using HLC, a higher number of *An. gambiae* s.l. were collected trying to bite outdoors (57%; 1047/1824) compared to those caught indoors (43%; 777/1824). The highest indoor human biting rates (HBRs) were reported in Tomato Camp (14 bites/person/night) and Frank Town (10 bites/person/night). The highest outdoor HBRs were observed in Jeneta (17/person/night) and Frank Town (13/person/night). *An. gambiae* s.l. sporozoite rates as determined by *Plasmodium* circumsporozoite enzyme-linked immunosorbent assay were 5.4% (107/1999) in Tomato Camp, 2.6% (49/1,863) in Frank Town, and 2.7% (46/1698) in Jeneta. The high densities and sporozoite infection rates of *An. gambiae* s.l. indicate continued malaria transmission risk and the need to scale up vector control interventions, mainly optimization of access to long-lasting insecticide treated bed nets, to improve community-wide protection from indoor exposure to infective mosquito bites.

780

SEX-SPECIFIC RESPONSES OF *ANOPHELES GAMBIAE* MOSQUITOES TO A MOSQUITO-BORNE ALPHAVIRUS INFECTION

Karen Kemirembe, Jason Rasgon

The Pennsylvania State University, University Park, PA, United States

In humans, hormone- related sex differences dictate various health aspects. For example, they affect how we metabolize medications, sex-specific treatment outcomes, and disease symptoms. In mosquitoes, sex differences are integral in important aspects of their biology; such as female blood-feeding, reproduction, and pathogen transmission making females, and not the males, the primary focus of most research. Male mosquitoes, in contrast, only feed on sugar. Because male mosquitoes can acquire some virus pathogens from their infected mothers by vertical transmission and pass these on to their female counterparts during mating, it is important not to ignore their potential role in disease transmission. Since female mosquitoes are more likely to encounter viral pathogens during blood feeding, we hypothesize that there will be sex-specific differences in the response of mosquitoes to pathogen infection. My research therefore aims to compare responses of male and female *Anopheles gambiae* mosquitoes to a mosquito- borne alphavirus (O'Nyong Nyong Virus [ONNV]). Results on survival comparisons, within- host virus multiplication, modes of transmission will be discussed. Experiments on sex-specific transcriptional differences upon ONNV infection are also underway. My results will inform on the overlooked possible contributions of male mosquitoes to virus persistence in the environment, help inform research efforts to use male mosquitoes, rather than just the females, as tools to reduce mosquito borne infections, and help predict the potential drawbacks of recently developed techniques such as mosquito sex ratio distortion for controlling vector-borne diseases.

781

ENHANCED SURVEILLANCE FOR DENGUE, ZIKA AND CHIKUNGUNYA IN THE SOLOMON ISLANDS

Tanya Russell[1], Albino Bobogare[2], David MacLaren[1], Emma McBryde[1], Paul Horwood[1], Tom Burkot[1]

[1]*James Cook University, Cairns, QLD, Australia,* [2]*National Vector Borne Disease Control Program, Honiara, Solomon Islands*

The transmission of dengue has been increasing at an alarming rate, more than doubling in the Western Pacific Region since 2008. At the same time, Zika and chikungunya have been emerging, but little is known about transmission in the Western Pacific region. Enhanced surveillance is essential to contain these threats and to respond rapidly to outbreaks. We assessed exposure to arboviruses including dengue, Zika and chikungunya, in the Solomon Islands by a cross-sectional serosurvey with a concurrent questionnaire to determine risk factors, fever histories (including malaria diagnosis) and potential dispersal though travel histories. The survey sampled almost 2400 people across at 23 villages in 4 provinces of the Solomon Islands including both the national and two provincial capitals as well rural villages. Summarised results detailing the antibody prevalence and risk factors of dengue, Zika, chikungunya and Ross River viruses will be presented together with information on the distribution of *Aedes aegypti* and *Ae albopictus*. The study population was also highly mobile with frequent domestic and international travel reported. This has implications for the spread of these important human viruses and the need for effective national and regional surveillance systems to improve regional health security.

782

MALARIA TRANSMISSION PROFILE ACROSS BENIN DEPARTMENTS: AN ESSENTIAL ELEMENT FOR BETTER PLANNING OF VECTOR CONTROL INTERVENTIONS

Filemon Tokponnon

National Malaria Control Program, Cotonou, Benin

Entomological surveillance in Benin has historically been limited to zones where indoor residual spraying is performed or where long-standing sentinel surveillance sites exist. However, significant geographical surveillance gaps exist. The National Malaria Control Program (NMCP) assessed population dynamics of *Anopheles* vectors and malaria transmission in each of Benin's 12 departments to generate an entomological profile across Benin during the rainy season. The study was carried out in two communes per department (24/77 communes) chosen to ensure diverse geographic and ecological scope. We selected two villages per commune and four households (HH) per village to collect mosquitoes using nighttime Human Landing Catches (HLCs). In each HH, an indoor and outdoor HLC session occurred between 7pm-7am for two consecutive nights during one of the months between July-September 2017. Captured *Anopheles* were identified and ovaries were dissected to determine parity. Heads and thoraces were tested for sporozoites of *P. falciparum* by ELISA. The Entomological Inoculation Rate (EIR) was calculated as the product of mosquito bite rate and sporozoite index. Bite rates from *An. gambiae s.l.,* the main vector identified in this study, varied considerably from one commune to another. Analyses revealed an average sporozoite infection index of 3.5%. The EIR ranged from 0.02 infectious bites (ib) per human per night in the departments of Ouémé and Plateau to 1.66 ib/human/night in Collines. According to the scale of transmission level, Avrankou, Sakété and Nikki are areas of low transmission (0<EIR<3 ib/human/year), Adjarra, Adja Ouèrè, Zè, Toffo, Bopa, Pehunco, Pèrèrè and Kandi are medium transmission (3<EIR<30 ib/human/year), and other districts are high transmission (EIR> 30 ib/human/year). The study showed the heterogeneous and diverse nature of malaria transmission in Benin that is not readily apparent when only assessing entomological surveillance from sentinel sites. Moving forward, NMCP will use the results of this study to stratify and plan vector control interventions in districts with high EIRs to better protect populations most at risk.

783

CONTRIBUTION OF INSECTICIDE TREATED MOSQUITO NETS DISTRIBUTION IN PRIMARY SCHOOLS IN MAINTAINING HOUSEHOLD COVERAGE, ATLANTIC DEPARTMENT, BENIN, 2018

Richard Dossou Yovo

[1]*Accelerating the Reduction of Malaria Mortality and Morbidity Project (ARM[3]), Medical Care Development International, Cotonou, Benin, Cotonou, Benin*

To maintain household (HH) coverage of insecticide-treated mosquito nets (ITN), WHO recommends continuous ITN distribution in schools and health facilities in addition to mass campaigns. In July 2018, eight months after a mass ITN campaign, Benin piloted ITN distribution in 681 Atlantique Department public schools; 36,557 and 19,512 ITNs were distributed to each CI (6-year-old) and CM2 (11-year-old) student, respectively. Pregnant women and children <1 year old continued to receive ITNs at routine health visits. To assess impact on HH coverage, surveys were performed before (December 2017) and after (September 2018) school distribution in 475 HH in Atlantique Department where school ITN distribution occurred and in Zou Department where no school distribution occurred. HH were recruited using stratified two stage cluster sampling. Departments were divided into communes. In each commune, 2-3 villages were randomly selected with the probability of selection proportional to village size for a total of 19 villages; 25 HH were randomly selected per village. Data analyses were performed with SPSS 20. Adjusted Pearson Chi2 tests to account for clustering were used to compare proportions with 95% confidence level. Most HH were in rural areas (Atlantique: 79%, Zou: 89%); 65.9% (95% CI: 61.6, 70.2) and 62.5% (95% CI: 58.14, 66.85) of HH in Atlantique and Zou, respectively, had ≥1 child enrolled in primary school. In both departments, >75% of HH had ≥1 ITN at baseline (Atlantique: 78.7% [95% CI: 75.0, 82.4, Zou: 80.6% [95% CI: 77.0, 84.2] and <50% had ≥1 ITN for every two people (Atlantique: 41.8% [95% CI: 37.4, 46.2], Zou: 45.7% [95% CI: 41.2, 50.2]). After school distribution, the proportion of HH with ≥1 ITN remained stable compared to baseline in Atlantique (from 79% to 78%) but decreased in Zou (from 88% to 81%) (P = 0.02). The proportion of HH with ≥1 ITN for two people remained stable in Atlantique (from 42% to 42%) (P=0.89) and Zou (from 48% to 46%) (P=0.09). School ITN distribution can play a role in maintaining HH ITN coverage. Further research is needed to evaluate cost-effectiveness of continuous distribution channels in combination with other strategies.

784

DIVERGENCES IN BLOOD-FEEDING AND RESTING BEHAVIORS OF *ANOPHELES GAMBIAE* AND TRANSMISSION OF MALARIA AND LYMPHATIC FILARIASIS IN RICE GROWING AREAS IN CÔTE D'IVOIRE

Julien B. Zahouli[1], Aboulaye Méité[2], Benjamin G. Koudou[1], Jürg Utzinger[3]

[1]*Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire,* [2]*Programme National de Lutte contre les Schistomiases, Geo helminthiases et Filariose, Abidjan, Côte D'Ivoire,* [3]*Swiss Tropical and Public Health Institute, Basel, Switzerland*

Anopheles gambiae females' behavior patterns during their gonotrophic cycles are crucial for the transmission of malaria and lymphatic filariasis, and vector control success. We assessed blood-feeding and resting behaviors of *An. gambiae* and the transmission of *Plasmodium falciparum* and *Wuchereria bancrofti* along a rural-suburban gradient in irrigated rice growing areas in Côte d'Ivoire. Mosquitoes were collected indoor and outdoor using light-traps, man-nights and pyrethroid sprays in rural and suburban areas. The ovaries and salivary glands of *An. gambiae* females were dissected. *P. falciparum* and *W. bancrofti* were identified using PCR (Polymerase Chain Reaction). *An. gambiae* was the predominant species, representing 97.4% in suburban and 81.5% in rural areas. Biting rates significantly correlated with rice field landscape development stages and peaked during transplanting and tillering. Daily host-seeking cycles

showed that the biting rates increased gradually from 6 p.m., reached peaks around midnight and decreased progressively to reach minimums at 6 a.m. in all areas. However, biting and resting behaviors were indoor-centered in rural and house-independent in suburban areas: endophagic rate and indoor resting density were 69.4% (n = 4,798) of 14.9 females/bedroom/day (f/b/d) in rural, and 49.3% (n = 6,775) and 2.9 f/b/d in suburban areas, respectively. The parturity rates were estimated at 84.5% in suburban and 75.8% in rural areas. *P. falciparium* infection rates and inoculation entomological rates were estimated at 8.1% and 6.4 infected bites/person/night (ib/p/n) in rural, and 6.6% and 6.5 ib/p/n in suburban areas. *W. bancrofti* infection rates and average loads were of 0.53% and 1.86 L3/infective female (L3/if) in suburban, and 0.34% and 2.0 L3/if in rural areas, respectively. Tendency of *An. gambiae* females to change their blood-feeding and resting behaviors across an urbanization level may support malaria and lymphatic filariasis transmission and compromise current vector control strategies based on ITNs (Insecticide-Treated Nets) and IRS (Indoor Residual Spray). Integrated vector management should be required.

785

IMPACTS OF LARVA-ACQUIRED *AEDES AEGYPTI* MICROBIOTA ON VECTOR COMPETENCE FOR ZIKA VIRUS

William Louie, Lark L. Coffey

University of California Davis, Davis, CA, United States

The mosquito microbiome is an important factor shaping the ability of a mosquito to transmit arboviruses like Zika virus (ZIKV), termed vector competence. Proposed mechanisms for microbial influence on vector competence include but are not limited to priming of the mosquito immune system. However, our understanding of the scale and variability of microbiome-vector interactions remains in its infancy. Because mosquitoes initially acquire microbes from their aqueous environment as larvae, and a significant fraction of larvae-derived microbiota persist in the adult stage, it is expected that mosquitoes with increased microbial exposure as larvae become less competent vectors. Moreover, higher observed transmission rates by laboratory-colonized mosquitoes relative to field-caught mosquitoes, historically attributed to mosquito genetic bottlenecking, may also be explained by reduced microbial exposure in laboratory settings. The goal of this project is to determine the impacts of bacterial microbiota acquired during larval development on ZIKV vector competence in *Aedes aegypti*, the primary ZIKV vector worldwide. We observed interesting phenotypic differences in mosquitoes reared in water with reduced microbial diversity, such as delayed pupation time and darkening of fourth-instar larval bodies. Upon exposure to a ZIKV-spiked bloodmeal, 97% of these mosquitoes became ZIKV-infected while less than 40% of mosquitoes reared in microbe-rich stagnant water became ZIKV-infected. These preliminary results suggest that microbial exposure during the larval phase of development in *Aedes aegypti* mosquitoes confers resistance to ZIKV infection.

786

CHANGING EPIDEMIOLOGICAL PATTERN OF VISCERAL LEISHMANIASIS IN NEPAL

Lila Bikram Thapa[1], Surendra Uranw[2], Bibek Kumar Lal[1]

[1]*Ministry of Health and Population, Kathmandu, Nepal,* [2]*Tropical and Infectious Disease Centre/B.P. Koirala Institute of Health Sciences, Dharan, Nepal, Nepal*

On the Indian subcontinent, visceral leishmaniasis (VL) is targeted for elimination as a public health problem by 2017. Nepal has achieved the elimination target at district level in 2013 and has been sustained the situation since then. Recently, we conducted a field surveys in non-program hilly districts in Nepal where increasing number of VL cases have been persistently reported since 2000. A house-to-house survey in 14 villages from eight hilly districts documented retrospectively 54 cases of VL, predominantly males, mostly pediatric cases who were reported in the last five years. Anti-Leishmania antibodies were found in 22/23 past-VL cases, in 40/416 (9.6%) persons without VL and in 12/155 (7.7%) domestic animals. An age- and sex-matched case-control study showed that exposure to known VL-endemic areas was no risk factor for VL, but having a VL case in the neighborhood was. SSU-rDNA PCR for Leishmania sp. was positive in 24 (5%) of the human, in 18 (12%) of the animal samples and in 16 (14%) bloodfed female *Phlebotomus argentipes* sand flies. *L. donovani* was confirmed in two asymptomatic individuals and in one sand fly through hsp70-based sequencing. This study proves that there is indeed ongoing local transmission of *Leishmania donovani* in areas at an altitude above 600 meters, districts considered hitherto non-endemic for VL. This geographical expansion of cases and ongoing local transmission could challenge the aim of the VL elimination program in Nepal. Hence, policy makers should give a high priority in expanding active surveillance and control activities to achieve the realistic goal.

787

NOSOI: TRANSMISSION CHAIN SIMULATOR IMPLEMENTING WITHIN-HOST DYNAMICS TO LEVERAGE VECTOR COMPETENCE DATA

Sebastian Lequime[1], Paul Bastide[1], Simon Dellicour[2], Albin Fontaine[3], Guy Baele[1], Philippe Lemey[1]

[1]*KU Leuven, Leuven, Belgium,* [2]*Université Libre de Bruxelles, Brussels, Belgium,* [3]*Institut de Recherche Biomédicale des Armées, Marseille, France*

Vector competence (VC) defines the intrinsic ability of a vector to carry and transmit a pathogen. VC is usually scored experimentally as a prevalence of infected and infectious vectors at given times post-pathogen exposure. Each year, numerous experimental studies aim to evaluate vector species or local population's competence for vector-borne pathogens, ultimately intending to understand epidemiology and assess local risk of transmission for potentially introduced vector-borne pathogens. These experimental data however usually remain purely descriptive and poorly reflect the dynamic nature of VC. Thank to the estimation of within-host dynamics parameters when performing vector-competence assays, combined with the use of epidemiological model, vector competence studies can translate VC dynamic changes into their epidemiological consequences. Such modelling efforts are yet to become conventional: epidemiological modeling rarely consider within-host dynamics, usually relies on non-trivial mathematics and very few authors even share the practical implementation (i.e. code) of their models. To address this issue, we present Nosoi, a stochastic agent-based transmission chain simulator specifically designed to integrate within-host dynamics in a flexible framework. Nosoi is open-source and available as a R package. A series of tutorials is available on Nosoi's website (https://slequime.github.io/nosoi/), one of which is intended for vector competence studies, specifically designed to guide the user on how to use the simulator, tune it to its needs and visualize its output. Nosoi allows for user-set models of various level of complexity (including inter-individual variations, geography or the influence of other covariates), tailoring them to be as close as possible to local settings based on previous knowledge, thereby leveraging experimentally acquired data into epidemiological insights for vector-borne diseases.

Serosurveys published following major outbreaks of Zika virus (ZIKV) have so far shown a high level of seroprevalence from samples collected within 12 months of the first confirmed case. A common assumption is that ZIKV infection confers long-term protection against reinfection, preventing ZIKV from re-emerging in previously affected areas for many years. However, the long-term immune response to ZIKV following an outbreak remains poorly documented. We compared results from eight serological surveys, with sample sizes ranging from 49 to 700, before and after known ZIKV outbreaks in the Pacific region: five from cross-sectional studies of schoolchildren and the general population in French Polynesia over a seven-year period; and three from a longitudinal cohort in Fiji over a four-year period. We found strong evidence of a decline in seroprevalence in both countries over a two-year period following first reported ZIKV transmission. In the cohort in Fiji, there was also a significant decline in antibody titres against ZIKV. However, the decline in seroprevalence was concentrated in adults, while high seroprevalence persisted in children. To our knowledge, our study is the first to investigate long-term seroprevalence patterns and antibody dynamics following the introduction of ZIKV. Given that ZIKV outbreaks in Latin America were first reported 2-3 years after the outbreak in French Polynesia, findings from this study could be an early indication of what might subsequently be observed in Latin America. Several modelling studies have suggested that the ZIKV epidemic is over in countries affected by the recent epidemic. Our results show that long-term ZIKV neutralization antibody levels can wane substantially in adults following an initial outbreak; if this leads to reduced herd immunity to ZIKV, the potential for future re-emergence of infection may need to be reconsidered.

DETERMINING ENTOMOLOGICAL DRIVERS OF MALARIA TRANSMISSION IN ENDEMIC REGIONS IN NAMIBIA

Iitula Iitula[1], Stark T. Katokele[1], Deodatus Maliti[1], Ophilia Lukubwe[1], Tabeth Mwema[2], Rosali Joseph[2], Dennis Walusimbi[3], Sheila Ogoma[3], Elodie Vajda[4], Neil Lobo[5], Tara Seethaler[3], Deepa Pindolia[3], George Shirreff[3], Joseph Zvoushoma[3], Ayokunle Abogan[3], Charlotte Dolenz[3], Allison Tatarsky[4], Yasmin Williams[4], Cara Smith-Gueye[4], Davis Mumbengegwi[2], Petrina Uusiku[1]

[1]*National Vector-borne Disease Control Programme, Windhoek, Namibia,* [2]*University of Namibia, Windhoek, Namibia,* [3]*Clinton Health Access Initiative, Boston, MA, United States,* [4]*University of California San Francisco, San Francisco, CA, United States,* [5]*University of Notre Dame, Notre Dame, IN, United States*

Despite 85.5% coverage of indoor residual spraying (IRS) and improved case management, Namibia has seen a steady rise of the malaria incidence from 1.4 cases per 1000 population in 2012 to 14.8 cases per 1000 population in 2018. Transmission is characterized by a series of annual epidemics associated with seasonal heavy rains, especially in the northern districts of the country. In order to reach the goal of eliminating malaria by 2022 in Namibia, the National Vector-borne Diseases Control Programme (NVDCP) sought to investigate key entomological determinants that could be driving malaria transmission in priority regions. Entomological surveillance was conducted in 9 sentinel sites in the northern regions of the country between March and June of 2018 and 2019. Human landing catch and pyrethrum spray catch mosquito sampling methods were used to determine the malaria vector species composition, their temporal and geographical distribution, as well as the biting and resting behavior. Furthermore, behavioral interactions between humans and mosquitoes were measured based on the risk of exposure of humans to infectious bites by comparing the time humans are likely to be indoors under bed nets. Susceptibility of wild mosquito populations to insecticides used in IRS was evaluated. Molecular assays revealed that approximately equivalent numbers of *Anopheles arabiensis* and *An. gambiae* sensu stricto were found across the sites. Approximately 75% of the bites occurred outdoors throughout the night. In addition, resistance to deltamethrin and DDT was suspected or confirmed in two out of the nine sentinel sites prompting the NVDCP to introduce Actellic 300CS for IRS in some regions. This programmatic evaluation highlights the significance of determining the change in malaria vector populations, opportunities to understand the efficacy and limitations of vector control interventions, and the use of entomological data to better target interventions and reduce malaria transmission.

USING LIVE CATCHES OF MOSQUITOES AS A TOOL TO ASSESS MALARIA TRANSMISSION IN ONE VILLAGE OF MALI: COMMUNITY ACCEPTANCE AND EFFICACY

Daman Sylla[1], Adama Sacko[1], Jen C.C. Hume[2], Abdrahamane Fofana[1], Emily Higbee[2], Boubacar Coulibaly[1], Makan Camara[1], Lakamy Sylla[1], Salifou Kone[1], Gaoussou Fofana[1], Moribo Coulibaly[1], Moridie Sidibe[1], Karim Sawadogo[1], Cheick O. Sanogo[1], Sale Sidibe[1], Chata Doumbia[1], Boubacar Tembely[1], Issaka Sagara[1], Jennifer Kwan[2], Sekou F. Traore[1], Patrick E. Duffy[2], Mamadou B. Coulibaly[1]

[1]*MRTC/USTTB, Bamako, Mali,* [2]*National Institute of Allergy and Infectious Diseases/National Institutes of Health, Bethesda, MD, United States*

Understanding malaria transmission is key for the implementation of certain types of malaria prevention and control strategies such as vaccines that interrupt malaria transmission (VIMTs). Many tools are used to measure malaria transmission, however, there are very few data on the use of large scale live catches of mosquitoes for that purpose. Here we measure malaria infection rates using live catches of mosquitoes collected from human dwellings. Every month a team of 4 technicians and 32 guides collected in 63 compounds comprising 503 huts in Bancoumana village. From March 2018 to February 2019, *Anopheles* mosquitoes were collected using mouth aspirators in a number of huts varying from 372 to 494, for a total of 5267 hut collections. Mosquitoes were allowed to rest in a field insectary for seven days before dissection. The survival to dissection for oocyst detection, the percent infected (as measured by oocysts), were determined as well as the average mosquito densities per hut by month. 95% of the hut owners consented for mosquito collection. Overall, 3,447 *Anopheles* were collected ranging from 5 in February to 1257 in September with a mean of 287 mosquitoes per month. The monthly mosquito density per hut ranged from 2.9 in September to 0.01 in February with a mean of 0.7 (SD=1.0). The mean survival rate was 76% (N=3447) ranging from 40% (N=5) in February to 100% (N=6) in January. The mean infected rate was 2.05% [0-10] (N=2625). In conclusion, the live catches seem to be well accepted in the community. This lays the groundwork for exploring such a tool for measuring transmission before and after implementing a VIMT or any other transmission blocking interventions.

791

EVALUATION OF THE BLOOD FEEDING STATUS AND PARITY IN *AEDES AEGYPTI* IN IQUITOS, PERU

Helvio Astete

Naval Medical Research Unit-6, Iquitos, Peru

Aedes aegypti is considered the most important arboviral vector of public health concern because it can transmit arboviruses such as dengue to humans in urban environments. Female *Ae. aegypti* seek blood meals to obtain the required nutrients for egg maturation, but characteristically feed multiple times during each egg-laying cycle, allowing this species to infect multiple people after becoming infectious. For dengue virus, *Ae. aegypti* would need a minimum of 8 days after ingestion of virus to transmit to additional hosts during subsequent blood meals. Understanding the parameters associated with blood feeding behavior and parity status (a crude surrogate for mosquito age) may have more epidemiological significance than vector densities alone and allow for modeling to better understand virus transmission risks. We compared the feeding and parity status of mosquitoes collected during a double-blinded randomized cluster trial evaluating the efficacy of a mosquito spatial repellent product. Adult Prokopack aspirator collections were carried out at 2-week intervals in 26 clusters of approximately 150 households each. We collected 11,680 female *Ae. aegypti* from January 2017 to December 2018, and 69.85% (8,159) were scored for blood feeding status and dissected to determine parity status (nulliparous, parous, gravid). 58.11% of collected mosquitoes were fully engorged with fresh blood, 16.46% had partial or were digesting blood meals, and 25.43% had no blood meal. The majority of dissected female mosquitoes were parous (26.03%) and gravid (67.45%) with only 6.52% nulliparous. Blinding will not be broken until all laboratory testing and data cleaning has taken place, therefore results have not yet been analyzed for mosquito repellent efficacy. We will assess if association of frequency of blood feeding with mosquito age is affected by the spatial repellent product. If reduced transmission risk is observed, these endpoints could be used in future vector control intervention trials to evaluate novel products. Key words: Gravity, nulliparity, population structure, gonotrophic cycle.

792

EVOLUTION OF COLD TOLERANCE TRAITS IN THE INVASIVE MOSQUITO *AEDES ALBOPICTUS*

Alexandra Mushegian, Zachary Batz, Peter Armbruster

Georgetown University, Washington, DC, United States

The Asian tiger mosquito, *Aedes albopictus*, is a significant vector of arboviruses including dengue and Chikungunya. This mosquito has spread rapidly to all continents except Antarctica over the last 35 years. One of the key adaptations underlying this rapid spread is the ability to overwinter in the form of diapausing eggs, which are produced by adult females in response to changes in day length signaling impending winter. Previous results from our lab demonstrated that diapause timing in *Ae. albopictus* evolved rapidly during invasion and range expansion in eastern North America. As such, diapause timing plays an important role in determining the mosquito's abundance over space and time in temperate habitats. Given the ecological trade-offs involved in winter diapause, diapause incidence and timing are also expected to be important in determining how mosquito populations respond to ongoing global warming. We have found geographic differentiation among North American populations for thermal performance and traits expressed during diapause. We are also currently measuring diapause incidence and timing of populations collected along a latitudinal cline in the mosquito's native and introduced range (Japan and the U.S., respectively). This study recapitulates a previous study performed 10 years earlier with many populations collected from the exact same sites. Our results will be used to test the hypothesis that diapause timing and incidence have evolved in response to climatic shifts and repeated introductions. Understanding the evolutionary changes underpinning adaptation of Ae. albopictus to diverse climatic regimes will be crucial for modeling range shifts and local population dynamics of this vector under climate change.

793

EFFECT OF SUCROSE CONCENTRATION AND FASTING IN *PLASMODIUM VIVAX* EXPERIMENTAL INFECTIONS OF *NYSSORHYNCHUS* (AKA *ANOPHELES*) *DARLINGI*

James Beuzeville-Jaen[1], Carlos Tong[1], Manuela Herrera-Varela[1], Carmen Reategui[2], Joseph M. Vinetz[3], Jan E. Conn[4], Marta Moreno[5]

[1]*Laboratorio ICEMR-Amazonia, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Iquitos, Peru,* [2]*Universidad Nacional de la Amazonía Peruana, Iquitos, Peru,* [3]*Section of Infectious Diseases, Yale University School of Medicine, New Haven, CT, United States,* [4]*Wadsworth Center, New York State Department of Health, Albany, NY, United States,* [5]*Department of Infection Biology; London School of Hygiene & Tropical Medicine, London, United Kingdom*

Nyssorhynchus (AKA *Anopheles*) *darlingi*, major malaria vector in South America, was successfully colonized in 2013 in the Peruvian Amazon. Since then, *Ny. darlingi* has been used in experimental infections with *Plasmodium vivax* to study the biology of transmission (i.e. asymptomatic infections), in transmission blocking assays and in production of sporozoites for *P. vivax* liver stages experiments. Starving periods and sucrose concentration (daily sugar intake) of the adult females prior to blood feeding are of vital importance given that sugar availability has been correlated with the predisposition to feed and therefore related to the success of the parasite infection. Here, we sought to determine the effect of sucrose concentrations and starving period on development of *Plasmodium vivax* in *Ny. darlingi.* Six groups, of 60 one-day-old female mosquitoes, were fed on sugar concentrations, three of those with 5% and other three with 10%, then three starving periods were tested in each category (24, 48 and 72 h). To assess the effect of these treatments on *Plasmodium vivax* parasite development, direct membrane feeding assays were conducted and mosquito midguts dissected 7-8 days post infected blood meal. Experiments were carried out in five different times with five *P. vivax*-blood donor. A total of 924 mosquitoes were dissected an average of 185 (SE±55) mosquitoes per infection. A higher infection prevalence of 84.2% infected mosquitoes (60% - 100%) was detected in those fed on 5% sugar and 24h starving compared with other treatments. The highest infection intensity was found in a combination of 10% sugar and 48h starvation period, with an average of 72 oocyst per mosquito (0 - 424). Infection percentage was affected by sugar concentration and the oocyst density by starving treatment. This study provides valuable information about parasite development in the *vivax-darlingi* model with important implications for malaria transmission in the Amazon region.

794

THERMAL PERFORMANCE OF *AEDES AEGYPTI* AND IMPLICATIONS FOR CLIMATE CHANGE

Nina Dennington, Marissa K. Grossman, Janet Teeple, Matthew B. Thomas

The Pennsylvania State University, University Park, PA, United States

Many aspects of mosquito life history are influenced by environmental temperature. Accordingly, there is considerable concern that increases in temperature due to ongoing climate change could lead to shifts in the dynamics and distribution of vectors such as *Aedes aegypti*, with concomitant changes in the risk of transmission of diseases like dengue, Zika and yellow fever. Current mechanistic models that predict optimal temperatures for transmission tend to assume there are 'average' thermal performance curves that are representative for a given vector species. However, if there is thermal adaptation to a local environment this could create population-level differences in thermal performance, challenging the 'one size fits all' approach. In this study, we explored whether there

are population differences in thermal performance by generating thermal performance curves for five field populations of *Ae. aegypti* from Mexico, together with a standard laboratory strain. We reared these six populations at a range of temperatures between 13°C and 37°C and measured various life history traits including development time, fecundity, and adult survival. We found differences between populations in the temperature optima and the critical thermal minima and maxima, for a range of life history traits. Our results suggest that single species-level thermal performance curves might be insufficient for predicting the outcome of infectious disease transmission at the local level under conditions of climate change.

795

THE USE OF SPATIAL VIDEO GEONARRATIVES TO DESCRIBE LOCALIZED ENVIRONMENTAL RISK PATTERNS FOR ARBOVIRAL TRANSMISSION IN URBAN KENYA

Amy R. Krystosik[1], Andrew Curtis[2], Paul Mutuku[3], Sandra Bempah[2], Jayakrishnan Ajayakumar[2], Lorriane Odhiambo[4], Donal Bisanzio[5], Jenna Forsyth[6], Luti Mwashee[7], Beja Adamz[7], Francis Mutuku[3], A. Desiree LaBeaud[1]

[1]*Stanford University School of Medicine, Department of Pediatrics, Division of Infectious Disease, Stanford, CA, United States,* [2]*Kent State University, Department of Geography, GIS, Health and Hazards Lab, Kent, OH, United States,* [3]*Technical University of Mombasa, Environment and Health Sciences Department, Mombasa, Kenya,* [4]*Kent State University, College of Public Health, Kent, OH, United States,* [5]*RTI International, Washington, DC, United States,* [6]*Stanford University School of Earth, Stanford, CA, United States,* [7]*Vector borne disease control unit, Msambweni Field Laboratory, Kwale County, Kenya*

Urban arboviral disease mitigation depends on costly vector control targeted to high-risk areas which are difficult to identify. Disease ecology and epidemiology vary over space and time, requiring fine scale data on environmental and behavioral factors to evaluate disease risk. Spatial video geonarratives (SVGs) are a community based participatory method of capturing fine scale environmental data over time. We have captured 37/80 hours of SVGs from key informants (local vector control technicians, community health workers, leaders and residents) during the dry season in Ukunda (17 informants) and Likoni (20 informants), in Kwale County, Kenya, regions previously studied. Informants provided commentary on fine scale environmental risks during GPS and video recorded neighborhood walks with a technician. Using novel software, commentaries are spatialized to make risk maps. Commentary transcription and translation, and SVG mapping, and coding are ongoing (n=8/37). Using the SVGs, we will develop an index of vector-borne risk (SVG index) using contextualized environmental risks (e.g. trash and standing water) at 0.1km^2 sub-sections of known disease risk. SVG environmental risks hotspots will be compared with previously identified dengue and chikungunya exposure and *Aedes* spp. vector abundance hotspots by visual inspection and using a geographically weighted Poisson regression controlling for known confounders. Preliminary results from SVG data suggest trash clusters over space due to geographic and behavioral factors, and that there is a locally perceived connection to vector abundance in the rainy season. Informants identified breeding sites such as holes in the ground that fill with rainwater, trash—coconut shells, dump sites, plastic containers—and uncovered household containers and vegetation patches or plant types as spatial-micro risk environments. Micro-scale risk pattern identification will allow forecasting fine scale, locally informed, high-risk exposure areas and provide policy recommendations to more effectively target vector control efforts where public health resources are limited.

796

NANOTRAP PARTICLE EXTENDS THE DURATION OF DETECTABLE VENEZUELAN EQUINE ENCEPHALITIS VIRUS IN HUMAN BLOOD

Shih-Chao Lin[1], Ivan Akhrymuk[1], Monique van Hoek[1], Benjamin Lepene[2], Kylene Kehn-Hall[1]

[1]*George Mason University, Manassas, VA, United States,* [2]*Cere Nanosciences Inc., Manassas, VA, United States*

Nanotrap® (NT) particles are hydrogel microparticles developed for target analyte separation and discovery applications. NT particles consist of cross-linked N-isopropylacrylamide (NIPAm) copolymers that are functionalized with a variety of chemical affinity baits to enable broad-spectrum collection and retention of target proteins, peptides, nucleic acids, and pathogens. NT particles have been shown to capture and enrich multiple pathogens including Venezuelan equine encephalitis virus (VEEV). This study describes the practical application of the NT particle technology for improved sample stability and detection of VEEV capsid protein spiked in human plasma or whole blood at elevated temperature storage conditions. We first established the baseline of stability of VEEV capsid at different temperatures in plasma or blood and evaluated the capsid levels by western blotting. We then co-incubated magnetic NT particles and VEEV at 37ºC and 40ºC and/or 54ºC for up to 72hrs. Compared to virus without NT treatment, the duration of detectable levels of VEEV in plasma and blood were remarkably increased across all temperatures. Next, we investigated the effects of humidity on the viral stability afforded by NT particles. Our results show that the humidity levels at both 16% and 98% did not cause discernible changes in NT capability over time, suggesting the suitability to utilization of NT could be extensive. Finally, we intranasally infected C3H mice with VEEV/TC83 and tested NT efficacy in mouse blood. Our findings demonstrated that NT particles could substantially increase the detectable VEEV capsid from the blood of infected animals. Taken together, our data demonstrate the ability of NT particles to preserve VEEV capsid protein in human blood samples over time and temperature. These results have implications for the use of NT particles as a tool to preserve infectious agents in clinical samples.

797

CHIKUNGUNYA AND DENGUE VIRUS SEROPREVALENCE AMONG CHILDREN IN COASTAL AND WESTERN KENYA AND RISK FACTORS FOR EXPOSURE

Shama Cash-Goldwasser[1], Jonathan Altamirano[2], Bryson Ndenga[3], Charles Muiruri Ng'ang'a[4], Said Lipi Malumbo[4], Jael Sagina Amugongo[4], Loice Lwamba[3], Francis Denga[3], Sandra Musaki[3], Francis Mutuku[5], A. Desiree LaBeaud[2]

[1]*Stanford University, Stanford, CA, United States,* [2]*Department of Pediatrics, Division of Infectious Diseases, Stanford University, Stanford, CA, United States,* [3]*Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya,* [4]*Vector Borne Disease Control Unit, Msambweni Field Laboratory, Kwale, Kenya,* [5]*Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya*

Chikungunya virus (CHIKV) and dengue virus (DENV) are recognized as endemic causes of fever among children in Kenya, where both viruses have caused increasingly large and frequent outbreaks. These diseases are poorly controlled, partly due to a lack of systematic surveillance programs. We conducted this study to determine the degree of exposure to CHIKV and DENV as well as risk factors for exposure among children in Kenya. From 2014 - 2018, we prospectively followed a cohort of children recruited from urban and rural communities in both coastal and western Kenya. We enrolled healthy children 1 - 12 years of age and followed them every 6 months. At each visit, a blood sample was taken and demographic surveys were administered. Blood was tested by IgG ELISA for antibodies to CHIKV and DENV. Over the five years of the study, 3,521 children were tested for CHIKV and DENV antibodies. Overall, 9.8% were CHIKV seropositive and 5.5% were DENV seropositive. The respective CHIKV and DENV seroprevalences by age were: 6.7% vs 3.6% in the under 5

year age group; 11.3% vs 6.2% in the 6-11 age group; and 15.5% vs 9.6% in the 12-17 age group. Differences by age were significant for both viruses (p<0.0001). The respective CHIKV and DENV seropositivities by study site were: 9.8% and 10.8% in the rural coast; 3.8% and 4.5% in the urban coast; 21.2% and 4.8% in the rural west; and 5.3% and 2.9% in the urban west. Seroprevalence in rural sites was significantly higher than in urban sites for both viruses (p<0.0001). Our results show that exposure to CHIKV is more common than DENV across all age groups of children in Kenya, and that a significant number of children < 5 years of age are exposed to both viruses. We observed an association between rural residence and seropositivity. This is in contrast with data from other settings, where the association between urban residence and disease risk is thought to be related to the habitat preference of the mosquito genus that serves as the primary vector for both viruses. Our findings have important implications for disease prevention efforts. Multivariate analysis of risk factors for infection with CHIKV and DENV is ongoing.

798

IMMUNOLOGICAL INSIGHTS BASED ON ANTIBODY BINDING EPITOPES ON THE CHIKUNGUNYA VIRUS ENVELOPE

To identify the Chikungunya virus (CHIKV) structures that elicit a protective immune response, we have epitope mapped over 70 monoclonal antibodies (MAbs) against the CHIKV envelope glycoprotein E2/E1, using a comprehensive shotgun mutagenesis library of 910 E2/E1 alanine-scan mutants. Published studies used epitope maps to characterize broadly cross-reactive and ultrapotent neutralizing MAbs that blocked post-attachment steps, and whose binding mapped to functionally-important E2 domains A or B, suggesting that MAbs inhibit virus-host membrane fusion by preventing exposure of the E1 fusion loop. Other studies characterized MAbs that induce structural changes on E2 domains A and B. We also isolated 7 human MAbs against CHIKV E2/E1, including previously unreported cross-reactive, but non-neutralizing, MAbs against the highly conserved E1 fusion loop. Neutralizing epitopes are confined to the exposed topmost and outer surfaces of the E2/E1 trimer, providing a rationale for using the trimer for vaccine design and therapeutic MAb development. Our most potent MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), showed high-affinity binding (320 pM), and gave therapeutic and prophylactic protection in animal models up to 24 h post-exposure. Epitope mapping identified an inter-subunit conformational epitope on E2 domain A. Subsequent studies demonstrated that IM-CKV063 blocks both virus entry and virus release, and that optimal therapeutic activity required interaction of MAb Fc region with Fcγ receptor. We also used CHIKV E2/E1 mutants to map the binding site of cell adhesion molecule Mxra8, identified as an entry mediator for CHIKV, and other alphaviruses, by infectivity screens of cells targeted by CRISPR/Cas9 gene knockouts. Mxra8 enhanced virus attachment and internalization into cells, mapping suggests that Mxra8 binds to E2 A and B domains. Mxra8-Fc protein or anti-Mxra8 MAbs blocked CHIKV infection in multiple human cell types and in mice, suggesting Mxra8 as a target for therapeutics against CHIKV and other arthritogenic alphaviruses.

MAPPING AND FORECASTING CHIKUNGUNYA AT GLOBAL SCALE

Radina P. Soebiyanto[1], Assaf Anyamba[1], Bhaskar Bishnoi[1], Sarah Hutchinson[1], Mohammad Al-Hamdan[2], Muhammad Barik[2], Richard Damoah[1], Wassila Thiaw[3], Kenneth J. Linthicum[4]

[1]*NASA Goddard Space Flight Center, Greenbelt, MD, United States,* [2]*NASA Marshall Space Flight Center, Huntsville, AL, United States,* [3]*National Oceanic and Atmospheric Administration, National Centers for Environmental Predictions, Climate Prediction Center, International Desks, College Park, MD, United States,* [4]*US Department of Agriculture, Agricultural Research Service, Center for Medical, Agricultural and Veterinary Entomology, Gainesville, FL, United States*

Chikungunya has reemerged and emerged in new areas, affecting millions of people with significant economic burden, further raising concerns on preparedness for the next epidemic. A multitude of factors contribute to the (re)-emergence Chikungunya, from genetic mutation, susceptibility, travel to climate conditions. Despite these factors, suitable climate remains the background and necessary condition for an epidemic to occur. Availability of climate data allows us to continuously assess conditions suitable for chikungunya, deriving information on when, where and what is the risk for chikungunya. This information provides a tool to aid decision makers in preparedness efforts. We are developing climate-based global chikungunya risk mapping system, updated monthly and available through our CHIKRisk app. To develop the risk map, we used 1045 point-locations where chikungunya cases were reported (year 2000 - 2017), compiled from ProMED reports. 1469 chikungunya pseudo absence locations were generated while considering chikungunya seasonality in endemic areas. We used 5 climate monthly measures - land surface and air temperature, precipitation, specific humidity, soil moisture - and their derived composites (anomaly, 3-monthly, 1-month lag, etc.), a total of 90 variables. These datasets and population density were then used to calibrate machine-learning models to predict chikungunya. We found random forest model had highest accuracy in predicting locations with reported chikungunya (88.9%, 95% Confidence Interval (CI) of 86.1 - 91.2%). A forecast model was developed with air temperature and precipitation forecasts, with the model accuracy of 85.9% (95% CI of 82.9 - 88.6%). These risk maps are now produced every month and available through CHIKRisk App. The recent chikungunya outbreaks in Sudan and India were captured in both risk maps. We are validating the risk maps with reported data as we continue to compile and geo-reference chikungunya reports in 2019. Availability of these monthly risk maps can aid decision makers in making robust policies for chikungunya preparedness, prevention and control efforts.

POPULATION DIVERSITY-ALTERING MUTATIONS AS A METHOD FOR IMPROVING A LIVE-ATTENUATED CHIKUNGUNYA VIRUS VACCINE

Christopher M. Weiss, Hongwei Liu, Kasen K. Riemersma, Lark L. Coffey

University of California Davis, Davis, CA, United States

Chikungunya virus (CHIKV) is a mosquito-borne alphavirus that causes a debilitating febrile illness marked by severe polyarthritis and polyarthralgia. Over the past decade and a half, CHIKV has rapidly spread across the globe, due in part to expanded vector competence, establishing autochthonous transmission in the tropics and subtropics, including South and Central America since 2013. While several CHIKV vaccine candidates are currently being assessed for human use, none have been approved. A previously developed live-attenuated vaccine (LAV) candidate, CHIKV 181/25 (also called TSI-GSD-218), while immunogenic, was pulled from FDA phase II clinical trials after roughly 8% of vaccinees developed complications owing to virulent reversion of the LAV. The goal of this study is to improve safety of the CHIKV LAV through the inclusion of two previously-described mutability-altering substitutions in the alphavirus replicase complex, while preserving the immunogenicity afforded by CHIKV 181/25. Our vaccine candidate, CHIKV-P2.P4, demonstrated similar replication kinetics to the parental LAV with no increase in morbidity or mortality in susceptible mouse models. Unexpectedly for a purported anti-mutator candidate, deep sequencing of replicate passaged CHIKV-P2.P4 showed a slightly elevated accumulation of both synonymous and non-synonymous mutations, with expected genomic hotspots prone to greater genetic variability. However, this augmented genetic diversity did not result in the genetic reversion of CHIKV-P2.P4 at *loci* responsible for attenuating the parental CHIKV 181/25 LAV. CHIKV-P2.P4 provided sterilizing immunity

in mice challenged with an Indian Ocean Lineage CHIKV strain, and produced comparable neutralizing antibody titers to the parental LAV. Our data indicate that CHIKV-P2.P4 is highly immunogenic, but additional ongoing work is required to assess candidate safety and reconcile LAV diversification over time.

801

THE BASIC REPRODUCTION NUMBER (R_0) OF CHIKUNGUNYA IN COLOMBIA DURING 2014-2016 AND ITS CORRELATION WITH ECO-ENVIRONMENTAL FACTORS

Víctor H. Peña-García[1], Rebecca Christofferson[2]

[1]*Universidad de Antioquia, Medellín, Colombia,* [2]*Louisiana State University, Baton Rouge, LA, United States*

Chikungunya virus arrived to Colombia in 2014 into a presumed fully susceptible population. This resulted in a quick and intense spread across numerous municipalities, resulting in an epidemic that affected an estimated of 450,000 people. We wanted to analyze the eco-environmental factors associated with the spread of CHIKV that produced significant outbreaks in different municipalities. To do this, we estimated the basic reproduction number (R_0) in 85 municipalities, which jointly were responsible of the 65.6% of reported cases in Colombia. At first, we divided municipalities into higher and lower R_0 and compared both groups across 13 different environmental and ecological variables like those related to temperature, demographic, and geographical variables. These variables were analyzed by correlation analyses to confirm their association with R_0. We found that temperature-related variables are significantly related to higher R_0 while other variables like duration of outbreak and size of the urban area are inversely related to R_0. We conclude that those municipalities with high R_0 associated with high temperatures had fast growth of cases in a shorter time period (with faster cessation of outbreak transmission), resulting in fewer cases than when transmission was associated with lower (but still >1) values of R_0 where transmission was slow and steady, resulting in a higher cumulative number of cases. We propose, then, that transmission may follow a tortoise-hare model such as proposed for viremia-based transmission by Althouse and Hanely (2015). That is, slow-and-steady wins the race.

802

EVALUATION OF TWO COMMERCIALLY AVAILABLE CHIKUNGUNYA VIRUS IGM ENZYME-LINKED IMMUNOASSAY (ELISA) IN AN ENDEMIC REGION FOR CHIKUNGUNYA, DENGUE AND ZIKA VIRUSES

Mariana Kikuti[1], Laura B. Tauro[2], Patricia S. Moreira[3], Leile Camila J. Nascimento[3], Moyra M. Portilho[3], Gubio C. Soares[4], Scott C. Weaver[5], Mitermayer G. Reis[3], Uriel Kitron[6], Guilherme S. Ribeiro[4]

[1]*University of Minnesota, St. Paul, MN, United States,* [2]*Conicet-UNAM, Puerto Iguazu, Argentina,* [3]*Fundacao Oswaldo Cruz, Salvador, Brazil,* [4]*Universidade Federal da Bahia, Salvador, Brazil,* [5]*University of Texas Medical Branch, Galveston, TX, United States,* [6]*Emory University, Atlanta, GA, United States*

In order to provide appropriate clinical management, laboratory diagnostic tools are necessary to distinguish Chikungunya virus (CHIKV) infections from other febrile illness. We evaluated the diagnostic performance of the Inbios (Seattle, US) and the Euroimmun (Luebeck, Germany) CHIKV IgM ELISAs on acute- and convalescent-phase sera from 915 patients enrolled in an acute febrile illness surveillance study performed in Salvador, Brazil from Sept/2014 to Jul/2016, a period of simultaneous CHIKV, dengue (DENV), and Zika (ZIKV) virus transmission. Using a positive CHIKV RT-PCR result as the gold standard, sensitivities for acute-phase samples (collected a median of 1 day post onset of symptoms (dpos)) were 4.0% (6/149) for the Inbios IgM-ELISA and 10.3% (15/145) for the Euroimmun IgM-ELISA. Sensitivities for the convalescent-phase samples of CHIKV RT-PCR-positive patients (collected in median 19 dpos) were 92.1% (58/63) for the Inbios IgM-ELISA and 92.9% (63/65) for the Euroimmun IgM-ELISA. Among DENV RT-PCR-positive cases, specificities of the Inbios IgM-ELISA were 83.9% (26/31) in acute-phase samples and 93.3% (14/15) in convalescent-phase samples, whereas the Euroimmun IgM-ELISA specificities were 82.8% (24/29) in acute-phase samples and 83.3% (15/18) in convalescent-phase samples. Among ZIKV RT-PCR-positive cases, Inbios IgM-ELISA specificities were 92.9% (13/14) and 100% (7/7) for acute- and convalescent-phase samples, respectively, and Euroimmun IgM-ELISA specificities were 83.3% (10/12) and 87.5% (7/8), respectively. Considering patients with negative RT-PCR for all three arboviruses, the Inbios IgM-ELISA specificities were 89.1% (631/708) and 90.2% (259/287) for acute- and convalescent-phase samples, respectively, and the Euroimmun IgM-ELISA specificities were 89.5% (153/171) and 83.3% (140/168), respectively. These findings indicate an overall good sensitivity of both tests for convalescent-phase samples. However, the Euroimmun CHIKV IgM-ELISA had lower specificity than the Inbios CHIKV IgM-ELISA, which might result in a higher rate of false positive when applied in low prevalence scenarios.

803

TRANSMISSION OF CHIKUNGUNYA IN A BRAZILIAN URBAN SLUM SETTING: SEROPREVALENCE AND ASSOCIATED FACTORS

Rosangela Oliveira dos Anjos[1], Vanio André Mugabe[2], Patrícia Sousa Moreira[1], Caroline Xavier Carvalho[1], Moyra Machado Portilho[1], Gielson Almeida do Sacramento[1], Nivison Ruy Nery Junior[1], Mitermayer Galvão dos Reis[1], Uriel Kitron[3], Albert Ko[4], Federico Costa[1], Guilherme Sousa Ribeiro[1]

[1]*Oswaldo Cruz Foundation, Salvador, Brazil,* [2]*Institute of Collective Health, Federal University of Bahia, Salvador, Brazil,* [3]*Emory University, Atlanta, GA, United States,* [4]*Yale School of Public Health, New Haven, CT, United States*

Chikungunya virus (CHIKV) was first detected in Brazil in 2014, and then spread, causing outbreaks throughout the country. This study aimed to assess the prevalence and factors associated with previous CHIKV infection in a neighborhood of Salvador in which an outbreak had occurred in 2015 and to estimate the frequency of clinical disease. Between November 2016 and February 2017, 1,776 participants with age ≥ 5 years were enrolled in a cross-sectional study. We collected demographic, socioeconomic, and clinical data by interview. Serum samples were tested for CHIKV IgG antibodies by an indirect enzyme-linked immunoassay (Euroimmun). Poisson regression with robust variance was used to calculate the prevalence ratios (PR) and 95% CI adjusted for design effect. The prevalence of IgG CHIKV antibodies was 11.8% (95% CI: 9.8-13.7%). In the multivariate analyses, we found that infections were more common among individuals who were illiterate (PR: 1.62; 95% CI: 1.03-2.54), resided in unpaved streets (PR: 1.56; 95% CI: 1.12-2.16), reported a prior medical diagnosis of chikungunya (PR: 2.77; 95% CI: 1.89-4.05), and reported an episode of arthralgia (PR: 1.91; 95% CI: 1.35-2.71) and rash (PR: 1.50; 95% CI: 1.06-2.12) after January, 2015. Among the 209 patients with CHIKV IgG antibodies, 15.3% reported having fever and arthralgia after January 2015. Our findings indicate that although CHIKV caused an outbreak in Salvador in 2015, overall seroprevalance after the outbreak remains low and may not confer sufficient herd immunity to preclude additional epidemics in the near future. We also found that even within this overall poor urban slum population, there are social heterogeneity associated with the risk for CHIKV transmission. Finally, although self-reporting of symptoms was a limitation of the study, the low frequency of reported CHIKV-associated symptoms amongst those with CHIKV IgG suggest that strain or host specific differences may determine the natural history of CHIKV infection.

804

AN EMERGING THREAT TO PUBLIC HEALTH IN PERU: DETECTION OF THE MAYARO VIRUS

Miguel A. Aguilar-Luis[1], Tamara Gil Ramirez[1], Luis J. del Valle[2], Saul Levy Blitchtein[1], Wilmer Silva Caso[1], Víctor Zavaleta- Gavidia[3], Jorge Bazán-Mayra[3], Daniel Cornejo[3], Juana M. del Valle-Mendoza[1]

[1]*Investigation Center and Innovation of the Health Sciences Faculty, Universidad Peruana de Ciencias Aplicadas (UPC), Av. San Marcos cdra* [2] *Cedros de Villa, Lima, Peru,* [2]*Barcelona Research Center for Multiscale Science and Engineering, Department d' Enginyeria Quimica, EEBE, Universidad Politecnica de Catalunya (UPC), Barcelona Tech, Barcelona, Spain,* [3]*Dirección Regional de Salud de Cajamarca, Cajamarca, Peru*

Mayaro virus (MAYV; Togaviridae; Alphavirus) is emerging infectious disease and can cause health complications similar to infections caused by dengue (DENV) or Chikungunya (CHIKV) viruses. Arbovirus infections emerged in the Americas and rapidly spread, affecting millions of people from 2013–2016, establishing high-risk areas for MAYV infection. MAYV produce severe complications, such as intermittent fever, neurological complications, myocarditis, and even death. In Peru, can to be misdiagnosed as CHIKV infection due to their similarities. The aim of this study was to detect Mayaro virus in patients with febrile illnesses from endemic areas of Peru. A total of 357 patients with suspected febrile illnesses from an endemic region of North of Peru participated in this study. Clinical symptoms were assessed, and blood serum samples were collected. The resulting cDNA from each serum sample processed was amplified by PCR analysis in a LightCycler 2.0 system using primers that amplify partial regions of the nsP1 gene. There were a total of 40 (11.2 %) cases positives to MAYV. Among this, 47.5 % (n = 19) were women and 52.5 % (n = 21) were men. The populations with age groups of 18-39 years and 40-59 years were the most affected with MAYV in 37.5 % (n = 15) and 32.5 % (n = 13) respectively. The most common symptoms reported were headache with 77.5 % (n = 31), myalgia in 55.0 % (n = 22) and arthralgias in 55.0 % (n = 20) of cases positives. In conclusion, Mayaro virus is present in endemic areas of Peru, however it may be misdiagnosed as Dengue Virus, CHIKV or Zika Virus due to the similar clinical presentation. It is an important emerging disease in South America region and requires highly sensible and specific tests to make an accurate diagnosis. This virus should be included in national surveillance programmes to have an insight on its transmission, pathogenicity, virulence and local epidemiology.

805

USING BIG DATA TO MONITOR THE INTRODUCTION AND SPREAD OF CHIKUNGUNYA, EUROPE, 2017

Joacim Rocklöv[1], Yesim Tozan[2], Aditya L. Ramadona[1], Maquines O. Sewe[1], Bertrand Sudre[3], Jon Garrido[4], Chiara B. de Saint Lary[4], Wolfgang Lohr[1], Jan C. Semenza[4]

[1]*Umeå University, Umeå, Sweden,* [2]*College of Global Public Health, New York University, New York, NY, United States,* [3]*Umeå University, European Centre for Disease Prevention and Control, Stockholm, Sweden,* [4]*European Centre for Disease Prevention and Control, Stockholm, Sweden*

With regard to fully harvesting the potential of big data, public health lags behind other fields. To determine its potential, we harnessed big data (air passenger volume from international areas with active chikungunya transmission, Twitter data, and vectorial capacity estimates of *Aedes albopictus* mosquitoes) to the 2017 chikungunya outbreaks in Europe to assess the risks for virus transmission, virus importation, and short-range dispersion from the outbreak *foci*. We derived risk maps for autochthonous chikungunya transmission by combining vectorial capacity and mobility proximity estimates for the Lazio region in Italy and the Var department in France, August-October 2017. The risk areas for the outbreak in Var were identified to be located along the French and northern Spanish Mediterranean coastlines, Mallorca, and Rome in August; the risk regions for the Lazio outbreak in August included large parts of Italy and areas in France, Spain, and Greece. The size of the area at risk contracted in September and more so in October owing to less favorable climate conditions, except in the most southern region of Italy, such as the Calabria region, where the outbreak empirically continued longer in the fall. In Lazio, an analysis of the combination of vectorial capacity and mobility proximity revealed a higher transmission potential in August, with implications for targeting surveillance and outbreak control activities to this region. The largest area of risk for spread from Anzio was Rome, but the risk for spread from Rome was more widespread in the region. The areas at risk for spread in Lazio differed in August compared to September and October. We found that indicators based on voluminous and v*elocio*us data can help identify virus dispersion from outbreak *foci* and that vector abundance and vectorial capacity estimates can provide information on local climate suitability for mosquito-borne outbreaks. In contrast, more established indicators based on Wikipedia and Google Trends search strings were less timely. We found that a combination of novel and disparate datasets can be used in real time to prevent and control emerging infectious diseases.

806

SINGLE ADMINISTRATION OF LIVE-ATTENUATED TETRAVALENT DENGUE VACCINE CANDIDATE, KD-382, INDUCED LONG-LASTING (>3.5 YEARS) NEUTRALIZING ANTIBODY AGAINST ALL FOUR SEROTYPES IN DENGUE NAÏVE CYNOMOLGUS MONKEYS

Yasuhiko Shinmura[1], Masaya Yoshimura[1], Kazuhisa Kameyama[1], Kengo Sonoda[1], Sutee Yoksan[2], Kazuhiko Kimachi[1]

[1]*KM Biologics Co., Ltd., Kikuchi, Kumamoto, Japan,* [2]*Mahidol University, Bangkok, Thailand*

One of challenges in dengue vaccine development, there being four serotypes of dengue virus, is that a vaccine has to induce long lasting neutralizing antibody response against all four serotypes simultaneously with minimum administration number. Our tetravalent dengue vaccine candidate, KD-382, is a live attenuated and genetically unmodified vaccine using a classical host range mutation strategy and thus is expected to induce strong and comprehensive immune response similar to those induced by natural infection. To date, we have shown that dengue-naïve cynomolgus monkeys administered a single dose of KD-382 seroconverted for all four serotypes. However, it is important to show how long neutralizing antibodies induced by KD-382 can be expected to last. We administered a single dose of KD-382 (5, 5, 5, 5 Log_{10} PFU/dose) to 6 cynomolgus monkeys (male and female), and are measuring the neutralizing antibody titer against parent strains for each serotype at intervals using a standard focus reduction neutralization (FRN) assay. This study has currently been running for over 3.5 years, and we have confirmed that neutralizing antibody titers against all four serotypes ($FRNT_{50}$=1:>10) persist for at least 3.5 years. The geometric mean neutralizing antibody titers at 42 months for serotypes-1, -2, -3, and -4 were 3.2, 2.5, 2.4 and 2.9 (Log_{10} $FRNT_{50}$), respectively. This neutralizing antibody persistence for over 4 years suggested that in dengue naïve cynomolgus monkeys, with a single administration, KD-382 can induce a strong neutralizing antibody response against all four dengue serotypes simultaneously and thus has high potential as a dengue vaccine. We will continue our observations up to 5 years, but as no decrease in neutralizing antibody titer has been observed so far, we expect that neutralizing antibodies will last for even longer. A first-in-human Phase 1 clinical study for KD-382 is now ongoing in a dengue non-endemic country.

807

CO-CIRCULATION OF DENGUE, ZIKA AND CHIKUNGUNYA IN THE PERUVIAN AMAZON

Francesca Falconi-Agapito[1], Xiomara Merino[2], Karen Kerkhof[1], Kevin K. Ariën[1], Michael Talledo[2]

[1]*Institute of Tropical Medicine, Antwerp, Belgium,* [2]*Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru*

The similar clinical symptomatology and co-circulation of arthropod-borne viruses (arboviruses) such as Dengue (DENV), Zika (ZIKV) and Chikungunya (CHIKV) requires accurate diagnostics. PCR is highly specific and sensitive, although only useful during the short viremic phase of the disease. When this phase is passed, diagnosis should be based on serology. Serology tests for arboviruses suffer from low specificity due to high genetic and antigenic similarity, especially among the flavivirus family, with detection of cross-reactive antibodies. Further serological studies are needed in areas where different arboviruses co-circulate, in order to understand its utility for diagnosis. In this study, the IgM and IgG antibody responses against DENV, ZIKV and CHIKV were evaluated in dengue PCR (+) patients (n=32). The commercial Dengue duo RDT from Alere and the IgM/IgG ELISA for DENV, ZIKV and CHIKV from Euroimmun were used. The screened samples were collected in Iquitos and Yurimaguas, cities located in the Peruvian Amazon. From each patient, two samples were collected: an acute samples (AS) up to 9 days after the onset of symptoms and a convalescent sample (CS). All samples were PCR negative for ZIKV and CHIKV. For dengue, 18/25 AS were positive to NS1 antigen in the RDT. IgM antibodies against DENV were detected in 11/25 and 11/29 AS tested with RDT and ELISA assays, respectively. Eight additional patients seroconverted at the convalescent phase of the disease when tested for IgM in the ELISA. IgG antibodies against dengue were detected in 28/32 AS, suggesting that these patients had a secondary infection of dengue. The remaining four patients showed IgG seroconversion in the CS. Neither patient showed IgM or IgG responses against CHIKV and ZIKV at the acute phase of the disease. Surprisingly, 7/29 patients from Yurimaguas were IgG positive to CHIKV. The IgG levels remained positive in the CS, thus suggesting a history of CHIKV infection. Although sporadic CHIKV PCR (+) have been reported in Yurimaguas by the Ministry of Health, to our knowledge this is the first serological evidence of a past CHIKV outbreak in the area.

808

PERFORMANCE EVALUATION OF A RDT DENGUE IGG ASSAY FOR PRE-VACCINAL SEROSTATUS DETERMINATION

Anthony Palvadeau, Muriel Cardona, Catherine Bachard, Muriel Costaille, Nadia Sagot, Akram Yahia-Ammar, Gaëlle-Anne Cremer, Stéphanie Antil-Delbeke, Patrice Sarfati

Bio-Rad, Marnes-la-Coquette, France

CYD-TDV, the world first tetravalent dengue vaccine was licensed in December 2015 and has been approved in 19 countries. In high seroprevalence areas clinical trial data demonstrated overall population benefits. However, recent field data indicated that people inoculated with CYD-TDV who were seronegative at time of the first vaccination have an excess risk to develop a severe form of the disease when primary infected by Dengue virus. Today, WHO recommends performing a pre-vaccination screening in order to determine the serostatus of each patient before vaccination. In this context, we have developed the first prototype of rapid diagnostic test to detect Dengue IgG for recent and past infection for the 4 serotypes in less than 20 minutes. This rapid test can be used in whole blood, plasma and serum specimens. Performance and seroprevalence studies of this new RDT Dengue IgG rapid test were performed. Specificity has been evaluated on 127 seronegative blood bank specimens and 97 seronegative hospitalized patients from non-endemic area. Sensitivity has been evaluated on 206 seropositive anti-Dengue IgG specimens. Cross-reactivity has been measured on Yellow Fever IgG and West Nile IgG positive samples. Results have shown a specificity of 99.1% (222/224) for specimens from non-endemic area and a sensitivity of 96.1% (198/206). No cross-reactivity was observed on West Nile and Yellow Fever positive specimens. Cross-reactivity on Zika positive samples could not be evaluated as all samples came from endemic settings and were all Dengue seropositive. In the seroprevalence study, a selection of 30 serums from high prevalence endemic area (India) has also been tested. A total of 76.6% (23/30) was found positive with RDT Dengue IgG. These results are in agreement with the published range of seroprevalence found in India. In conclusion, RDT Dengue IgG shows expected performance including in high seroprevalence area and would fit with performances required by the WHO recommendation for a Dengue pre-vaccinal screening strategy.

809

HUMAN MAJOR HISTOCOMPATIBILITY COMPLEX CLASS I CHAIN-RELATED (MIC) GENE ASSOCIATIONS WITH DENGUE INFECTIONS IN BANGKOK

Henry A. Stephens[1], Panpimon Luangtrakool[2], Sasijit Vejbaesya[2], Komon Luangtrakool[2], Siripen Kalayanarooj[3], Anon Srikiatkhachorn[4], Louis Macareo[5], Stefan Fernandez[5], Richard Jarman[6], Alan Rothman[4]

[1]*University College London, London, United Kingdom,* [2]*Siriraj Hospital, Bangkok, Thailand,* [3]*Queen Sirikit National Institute of Child Health, Bangkok, Thailand,* [4]*University of Rhode Island, Providence, RI, United States,* [5]*Armed Forces Research Institute of Medical Science, Bangkok, Thailand,* [6]*Walter Reed Army Institute of Research, Silver Spring, MD, United States*

Human genome-wide association studies of dengue patients in mainland SE Asian populations have detected and replicated intron-specific associations with the non-classical MHC class I chain-related gene *MICB*, a known target for the ubiquitous activating NK receptor NKG2D which is expressed on both NK and T cells. MIC proteins are stress-related molecules expressed at the cell surface of virus infected cells, but can also be released from the cell surface as soluble proteins after proteolytic cleavage. Soluble MIC can block NKG2D bearing NK cells in the periphery before they engage with virus infected cells, which is considered a form of immune evasion. In this candidate gene association study, we have determined exon-specific *MIC* allele profiles in a discovery cohort of Bangkok patients with dengue fever (DF) and dengue haemorrhagic fever (DHF) (n=166), then compared these groups with the equivalent *MIC* frequencies in ethnically and geographically matched controls (n=149). We detected an association between allele *MICB*002* and protection from acquiring DHF after secondary dengue infections (OR = 0.41, 95% CI = 0.21<OR<0.68) and confirmed this association in a replication cohort of dengue patients (N= 222; OR = 0.43, 95% CI = 0.22<OR<0.82). *MICB*002* is a known low expresser of soluble proteins, which can block NKG2D baring cells in the periphery and impede the cytotoxic and immuno-regulatory activities of NK and T cells. Our results indicate that the expression and the likely retention of *MICB*002* encoded proteins on the surface of dengue infected cells confers a significant protective advantage in controlling this infection via NK and T cells.

810

THE CHANGING EPIDEMIOLOGY OF DENGUE FEVER IN EUROPE AS INFLUENCED BY CLIMATE CHANGE, GLOBALIZATION, AND CONFLICT-INDUCED MIGRATION

Elisabeth Nelson, Erin M. Sorrell

Georgetown University, Washington, DC, United States

The mosquito-borne virus that causes dengue fever represents one of the most significant threats to global health in the 21st century. Over half of the world's population lives in areas at risk of dengue transmission, with cases increasing 30-fold in the past 50 years. A combination of phenomena has allowed for an unprecedented global expansion of both the dengue virus and the mosquito species that act as main vectors of the disease. Europe, previously unaffected by dengue for most of the 20th century, resides on the brink of dengue re-introduction. Here we focus on the impacts of climate change and migration on the incidence of dengue

fever in Europe between 2008 and 2015 through the analysis of dengue case reports, in correlation with climate data, and flight and migration patterns. Our study indicates that since the 1990s warming winters have correlated with the *Ae. albopictus* expansion. Peaks in dengue incidence among travelers and the prevalence of outbreaks in endemic regions are correlated with peaks in travel to Europe during the summer months. This creates an extreme risk for autochthonous transmission as Europe is most climactically similar to the tropics during this time interval. Germany, France, and the United Kingdom were selected for in-depth analysis of the converging risk factors: *Ae. albopictus* habitat coverage, risk for habitat expansion, and viral introduction into local populations. These countries have the three largest airports in Europe, allowing for sustained introduction of the dengue virus through returning travelers. Our analysis suggests that active surveillance is necessary to quell autochthonous transmission. Furthermore, seasonal outbreaks appear increasingly likely however complete continental endemicity seems improbable. Previous studies have investigated the interaction between one or two of the risk factors for dengue and *Ae. albopictus* spread in Europe. This study is the first to investigate human and environmental factors, as well as the complex interplay and circumstantial overlap leading to autochthonous transmission. Further research is needed to better understand the future risks.

EPIDEMIOLOGIC TRENDS OF DENGUE IN U.S. TERRITORIES - 2010-2018

Kyle R. Ryff, Dania M. Rodriguez, Aidsa Rivera, Tyler M. Sharp, Stephen H. Waterman, Laura E. Adams, Gabriela Paz-Bailey

Centers for Disease Control and Prevention, Dengue Branch, San Juan, PR, United States

Dengue is a flavivirus transmitted by infected *Aedes* mosquitos. Dengue remains one of the most globally important mosquito-transmitted viral infections. In the United States, dengue became a nationally notifiable disease in 2010, and cases are reported to the Centers for Disease Control and Prevention through ArboNet, the national arboviral surveillance system. We present characteristics of confirmed and probable dengue cases in the United States territories of Puerto Rico, American Samoa and the United States Virgin Islands (USVI) during 2010 to 2018. Laboratory-positive dengue cases are classified using the Council of State and Territorial Epidemiologists (CSTE) dengue case definitions for confirmed and probable cases. Severe dengue cases were also classified following CSTE guidance. We describe cases by selected characteristics and estimate rates per 1,000 persons using 2010 US census population data. During 2010-2018, a total of 30,394 dengue cases were reported to ArboNet from Puerto Rico (28,990, 95%), American Samoa (1,054, 3%), and USVI (350, 1%). Dengue rates in Puerto Rico varied from 3.0/1,000 persons in 2010 to 0.0008/1,000 in 2018. In USVI, rates ranged from 0 in 2010 to 1.6/1,000 persons in 2013, and in American Samoa from 0 in 2010 to 9.2/1,000 in 2017. Number of cases and rates by age group were highest among 10–14 and 15–19 year-olds. Hospitalization and severe dengue followed similar patterns by age, with the highest rates among the 10—19 year olds. Puerto Rico had the highest number of severe dengue cases (n=544) followed by USVI (n=6). A total of 68 fatal cases were reported from Puerto Rico; no fatal cases were reported by USVI or American Samoa. Dengue deaths were highest in adults. Dengue is endemic in Puerto Rico; American Samoa and USVI experience periodic dengue outbreaks. The highest burden of disease is among children, although deaths mainly occurred among adults. These trends characterize risk in areas of high dengue activity in the U.S. and can be useful to guide preparedness and disease prevention activities.

A UNIVERSAL DENGUE VACCINE ELICITS NEUTRALIZING ANTIBODIES AGAINST STRAINS FROM ALL FOUR DENGUE SEROTYPES

Naoko Uno, Maria T. Arevalo, Ted M. Ross

University of Georgia, Athens, GA, United States

Developing a vaccine for Dengue virus (DENV) has been difficult to achieve. It is critical for a DENV vaccine to elicit protective immune responses against viruses representing all four DENV serotypes without enhancing disease. In the current study, DENV subviral particles (SVP) were designed to express an envelope (E) glycoprotein that elicits broadly reactive neutralizing antibodies. Each E antigen was designed using computationally-optimized broadly reactive antigen (COBRA) methodology. DENV E sequences were obtained from GenBank and a layered, consensus-building approach was used to derive four final COBRA DENV sequences. COBRA and wild-type SVPs (prM-E) were expressed and purified from mammalian cell lines expression vector. Two studies were performed: 1) in female C57BL/6 mice (age 6-8 weeks) and 2) in rhesus macaques (*Macca mulata*) that were immunologically naïve to DENV or pre-immune with antibodies to DENV serotype 1 or DENV serotype 2. Animals were vaccinated with DENV SVP intramuscularly individually or in a tetravalent mixture. Immune sera were collected and total IgG antibody titers to DENV E were analyzed by ELISA and the ability to prevent virus infection *in vitro* was assessed in a focus reduction neutralization test ($FRNT_{50}$) against a panel of 12 prototype and modern strains from all four serotypes. Mice vaccinated with wild type DENV SVPs expressed anti-E IgG antibodies that were specific to strains in each homologous serotype and stimulated B cells against DENV from all 4 serotypes. The elicited antibodies neutralized serotype specific viruses. COBRA DENV SVPs elicited a broader breadth of antibodies that neutralized various strains across all four serotypes. The COBRA DENV E immunogen neutralized all 12 strains of DENV *in vitro*, comparable to tetravalent SVP vaccination.

Dengue viruses 1-4 (DENV1-4) are theorized to be under selective pressure to escape from neutralization but also to take advantage of prior immunity via antibody-dependent enhancement. In this study, we tracked antigenic dynamics of DENV1-4 isolated in Bangkok, Thailand in relation to temporal, regional, and global DENV antigenic diversity. Thailand DENV1-4 strains isolated from 1980-2014 (n=265) were titrated against sera from non-human primates (n=20, each inoculated with distinct DENV strains) using the Plaque Reduction Neutralization Test (PRNT). We also studied DENV1-4 strains from 19 other countries (n=57). $PRNT_{50}$ titers (n=6,843) were interpreted as antigenic distances using antigenic
