Between 1970 and 2012, South America (SA) and the Caribbean region accounted for approximately one-third of all leptospirosis outbreaks reported globally. Annual morbidity per 100,000 residents varied significantly from 3.9 in SA to 50.7 in the Caribbean. Drivers of infection, such as exposure to carrier mammals, contaminated water or soil, differ across geographical areas. This geographical variation is not accounted for in non-spatial models, leading to potential inaccuracies. This study aimed to explore spatial variation at the household level of drivers of leptospirosis seroprevalence in the DR using a geographically weighted regression (GWR) and provide evidence to inform public health interventions. Human infection and socio-demographic data were collected from 2,078 participants in 23 communities in two distinct provinces (Espaillat and San Pedro de Macoris (SPM)), in a 3-stage random cross-sectional serosurvey conducted from Jun-Oct/2012. Based on conceptual risk frameworks for leptospirosis, publicly available remote sensing and census data supplemented the survey. Bivariate mixed-effect models identified variables (p <0.2) for the GWR. In the non-spatial model, significantly higher odds ratio (OR) of leptospirosis seropositivity were observed in older age groups, males, households in a flooding risk area, and increased density of rivers and bare ground within 250 meters of households. Conversely, higher mean value of gross domestic product (GDP) at the community level was associated with lower OR of leptospirosis seropositivity. The GWR identified spatial variation in the effect of each covariate included in the model within and across the two provinces. OR of contact with freshwater varied the most across space (7.8, range 0.8-8.2) with limited variation observed in the OR of GDP while still significantly protective across both regions. Older age groups, males, farmers, and contact with rats were associated with higher ORs of leptospirosis seropositivity in SPM compared with Espaillat. These results and framework can be used to inform more targeted and cost-effective public health actions in the DR and regionally.

UTILIZATION OF NEAR REAL-TIME ENVIRONMENTAL DATA FOR AN 'EARLY WARNING SYSTEM' TO INCREASE PUBLIC PREPAREDNESS OF THE SEASONALITY AND SPREAD OF LYME DISEASE IN THE UNITED STATES

Patrick H. Kelly[1], Sarah Willis[1], James H. Stark[1], Agustín Estrada-Peña[2]

[1]Pfizer, New York City, NY, United States, [2]Ministry of Health, Madrid, Spain

Quantifying the spatiotemporal spread and risk of Lyme disease (LD) in humans remains a major global challenge. Predictive models can identify environmental associations with LD incidence to better inform risk trends. We demonstrate how environmental data can provide near real-time information on the seasonal onset of LD (seasonal model) and which factors most describe the spread of LD in the United States (US) since 2003 and projected into 2030 (spatial model). Centers for Disease Control and Prevention LD incidence data (2001-2021) in 16 high incidence (>10 cases/100,000 persons) and 18 low-incidence LD jurisdictions were used for the spatial model. Administrative claims data were used to estimate LD incidence (2001-2019) in two high incidence states for the seasonal model. Explanatory variables of climate, normalized difference vegetation index (NDVI), land cover, *Ixodes scapularis* presence, and distribution of tick hosts and reservoirs for *Borrelia burgdorferi* were used to train generalized linear and machine-learning algorithms. The seasonal model found a strong association (R^2=0.90) between daily temperatures (p<0.001) and weekly accumulation of NDVI (p<0.001) with the weekly percentile of reported LD cases. NDVI accumulation (>5) and percentile (25th) of annual reported LD cases accelerated by 3 and 5 weeks, respectively, between 2001-2018 suggestive of increasing LD incidence is in part due to earlier or longer LD seasons (p<0.0001). Spatial models (AUC: 0.98) found the variables that best explained LD spread were mostly (71%) non-climate, including county adjacency of LD cases (22%), *I. scapularis* presence (8.4%), variable forest growth (6.3%), and shrew and skink abundances (5.1% each). By 2030, the model predicted 600 counties (20.5% increase from 2019) categorized as high-incidence LD counties with northward expansion into Canada and westward from US Midwest and Northeast regions. We show how our models utilized as 'early warning systems' could be valuable public health tools to increase public preparedness and uptake of protective measures including vaccination to mitigate increasing global health threats like LD.

COUNTRIES' PROGRESS TOWARDS GLOBAL HEALTH SECURITY WITH INCREASED HEALTH SYSTEMS RESILIENCE DURING THE CORONAVIRUS DISEASE-19 (COVID-19) PANDEMIC: A DIFFERENCE-IN-DIFFERENCE STUDY OF 191 COUNTRIES

Tyler Y. Headley[1], Sooyoung Kim[2], Yesim Tozan[3]

[1]New York University Abu Dhabi, Abu Dhabi, United Arab Emirates, [2]New York University School of Global Public Health, Department of Public Health Policy and Management, New York, NY, United States, [3]New York University School of Global Public Health, Department of Global and Environmental Health, New York, NY, United States

Research on health systems resilience during the COVID-19 pandemic frequently used the Global Health Security Index (GHSI), a composite index of six categories spanning 37 indicators which score countries' health security and related capabilities. Conflicting results, however, raised questions about the index's validity. This study attempted to clarify these varying results and better characterize the effect of countries' progress towards Global Health Security (GHS) on health systems resilience during the pandemic. We used longitudinal data from 191 countries and a difference-in-difference causal inference strategy to quantify the effect of GHSI scores on countries' essential childhood immunization coverage rates. We divided countries into treatment and control groups for all tested indices by testing cutoff values on a sliding scale to determine the minimum value at which a safeguarding effect was observed. All analyses were adjusted for potential confounders and World Bank governance indicators were employed for robustness tests. While overall GHSI scores prevented declines in childhood immunization coverage rates from 2020 - 2022 (coef: 0.91; 95% CI: 0.41 - 1.41), this safeguarding effect was strongest in 2021 (coef: 1.23; 95% CI: 0.05 - 2.41) as compared with 2020 (coef: 0.74; 95% CI: 0.28 - 1.20) and 2022 (coef: 0.76; 95% CI: 0.06 - 1.46). The coefficient sizes for overall GHSI scores were smaller than the coefficients of many of the GHSI's sub-components, including countries' environmental risks (coef: 4.28; 95% CI: 2.56 - 5.99), biosecurity (coef: 1.87; 95% CI: 0.83 - 2.91), and emergency preparedness and response planning (coef: 1.82; 95% CI: 0.54 - 3.11). Our findings indicate that GHS was positively associated with health systems resilience during the pandemic, that GHS may have had the most significant protective effects in 2021 as compared with 2020 and 2022, and that countries' underlying characteristics, including governance quality, also played a key role in health systems resilience during the pandemic.

6783

DISTRICT READINESS TO RESPOND TO INFECTIOUS DISEASE PUBLIC HEALTH EMERGENCIES ACCORDING TO THE 7-1-7 TIMELINESS METRICS IN EASTERN UGANDA

Richard Ssekitoleko[1], Herbert Isabirye[2], Benjamin Fuller[3], Margaret R Lawrence[3], Solome Okware[1], Annet Alenyo[1], Immaculate Atuhaire[1], Andrew Bakainaga[1], Elizabeth Mgamb[1], Yonas Tegegn Woldemariam[1], Christopher C. Moore[3]

[1]World Health Organization, Kampala, Uganda, [2]Infectious Disease Institute and the National Public Health Emergency Operations Center, Kampala, Uganda, [3]University Of Virginia, Charlottesville, VA, United States

Among districts in Uganda, there is varying capacity to respond to Public Health Emergencies (PHEs). The WHO categorizes PHEs into 4 levels. Grades 1-3 necessitate a WHO response; ungraded PHEs are monitored. The 7-1-7 timeliness metrics include detecting an infectious disease outbreak in 7 days, notifying authorities in 1 day, and response completion in 7 days. These metrics allow for the assessment of the performance of surveillance, reporting, investigation, and response systems. Required capacities and response components include response initiation, epidemiological investigation, laboratory confirmation, medical treatment, countermeasures, communications and community engagement, and response coordination. We determined; 1) the number of WHO-ungraded PHEs in the Mbale and Teso regions of Eastern Uganda from January-March 2024, and 2) the ability of districts to respond according to 7-1-7 metrics. We identified 5 WHO-ungraded infectious disease outbreaks including anthrax (x2), cholera, measles, and rabies in 5 (19%) of 27 districts in Eastern Uganda. The median (IQR) number of days for detection, notification, and response was 8 (4-24.5), 3 (1.5-11), and 15 (8-19.5), respectively. None of the districts met all 7-1-7 targets due to deficiencies in vaccine access, drug availability, clinician training, and notification, which resulted from poor reporting structures for animal and human teams for zoonoses. Delays in response initiation included laboratory confirmation and putting countermeasures in place. Enhancing public health responses at the district level requires multi-hazard risk assessments, contingency plans, and capacity-building for rapid response teams. Using the 7-1-7 metrics could help districts conduct early action reviews to identify performance setbacks and guide resource allocation. Guiding documents can help districts effectively respond to ungraded PHEs.

A SUBSET OF CAMBODIAN *PLASMODIUM VIVAX* PARASITES TREATED WITH ARTESUNATE DISPLAY SLOW CLEARANCE AND A DELAYED AND UNIQUE GENE EXPRESSION RESPONSE

Kieran Tebben[1], Virak Eng[2], **David Serre**[1], Jean Popovici[2]

[1]University of Maryland School of Medicine, Baltimore, MD, United States, [2]Institut Pasteur du Cambodge, Phnom Penh, Cambodia

Artemisinin-based combination therapies (ACTs) are the frontline antimalarial drugs for the treatment of malaria infections but the efficacy of artemisinin has been threatened by the rise and spread of resistance in *Plasmodium falciparum* since its emergence in Cambodia in the 2000s. Here, we analyze 158 *P. vivax* infections from Cambodian patients treated with 2 mg/kg/day of artesunate for 7 days. All infections were successfully cleared by day 4. However, 9 of the infections (5.7%) showed parasite clearance time (defined as the slope half-life after regression of log-transformed parasite counts) greater than 5 hours, meeting the WHO definition of artemisinin resistance. We observed no significant association between slow clearance and either patient- (e.g., age, weight) or infection characteristics (e.g., parasitemia, stage composition). We characterized by RNA-seq the parasite gene expression of 15 fast- and 16 slow-clearing infections at baseline and 1, 2 and 4 hours after treatment. While the fast-clearing parasites showed significant changes in gene expression immediately upon treatment (with 408 and 1,463 genes differentially expressed 1 and 2 hours after treatment, respectively), slow-clearing parasites displayed a significantly delayed gene expression response (with no genes differentially expressed one hour after treatment and 1,384 and 2,443 differentially expressed genes 2 and 4 hours after treatment). Many of the genes that changed their expression after treatment in both fast- and slow-clearing parasites were indicative of a global shutdown of transcription and translation, as well as of an overall decrease of proteosome activity (similar to the effects of artesunate on *P. falciparum*). By contrast, many genes only differentially expressed in the slow-clearing parasites were associated with hemoglobin endocytosis (e.g., VSP45, PIP3) and hemoglobin digestion (e.g., falcilysin, vivapain). Overall, our results indicate that some Cambodian *P. vivax* parasites are cleared slowly after artesunate treatment, possibly due to their lower hemoglobin metabolism that would reduce the efficiency of the drug.

6785

EVALUATION OF AN IMPROVED SYBR GREEN I ASSAY FOR SURVEILLANCE OF ANTIMALARIAL RESISTANCE IN *EX VIVO* AND CULTURED ISOLATES

Agnes C. Cheruiyot, Redemptah Yeda, Farid Abdi, Dennis Juma, Benjamin.Opot@usamru-k.org Opot, Raphael Okoth, Jackline Juma, Risper Maisiba, Maurine Mwalo, Edwin Mwakio, Timothy E. Egbo, Hosea Akala

Kenya Medical Research Institute/ USAMRU-A, Kisumu, Kenya

Malaria morbidity and mortality continues to be a public health concern in endemic regions and has been aggravated by emergence of artemisinin resistance. A SYBR Green I fluorescent based assay has been widely used in drug testing of fresh isolates. However limited studies have reported on parallel evaluation of SYBR green I assay using *ex vivo* and culture adapted isolates. We retrospectively analyzed susceptibility data for six drugs to evaluate SYBR Green I assay ability to produce comparable data in *ex vivo* and cultured isolates. Samples were collected under an approved surveillance protocol between 2018 to 2023 collected from hospital sites in all the six malaria epidemiological zones in the country. Total of 530 isolates were tested, *ex vivo* (330) and 200 tested through adaptation against chloroquine (CQ), quinine (QN), artemether (AT), lumefantrine (LU), artemisinin (AR) and amodiaquine (AMQ). Response curves were obtained from relative florescence units (RFU) using Graph Pad Prism. *Ex vivo* versus cultured isolates data for each drug was compared using Wilcoxon matched paired test. Chloroquine had a median concentration of 9.447ng/ml (4.732-15.79) in isolates tested for *ex vivo* and 15.82ng/ml (9.783-25.41) in cultured isolates, p=0.0001. QN median, 21.41ng/ml (11.93-35.17) in *ex vivo* and 22.45 ng/ml (14.10-40.09) in cultured isolates, p=0.17. AR median, 2.762 ng/ml (1.425-4.302) in *ex vivo* and 3.071 ng/ml (2.029-4.352) in cultured. AT 1.884 ng/ml (1.010-3.241) in *ex vivo* and 1.848 ng/ml (1.164-3.116) in cultured, p=0.91. LU, 9.791 ng/ml (2.196-29.55) in *ex vivo* and 10.57 ng/ml (2.924-25.20) in cultured, p=0.19. AQ, 1.897 ng/ml (0.8870-4.142) in *ex vivo* and 1.199 ng/ml (0.7374-2.870) in cultured isolates p=0.10. Median IC_{50}s in five drugs compared in *ex vivo* versus cultured adapted had no significant variation except chloroquine which had a variation but still within the resistance threshold. Therefore in remote laboratory settings where samples cannot be received and tested within 6 hours of collection, they can be cultured and thereafter drug screening done at a convenient time without compromising on data integrity.

6786

EMERGING BIOLOGICAL THREATS TO MALARIA CONTROL IN UGANDA: EVIDENCE OF VALIDATED MARKERS OF PARTIAL ARTEMISININ RESISTANCE AND *PFHRP2/3* DELETIONS IN A HIGH TRANSMISSION SETTING

Dr. Bosco B. Agaba[1], Trevor Jye[2], David Smith[3], Prof. Antonio Martin[4], Associate Prof. Beshir Khalid[5], Prof. Moses R. Kamya[6], Prof. Pontiano Kaleebu[7], Prof. Piot Peter[4], Prof. Qin Cheng[8]

[1]Malaria Control Division/London School of Hygiene and Tropical Medicine/ Peter Piot Fellow for Global Health Innovation: Epidemic Preparedness & Response/Mbarara University of Science and Technology, kampala, Uganda, [2]QIMR Berghofer Medical Research Institute, Brisbane, Australia, [3]5Australian Defence Force Malaria and Infectious Disease Institute, Australia, Brisbane, Australia, [4]London School of Hygiene and Tropical

Medicine, London, United Kingdom, [5]London School of Hygiene and Tropical Medicine, London, Australia, [6]Infectious Diseases Research Collaboration, kampala, Uganda, [7]London School of Hygiene and Tropical Medicine/Uganda Virus Research Institute, Entebbe, Uganda, [8]Australian Defence Force Malaria and Infectious Disease Institute, Australia, Brisbane, Australia

Artemisinin-based combination therapy is the recommended treatment option for uncomplicated malaria, however emergency of partial artemisinin resistance threatens their effectiveness. Similarly, P. falciparum histidine-rich protein-2 (HRP2) based Rapid diagnostic tests (RDTs) are extensively deployed, however deletion of the *pfhrp2/3* gene threatens their usefulness. Genomic surveillance was conducted in Karamoja, Lango, Acholi and West Nile regions between 2021 and 2023. Symptomatic patients were screened for presence of parasites with HRP2 and pLDH detecting RDTs. Dried blood spots (DBS) were used to confirm parasite species with a conventional multiplex PCR, *pfhrp2* and *pfhrp3* gene with a real-time multiplex qPCR and *pfk13* mutations by Sanger sequencing with Big Dye Terminator. Regional variations in proportions of *PfK13* mutations were assessed using the chi square or Fisher's exact tests while Kruskal-Wallis test was used to compare absolute parasite DNA levels between wild type and mutants parasites. Overall, 238/240 samples (99.2%) were successfully sequenced. Three mutations were identified; *PfK13* C469Y in 32/238 (13.5%) samples, *PfK13*A675V in 14/238 (5.9%) and *PfK13* S522C in (1/238 (0.42%). The prevalence of *PfK13* C469Y mutation was significantly higher in Karamoja region (23.3%), P=0.007. Majority of parasites in West Nile are of wild type (100%), P=0.002. Relative parasite DNA quantity did not differ between the wild type C469Y and A675V alleles (Kruskal-Wallis test, p=0.6373). Overall, qPCR confirmed single *pfhrp2* gene deletion in 1 out of 416 (0.2%) samples that were confirmed of *P. falciparum* mono-infections. Prevalence of validated markers *PfK13* A675V and *PfK13*C469Y in multiple geographical locations provides additional evidence of emerging threat of artemisinin resistance in Uganda. Findings showed limited threat of *pfhrp2/3* gene deletions suggesting HRP2 RDTs are still useful diagnostic tools. Periodic genomic surveillance is recommended to monitor the proportions of gene deletions and its effect on RDTs as well monitor levels of *PfK13* mutations in parallel with in-vivo therapeutic efficacy studies.

6787

ARTESUNATE-PYRONARIDINE IS EFFICACIOUS FOR THE TREATMENT OF UNCOMPLICATED *PLASMODIUM VIVAX* INFECTIONS AND BLOCKS TRANSMISSION MORE THAN CHLOROQUINE IN ETHIOPIA.

Migbaru Keffale Bezabih[1], Sinknesh Wolde[1], Misganaw Misganaw[1], Hiwot Teka[2], Bereket Hailegiorgis[3], Natnael Lemessa[1], Legesse Alamerie Ejigu[1], Samuel Girma[2], Mekonnen Tadesse[3], Fikregabrail Aberra Kassa[1], Mikiyas Gebremichael[1], Wakweya Chali[1], Amanuel Shimelash[1], Melat Abdo[1], Addisu Gizat[1], Getinet Habtamu[1], Gudisa Assefa Bayissa[4], Teun Bousema[5], Fitsum G. Tadesse[6]

[1]Armauer Hansen Research Institute (AHRI), Addis Ababa, Ethiopia, [2]U.S. President's Malaria Initiative, USAID, Addis Ababa, Ethiopia, [3]ICAP at Columbia University, Addis Ababa, Ethiopia, [4]Ministry of Health, Addis Ababa, Ethiopia, [5]Armauer Hansen Research Institute (AHRI), Nijmegen, Netherlands, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

In Ethiopia, *Plasmodium vivax* accounts for approximately 40% of malaria cases. The rapid generation of gametocytes contributes to high infectivity of clinical *P. vivax* patients, even before symptoms arise. The impact of antimalarial treatment on this infectivity and the importance of primaquine to prevent onward transmission remains uncertain. We assessed the efficacy, safety, and transmission-blocking effects of artesunate-pyronaridine (PA) and chloroquine (CQ) in combination with 14 days of primaquine (PQ). *P. vivax* infected patients (n=206) were randomly enrolled in the CQ (n=99) and PA (n=107) arms plus PQ administered starting on day 0 to evaluate efficacy on day 28 or 42. To assess transmission potential in the absence of PQ, additional patients were enrolled to receive delayed PQ starting on day 3 following schizonticidal treatment with CQ (n=15) or PA (n=15). Transmission to mosquitoes was thus evaluated by direct membrane feeding on days 0, 1, 2 and 3 after CQ (n=15), CQ + PQ (n=15), PA (n=15), and PA + PQ (n=15). Treatment success on day 42 was high in both the CQ + PQ (95.3%, 82/86) and PA + PQ (98.0%, 97/99) arms. One early treatment failure was observed in the CQ arm whilst 5 late failures were observed in both arms (CQ, 3/86, PA, 2/99). Asexual parasite clearance was higher in the PA (87.7%, 93/106) than CQ (46.5%, 46/99, *P*=0.001) arm on day 1. Similarly, shorter gametocyte clearance time was observed in PA than the CQ arm (*P*<0.001). Before treatment, 91.7% (55/60) of patients infected mosquitoes. On day 1, 46.7% (7/15) and 13.3% (2/15) of patients still infected mosquitoes in the CQ and PA arm, respectively. In the arms that included PQ, only 26.7% (4/15) patients in the CQ + PQ arm was infectious whilst no infection was observed in the PA + PQ arm. None of the patients infected mosquitoes on days 2 and 3. While both the first line, CQ, and alternative drug, PA, were efficacious for the treatment of uncomplicated *P. vivax* malaria in Ethiopia, PA cleared *P. vivax* asexual parasites as well as gametocytes faster than CQ with indications for a greater transmission blocking effect compared to CQ.

INTERACTIVE GENETIC EPIDEMIOLOGY TOOLS FOR SURVEILLANCE OF DRUG-RESISTANT MALARIA PARASITE STRAINS

Ethan James Booth, Varanya Wasakul, Tess Verschuuren, Olivo Miotto

Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand

The rapid emergence and spread of drug-resistant malaria threaten elimination efforts in the Greater Mekong Subregion (GMS). The GenRe-Mekong project, in collaboration with National Malaria Control Programs (NMCPs), conducts genetic surveillance of *Plasmodium falciparum* to monitor drug resistance in the GMS. Translating the generated genetic data into graphic outputs easily interpreted by NMCPs requires extensive analyses, posing a major challenge that demands powerful and intuitive tools. We developed the grcMalaria package for genetic analyses and drug resistance mapping using the R language. The package processes standardized genetic surveillance data, as defined by the SpotMalaria Data Dictionary, using public-domain libraries and data sources. Its companion Web-based interface is based on the R Shiny platform, allowing interactive usage of the R package without requiring programming knowledge. The grcMalaria package turns genotyping data into intuitive geographical maps of drug resistance, allele prevalence, diversity, and relatedness with minimal coding. It also provides clustering analyses that identifies and maps genetically similar strains. Furthermore, the grcMalaria Web application provides easy-to-use access to key features of grcMalaria, bypassing the need for R installation and scripting. The grcMalaria R package and web application offer easy access to crucial information on the spread of drug-resistant parasite strains, and help predict changes in drug efficacy at regional, national, provincial and district levels. These tools render genetic epidemiological analysis accessible, and allow NMCPs to integrate and contextualize their findings within broader regional analyses, strengthening future elimination strategies.

PARTNERSHIP FOR ANTIMALARIAL RESISTANCE MONITORING IN AFRICA (PARMA) HUBS: LOCALIZATION AND CAPACITY STRENGTHENING FOR AFRICAN RESEARCHERS BY AFRICAN RESEARCHERS

Awa Deme[1], Irene Cavros[2], Mamadou A. Diallo[1], Mouhamad Sy[1], Bassirou Ngom[1], Amy Gaye[1], Aita Sene[1], Djiby Sow[1], Tolla Ndiaye[1], Ibrahima M. Ndiaye[1], Daba Zoumarou[1], Jessica McCaffery[3], Marko Bajic[3], Cassandra Webster[4], Jehan Ahmed[5], Daouda Ndiaye[1]

[1]International Research Training Center on Genomics and Health Surveillance (CIGASS), Dakar, Senegal, [2]U.S. President's Malaria Initiative, Malaria Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]U.S. President's Malaria Initiative, Laboratory Science

and Diagnostics Branch, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]CDC Foundation, Atlanta, GA, United States, [5]PATH, Washington, DC, United States

Therapeutic efficacy studies (TESs) are recommended by WHO to be performed every two years in malaria-endemic countries to evaluate antimalarial therapies. Testing samples collected in a TES helps explain treatment failure at the molecular level and allows for timely revisions to national and global policies. The Partnership for Antimalarial Resistance Monitoring in Africa (PARMA) project trains local scientists in malaria-endemic countries to perform these tests independently.
The first PARMA hub was launched in 2022 at the Centre International de recherche, de formation en Génomique Appliquée et de Surveillance Sanitaire (CIGASS) in Dakar, Senegal to address the growing number of TESs and to center analysis and training on the African continent. During training, researchers learn to perform molecular correction to distinguish recurrent from new infections, sequence samples to characterize molecular markers of drug resistance, and analyze bioinformatic data to identify key mutations. The Senegal PARMA hub has proved to be a meaningful opportunity to build expertise, partnership, and collaboration among TES researchers across Africa. Between 2022 and 2024, the hub generated molecular data for 5 countries, hosted 7 African researchers from 4 countries, and produced standardized high-quality reports for stakeholders. One important challenge is bridging the gap between a country sending researchers for PARMA training and the ability of that country to perform the next TES analysis domestically. Because training is intended to encompass a broad overview of topics, developing expertise requires additional practice at the bench. This also depends on key external infrastructural factors such as availability of equipment and reliable electricity. To bridge the gap, in the next 2-3 years the project aims to leverage existing sequencing instruments and highly multiplexed next-generation sequencing panels to lower costs, improve efficiency, and more easily deploy TES assays in countries without highly equipped labs. At least two additional hubs in sub-Saharan Africa will be set up within five years for greater reach and throughput.

6790

NEW INSIGHTS ON SELECTION OF MALARIA PARASITES REVEALED BY GENOMES OF OLDEST ARCHIVED *PLASMODIUM FALCIPARUM* POPULATION SAMPLES

Alfred Amambua-Ngwa[1], Mouhamadou Fadel Diop[1], Christopher J. Drakeley[2], Umberto D'Alessandro[1], Dominic Kwiatkowski[3], David J. Conway[2]

[1]Medical Research Council Unit The Gambia at London school of Hygiene and Tropical Medicine, Banjul, Gambia, [2]London school of Hygiene and Tropical Medicine, London, United Kingdom, [3]MRC Centre for Genomics and Global Health, Big Data Institute, Oxford University, Oxford, United Kingdom

Studies of selection on malaria parasites have been driven by the goal of understanding the emergence of resistance to different classes of antimalarial drugs. Investigations on other selective processes and their targets has been overshadowed by that on the evolution of drug resistance. To investigate such processes, *Plasmodium falciparum* genomes were sequenced from malaria-infected blood samples collected in The Gambia between 1966 and 1971, before any drug resistance was detected in West Africa. Genomic complexity within infections was higher than in recently collected samples, consistent with a higher intensity of transmission during this period. Although the overall genomic diversity is similar over time, there were fewer clusters of related parasites among the older samples, suggesting that parasite inbreeding was less frequent. There was no signature of selection on drug resistance loci, but strong signatures of directional selection were seen at several chromosomal locations coding mostly for immune and invasion-related genes. A few of these have also been seen in more recent samples, but some are unique and indicate older selective processes. A genomic scan over time confirms major drug resistance loci have undergone marked changes, but changes are also seen at other loci. The most significant of these are at the *gdv1* locus on chromosome 9 that regulates conversion to sexual transmission stages, and at the *Pfsa1* locus on chromosome 2 and *Pfsa3* locus on chromosome 11, both associated with parasite infections of individuals carrying the HbS haemoglobin variant. These results highlight the significant role of human immune and genetic factors in shaping the evolution of malaria parasites

The population structure of the malaria parasite *Plasmodium falciparum* can reveal underlying demographic and adaptive evolutionary processes. Here, we analyze population structure in 4,376 *P. falciparum* genomes from 21 countries across Africa. We identified a strongly differentiated cluster of parasites, named AF1, comprising ~1.2% of samples analyzed, geographically distributed over 13 countries across the continent. Members of AF1 carry a genetic background consisting of a large number of highly differentiated variants, rarely observed outside this cluster, at a multitude of genomic loci distributed across most chromosomes. At these loci, AF1 haplotypes appear to have common ancestry, irrespective of the sampling location; outside the shared loci, however, AF1 members are genetically similar to other parasites from the same region. AF1 parasites sharing up to 23 genomic co-inherited regions were found in all major regions of Africa, at locations over 7,000 km apart. Many of the differentiated variants are functionally related, comprising structural variations and single-nucleotide polymorphisms in components of the merozoite surface protein 1 complex, and several other genes involved in interactions with host red blood cell membranes, including invasion, egress and erythrocyte antigen export. This is the first report of a genetic background of such complexity and geographical spread. We coined the term *cryptotype* to denote that AF1 is difficult to detect due to its low frequency, and its recombination with local strains. As AF1 spread across the continent, it appears that the

constellation of mutations remained mostly intact in spite of recombination events, suggesting a selective advantage. We propose that AF1 parasites have adapted to an as yet unidentified evolutionary niche, by acquiring a complex compendium of interacting variants that are otherwise absent from Africa. *In vitro* studies may identify AF1's evolutionary niche, providing new perspectives on host-parasite interactions. It is also possible that other cryptotypes circulate in Africa, and new analysis methods may be needed to identify them.

UNDERSTANDING GENETIC AND TRANSCRIPTIONAL COMPLEXITY IN MALARIA: INSIGHTS FROM SINGLE-CELL RNA-SEQUENCING IN MALI

Sunil Kumar Dogga[1], Jesse Rop[1], Seri Kitada[1], Yomna Gohar[2], Antoine Dara[3], Dinkorma Ouologuem[3], Fatalmoudu Tandina[3], Sekou Sissoko[3], Arthur Talman[4], Abdoulaye Djimdé[3], Mara Lawniczak[1]

[1]Wellcome Sanger Institute, Hinxton, United Kingdom, [2]Institute of Medical Microbiology and Hospital Hygiene, Heidelberg, Germany, [3]University of Science, Techniques and Technologies of Bamako, Bamako, Mali, [4]MIVEGEC, University of Montpellier, IRD, CNRS, Montpellier, France

Malaria, caused by *Plasmodium* parasites transmitted through mosquito bites, poses a significant threat to human life. Regions with a high prevalence of malaria often exhibit complex infections, where individuals harbour multiple genetically distinct strains of *P. falciparum*, some showing symptoms while others remaining asymptomatic. Our study, employing Chromium 10x single-cell RNA sequencing (scRNA-seq), delved into the circulating sexual and asexual populations of *Plasmodium* parasites among approximately 60 volunteers in Faladie, Mali, sampled during the transmission seasons of 2021 and 2022. Using both short and long-read RNA single cell sequencing techniques, we scrutinised the transcriptional and genotypic diversity of parasites within and between hosts, offering unprecedented insights for the first time into strain-specific patterns within malaria carriers. Leveraging full-length single-cell RNA sequencing (MAS-seq/Kinnex), we explored isoform differences between strains and cell types, revealing an additional layer of transcriptional complexity. Expanding our analysis to include *P. ovale* and *P. malariae*, which are prevalent in Mali, we examined their intraerythrocytic life stages at single-cell resolution for the first time. Our investigation across these species seeks to understand the behaviour of individual strains within complex infections and their potential role in determining the symptomatic status of the hosts and propensity for sexual conversion. Moreover, we made these detailed cell atlases accessible as a valuable resource for the malaria research community via the Malaria Cell Atlas website www.malariacellatlas.org.

6793

GENETIC VARIATIONS IN *PLASMODIUM FALCIPARUM* INVASION LIGANDS AND THEIR COGNATE HUMAN RECEPTOR VARIANTS IN MALARIA CASES FROM THE GAMBIA

Nora Nghochuzie Nganyewo[1], Martha Anita Martha[1], Mouhamadou Fadel Diop[1], Eniyou C. Oriero[1], Lucas N. Amenga-Etego[2], Alfred Amambua-Ngwa[1]

[1]Medical Research Council Unit The Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia, [2]West African Centre for Cell Biology and Infectious Pathogens, Accra, Ghana

The malaria parasite *Plasmodium falciparum* invades the human erythrocytes through ligand-receptor interactions which initiate the clinical signs of malaria. The genes encoding the parasite ligands and human receptors might have experienced some evolutionary changes as a result of these interactions, and this could impact malaria incidence and outcomes. However, variations in parasite ligands and their corresponding receptors in the same individuals have received far less attention even though such studies may be useful in vaccines and drug design, refinement of control strategies as well as provide better understanding of disease development, and progression. To investigate this, a paired study of *P. falciparum* merozoite invasion ligands and their corresponding erythrocyte receptor genes from the same infected individual was carried out using the Nanopore amplicon sequencing approach. Blood samples were collected from 288 malaria-positive individuals from four health facilities in The Gambia. Genomic DNA was extracted from the samples and 12 *P. falciparum* genes: EBA175, EBA181, EBA140, Clag2, Clag8, Rh4, Rh5, merozoite surface protein (MSP)1, MSP6, Duffy binding-like MSP (DBLMSP), erythrocyte binding-ligand 1 (EBL-1), and surface-associated interspersed protein 4.2 (SURFIN4.2), and four human receptors: glycophorin (GP) A, GPB, GPC, and complement receptor 1 (CR1) were sequenced. Moderate to high levels of within-host complexity of infection across sites and high inter-SNP linkage disequilibrium were observed in the DBLMSP and SURFIN4.2 genes of *P. falciparum*, and the human glycophorin B, C, and CR1 gene. There was also a lack of spatial structure between *P. falciparum* from different sites while for the human population, individuals from Basse (Upper River Region) were more distinct from the rest of the population. Analysis of the distribution of variants in receptors identified several SNPs in CR1 and a single variant in GPC associated with severe malaria. These findings suggest that specific host-parasite allelic combinations may determine the infection and severity of malaria.

6794

DEFINING IMMUNE ESCAPE POLYMORPHISMS IN *PLASMODIUM VIVAX*: INSIGHTS FROM THE ANALYSIS OF ALLELIC TURNOVER OF 16 ANTIGENS IN A LONGITUDINAL COHORT OF PAPUA NEW GUINEAN CHILDREN

Alison Paolo Namuco Bareng[1], Myo Naung[1], Zahra Razook[1], Alicia Arnott[2], Enmoore Lin[3], Benson Kiniboro[3], Moses Laman[3], Leanne Robinson[4], Ivo Mueller[2], Alyssa Barry[1]

[1]Deakin University, Victoria, Australia, [2]Walter and Eliza Hall Institute, Victoria, Australia, [3]Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, [4]Burnet Institute, Victoria, Australia

Plasmodium vivax, a malaria species causing relapse infection, generates a number of "antigenically distinct strains" that trigger sequential waves of immune escape within hosts. Understanding parasite genetic diversity aids in identifying circulating strains in the population, providing important information in designing broadly efficacious vaccines. However, the exact genetic determinants underlying antigenic diversity remain unknown. This study is one of the first investigations to identify immunologically relevant diversity and polymorphisms in the leading *P. vivax* antigen vaccine candidates. We employed multiplexed long-read amplicon sequencing on 603 samples (paired infection among 126 children) obtained from a longitudinal paediatric cohort in Papua New Guinea. Sequence comparison between paired infections in the same individual was conducted to identify the association between the polymorphic sites and the patient's clinical outcome (symptomatic or asymptomatic infection). Immune escape polymorphisms were defined when the proportion of the polymorphic site associated with a transition to symptomatic infection was significantly varied ($p \leq 0.5$) from those associated with asymptomatic transition. The within-host analysis revealed polymorphisms in blood-stage antigens, including AMA-1, DBP, MSP-1, and CyRPA, significantly linked to symptomatic malaria, suggesting involvement in strain-specific immunity. These polymorphisms also surround residues crucial for merozoite binding and invasion, indicating that they could be maintained by immune selection pressure. Categorising these immune escape polymorphisms into immunologically distinct groups showed widespread distribution of non-vaccine strains, while the Sal-1 vaccine strain had relatively low global frequency, potentially compromising the efficacy of the current vaccine formulations. Overall, this study narrowed down the diversity into immunologically relevant strains, which could guide researchers in their rational selection of antigens or constructs to be considered in designing a highly and broadly effective *P. vivax* vaccine

6795

SOFTWARE TO ESTIMATE THE PROBABILITY THAT A RECURRENT MALARIA INFECTION IS A REINFECTION, RECRUDESCENCE OR RELAPSE.

Aimee R. Taylor[1], Yong See Foo[2], Michael T. White[1]

[1]Institut Pasteur, Université Paris Cité, Paris, France, [2]The University of Melbourne, Parkville, Melbourne, Australia

A recurrent *Plasmodium falciparum* infection can be caused by a failure to treat a preceding infection (recrudescence) or by a new mosquito inoculation (reinfection). In addition, a recurrent *P. vivax* blood-stage infection can be caused by the activation of latent liver-stage parasites called hypnozoites (relapse). Estimating the cause of recurrence is important; for example, when monitoring antimalarial resistance, in therapeutic efficacy studies of treatments for *P. falciparum*, recrudescence needs to be separated from reinfection; to improve treatment for *P. vivax*, in trials of radical cure treatment regimens, relapses need to be separated from reinfection and recrudescence. We developed an R package that practitioners can use to visually interrogate parasite genetic data used for recurrent state inference, and to estimate the probability that a recurrence is a relapse, recrudescence or reinfection (both Pv3Rs and Pf2Rs inference). The inferential framework is built around the modification of a model used previously to estimate relapse probabilities from genetic data on *P. vivax* infections in clinical trial participants. The original model demonstrated the feasibility of *P. vivax* recurrent state genetic inference, but was limited to data on only a few microsatellite markers and at most two recurrences per participant. The updated model is faster and more powerful. It scales linearly with the number of markers, generating probability estimates from genetic data on the many markers typical of amplicon sequencing data. It is able to directly estimate recurrent state probabilities for participants who experience more than two recurrences. Besides a few edge-cases, which we will describe, the estimates generated by the new model are comparable to those generated previously. In summary, we have built a user-friendly tool for malaria recurrent state inference. To facilitate uptake by practitioners and to promote enhancement by methodologists, we will describe the updates to the underlying model, demonstrate how to use the software, outline current limitations and describe future developments.

6796

GENETIC REGULATION OF *PLASMODIUM FALCIPARUM* OXIDATIVE STRESS RESPONSES

Camilla V. Pires[1], Jenna Oberstaller[1], Min Zhang[1], Chengqi Wang[1], Thomas Otto[2], Julian Rayner[3], John Adams[1]

[1]University of South Florida, Tampa, FL, United States, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom

Malaria caused by Plasmodium falciparum ranks among the deadliest infectious diseases worldwide, responsible for over 600,000 deaths in 2020. Continuing spread of drug-resistant parasites prioritize the search for new drug targets and understanding resistance mechanisms. Drug treatment, fever conditions, and infected sickle cells induce oxidative stress during the asexual stages. Recently, we demonstrated that oxidative stress compromises the effectiveness of antimalarial drugs, suggesting that prolonged exposure to intraerythrocytic microenvironmental oxidative stress, as would occur in endemic regions with high prevalence for sickle trait and other hemoglobinopathies, may predispose malaria parasites to develop tolerance to the oxidative damage caused by antimalarial drugs like artemisinin. To understand the underlying mechanisms linked to this phenomenon, we used large-scale forward genetic screens of P. falciparum piggyBac-transposon mutants to identify genetic mutants with altered sensitivity to oxidative stress. Comparing results from previous piggyBac genetic screens for dihydroartemisinin, heat-shock, and sickle-trait cell, revealed that the underlying mechanisms important in the oxidative stress inducible tolerance to artemisinin in malaria parasite is central to the other blood stage stress survival responses. The most significant altered parasite metabolic activities linked to increased sensitivity to stress conditions are linked to lipid metabolism, exported proteins, and RNA metabolism similar to changes associated with emerging artemisinin resistance in different field isolates. Further investigations are needed to elucidate how the genetic regulation of oxidative stress responses can lead to artemisinin resistance.

6797

ASSESSMENT OF STRATEGIES USED IN THE MALARIA ELIMINATION DEMONSTRATION PROJECT FOR THE REDUCTION OF MALARIA IN A TRIBAL DISTRICT OF MADHYA PRADESH, INDIA

Harsh Rajvanshi[1], Farzana Islam[2], Altaf Lal[1]

[1]Foundation for Disease Elimination and Control of India, Mumbai, India, [2]Jamia Hamdard University, New Delhi, India

The Malaria Elimination Demonstration Project (MEDP) in the tribal-dominated, malaria-endemic Mandla district of Madhya Pradesh, India, represents a pioneering public-private partnership aimed at addressing the persistent public health challenge of malaria, which constitutes a significant burden in India, particularly within tribal regions. India, noteworthy for being the only High-Burden High-Impact country in the WHO SEAR to report a decline in malaria cases amid the COVID-19 pandemic, sees approximately 70% of its malaria cases originating from tribal areas. MEDP, a collaborative effort involving the Indian Council of Medical Research, Government of Madhya Pradesh, and the Foundation for Disease Elimination and Control of India, was designed to leverage field-tested malaria elimination strategies, with adaptations to local contexts. The project's multifaceted approach encompassed the T4 strategy (tracking, testing, treating, and tracking treatment efficacy), optimisation of vector control measures such Long-Lasting Insecticidal Nets (LLINs) and Indoor Residual Spraying (IRS), alongside the deployment of a mobile surveillance tool and community-centric Information, Education, and Communication (IEC) initiatives. The project has published over 24 peer-reviewed manuscripts describing various learnings and findings. This study, employing a mixed-methods cross-sectional design, evaluated the project's impact on malaria case reduction, vector control practices, frontline worker knowledge and practices and identified implementation gaps by the state. Conducted across 71 malaria-reporting villages in Mandla, the study involved a diverse cohort of participants, including healthcare workers, malaria patients, supervisory staff, and technical experts. The findings highlighted notable achievements in case reduction and diagnostic and treatment efficiency among frontline staff and illuminated various challenges. The study uncovers valuable insights into effective malaria elimination strategies, which can be adapted to similar local and global contexts.

6798

ADVANCING MALARIA ELIMINATION ASSESSMENT IN LORETO, PERU THROUGH THE FREEDOM FROM INFECTION MODEL

Jorge Ruiz-Cabrejos[1], Luca Nelli[2], Bryan Fernandez-Camacho[1], Brian Peña-Calero[1], Jose Luis Barboza[1], Luciana Bartolini-Arana[1], Hugo Rodriguez-Ferrucci[3], Veronica E. Soto-Calle[4], Isabel Byrne[5], Monica Hill[5], Lynn Grignard[5], Kevin Tetteh[5], Alejandro Llanos-Cuentas[6], Chris Drakeley[5], Gillian Stresman[5], Gabriel Carrasco-Escobar[1]

[1]Health Innovation Laboratory, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Biodiversity, One Health and Veterinary Medicine. University of Glasgow, Glasgow, United Kingdom, [3]Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [4]Dirección de Prevención y Control de Enfermedades Metaxénicas y Zoonosis, Ministerio de Salud, Lima, Peru, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Institute of Tropical Medicine Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

Perú has experienced a substantial decrease in malaria incidence over the past two decades, after intense control programs successfully interrupted transmission in historically endemic regions. In 2023, 90% of malaria cases occurred within Loreto, prompting the National Malaria Elimination Plan to target this region for elimination by 2030. Currently, claims of elimination rely on the absence of reported malaria cases for 36 consecutive months,

following the World Health Organization's (WHO) standard approach, but this method fails to consider limitations and potential underperformance of the surveillance system (SS). This study aims to probabilistically identify areas in Loreto, Perú that are likely to have achieved malaria elimination. We employed a Bayesian modelling approach within the Freedom from Infection (FFI) framework to estimate the probability that malaria transmission is below a critical threshold, defined here as less than 1 case per 10,000 people (PFree). We used passive case detection data (PCD) from 474 health facilities across 53 districts from 2010 to 2022. The primary outcome was PFree measured for both *Plasmodium vivax* (*Pv*) and *P. falciparum* (*Pf*). We defined the threshold for elimination as having a PFree>0.95 for 36 consecutive months in the most recent 3 years (2020-2022) as per the WHO criteria, and compared concordance in classifying facilities as eliminated using the two methods. Overall, PFree values for *Pf* were higher than PFree values for *Pv*. Preliminary results had 24 HFs for *Pf* and 3 HFs for *Pv* with a PFree>0.95 for 36 consecutive months. In contrast, 181 and 126 HFs had zero cases reported for *Pf* and *Pv* respectively. Our results provide a data driven assessment of the progress made towards malaria elimination in the Peruvian Amazon jungle with potential application to others subnational areas in track for malaria elimination in the Region.

6799

COMMUNITY EXPERIENCES AND PERCEPTIONS OF THE BOHEMIA TRIAL OF IVERMECTIN MASS DRUG ADMINISTRATION: A LONGITUDINAL QUALITATIVE STUDY IN KWALE COUNTY, KENYA

Truphena N. Onyango, Khadija Nuru, Karisa Kazungu, Winnie Wangari, Caroline Jones

KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

The efficacy of ivermectin MDA for malaria control has been tested in clinical trials in sub-Saharan Africa. Multiple individual, social, and operational factors influence uptake and adherence to MDA. For sustained involvement of participants in MDA trials it is essential to understand the local context, including health concerns, previous experiences of MDA, and trial expectations. This knowledge helps develop appropriate community engagement strategies and interpret responses of participants to the trial and the MDA. This paper describes a longitudinal qualitative study undertaken to explore experiences of trial participation and perceptions of effects of ivermectin MDA among participants in the BOHEMIA cluster randomised trial of ivermectin MDA in Kwale, Kenya. Purposive maximum variation sampling was used to select five villages (2intervention and 3 control) involved in the trial. Before the start of the trial social science researchers lived in each village for a period of one month conducting participant and non-participant observations, in-depth interviews and focus group discussions. Just prior to the first round of MDA, the social scientists returned to the villages and stayed there throughout each of the 3 rounds of MDA, conducting participant and non-participant observations of the implementation process; and in-depth interviews on experiences and perceptions of the trial and the effects of the MDA. Observation reports for each village before and during the MDA were developed. 25 IDIs and 18 FGDs were conducted prior to the MDA and 22 IDIs during the MDA. The conduct of the trial (MDA distribution strategy, use of informed consent, detailed checking of eligibility) as well as confidence in the implementing institution, enhanced trust in the trial and the efficacy of the MDA. Poor past experiences with MDA and perceptions of exclusion from community engagement process contributed to unwillingness to participate. In intervention and control arms, the MDA was widely perceived to be effective at reducing mosquitoes and malaria. In the intervention arm the MDA was also perceived to be very effective at killing bedbugs.

6800

REACTIVE CASE DETECTION IN ZANZIBAR, A MALARIA ELIMINATION-TARGETED SETTING EXPERIENCING MALARIA UPSURGES IN 2023

Michael Gulaka[1], Abdulhamid Ramadhan[2], Mohamed Ali Kitwasi[2], Stella Makwaruzi[1], Saidi Mgata[1], Geofrey Makenga[1], Nicodemus Govella[1], Marguerite M. Clougherty[3], Roly Gosling[3], Shija J. Shija[2], Albert Ikonje[4], Sarah-Blythe Ballard[5], Naomi Serbantez[4], Sigsibert Mkude[1]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [3]Population Services International (PSI), Washington DC, WA, United States, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [5]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

Reactive case detection (RACD) is a malaria elimination intervention that aims to assess malaria transmission among individuals exposed to the same malaria risks as an index case. In Unguja, Zanzibar, in 2023, RACD was conducted by District Medical Surveillance Officers (DMSO) using malaria rapid diagnostic tests (mRDTs) on household members of parasitologically-confirmed malaria cases reported to the national malaria case notification (MCN) system. Positive cases were treated with artemether-lumefantrine. Data were collected using Android tablets and analyzed descriptively. In 2023, 18,283 malaria cases from Unjuja, Zanzibar, were reported to MCN (reference: 4,544 cases in 2022). Household (HH)-level case investigations were conducted for 9,203 (50%) of index cases, and 30,160 household members (including index case) were present during DMSO visits. Of these, 20,957 (70%) were HH members who consented to testing, and 2.5% (530/20,957) tested positive for malaria. HH denominator data were not collected; however, DMSOs reported that HH members, including those at highest risk for malaria infection (adult males), were frequently absent at the time of case investigation. The positivity rate varied across districts: rural Kaskazini A (5.6% [43/766]) and Kati (5.4% [126/2345]) had the highest, while urban Magharibi B (1.3% [68/5195]) and Magharibi A (1.2% [44/3731]) had the lowest. Individuals aged 15-<25 years had the highest positivity rate (3.4% [160/4532]), followed by 5-<15 (3.1% [152/4842]), under 5 (2.3% [56/2458]), and 25+ (1.8% [162/8966]) years. Males had a higher positivity rate (2.8% [272/9892]) than females (2.3% [258/11065]), p=0.055. RACD data demonstrated low coverage of index case HHs and family members, together with low test positivity rates. HH-focused RACD might not be targeting individuals sharing risk factors with the index case. For many, the likely source of infection is outside of the HH, such as the workplace or location of evening activities. As RACD is not a burden reduction tool, higher coverage, better targeted RACD would likely be of more benefit to areas where transmission is closer to zero.

6801

RE-EMERGENCE OF *PLASMODIUM VIVAX* MALARIA CASES IN BORDER AREAS OF MYANMAR AND STRATEGIC EFFORTS TO INTEGRATE NEW TOOLS AT NATIONAL LEVEL FOR ELIMINATION OF *P. VIVAX* MALARIA FROM 2021 TO 2023

Zwe Thihaa Kyaw, Wah Wah Thaw, Kyi Tun Lwin, Soe Htike, Day Naing Aung, Han Lin Aung, Khin Zarli Aye

PATH, Yangon, Myanmar

Despite advances in malaria control, *Plasmodium vivax* malaria remains a problem in border areas of Myanmar. Cases have increased from 43,578 in 2020 to 103,216 in 2022, posing a threat to the country's 2030 elimination goal. The main barriers to addressing *P. vivax* malaria include lack of glucose-6-phosphate dehydrogenase (G6PD) testing before antimalarial treatment, patient adherence to antimalarial treatment, and political instability. This abstract highlights PATH Myanmar's strategic efforts to revise the National Treatment Guideline (NTG) in partnership with the National Malaria Control Program (NMCP), to ultimately reduce the *P.*

vivax malaria case burden in Myanmar. PATH Myanmar has collaborated with the Partnership for Vivax Malaria Elimination (PAVE) to introduce four new tools in Myanmar: primaquine (PQ) treatment counselling, feasibility studies for G6PD testing, PQ shorter regimen, and the establishment of a pharmacovigilance (PhV) working group to raise awareness and knowledge of utilization of tools. PAVE developed an optimized radical cure road map in 2020, followed by the development of PQ adherence counselling tools in 2021. In 2022, PAVE organized the first technical advocacy meeting for use of optimized radical cure tools at the national level and for the introduction of a PhV system for antimalarial medication in Myanmar. In 2023, PAVE advocated to the NMCP for the implementation of operational research for G6PD testing and organized a central-level workshop focusing on PQ adherence counseling and integration of the PQ 7-days regimen into the NTG. Through these strategic efforts, the tools for PQ treatment adherence and counselling are used nationwide, and the PQ 7-days regimen will be integrated into the NTG. Moreover, a PhV system is being developed at the national level. Although operational research for G6PD testing has been delayed due to the political instability in Myanmar, PAVE efforts have successfully encouraged the NMCP to integrate new tools into the NTG to guide reduction of *P. vivax* malaria in Myanmar.

6802

OPTIMIZING LAST-MILE DELIVERY THROUGH THE INTEGRATION OF MALARIA COMMODITIES DISTRIBUTION IN MALAWI

Fikadu Batu[1], Daniel Taddesse Taddesse[1], Lumbani Munthali[2], Lumbani Makwakwa[3], Denver Raisi[1], Elias Mwalabu[1], Charles Nzawa[1]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project, Lilongwe, Malawi, [2]Ministry of Health-NMCP, Lilongwe, Malawi, [3]USAID, Lilongwe, Malawi

Efficient supply chain management is crucial for malaria management in Malawi, where 6.4 million cases were reported in 2023, necessitating timely and effective distribution of life-saving commodities. The country's supply of malaria commodities is predominantly funded by the U.S. President's Malaria Initiative (PMI) and the Global Fund (GF), and the historical use of separate storage and distribution systems had become a logistical burden to its National Malaria Control Program (NMCP). Monthly coordination of two plans resulted in duplication, complexity, inefficiency, delays, and higher costs, and recording transactions for two distribution streams at service delivery points meant an increased workload for health facility staff. To address this, the NMCP, supported by the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project, in coordination with GF and PMI, facilitated the signing of a Memorandum of Understanding (MOU) in 2022 between the GF project implementation unit (PIU) and GHSC-PSM. The MOU formalized the launch of an integrated distribution mechanism that facilitated visibility of central warehouse inventory data and distribution schedules, and alternated distribution every other month between the two service providers. This initiative resulted in a substantial (30%) reduction in overall distribution costs between October 2022-September 2023, notably in operational, transportation, and personnel expenses. Annual cost savings for the period totaled $133,000 for PMI alone. The reduced frequency in delivery, from 12 to 6 deliveries per year, significantly reduced the workload for health facility staff, while maintaining low stockout rates (<1% for first-line Artemisinin-based combination therapy treatments). These results of substantial cost savings, operational transparency, and improved efficiency in managing malaria commodities validate the integrated system's ability to enhance distribution and provide a basis for potential implementation in similar contexts, especially to optimize limited resources and improve last-mile delivery of health commodities.

EXAMINATION OF PATHOGENS AND FECAL MARKERS IN THE ENVIRONMENT DUE TO INADEQUATE SANITATION SERVICES IN THE ALABAMA BLACK BELT.

Olivia A. Harmon, Megan Lott, Joe Brown

The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

It is estimated that 2.2 million Americans live in homes that lack access to running water or basic plumbing. These shortcomings in access are even more likely to be experienced in Black, Indigenous, and Latino communities when compared to their white counterparts. One region where these inequalities in access to safe and reliable water and sanitation services persist is Alabama's Black Belt. This research aims to get an idea of the microbes present in the environment due to inadequate sanitation infrastructure in a small rural Black Belt community. We collected surface water and soil samples at properties owned by the Auburn Rural Studio and public spaces in the community over January, February, and May of 2023. We collected 125 samples (92 water samples and 33 soil samples) over the course of three months. Of the 125 samples collected 43 were cultured for total coliform, *E. coli*, and Enterococci by IDEXX, and 88 were examined for 48 molecular targets through real-time quantitative PCR using a custom TaqMan Array Card. Of the environmental samples collected and cultured by IDEXX, 43/43 (100%) contained total coliforms, 35/43 (81.4%) contained *E. coli*, and 31/31 (100%) contained enterococci. Of the 88 environmental samples analyzed by TaqMan Array Card, 39 (44.3%) contained gene targets specific to *E. coli* and 67 (76.1%) contained gene targets specific to enterococci. We found *Blastocystis spp.* in 5 of 63 soil samples (7.9%) and 16 of 25 water samples (64%) and *Cryptosporidium spp.* in 20/25 (80%) of surface water samples examined. There was no significant difference in concentration of *E. coli* or enterococci between sites that were impacted and unimpacted by inadequate sanitation in January ($p = 0.561$ for *E. coli* and $p = 0.941$ for enterococcus *Wilcoxon Rank Sum Test*) and February ($p = 0.102$ for *E. coli* and $p = 0.346$ for enterococcus *Wilcoxon Rank Sum Test*). However, the concentration of *E. coli* or enterococci was significantly higher from those samples collected in sites impacted by inadequate sanitation when compared to unimpacted sites in May ($p = 0.0284$ for *E. coli* and $p = 0.0158$ for enterococcus *Wilcoxon Rank Sum Test*).

6804

FECAL EXPOSURE PATHWAYS FOR CHILDREN IN LOW-INCOME, UNPLANNED COMMUNITIES OF URBAN MAPUTO, MOZAMBIQUE USING A QUANTITATIVE MICROBIAL RISK ASSESSMENT FRAMEWORK

Enteric pathogen exposures are critical drivers of child mortality in Mozambique with 6.6% of total deaths among children <5 attributed to enteric infections. Despite high prevalence of enteric infections in children, the household transmission pathway(s) driving these exposures are still being explored. To identify the critical exposures for children <24 months in low-income, unplanned communities in Maputo, Mozambique, we collected and analyzed environmental samples (n=574) for culturable *E. coli*: drinking water (source [n=48], stored [74]), food (solid [61], liquid [28]), hands (mother [78], child [76]), surface swabs (floor [75], food preparation area [71]), and soil [63] in the household setting. We estimated daily quantitative *E. coli* exposure doses for a child using a stochastic quantitative microbial assessment (QMRA) model (10,000 iterations, mc2d package) and caregiver-reported food consumption rates. Relative reductions in *E. coli* dose were calculated for water treatment (boiling once daily) and handwashing (uniform distribution: 1-4 times daily, 30-90% efficacy). Among all samples, 251 (44%) were positive for culturable *E. coli*, with the highest concentrations in soil (mean $\log_{10}$: 4.77 per 1g) and child's hands

(mean $\log_{10}$: 3.55 per two hands). The lowest *E. coli* concentration was for source drinking water (mean $\log_{10}$: 1.07 per 100 mL). Using the QMRA model, solid food consumption was the dominant *E. coli* exposure pathway: median 710.5 CFU/day (95th percentile range: 2.3, 2.0 x 10^{5}). The lowest *E. coli* dose was associated with child's hands: median 0.4 CFU/day (95th percentile range: 4.7 x 10^{-4}, 381.6). Simulating single interventions, boiling of stored water reduced the *E. coli* dose by > 99.999% to a median 1.4 x 10^{-4} CFU/day, whereas handwashing resulted in an attenuated dose reduction (22%) to a median 3.1 x 10^{-1} CFU/day. This study underscores the importance of food-mediated fecal exposures among children. Forthcoming enteric pathogen data aims to corroborate the relevant exposure pathways and impact on child health. Evaluation of targeted food interventions to interrupt food-mediated exposures are warranted.

UNDERSTANDING ANTIBIOTIC RESISTANCE, VIRULENCE, AND BIOFILM FORMATION IN *ACINETOBACTER BAUMANNII*: INSIGHTS FROM GORANCHATBARI SUB-CATCHMENT, DHAKA CITY

Mohammad Rafiqul Islam, Mohammad Atique Ul Alam, Md. Sakib Hossain, Amanta Rahman, Ashrin Haque, Md. Foysal Abedin, Md. Hajbiur Rahman, Md. Shafiqul Islam, Zahid Hayat Mahmud

icddr,b, Dhaka, Bangladesh

Increased incidence of hospital acquired infections may be attributed due to the existence of ESBL producing *Acinetobacter baumannii,* a serious health concern for both hospitals as well as community healthcare environment. The biofilm forming capacity makes them a persistent pathogen in these environments. This study aimed to isolate *A. baumannii* positive for ESBL production from environmental samples, characterization of key virulence and ESBL genes, assessment of antibiotic resistance profile and biofilm forming capacity. A total of 21 environmental samples were collected between April-December, 2022. In this study, 56 isolates of ESBL producing *A. baumannii* were investigated. The ESBL producing *A. baumannii* were subjected to PCR to detect resistance and virulence genes. Among those isolates, 71.4% and 5.4% contained bla_{TEM} and bla_{SHV} genes respectively. In the case of virulence factors, 76.8%, 69.6%, 64.3%, 62.5%, 28.6%, 10.7% and 5.4% of the isolates harbored *pgaB*, *bfmS*, *csuE*, *ompA*, *kpsMII*, *fimH* and *bap* genes respectively. Whereas, 26.8% of the isolates were positive for each of *ptk* and *epsA* genes. During the biofilm formation assay, it was observed that 1.8% of the isolates formed strong and 66.1% formed weak biofilm respectively at 25ºC. In addition, at 37ºC, 1.8% of isolates were moderate and 76.8% were weak biofilm formers respectively. Antibiotic susceptibility testing revealed that 8.9% of the studied isolates were found resistant to cefotaxime and 5.4% were to cotrimoxazole. In addition, 87.5% and 91.1% of studied isolates were found intermediately resistant to ceftriaxone and cefotaxime respectively. As indicated by this study, *A. baumannii*, which produces ESBLs, is rapidly migrating from clinical settings into the environment and could serve as a reservoir for antimicrobial resistance. The data could significantly impact how well public healthcare initiatives are implemented. Exposure to them may create a severe threat to public health.

6806

ENVIRONMENTAL EXPOSURES ASSOCIATED WITH ENTERIC PATHOGEN CARRIAGE IN CHILDREN AGED SIX MONTHS IN NORTHERN ECUADOR

Kelsey J. Jesser[1], Nicolette A. Zhou[2], Caitlin Hemlock[1], Molly K. Miller-Petrie[1], Christine S. Fagnant-Sperati[1], April Ballard[3], Paige Witucki[4], Andrea Sosa-Moreno[4], Gabriel Trueba[5], William Cevallos[6], Gwenyth O. Lee[7], Joseph N.S. Eisenberg[4], Karen Levy[1]

[1]University of Washington, Seattle, WA, United States, [2]University of Washington, SEATTLE, WA, United States, [3]Georgia State University, Atlanta, GA, United States, [4]University of Michigan, Ann Arbor, MI, United States, [5]Universidad San Francisco de Quito, Quito, Ecuador, [6]Universidad Central del Ecuador, Quito, Ecuador, [7]Rutgers University, New Brunswick, NJ, United States

Enteric pathogens are a major cause of mortality and morbidity globally, disproportionately impacting populations in low- and middle-income countries with limited access to water, sanitation, and hygiene (WaSH) resources. We identified environmental risk factors associated with enteric infection in 6-month-old infants along an urban-rural gradient in northern Ecuador; communities were grouped as urban, semi-urban, and rural with road or river access. We collected exposure data on household WaSH, animal exposure, floor material, crowding, and fecal contamination of drinking water and hand rinses, as well as covariates including mother and child demographics, child vaccination status, food insecurity, and socioeconomic status. Child stool samples were analyzed for bacterial (n=10), viral (n=6), and parasitic (n=6) pathogens using multiplex TaqMan Array Cards. We utilized multivariate models, elastic net regression, and distance-based statistical methods to explore factors associated with: i) any infection, ii) coinfection, iii) total number of pathogens, and infection with any iv) bacteria, v) virus, or vi) parasite. Among 276 children, most (87%) were positive for at least one pathogen and 71% were positive for multiple pathogens. Bacterial pathogens were most common (81%), followed by viruses (57%) and parasites (8.3%). Factors associated with reduced risk of infection (p<0.05) included: ceramic tile floors, improved hygiene, and unshared household toilet attached to a sewer system. Risk factors included living in a semi-urban or rural community; having unimproved sanitation; and having a drinking water source from a well or surface water. Seasonality was associated with the likelihood of infection, with fewer viral infections and more bacterial infections in the rainy season. We will also report on specific pathogens, for example *E. coli* detection in child hand rinse was associated with *Giardia* infection. Environmental conditions are associated with enteric infection risk, varying by pathogen type. This data suggests areas of focus for future WaSH interventions with the goal of reducing enteric disease burdens.

6807

SOIL-BORNE EXPOSURE TO ANTIMICROBIAL RESISTANT *E. COLI* AND SOIL-TRANSMITTED HELMINTHS THROUGH SOIL FLOORS IN RURAL BANGLADESH

Ayse Ercumen[1], Md. Sakib Hossain[2], Tahani Tabassum[2], Ashrin Haque[2], Amanta Rahman[2], Md. Hajbiur Rahman[2], Claire Anderson[3], Sumaiya Tazin[1], Suhi Hanif[3], Md. Rana Miah[2], Afsana Yeamin[2], Farjana Jahan[2], Abul Kasham Shoab[2], Zahid Hayat Mahmud[2], Mahbubur Rahman[2], **Jade Benjamin-Chung**[3]

[1]North Carolina State University, Raleigh, NC, United States, [2]icddr,b, Dhaka, Bangladesh, [3]Stanford University, Stanford, CA, United States

Floors made of soil are common in low-income countries and are increasingly recognized as an exposure route for childhood infectious diseases, including soil-transmitted helminth (STH) infections. Soil is also a critical reservoir for antimicrobial resistant organisms. We aimed to investigate associations between flooring material and detection of antimicrobial resistant *E. coli* and STH on floors among rural Bangladeshi households. We enrolled 49 households with a child <2 years (28 with soil floors, 21 with concrete floors) in villages of Sirajganj district in northwestern Bangladesh. Field staff identified the room where the child slept to swab a 50 x 50 cm area using a sterile pre-hydrated sponge and sweep floor dust from up to ten 50 x 50 cm areas with a clean brush. Swab samples were eluted from the sponge with sterile water and analyzed using IDEXX QuantiTray/2000 with Colilert-18 and cefotaxime supplementation to enumerate the most probable number (MPN) of cefotaxime-resistant *E. coli*. We detected *Ascaris lumbricoides* and *Trichuris trichiura* with qPCR in floor dust samples and with microscopy in floor swab samples. There was a mean of 8.0 g of dust on soil floors vs. 0.2 g on concrete floors (t-test p-value=0.005) per m^2. We detected cefotaxime-resistant *E. coli* on 86% of soil floors vs. 38% of concrete floors (chi2 p-value=0.001), with a mean $\log_{10}$-transformed MPN of 3.1 on soil floors vs. 1.6 on concrete floors (t-test p-value<0.0005). Using qPCR, we detected *Ascaris* on 18% of soil floors

and none of concrete floors, and *Trichuris* on 29% of soil floors and 31% of concrete floors. Using microscopy, we detected STH on 33% of soil floors and none of concrete floors (chi^2 p-value=0.01). Our findings indicate that soil floors are a source of child exposure to antimicrobial resistant organisms and STH in low-income countries; children can ingest soil from floors via dust or geophagia and indirectly through contaminated hands and objects. Efforts to mitigate infectious diseases and antimicrobial resistance in low-income countries should test flooring improvements to reduce soil-borne exposure to fecal organisms.

ASSOCIATION OF WATER, SANITATION AND HYGIENE (WASH) AND ANIMAL OWNERSHIP TO RELAPSE TO ACUTE MALNUTRITION (AM) FOLLOWING RECOVERY FROM SEVERE ACUTE MALNUTRITION (SAM) AMONG CHILDREN 6-59 MONTHS IN MALI, SOUTH SUDAN AND SOMALIA: A PROSPECTIVE COHORT STUDY

Lauren Eleanor D'Mello-Guyett[1], Sarah King[2], Sherifath Mama Chabi[3], Feysal A. Mohamud[4], Nancy Lamaka[5], John Agong[5], Malyun Mohamed[4], Karim Kone[3], Karin Gallandat[1], Mesfin Gose[5], Mohamed S. Omar[4], Magloire Bunkembo[3], Indi Trehan[6], Anastasia Marshak[7], Khamisa Ayoub[8], Ahmed H. Olad[9], Bagayogo Aliou[10], Heather Stobaugh[11], Oliver Cumming[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Action Against Hunger, Bamako, Mali, [4]Action Against Hunger, Mogadishu, Somalia, [5]Action Against Hunger, Juba, South Sudan, [6]University of Washington, Seattle, WA, United States, [7]Tufts University, Boston, MA, United States, [8]Ministry of Health for the Republic of South Sudan, Juba, South Sudan, [9]Federal Ministry of Health for the Federal Republic of Somalia, Mogadishu, Somalia, [10]Ministry of Health and Social Development for the Republic of Mali, Bamako, Mali, [11]Action Against Hunger, Washington DC, DC, United States

In the context of high burdens of acute malnutrition (AM), children recovered from severe acute malnutrition (SAM) may frequently relapse upon returning to households with inadequate water, sanitation and hygiene (WASH) conditions which may increase the risk of infection with enteric pathogens and disease. This study aimed to identify the association of WASH, and animal ownership, to relapse to AM. This prospective cohort study examined the association of WASH-related risk factors, and animal ownership, to relapse to AM over six months among children treated and recovered from SAM in Mali, Somalia, and South Sudan. A total of 1008 children recovered from uncomplicated SAM were recruited and followed for this study. Within six months after initial recovery, 32%, 64% and 21% of children relapsed to AM in Mali, South Sudan and Somalia, respectively. In Mali, the use of multiple drinking water sources led to a 71% increased risk of relapse to AM (aRR1.71, 95% CI:1.21-2.43, p=0.003) and a lack of soap led to a 71% increased risk (aRR1.71, 95% CI:1.03-2.82, p=0.037). In South Sudan, using an unimproved or surface drinking water source was associated with 20% increased risk of relapse to AM (aRR1.20, 95% CI:1.05-1.36, p=0.006), practising open defecation was associated to 14% increased risk (aRR1.14, 95% CI:1.00-1.29, p=0.043) and compounds with observable animal faeces had 13% increased risk (aRR1.13, 95% CI:1.04-1.24, p=0.006). Ownership of sheep (aRR0.57, 95% CI:0.40-0.81, p=0.002) and cattle (aRR0.79, 95% CI:0.72-0.86, p=0.000), was a protective in Mali and South Sudan, respectively. In Somalia, no risk factors for relapse were identified. Our study identified several WASH-related risk factors for relapse to AM including inadequate drinking water sources, practising open defecation, a lack of soap and exposure to animal faeces. Identifying the relative importance of factors for adverse outcomes following initial SAM recovery could help improve the identification of children and communities at greater risk of relapse and inform interventional efforts for post-discharge support to sustain recovery.

COMMUNITY PERCEPTIONS OF OPEN DEFECATION AND SCHISTOSOMIASIS CONTROL: LESSONS LEARNED FROM A RAPID ETHNOGRAPHIC ASSESSMENT STUDY IN THREE ENDEMIC LAKESHORE COMMUNITIES IN MAYUGE, UGANDA

Lucy Pickering[1], Edith Nalwadda[2], Lazaaro Mujumbusi[3], Agnes Ssali[3], Janet Seeley[3], Poppy H L Lamberton[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Independent Researcher, Entebbe, Uganda, [3]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda

Schistosomiasis is a neglected tropical disease, infecting over 240 million people globally, with over 4 million people infected in Uganda. Open defecation in high endemicity areas is a significant driver of transmission. Improved understanding of practices and perceptions of open defecation will help inform how best to reduce it. Data were collected over six weeks in each of three high endemicity communities using rapid ethnographic assessment, comprising 60 individual in-depth interviews, 19 focus group discussions, Village Health Team (VHT)-guided walks, transect walks, and structured observations. Guided walks focused on latrines and open defecation sites. Data were analyzed thematically using iterative categorization. Observations and walks revealed open defecation to be a commonly occurring practice in all communities, coupled with low private and public latrine coverage, and public latrines often described by VHT guides as unusable due to lack of cleanliness or being full. Interviews and focus group discussions supported these findings and further highlighted perceptions of public latrines as costly and dangerous to health when dirty, unequal access to private latrines, and perceptions of *who* engaged in open defecation: accusations ran along existing lines of status and inequality, emphasising children, certain tribes, people who use alcohol and in particular (low status, often itinerant) fishermen. This practice thus sits at the intersection of infrastructure, poverty, logistical and bodily limitations, and accusation as an amplifier of inequality. Reducing schistosomiasis transmission by reducing open defecation therefore requires a multi-scalar response: more public latrines coupled with effective cleaning and emptying, situated sensitively to where people live and work; affordable cost, and; working with communities on the risks of open defecation, why some (are perceived to) choose it, and identifying 'best fit' solutions that people will be willing to take up in order to reduce, even if not eliminate, onward *Schistosoma* transmission risk.

HOST GASTRIC CORPUS MICROENVIRONMENT FACILITATES *ASCARIS SUUM* LARVAL HATCHING AND INFECTION IN A MURINE MODEL

Yifan Wu[1], Grace Adeniyi-Ipadeola[1], Mahliyah Adkins-Threats[1], Matthew Seasock[1], Charlie Suarez-Reyes[1], Ricardo Fujiwara[2], Maria E. Bottazzi[1], Lizhen Song[1], Jason C. Mills[1], Jill E. Weatherhead[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Ascariasis (roundworm) is the most common parasitic helminth infection globally and can lead to significant morbidity . Children become infected with *Ascaris* spp. via oral ingestion of eggs. It has long been assumed that *Ascaris* egg hatching and larval translocation across the gastrointestinal mucosa to initiate infection occurs in the small intestine. Here, we show that *A. suum* larvae hatched in the host stomach in a murine model. Larvae utilize acidic mammalian chitinase (AMCase; acid chitinase; Chia) from chief cells and acid pumped by parietal cells to emerge from eggs on the surface of gastric epithelium. Furthermore, antagonizing AMCase and gastric acid in the stomach decreases parasitic burden in the liver and lungs and attenuates lung disease. Given Ascaris eggs are chitin-coated, the gastric corpus would logically be the most likely organ for egg hatching, though this is the first study directly evincing the essential role of the host gastric corpus microenvironment. In addition, we show that the gastric corpus

downregulates AMCase and acid in response to repeated *A. suum* infection to reduce larval migration. These findings point towards potential novel mechanisms for therapeutic targets to prevent ascariasis and identify a new biomedical significance of AMCase in mammals.

COMPREHENSIVE SINGLE CELL RNA SEQUENCING UNVEILS THE TRANSCRIPTIONAL DYNAMICS OF *PLASMODIUM VIVAX* HYPNOZOITE FORMATION

Gigliola Zanghi[1], Lindsay V. Clark[1], Nastaran Rezakhani[1], Wanlapa Roobsoong[2], Jetsumon Sattabongkot[3], Sumana Chakravarty[4], Stephen L. Hoffman[4], B. Kim Lee Sim[4], Stefan H.I. Kappe[1], Ashley M. Vaughan[1]

[1]Seattle Children's, Seattle, WA, United States, [2]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Bangkok, Thailand, [3]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Sanaria Inc., Rockville, MD, United States

On one of the primary objectives of *Plasmodium vivax* malaria parasite liver stage research is to understand the formation, persistence, and activation of hypnozoites, the dormant liver stage parasites that are responsible for recurrent relapses. However, this research faces severe challenges, due to the limited access to *P. vivax* sporozoites. To unravel the molecular pathways governing hypnozoite formation, we adopted a comprehensive strategy. We revisited the utilization of Chesson strain *P. vivax* sporozoites, as well as P. vivax field strains from Thailand, for hypnozoite biology analysis in conjunction with the highly infectable human hepatocyte cell line HCO4. Furthermore, we employed single-cell RNA sequencing to analyze the transcriptional profiles of both oocyst and salivary gland sporozoites as well as a time course of developing liver stage parasites - both schizonts and hypnozoites. Our efforts resulted in the transcriptional profiling of over 50,000 individual sporozoites and 500 liver stage parasites. We have delineated multiple gene expression clusters and, as to be expected, observe stark differences in expression profiles between sporozoites and liver stage parasites. Preliminary analysis indicates an upregulation of genes related to RNA-binding in the hypnozoite population, suggesting a potential regulatory role in hypnozoite formation. Additionally, we have devised a reliable RNA-FISH/IFA protocol capable of specifically identifying transcripts expressed solely in hypnozoites. This multifaceted approach promises a deeper understanding of hypnozoite biology and holds promise for uncovering novel interventions to mitigate relapses.

6812

PLASMODIUM VIVAX-INDUCED BONE MARROW ALTERATIONS PERSIST LONG AFTER ACUTE PHASE OF INFECTION

Joao Luiz Silva-Filho[1], Jessica RS Alves[2], Anne CG Almeida[3], Erich De Paula[2], Stefanie Lopes[4], Kevin Couper[5], Thomas Otto[1], Gisely Mello[6], Wuelton Monteiro[3], Marcus Lacerda[3], Fabio TM Costa[2], Matthias Marti[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]University of Campinas, Campinas, Brazil, [3]Tropical Medicine Foundation Dr. Heitor Vieira Dourado, Manaus, Brazil, [4]Fiocruz, Manaus, Brazil, [5]University of Manchester, Manchester, United Kingdom, [6]Tropical Medicine Foundation Dr. Heitor Vieira DouradoUniversity of Glasgow, Manaus, Brazil

Plasmodium vivax (*Pv*) infection can lead to poor clinical outcomes, despite low peripheral parasitaemia. Estimation of total *P. vivax* biomass based on markers in peripheral blood (PB) indicates a "hidden" population outside of circulation. Indeed, recent studies revealed a major *Pv* reservoir in bone marrow (BM) and spleen. The development of *Pv* parasites in the BM raises questions about the locally established host-parasite interactions and their clinical relevance in malaria pathogenesis. Here, we aimed to define *Pv*-induced immune responses in the BM and their effect on BM function and disease development. Matched BM aspirates and PB samples have been collected from a prospective longitudinal cohort of uncomplicated *Pv* patients from Brazil, to investigate parasite and host signatures in the hematopoietic niches of BM compared to blood. So far, we analysed host signatures by combining clinical data and multiplexed profiling of 64 protein markers in matched BM and PB material sampled at hospital admission (day 0), as well as 45 and 60 days after, in comparison to healthy donor BM samples. Luminex results demonstrate that *Pv* infection induces a wide range of host responses in the BM during acute phase, most of which persist long after infection is resolved. Persisting upregulated responses were related to megakaryopoiesis, lymphopoiesis, granulopoiesis, myeloid chemoattraction, neutrophil and endothelial cell activation, inflammasome activation, type II IFN response, Th1 response and T-cell exhaustion/inhibition. Persisting downregulated protein markers were related to BM function, such as hematopoietic quiescence, dendritic cell differentiation. In contrast, persisting responses are largely absent in the PB. Ongoing single cell and bulk transcriptomics of host response and parasite signatures in both compartments will be presented. This study emphasises the relevance to investigate the impact of *Pv* infection in the hematopoietic niches. As such, our work will contribute to a better understanding of *Pv* biology and pathogenesis, and hence to our efforts to reduce the burden of this important human disease.

6813

A HUMAN PLURIPOTENT STEM CELL DERIVED MODEL OF THE NEUROVASCULAR UNIT COMPRISED OF BRAIN MICROVASCULAR ENDOTHELIAL CELLS, ASTROCYTES, AND NEURONS IN CEREBRAL MALARIA

Adnan Gopinadhan[1], Finley Andrew[1], Rylee Anderson[2], Alejandro Soto[1], Jason M. Hughes[2], Andrea L. Conroy[1], Chandy John[1], Scott G. Canfield[2], Dibyadyuti Datta[1]

[1]Indiana University, Indianapolis, IN, United States, [2]Indiana University, Terre Haute, IN, United States

Damage to the blood-brain barrier (BBB) and neurovascular unit (NVU) leading to long-term neurologic impairment in cerebral malaria (CM) remains a poorly understood complication of *Plasmodium falciparum (Pf)* infections. How *Pf*-infected RBCs (*Pf*-iRBCs) sequestered to brain endothelial cells cause damage to neuronal cells without crossing the BBB is unclear. *In vitro* models have advanced our knowledge of CM-mediated BBB disruption, but few have investigated NVU damage. Previously, using induced pluripotent stem cell-derived brain microvascular endothelial cells (iPSC-BMECs) co-cultured with *Pf*-iRBCs, we've demonstrated *Pf*-mediated damage to the BBB. In this study, we have expanded our *in vitro* model of the BBB in CM to include iPSC-derived neurons and astrocytes along with BMECs in co-culture with *Pf*-iRBCs to represent the NVU in CM. Our novel, multicellular model of the NVU represents near *in vivo* like barrier resistance (3800 Ωxcm^2) by transendothelial electrical resistance (TEER) that is 10 times that observed in human primary BMEC based models ($\leq$400 Ωxcm^2). iPSC neurons and astrocytes were characterized using β-tubulin III and GFAP staining. Using HB3var03 parasite strain that binds endothelial surface proteins ICAM-1 and EPCR—key mediators of CM neuropathology, we conducted co-culture experiments up to 9 hours (h). At 6 h post co-culture with *Pf*-iRBCs, there was a significant reduction in barrier resistance of the iPSC-BMEC (1827 Ωxcm^2) compared to uninfected RBC co-culture (2937 Ωxcm^2); which remained low at 9 h (all $P<0.005$). We observed increased sodium fluorescein permeability indicative of a leaky barrier in *Pf*-iRBC co-cultures compared to uninfected RBC co-cultures at 6 h. Breaks in tight junction protein localization further confirmed BBB disruption in *Pf*-iRBC co-cultures at 6 h. Ongoing experiments will identify altered expression of endothelial surface markers and efflux proteins. Our multicellular iPSC-derived model of the NVU with enhanced barrier integrity replicates key features involved in the pathogenesis of CM and can serve as a surrogate to investigate pathogenic stimuli underlying NVU damage in CM.

6814

DIETARY EFFECTS ON THE COURSE OF VISCERAL LEISHMANIASIS IN A MOUSE MODEL

Natalie Jarvis, Grace Gutzman, Yani Chen, Bayan Zhanbolat, Patrick Nuro-Gyina, Jacilara Conceicao, Mary Wilson
University of Iowa, Iowa City, IA, United States

The demographics of leishmaniasis has changed dramatically in endemic regions of Brazil, concurrent with changes in socioeconomic status and consequent shift towards a high-fat high-cholesterol diet (HFHC). With this shift, a novel presentation of cutaneous leishmaniasis due to *L. braziliensis* has emerged in obese patients, characterized by poorer treatment response with higher recurrence rates in obese individuals, s reported previously. A direct link between diet-induced changes in metabolic and immune status and the manifestations of visceral leishmaniasis (VL) has not been established. We hypothesize that diet-induced changes in immunometabolism may also affect the progression and outcome of VL. To address this, we examined the effects of a HFHC and protein-deficient (LP) diet in a murine model of VL. BALB/c mice were maintained on HFHC, LP, or control diets for 4 weeks, then either infected or not with L. *infantum*. The course of infection was monitored by histology and by qPCR to document inflammation and parasite loads. The HFHC diet abrogated the expansion of parasite loads in the liver and caused exacerbated parasite growth in spleens ($P<0.0001$). Mice on a LP diet, in contrast, developed higher parasite loads in livers than control mice ($P<0.0001$). Control mice developed granulomas in the livers as the disease progressed. In contrast, mice on a HFHC diet developed a basal inflammatory response in the liver and failed to develop organized, mature granulomas ($P<0.0001$). Mice on a LP diet had increased numbers of granulomas in the liver ($P<0.0001$). These findings suggested that the basal inflammation of the HFHC diet led to failure to contain the parasite and early dissemination of infection to the spleen. Dietary factors may influence the changing spectrum of VL.

6815

PERSPECTIVES ON EQUITABLE PARTNERSHIPS IN GLOBAL HEALTH

Senait Kebede, Mischka Garel, Michael Chung, Rebecca Martin
Emory Global Health Institute, Emory University, Atlanta, GA, United States

Equitable global health partnerships (EGHPs) are gaining traction amid decolonization global health movements, spotlighting power imbalances rooted in colonial legacies. There is an increased call among global health institutions for a meaningful change that fosters equity, inclusivity, and fairness, and values local knowledge in research partnerships. The Emory Global Health Institute (EGHI) took a methodical approach, with a literature review and an explanatory sequential QUAN-QUAL mixed methods strategy to assess perspectives on EGHPs. A quantitative survey and key informant interviews were conducted among Emory faculty in the US and their partners in low- and middle-income countries (LMICs) engaged in global health research collaborations. Additionally, a decolonizing global health working group was convened to deliberate on the findings and establish priority areas. The literature identified key principles for advancing equitable partnerships: authentic collaboration, inclusion, shared benefits, commitment to the future, responsiveness to inequities, and humility. Survey analysis revealed agreement between US and LMIC partners across 16 out of the 22 indicators with marginal differences in responses with regards to infrastructure, communication, bidirectional training, fair compensation, financial transparency, and sustainability. LMIC partners prioritized capacity strengthening, equity principles, communication, and relationship building, while US participants focused on operational efficiency and equity. The findings are consistent with previous studies in the literature. Based on all the results and discussions the main priorities to advance EGHPs are; establishing tools and frameworks to integrate equity, measure progress, bidirectional capacity building, knowledge sharing, and creating a platform for constructive dialogue to influence policies for fair access to financial and technical resources. The building momentum to advance EGHPs can be furthered and expanded on with collective efforts to implement key principles and actionable steps that center equity in global health practice.

6816

INNOVATION FOR NEGLECTED DISEASES: TWO DECADES OF PROGRESS AND GAPS IN NEW DRUG APPROVALS

Paul G. Ashigbie[1], Rajiv Shah[2], Jonathan M. Spector[1], Thierry T. Diagana[3]
[1]Global Health, Biomedical Research, Novartis, Cambridge, MA, United States, [2]Global Health and Sustainability, Novartis, Basel, Switzerland, [3]Global Health, Biomedical Research, Novartis, Emeryville, CA, United States

Therapeutic innovations have an essential role to play in addressing the burden of neglected diseases. This study analyzes the approval landscape of novel medicines for diseases that disproportionately affect populations in low- and middle-income countries (LMICs) to inform drug research, development, and access strategies. We examined the online databases of 26 medicines regulatory authorities (from the record of World Health Organization-Listed Authorities), the WHO Prequalification Program, and other online platforms for medicines approved between 2003 and 2023. The focus was on 47 diseases identified by WHO, the Access to Medicines Foundation, or Policy Cures Research to be priority health conditions in LMICs. Inclusion criteria were new chemical entities (NCEs), new therapeutic biologics (NBs), new fixed-dose combinations (FDCs), new dosage forms of existing medicines, or "repurposed" medicines for new indications. We estimated the ratio of the number of approvals to the burden of each disease in Disability Adjusted Life Years (DALYs). Of 55 medicines approved over the study period, 11 were NCEs (eight medicines) or NBs (three medicines): three for tuberculosis; two each for Ebola, malaria, and sickle cell disease; and one each for human African trypanosomiasis and onchocerciasis. Eight of the 11 NCEs and NBs were approved after 2015. Forty-four of the approved medicines were repurposed drugs (12), FDCs (11), and new dosage forms (21). Of these, 23 were for tuberculosis, 11 for malaria, two each for sickle cell disease and leishmaniasis, and one each for six other diseases. No novel medicines were approved for 35 diseases. The number of approvals to DALY ratios in all disease areas studied was substantially lower than those that are typical for leading diseases in high-income countries. Therapeutic innovation for neglected diseases is severely limited, especially for new chemical or biologic entities, and unbalanced across disease areas. Given severe unmet needs including, in some cases, the threat of resistance to existing therapies, there is urgency to scale up R&D for novel medicines that address global health diseases.

6817

BUILDING CAPACITY FOR MATERNAL, NEWBORN AND CHILD HEALTH RESEARCH IN LOW-INCOME COUNTRY SETTINGS: A RESEARCH FELLOWSHIP EXPERIENCE IN ETHIOPIA

Kassahun Alemu Gelaye[1], Lisanu Taddesse[1], Clara Pons-Duran[2], Clara Pons-Duran[2], Bezawit Mesfin Hunegnaw[3], Robera Olana Fite[1], Abebe Belayneh Bekele[1], Frederick GB Goddard[4], Assaye K. Nigussie[5], Yifru Berhan[6], Delayehu Bekele[6], Theodros Getachew[7], Ebba Abate[8], Grace J. Chan[9]

In low- and middle-income countries, there is a need to build capacity for research to improve maternal, newborn and child health (MNCH). Collaborating with the Ministry of Health (MoH) and academic institutions, we co-designed the HaSET MNCH research fellowship program for academics and policymakers in Ethiopia. Based on interviews and focus group discussions on a landscape analysis of the MNCH research environment, we developed an innovative "learning by doing" model where fellows identified research questions, developed proposals, obtained IRB approvals, conducted research, analyzed data, disseminated their findings, and developed policy briefs. Post-doctoral fellows were paired with policymakers and health professionals at the MoH to foster translation of research findings to policy and programs. The HeSET fellowship curriculum was designed to include 10 modules covering topics from biostatistics to study operations and professional development. From March 2021 to July 2023, HaSET trained five post-doctoral fellows from local universities and four policymakers from the MoH and government research institutes to generate high-quality evidence to answer priority research questions and guide the implementation of national policies and programs. Leveraging existing data, the fellows completed 15 manuscripts and 11 policy briefs. Fellows presented their work at international and national conferences. The program established a functional research link between the Ministry of Health, regional health bureaus, local universities, and leveraged the expertise of a scientific advisory group for mentorship. This robust and comprehensive HaSET MNCH Research Fellowship cultivated a cohort of dedicated and effective public health professionals. Fellows conducted high-quality studies for informed policy decisions regarding MNCH interventions in Ethiopia. There is potential to scale the program to sustain successful capacity-building programs to build the next generation of leaders in research in low- and middle-income countries.

6818

EAST AND SOUTHERN AFRICAN CONSORTIUM FOR OUTBREAK EPIDEMIOLOGY TRAINING (ENTRANT)

Emily Webb[1], Nega Assefa[2], John Changalucha[3], Maryirene Ibeto[1], Joseph Jarvis[1], Achilles Kiwanuka[4], Madisa Mine[5], Julius Oyugi[6], Kwame Shanaube[7]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Haramaya University, Haramaya, Ethiopia, [3]Mwanza Interventions Trials Unit, Mwanza, Tanzania, United Republic of, [4]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [5]National Health Laboratories, Gaborone, Botswana, [6]University of Nairobi, Nairobi, Kenya, [7]Zambart, Lusaka, Zambia

East and Southern African countries are susceptible to disease outbreaks, and vulnerable to public health emergencies due to constrained health system resources. The East and Southern Africa Consortium for Outbreak Epidemiology Training (ENTRANT) programme was established with funding from EDCTP in collaboration with Africa CDC. The objective of ENTRANT is to provide epidemiological training and mentorship to early- to mid-career public health professionals working in the region. Through this we aim to promote the development of a critical mass of epidemiologists to work with National Public Health Institutes and Ministries of Health and thus strengthen public health and outbreak response capacity. ENTRANT is coordinated by a consortium of institutional partners relevant to outbreak response in the region, and supported by an independent Advisory Committee comprising experts in capacity strengthening for epidemiology in sub-Saharan Africa. A competitive application process was implemented to identify high-calibre public health professionals for entry into the programme. Fellows undertake MSc Epidemiology at London School of Hygiene and Tropical Medicine (LSHTM) followed by further focussed short course multidisciplinary training on the emergence, spread and response to pandemics. Fellows receive mentorship from LSHTM tutors and experienced epidemiologists in their home country, take part in regular transferable skills training and networking activities, and are supported to attend conferences. From a total of 324 applications, 15 public health professionals (eight female, seven male) from Botswana, Ethiopia, Kenya, Tanzania, Uganda and Zambia have been awarded Fellowships. To date, 13 have completed their MSc Epidemiology training, with the remaining Fellows due to complete in October 2024. Fellows who have completed formal training have gone on to work for Ministries of Health and public health research institutions. Fellows at all stages of the programme have formed a strong, mutually-supportive cohort through regular meetings and networking events.

6819

WHO ANC POLICY AND SKILLED BIRTH ATTENDANCE IN SUB-SAHARAN AFRICA

Michael Bride[1], **Bolanle Olapeju**[2]

[1]Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States, [2]Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Over half a million mothers are lost each year due to pregnancy-related complications. The World Health Organization (WHO) recommends that all pregnant women have a minimum of eight ANC contacts (WHO 2016 ANC policy) and delivery by an accredited health professional - such as a midwife, doctor or nurse. This study explores the association between skilled birth attendance at a prior pregnancy and the number of ANC contacts in the index pregnancy. A secondary analysis of data from 19 sub-Saharan African countries with available Demographic Health surveys from 2018 to date was performed. Key variables were skilled birth attendance (by a doctor, nurse, midwife and auxiliary nurse or midwife) during a participant's second most recent pregnancy and the number of ANC contacts in the most recently completed pregnancy in the past two years. Propensity score matching was used to explore the treatment effects of having a skilled birth attendance on the number of ANC contacts during pregnancy. 40,077 women had had at least two pregnancies in the five years preceding the survey. 60% of women had had a skilled delivery in their second most recent pregnancy which varied by county, with Ethiopia (37%) to Gabon (95%).The majority of these skilled providers (44%) were nurses. The mean number of ANC contacts in a woman's most recent pregnancy ranged from Mauritania (2.8) to Ghana (6.2) (mean 3.6). Having a skilled provider in their second most recent pregnancy had an average treatment effect of 1.20 (95% CI: 1.12-1.28), indicating a modest increase in number of ANC visits of their subsequent pregnancy compared to not having a skilled delivery, accounting for country, age, wealth, urbanization, and religion. This study highlights the influence of skilled delivery in current and subsequent pregnancies. Improving ANC contacts allows for an improved life course, providing more opportunities for health promotion, early detection of health complications, and many more benefits to the pregnant woman and unborn child. In countries with low percentages of skilled deliveries, improving access could increase ANC contacts and support more linkages to further health and wellbeing.

6820

ENHANCING THE QUALITY OF COMMUNITY HEALTH SERVICES IN MADAGASCAR: A MIXED METHODS EVALUATION OF A COMMUNITY HEALTH VOLUNTEERS (CHVS) PEER SUPERVISION MODEL IN FOUR REGIONS

Kanto Jude Ramanamahefa[1], **Samantha Herrera**[2], Tsinjo Fehizoro Razafindratsinana[1], Anna Bowen[3], Erica Berlin[4], Andry Rabemanantsoa[1], Hery Suzanette Gnetsa[5], Jose Clement Randrianarisoa[6], Jayne Webster[7], Jessie Hamon[7], Cara Smith Gueye[8]

[1]Population Services International, Antananarivo, Madagascar, [2]U.S. President's Malaria Initiative Insights, Washington, DC, United States, [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Antananarivo, Madagascar, [4]Population Services International, Washington, DC, United States, [5]Community Health Service, Ministry of Public Health, Antananarivo, Madagascar, [6]National Malaria Control

Program, Antananarivo, Madagascar, [7]London School of Hygiene and Tropical Medicine, London, United Kingdom, [8]University of California, San Francisco Malaria Elimination Initiative, San Francisco, CA, United States

In 2019, Madagascar's Ministry of Public Health (MoPH) launched a national community health strategic plan, aiming to strengthen community health services through improved supervision of community health volunteers (CHVs). CHVs are traditionally supervised by health facility (HF) heads; however, insufficient facility staffing and high workloads have resulted in inadequate supervision. The MoPH is collaborating with the USAID ACCESS program to implement a new CHV supervision model that engages high-performing CHVs as peer supervisors in 13 regions; an evaluation of the model is expected to guide national scale-up and planning in other countries. We completed a mixed-methods study in 2023, conducting secondary data analysis to characterize the program and collecting primary data in four regions. In 16 health facility catchment areas, we conducted in-depth interviews (IDIs) with peer supervisors (n=16), CHVs (n=32), HF heads (n=16), and other stakeholders engaged in the peer supervision model rollout (n=41). IDI themes included how the model worked, the functionality of model components, and feasibility and acceptability. Qualitative data were coded using NVivo; a deductive approach was used for the thematic analysis. The new model was perceived to result in greater information sharing between CHVs and peer supervisors, better management of health providers' schedules, and improved quality of CHV services, including reporting. Aspects of the model not found to work well included the process of selecting peer supervisors, inadequate clinical supervision, high ratio of CHVs to peer supervisors, less time for peer supervisors to engage in income-generating activities, and lack of supervision tools and training for the HF heads. The new model shows promise; however, several aspects require reconsideration to improve the model's acceptability and feasibility, including reducing the number of CHVs per peer supervisor, bolstering clinical supervision, and providing adequate remuneration, training, and tools for CHVs, peer supervisors, and HF heads. Findings were shared with MoPH and ACCESS to inform national scale-up of the model.

AI IN GLOBAL HEALTH: CHALLENGES AND OPPORTUNITIES

Naomi Waithira[1], Mavuto Mukaka[1], Evelyne Kestelyn[2], Keitcheya Chotthanawathit[1], Anne Osterreider[3], Trudie Lang[3], Phaik Yeong Cheah[1]

[1]MORU Tropical Health Network, Bangkok, Thailand, [2]Oxford Clinical Research Unit, Ho Chi Minh City, Vietnam, [3]University of Oxford, Oxford, United Kingdom

AI has enormous potential in healthcare, from aiding diagnosis to personalising medical care and predicting disease outbreaks. However, the accuracy of AI algorithms depends on the quality and diversity of the data used to train them. Concerns exist regarding the reliability and sufficiency of data from low-and-middle-income countries (LMICs) for training AI algorithms. There is a risk that a lack of contextually relevant data may result in incorrect algorithms or limited application of AI in LMICs. How, then, can we ensure that the benefits of technology are accessible to all? We present the results of a mixed-methods study exploring challenges and opportunities in using existing health data from LMICs. We conducted a cross-sectional study with 643 clinical researchers and 24 in-depth interviews with computational health scientists. The study reveals low data usage, especially for AI, mainly due to challenges with data findability. The study also highlights inequity in gains realised from data reuse. Career progression from data reuse was associated with affiliation with high-income and upper-middle-income countries (p=0.046, chi=8.0), while scientific progress through publications and collaborations was associated with gender (p=0.012, chi=10.9), with males more likely to benefit. Publicly publishing metadata of health datasets in machine and human-readable formats will enhance data discoverability without compromising data privacy. Intentional efforts to encourage and enable more analysts in LMICs, especially females, may reduce the equity gap. Capacity building in data management may improve the overall quality of prospectively collected data, while targeted efforts to curate existing data will increase the pool of data available for secondary use, including AI applications.

6822

CLINICODEMOGRAPHIC PROFILE AND SURVIVAL PROSPECTS OF WOMEN WITH PERIPARTUM CARDIOMYOPATHY IN TANZANIA: A PROSPECTIVE COHORT STUDY.

Pedro Kisali Pallangyo, Zabella Mkojera, Makrina Komba, Peter R. Kisenge

Jakaya Kikwete Cardiac Institute, Dar es Salaam, Tanzania, United Republic of

Background: Irrespective of a higher rate of complete recovery relative to other forms of systolic heart failure, peripartum cardiomyopathy (PPCM) remains the leading cause of non-obstetric feto-maternal morbidity and mortality worldwide. In view of the paucity of data, this present study aimed to shed light on the clinicodemographic characteristics and prognosis of PPCM in Tanzania. Methods: This prospective, multicenter PPCM study in Tanzania commenced in April 2016. Data was systematically collected at the very first contact and then upon three-, six-, and twelve-months visits. Clinical outcomes including complete recovery (LVEF>55%), persistent dysfunction, and death were recorded. Bivariate comparison and subsequent Cox proportional-hazards regression model were used to compare the women with respect to the primary end point. Results: We screened 1639 women and consecutively recruited 1210 who met the inclusion criteria. The mean age at diagnosis was 29.4 ± 6.7 years and in 31.2% women it was their first pregnancy. During a mean follow-up of 889 days, 23.6% of women had complete recovery, 48.2% had persistent LV systolic dysfunction, and 28.1% died. We observed thromboembolic events in 10.2% of women and infant mortality rate was 23.4%. Amongst 870 survivors (286 resolved, 584 persistent heart failure), 121 women (78 in the resolved group and 43 in the persistent heart failure) had subsequent deliveries. Recurrence was observed in 51.3%, resolution in 31.4%, and death in 8.3%. Following multivariate analysis in a cox regression model of 16 variables; Atrial fibrillation (HR 5.0, 95%CI 2.6-9.8, p<0.001), LVIDd ≥60 (HR 2.8, 95%CI 1.9-4.3, p<0.001), EF<30% (HR 1.7, 95%CI 1.1-2.5, p<0.001), TAPSE<14 (HR 7.4, 95%CI 5.1-11.1, p<0.001), and LV thrombus (HR 2.3, 95%CI 1.3-3.9, p<0.01) proved to be the predictors of mortality. Conclusions: In this largest cohort of African women with well-phenotyped PPCM, we observed myocardial recovery in just under a quarter of patients and maternal death in over a quarter of the enrolled women. Despite its relative rarity yet poor prognosis, PPCM remains a challenge to diagnose, prognosticate, and treat.

6823

BURDEN, DISTRIBUTION, TIMING AND CAUSES OF STILLBIRTH AND NEONATAL MORTALITIES IN A HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM (HDSS) IN KAREMO AND MANYATTA IN WESTERN KENYA, 2018-2023

George Aol Otieno[1], Richard O. Onyando[1], Godfrey M. Bigogo[1], Joyce Were[1], Beth A. Odhiambo[1], Stephen O. Munga[1], Beth T. Barr[2], Nehemia O. Abongo[1], Brian Genga[1], Jonathan A. Muir[1], Victor Akelo[3], Aggrey Igunza[1], Thomas Misore[1]

[1]kenya Medical Research Institute, Kisumu, Kenya, [2]nyanja Health Research Institute, Salima, Malawi, [3]liverpool School Of Tropical Medicine, Kisumu, Kenya

Sub-Saharan Africa has the highest stillbirth and neonatal mortality rates worldwide. We sought to estimate the burden, distribution, timing and causes of stillbirth and neonatal mortality using data from a Health and Demographic Surveillance System (HDSS) site operated by the Kenya Medical Research Institute and CHAMPS in western Kenya. Approximately 179,317 residents, in Karemo - Siaya County and Manyatta - Kisumu County are monitored every six months using a standardized questionnaire about events that happened since prior visit. All women of reproductive

age (12-49 years) are asked about their pregnancy status and outcome. Community health volunteers report deaths, births and pregnancies. Minimally invasive tissue sampling was conducted on stillbirth and neonatal deaths. Aseries of biopsies, blood and body fluids samples were analyzed and cause of death determined by medical experts. A total of 454 stillbirth and 606 neonatal deaths were reported of which 277 stillbirths and 268 neonates had cause of deaths determined. Between 2018 and 2023, stillbirth mortality rate (SMR) in Karemo was 18.0 and 23.6 and in Manyatta 12.4 and 28.1 deaths per 1000 births; Neonatal mortality rates (NMR) in Karemo was 23.1 and 23.2 and in Manyatta 13.9 and 22.6 deaths per 1000 livebirths. SMR among women aged 15-19 was 15.6, 20-24 (17.0), 30-34(20.0) 35-39 (24.8) and 45-49 (48.8) deaths per 1000 births. NMR among women aged 12-14, 15-19, 25-29, 30-34, 40-44 and 45-49 years was 32.8, 30.4. 20.2, 20.8, 31.0 and 54.1 deaths per 1000 livebirths respectively. Overall, 57% of the stillbirth deaths happened among fetuses over 38 weeks old; 63% of neonatal deaths happened on the delivery day. Leading cause of neonatal deaths were intrauterine hypoxia (33%), sepsis (20%) and respiratory distress syndrome (18%) while intrauterine hypoxia (88%) was leading cause of stillbirths. We observed an increase in neonatal and stillbirth mortality rates overtime. The highest mortality rates were observed among young women and those with advanced ages. Most deaths happened around time of delivery due to intrauterine hypoxia. There is need for improved obstetrical care for pregnant women in the study.

6824

VACCINATION COVERAGE AND TIMELINESS AMONG INFANTS IN ETHIOPIA

Clara Pons-Duran[1], Bezawit Mesfin Hunegnaw[2], Chalachew Bekele[2], Kassahun Alemu[1], Raffi Pontes[3], Fiseha Tadesse[4], Melkamu Ayalew[5], Abraham Alebie[2], Lisanu Taddesse[1], Delayehu Bekele[2], Sebastien Haneuse[3], Grace J. Chan[3]

[1]HaSET Maternal and Child Health Research Program, Addis Ababa, Ethiopia, [2]St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [3]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [4]Debre Birhan Hospital, Debre Birhan, Ethiopia, [5]Federal Ministry of Health, Addis Ababa, Ethiopia

Vaccinations are key for preventing and controlling infectious diseases. However, in Ethiopia, a significant proportion of children remain unimmunized. This study aimed to describe the vaccination coverage among children in a rural site in Ethiopia, and to quantify the proportion of infants who were vaccinated on time according to the National vaccination schedule. We analyzed data of a longitudinal study conducted in Ethiopia, which includes a health and demographic surveillance system (HDSS) with house-to-house surveillance every 3 months. The study population were children born between 2018 and 2021, and enrolled in the HDSS. Vaccination data were collected through questionnaires administered as part of the routine surveillance. Data were abstracted from vaccination cards and caregivers reports. We used two analytical approaches to calculate the vaccination coverage of the full set of vaccines recommended in Ethiopia, the coverage of each specific recommended vaccine, and timeliness of vaccine administration. Data of 7,417 children were included in the analysis. The proportion of fully vaccinated children was between 25.8% (2018) and 30.6% (2021) using a longitudinal approach, and between 32.0% (2018) and 41.8% (2021) using a method that mimics a cross-sectional survey. Coverage of specific vaccines followed a similar pattern. Three quarters and 2 thirds of children who were measles vaccinated before 1 year of age received the vaccine within 4 weeks of vaccine eligibility using the longitudinal and the cross-sectional strategies, respectively. Four out of 10 received the third doses of oral poliovirus, pentavalent and pneumococcal vaccines, and the second dose of rotavirus vaccine within 4 weeks of vaccine eligibility. Vaccination rates in the study area were low. Less than half of infants received their vaccinations within 4 weeks of the recommended administration time. To ensure an accurate assessment of vaccine coverage and timeliness, it is recommended to implement strategies that leverage longitudinal data, reducing reliance on cross-sectional studies, and allowing for more precise monitoring of immunization efforts.

6825

UNDERSTANDING IMPACT OF DOMESTIC VIOLENCE ON PERINATAL DEATH IN RURAL BANGLADESH; FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE, BANGLADESH

Mohammad Zahid Hossain[1], Afsana Afrin[1], Shahana Parveen[1], Daliya Yeasmin[1], Afruna Rahman[1], Shams El Arifeen[1], Emily Susan Gurley[2]

[1]Icddr,b, Dhaka, Bangladesh, [2]John Hopkins University, Baltimore, MD, United States

Domestic violence is a public health issue, different studies suggested that globally 15% to 71% of women experienced some form at some point in their lives. An estimated 40% to 70% of Bangladeshi married women experience domestic violence from their husbands, in-laws, and/or close relatives at least once during their lifetime. A countrywide sample-based study found that 3 out of 4 Bangladeshi women experienced domestic violence from their husbands especially who were less educated and poor. Various studies suggested that domestic violence during pregnancy can cause adverse pregnancy outcomes. The Child Health and Mortality Prevention Surveillance (CHAMPS) in Bangladesh is identifying the causes of stillbirths and death among children under five by employing minimally invasive tissue sampling (MITS) with clinical documents and verbal autopsies (VAs). We have reviewed VAs of 800 MITS cases, including narratives where mothers described the death events of their babies. A total of 12 mothers participating in the study (12/800; 1.5%) mentioned experiencing domestic violence during their pregnancies. Out of these 12 cases, 7 (58%) were stillbirths and 5 (42%) were early neonatal deaths. All MITS reports, clinical documents, and VAs were reviewed by an expert panel composed of epidemiologists, neonatologists, pediatricians, obstetricians, and pathologists to determine the cause of death. The panel considered domestic violence as a contributing maternal factor for perinatal death in 5 out of the 12 cases (5/12, 42%), all of which involved domestic violence close to the delivery date. Reporting of the violence was based on interviews with the mother at home, which could lead to underestimation of the problem due to fears of disclosing. Additional strategies could be used to identify women experiencing domestic violence during pregnancy. Engagement of field-level government health workers, and the introduction of social prescriptions by engaging support groups and community people can help these women in the future and connect them with appropriate authorities to prevent domestic violence and save lives.

6826

MASS AZITHROMYCIN DISTRIBUTION AND CAUSE-SPECIFIC MORTALITY AMONG CHILDREN AGED 1-59 MONTHS IN BURKINA FASO

Ali Sie[1], Mamadou Ouattara[1], Mamadou Bountogo[1], Boubacar Coulibaly[1], Valentin Boudo[1], Thierry Ouedraogo[1], Elisabeth Gebreegziabher[2], Huiyu Hu[2], Elodie Lebas[2], Benjamin F. Arnold[2], Thomas M. Lietman[2], **Catherine Oldenburg**[2]

[1]Centre de Recherche en Santé de Nouna, Nouna, Burkina Faso, [2]University of California, San Francisco, San Francisco, CA, United States

Mass azithromycin distribution has been shown to reduce all-cause child mortality in several settings in the Sahel, with an approximately 14-18% relative reduction in the risk of mortality in children living in communities receiving twice-annual mass azithromycin distribution compared to placebo. A previous trial in Niger found that mass azithromycin distribution to children aged 1-59 months reduced cause-specific mortality due to malaria, dysentery, meningitis, and pneumonia. However, this study was done in the absence of seasonal malaria chemoprevention (SMC), a mass drug administration strategy that involves distribution of sulfadoxine-pyramethamine and amodiaquine monthly to children aged 3-59 months during the high malaria transmission season. Here, we evaluated cause-specific mortality in a trial of mass azithromycin distribution compared to placebo in Burkina Faso, in a setting that was receiving SMC. The Child Health with Azithromycin Treatment (CHAT) trial randomized 341

communities in Nouna District, Burkina Faso to twice-yearly mass distribution of a single oral 20 mg/kg dose of azithromycin or matching placebo to children aged 1-59 months of age. Six rounds of distribution occurred over a 36-month period. An enumerative census was conducted during each twice-yearly distribution, during which vital status for all children in the community was collected. Verbal autopsy was performed to assess cause of death. Of 1,086 deaths recorded in the trial, verbal autopsy results were available for 919 (85%). The most common causes of death were infectious, including malaria (34%), diarrhea (24%), and pneumonia (9%). Children living in communities receiving azithromycin had significant reduction in malaria mortality (incidence rate ratio, IRR, 0.67, 95% confidence interval, CI, 0.50 to 0.90, P=0.008). Other infectious causes of mortality, including diarrhea and pneumonia, were lower in communities receiving azithromycin but were not statistically significantly different. Mass azithromycin distribution for child mortality has benefits in the context of SMC for reducing mortality, including for malaria mortality.

6827

CLUSTER VARIATION IN UNDER-FIVE MORTALITY IN A PROACTIVE CASE DETECTION INTERVENTION BY COMMUNITY HEALTH WORKERS IN MALI: ANALYSIS OF THE PROCCM TRIAL

Emily Treleaven[1], Amadou Beydi Cisse[2], Oumar Tolo[2], Noumoutie Sanogo[2], Kalo Dao[2], Djoume Diakite[2], Ari Johnson[3], Kassoum Kayentao[4]

[1]University of Michigan, Ann Arbor, MI, United States, [2]Muso, Bamako, Mali, [3]Muso, San Francisco, CA, United States, [4]Malaria Research & Training Center, Bamako, Mali

Community-based services delivered by community health workers (CHWs) have been shown to improve access to care for diarrhea, malaria, pneumonia, and malnutrition among children under five. Yet, evidence from national CHW programs has been mixed, in part from a lack of evidence on optimal delivery design, including how best to specify CHW workflows. In a three-year cluster-randomized trial, we tested the effectiveness of proactive case detection versus passive workflow by CHWs in rural Mali. Village clusters (N=137) were 1:1 randomized to receive daily case-finding home visits by CHWs or passive workflow (control), in which CHWs worked from a fixed post in the community. Using lifetime birth history data among women ages 15 to 49 at enrollment from annual surveys of all households in the study area at 12, 24, and 36 months, we analyzed cluster-level variance and predictors of U5M controlling for intervention arm, age, and child sex in mixed-effects regression models. We enrolled 31,587 children under five years of age over the trial (16,248 intervention, 15,339 control; 52,970 person-years of observation); 1,736 died during the trial period with no significant difference in under-five mortality (U5M) by study arm. We found substantial variation in crude death rates by cluster, ranging from 0.0 (8 clusters) to 142.3 deaths per 1,000 person-years (mean 32.5, SD 19.0). However, we observed greater within-cluster than between-cluster variance (ICC 0.039, SE 0.009). Distance to the nearest primary health center was not meaningfully associated with U5M in the intervention context, while CHW coverage indicators were associated with U5M. Children who lived in a cluster where < 50% of symptomatic children received care from a trained provider within 24 hours were twice as likely to die as children in clusters where > 75% of symptomatic children received timely care with a trained provider (OR 2.05, 95% CI 1.28, 3.29). Placing a trained, supervised, paid, and supplied CHW in each cluster can address distance-related barriers to care; empowering CHWs to identify and correctly treat symptomatic children in a timely manner can promote further reductions in U5M.

6828

COMBINATION OF A REDUCTASE INHIBITOR WITH PRIMAQUINE PREVENTS HEMOLYSIS OF G6PD DEFICIENT RBCS

Ariel M. Hay[1], Paul Buehler[2], Joseph Kao[2], Derek R. Lamb[2], Robert Commons[3], Eric A. Legenzov[2], Mitasha S. Palha[2], **James C. Zimring**[1]

[1]University of Virginia, Charlottesville, VA, United States, [2]University of Maryland, Baltimore, MD, United States, [3]Menzies School of Health Research, Darwin, Australia

The only two approved drugs that clear the hepatic hypnozoite phase of *P. vivax* (the 8-aminoquinolines (8-AQ) - primaquine and tafenoquine) can cause potentially lethal hemolysis in glucose-6-phosphate dehydrogenase deficient (G6PDd) patients due to drug metabolites that generate reactive oxygen species (ROS) in RBCs through redox cycling. Primaquine-5,6-orthoquinone (5,6-POQ) is a major hemolytic primaquine metabolite (PM). An enzymatic reductase in RBCs is required to drive redox cycling of PMs, but the specific enzyme(s) have never been identified. Using electron paramagnetic resonance (EPR) to measure superoxide, we report that treatment of intact murine RBCs with 5,6-POQ induced a robust increase in steady state superoxide levels (44 nM) compared to vehicle treated RBCs (5 nM), p =0.001. The addition of ES936, a selective inhibitor of the NAD(P)H:quinone oxidoreductase (NQO1), reduced levels of 5,6-POQ induced superoxide to 28 nM. Because most hemolysis is extravascular (consumption by macrophages), murine RBCs humanized to express the A- variant of human G6PD (hG6PD(A-)) were infused into mice and in vivo circulation was used as a metric of hemolysis. 5,6-POQ treatment of hG6PD(A-) RBCs resulted in a rapid clearance of 33% of RBCs with no clearance of control non-deficient RBCs. ES936 reversed 44% of 5,6-POQ induced hemolysis (p = 0.002). In addition to elucidating basic primaquine toxicology, these findings constitute a novel therapeutic approach with the potential to allow combination of an ES936-like inhibitor with primaquine or tafenoquine to achieve radical cure of *P. vivax* regardless of G6PD status. ES936 is predicted to not decrease the anti-relapse activity of 8-AQs for two reasons. First, ES936 does not inhibit cytochrome P450s, which drive redox cycling in hepatocytes but are not expressed in RBCs. Second, as an irreversible inhibitor, a short course of ES936 has been shown to only transiently inhibit reductases in hepatocytes (that can resynthesize the enzyme) but is predicted to provide permanent inhibition in RBCs, which cannot synthesize new proteins.

RUXOLITINIB AS AN ADJUNCTIVE TREATMENT TO REDUCE INFLAMMATORY RESPONSES IN MALARIA: A RANDOMIZED PLACEBO CONTROLLED TRIAL IN VOLUNTEERS EXPERIMENTALLY INFECTED WITH *PLASMODIUM FALCIPARUM*

Bridget E. Barber[1], Rebecca Webster[1], Nischal Sahai[2], Indika Leelasena[2], Eniko Ujvary[2], Sue Mathison[2], Luzia Bukali[1], Damian Oyong[3], Fabian de Labastida Rivera[1], Jessica Engel[1], Dean W. Andrew[1], Megan S. Soon[1], Nicholas L. Dooley[3], Jessica R. Loughland[1], Jeremy Gower[1], Jenny Peters[1], Ria Woo[1], Adam Potter[1], Stacey Llewellyn[1], Fiona Amante[1], Teija Frame[1], Julianne Hamelink[1], Mayimuna Nalubega[1], Reena Mukhiya[3], James S. Case-fatality from severe malaria remains high despite the use of highly effective antiparasitic agents, due in part to the marked host inflammatory response to infection. Identification of agents that interrupt inflammatory pathways, without compromising anti-parasitic immune responses, may lead to novel adjunctive treatments for severe malaria. The JAK 1/2 inhibitor ruxolitinib exerts potent anti-inflammatory effects in *in vitro* models, and reduces inflammatory biomarkers when used

in the treatment of myeloproliferative disorders. Ruxolitinib also targets type-1 interferon mediated immunoregulatory pathways that impede development of antiparasitic immunity. We conducted a randomised placebo-controlled trial to evaluate the ability of ruxolitinib to reduce inflammatory responses and boost antimalarial immunity when administered alongside antimalarial treatment to volunteers experimentally infected with *Plasmodium falciparum*. Twenty participants were inoculated with blood-stage *P. falciparum*, and randomised on day 8 or 9 to receive artemether/lumefantrine in combination with either ruxolitinib (n=11) or placebo (n=9). All study drugs were given twice daily for 3 days. The primary endpoint was safety and tolerability. Ruxolitinib was safe and well tolerated, with a median of 4 (range 0 - 16) adverse events per participant in the ruxolitinib group compared to 7 (range 0 - 24) in the placebo group (p=0.25). Most adverse events were mild to moderate, and consistent with clinical symptoms of malaria. In the placebo group, the inflammatory marker CRP increased significantly following treatment. This increase was not seen in participants treated with ruxolitinib, with CRP levels on day 3 post-treatment significantly higher in the placebo vs ruxolitinib groups (p<0.01). Participants treated with ruxolitinib also had reduced post-treatment increases in ICAM-1 (p<0.001) and the liver enzyme alanine transaminase (p<0.001), and a reduced post-treatment fall in lymphocytes (p<0.001). Further studies evaluating the ability of ruxolitinib to reduce inflammatory responses and improve outcomes in clinical malaria are warranted.

6830

IMPROVING ANTIMALARIAL DRUG EFFICACY ASSESSMENT: COMPARATIVE ANALYSIS OF LENGTH POLYMORPHIC MARKERS AND CLASSIFICATION ALGORITHMS IN TWO PHASE II CLINICAL TRIALS

Daniela Montero Salas[1], Monica Golumbeanu[1], Sara L. Cantoreggi[1], Celine Risterucci[2], Cornelis Winnips[2], Christian Nsanzabana[1]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Novartis Pharma, Basel, Switzerland

Development of new antimalarial drugs with new modes of action is crucial due to the emergence and spread of artemisinin partial resistance in Southeast Asia and Africa, and treatment failures after treatment with ACTs. Sensitive and robust methods for PCR-correction to distinguish recrudescences (treatment failures) from reinfections following new mosquito bites are essential to determine the accurate efficacy of a treatment in clinical trials. Since 2021, the WHO recommends genotyping the length polymorphic markers *msp1* and *msp2*, and replacing the marker *glurp* for one selected microsatellite due to biases that hinder the correct classification of recrudescences and reinfections. We reassessed the efficacy of two phase II clinical trials, including approximately 750 patients in total, by genotyping four combinations of length polymorphic markers, including *msp1* and *msp2*, and different microsatellites as the third marker (*PfPK2*, *Poly-α* and *TA40*), and compared them to *glurp*. We used three algorithms to classify recurrences into recrudescences or reinfections: the currently recommended WHO/MMV, the two out of three and the Bayesian algorithms. We compared twelve marker-algorithm combinations in total. We found that the use of *glurp* coupled with the WHO/MMV algorithm, used in the trials, indicated the least number of recrudescences across all methods tested, potentially underestimating treatment failure. We also found that the bin size used to classify two alleles as equal or different can influence the efficacy results and should be standardized in genotyping guidelines. The results observed in this study confirm, on the largest scale to our knowledge, results observed with *in silico* simulations, mixed laboratory strains or smaller-scale trials. The amount of samples included significantly increments the information available to determine a better recommendation for a sensitive and robust method, coupled to an appropriate algorithm of classification to determine treatment efficacy, which would translate in providing patients with a new effective treatment and bringing us closer to malaria elimination.

FUNGAL DERIVED DEOXAPHOMINES TARGET *PLASMODIUM FALCIPARUM* SEGREGATION THROUGH INHIBITION OF PFACTIN1

Sarah Jiang[1], Jin Woo Lee[2], Jennifer Collins[3], Samuel Schaefer[1], Daisy Chen[1], Flore Nardella[3], Karen Wendt[4], Thilini Peramuna[4], Raphaella Paes[3], Greg Durst[5], Kirsten Hanson[6], Debopam Chakrabarti[3], Robert Cichewicz[4], Elizabeth Winzeler[1]

[1]UCSD, San Diego, CA, United States, [2]Duksung Women's University, Seoul, Korea, Republic of, [3]University of Central Florida, Orlando, FL, United States, [4]University of Oklahoma, Norman, OK, United States, [5]Lgenia Inc, Fortville, IN, United States, [6]University of Texas at San Antonio, San Antonio, TX, United States

Malaria remains a deadly disease that impacts millions every year. Resistance to all current frontline drugs has been observed, underscoring the urgent need for new therapeutic agents. Herein, we report the discovery of a natural product scaffold isolated from the fungi *Trichocladium asperum* with potent antiplasmodial activity. In total, six analogs were identified and have been dubbed methyldeoxaphomin NPDG A-F. The most potent compound, methyldeoxaphomin NPDG F displayed an EC_{50} of 550 nM in Dd2 and 290 nM in 3D7, with a selectivity index >60 over human HepG2 cells. This compound exhibited a gradual rate of killing, similar to atovaquone, with a lag phase of 24 h and a log (PRR) of 0.64. Morphologically, methyldoxaphomin NPDG F induced numerous abnormalities in merozoite segmentation during schizogony in both the blood and liver stages of *P. falciparum* and *P. berghei*, respectively. The *in vitro* evolution with NPDG F and whole genome sequencing revealed the probable drug target to be Pfactin1 (PF3D7_1246200). Of the 29 missense mutations found in the core genome of Dd2-Pol δ, 4 were observed in Pfactin1. A single nucleotide mutation, A136S, independently confers resistance in two of the three biological replicates. In the third biological replicate, SNPs A171V and I290L were found in 76% of the parasites with the remaining 24% bearing the mutations A171S and I290L. A molecular docking study with Pfactin1 found that methyldeoxaphomin NPDG F occupies the same binding pocket as cytochalasin D. The amino acids A171 and A136 line the binding cavity, while I290L was localized to the periphery. Resistance line parasites were found to be cross resistant to cytochalasin D (but not actin stabilizer Jasplakinolide), suggesting NPDG F displays a similar mode of action and interaction with PfActin1. Isobologram data also demonstrated that this compound exhibits an antagonistic effect with known inhibitors of actin polymerization, Latrunculin B and SMIFH2. Taken together, these findings support the inhibition of Pfactin1 polymerization as the likely mechanism of action of NPDG F, augmenting drug discovery efforts to target *Plasmodium* motor proteins.

PLASMODIUM FALCIPARUM FIELD ISOLATES TO GUIDE CLINICALLY RELEVANT DOSE RATIOS FOR CABAMIQUINE: PYRONARIDINE COMBINATION USING TRANSLATIONAL MODELING

Mohamed MAIGA[1], Sebastian G. Wicha[2], Perrine Courlet[3], Abdoulaye Djimdé[1], Thomas Spangenberg[4], Laurent Dembélé[1], Claudia Demarta-Gatsi[4]

[1]Université des Sciences des Techniques et des Technologies de Bamako (USTTB), Bamako, Mali, [2]Universität Hamburg, Hamburg, Germany, [3]Merck Institute for Pharmacometrics, Ares Trading S.A., Lausanne, Switzerland, an affiliate of Merck KGaA, Darmstadt, Germany, [4]Global Health Institute of Merck, Ares Trading SA, Eysins, Switzerland, an affiliate of Merck KGaA, Darmstadt, Germany

The emergence of drug resistance calls for the development of effective antimalarial combinations. However, the selection and combination of drug dose regimens involve complex considerations based on a totality of evidence approach, including pharmacokinetic (PK) and pharmacodynamic (PD) data, including potential interactions. We evaluated PD interactions between cabamiquine and pyronaridine, a combination currently in Phase 2 clinical trial. To do so, we used a real-world setting using immediate *ex vivo*

Plasmodium falciparum field isolates combined with translational modelling. The apparent parasite killing rate was simulated for cabamiquine and pyronaridine, alone and in combination to generate an interaction heat map. Concentration and time-dependent *in vitro* cidal activity of cabamiquine and pyronaridine alone as well as in combination were determined using *P. falciparum* field isolates and standard 48 hours SYBR Green assay-Mitotracker readout at different concentrations and time points. Potential PD interactions were quantified using non-linear mixed effects modelling describing the parasite growth and drug mediated-killing. These data are then fed into model to generate an interaction map that later is used to simulate meaningful clinical dose ratios.The parasite kinetics of field isolates was well described by the model. Whereas for cabamiquine, the regrowth observed in monotherapy arm suggesting adaptive resistance, was suppressed in combination when pyronaridine concentrations exceeded its EC50, highlighting the importance of the combination in controlling possible adaptive resistance to one of the two drugs. A stable killing rate was observed in cases where concentrations of pyronaridine or cabamiquine exceeded either EC50 after full adaptation. Finally, we were able to generate a range of EC50s for the two drugs, both as monotherapy and combination, that could then be translated into human doses.
This study innovatively used *P. falciparum* field isolates data, modeling and simulation techniques to assess cabamiquine and pyronaridine combination selection and reducing animal testing in pre-clinical studies.

DIHYDROARTEMISININ-PIPERAQUINE PLUS SULFADOXINE-PYRIMETHAMINE FOR INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANT WOMEN: A DOUBLE-BLINDED RANDOMIZED CONTROLLED TRIAL

Abel Kakuru[1], Jimmy Kizza[1], Miriam Aguti[1], Harriet Adrama[1], John Ategeka[1], Peter Olwoch[1], Miriam Nakalembe[2], Joaniter Nankabirwa[1], Bishop Opira[1], Timothy Ssemukuye[1], Nida Ozarslan[3], Anju Ranjit[3], Erin Dela Cruz[3], Stephanie Gaw[3], Tamara D. Clark[3], Michelle E. Roh[3], Prasanna Jagannathan[4], Philip J. Rosenthal[3], Moses R. Kamya[2], Grant Dorsey[3]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Makerere University College of Health Sciences, Kampala, Uganda, [3]University of California, San Francisco, San Francisco, CA, United States, [4]Stanford University, San Francisco, CA, United States

The spread of antifolate resistance threatens the effectiveness of sulfadoxine-pyrimethamine (SP) for intermittent preventive treatment of malaria in pregnant women (IPTp) in Africa. Dihydroartemisinin-piperaquine (DP), an alternative to SP for IPTp, has shown superior antimalarial effects, but it does not reduce the risk of adverse birth outcomes compared to SP, suggesting that SP may have non-malaria benefits that impact on birth outcomes. Combining DP and SP could optimize the benefits of IPTp. We are conducting a double blinded randomized controlled trial comparing monthly IPTp with SP vs. DP vs. DP+SP (1:1:1) in HIV-uninfected pregnant women living in Busia district, Uganda, a high malaria transmission setting. From December 2020 to December 2023, we completed enrollment of 2757 women who were between 12-20 weeks of gestation. At enrollment, the prevalence of parasitemia was 38% by microscopy and 70% by PCR. Women are started on study drugs at 16 or 20 weeks of gestation and followed in a study clinic for all medical care. The primary outcome is the risk of a composite adverse birth outcome (spontaneous abortion, preterm delivery, low birth weight, small for gestational age, stillbirth, or neonatal death). Secondary outcomes included measures of malaria during pregnancy and at delivery and presence of reproductive tract infections (RTIs) at delivery. As of December 31, 2023, 199 women were prematurely withdrawn before delivery and 2101 had delivered. Malaria incidence during pregnancy was 1.19 and 0.18 episodes per person year before and after starting study drugs, respectively. Of the 2101 deliveries, 605 (28.8%) had a composite adverse birth outcome. The risk of placental malaria was 733/1723 (42.5%) by histopathology (presence of parasites or malaria pigment) and parasite DNA was detected in placental blood by PCR from 239/1918 (12.5%). At delivery, the risk of *Chlamydia trachomatis* was 107/1797 (6.0%), 47/1797 (2.6%) for *Neisseria gonorrhea*, 132/1989 (7.3%) for *Trichomonas vaginalis*, and 131/1343 (9.8%) for group B *Streptococcus*. We expect all women to deliver by August 2024. Unblinded results of the trial will be presented.

6834

EFFECT OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY ON VAGINAL MICROBIOTA, HOST IMMUNE RESPONSE AND PREGNANCY OUTCOMES: A CASE-CONTROL STUDY FROM THE ASPIRE TRIAL IN ZAMBIA

Tanweer Beleil[1], Marwah Bagabas[1], Patricia Hunter[2], Sherrianne Ng[1], Jemima Hair[2], Gonçalo Correia[1], Yun S. Lee[1], Enesia B. Chaponda[3], Ephraim Chikwanda[4], Mike Chaponda[4], Nigel Klein[2], Lynne Sykes[1], Jane Bruce[5], Ludovica Ghilardi[5], Philippe Mayaud[5], Daniel Chandramohan[5], Phillip R. Bennett[1], R Matthew Chico[5], David A. MacIntyre[1]

[1]Imperial College London, London, United Kingdom, [2]University College London, London, United Kingdom, [3]University of Zambia, Lusaka, Zambia, [4]Tropical Diseases Research Centre, Ndola, Zambia, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom

High prevalence of malaria and curable sexually transmitted and reproductive tract infections (STI/RTI) represent significant burden among pregnant women in East and Southern Africa. These are associated with adverse outcomes including preterm birth and low birthweight (LBW). The ASPIRE trial compared intermittent preventive treatment of malaria in pregnancy (IPTp) using sulfadoxine-pyrimethamine (SP) vs SP with metronidazole (MTZ) vs dihydroartemisinin-piperaquine (DP) with MTZ to reduce adverse pregnancy outcomes attributable to malaria and curable STIs/RTIs. Mechanisms by which these treatments may improve outcomes remain unclear. We aimed to investigate the effects of IPTp regimens on the vaginal microbiota, STI profiles and host immune response in term deliveries vs preterm and/or LBW. DNA was extracted from vaginal swabs collected from randomly selected sub-groups (SP n=99; SP+MTZ n=98; DP+MTZ n=94) at i) enrolment, prior to IPTp, ii) not less than one month after enrolment, before second IPTp dose, iii) prior to last IPTp dose before delivery. Microbiota were characterised using metataxonomic profiling. STIs were detected using quantitative PCR. Immune mediators were investigated using multiplexed Luminex assays. At enrolment, five vaginal microbiota community state types (CSTs) were identified i) *Lactobacillus iners* dominated (47.1%), ii) high-diversity compositions (36.4%), iii) *L. crispatus* (14.4%), *L. gasseri* (1.7%) and *L. jensenii* (0.3%). No change in vaginal microbiota composition was observed in women receiving three or more doses of SP or SP+MTZ. However, DP+MTZ was associated with reduced prevalence of high-diversity vaginal microbiota compositions and increased *L. iners* dominance (P<0.002). Integration of vaginal microbiota profiles with immune mediators, STI profiles, and clinical data is ongoing. Our data indicates that DP+MTZ is associated with reduced vaginal microbiota diversity, and may provide insight into how antenatal interventions alter microbe-host interactions associated with pregnancy outcome.

6835

SEROPREVALENCE OF *TAENIA SOLIUM* ANTIBODIES AND ASSOCIATED RISK FACTORS AMONG CHILDREN 0-14 YEARS IN NIGERIA

Jennifer Akamboe[1], Samuel A. Oyebanjo[2], Mary L. Kamb[1], Andrew Hill[1], Nishanth Parameswaran[1], Nnaemeka C. Iriemenam[3], Gretchen Cooley[1], Nwachukwu E. William[4], Nwando Mba[4], McPaul I. J. Okoye[3], Jeffrey W. Priest[5], Diana L. Martin[1], Paul Cantey[1], Chikwe Ihekweazu[4]

[1]Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Malaria, Atlanta, GA, United States, [2]Institute of Human Virology, Abuja, FCT, Nigeria, [3]Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention, Abuja, FCT, Nigeria, [4]Nigeria Centre

for Disease Control and Prevention, Abuja, FCT, Nigeria, [5]Division of Foodborne, Waterborne and Environmental Diseases, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Children are vulnerable to *Taenia solium*, a parasitic tapeworm causing cysticercosis and taeniasis. Brain cysts may cause seizures. We sought to better understand risk factors for and prevalence of *T. solium* in Nigeria. We used data from a nationally representative, cross-sectional household survey estimating HIV incidence (2018) in which questionnaires and dried blood spots were collected from >31,000 children <15 years old. We determined the seroprevalence of *T. solium* IgG antibodies to rES33 (taeniasis) and T24H (cysticercosis) detected in a multiplex bead assay. We performed separate bivariate and multivariate logistic regression of weighted survey data for taeniasis and cysticercosis using household questionnaire and laboratory data. Positive antibodies against each antigen were detected in children from all states, with an overall antibody seroprevalence of 6.0% for T24H (range, 1.4%-19.3%) and 2.8% for rES33 (range, 0.5%-5.3%). Bivariate analyses found risk for each disease varied by state of residence and was significantly (P<0.05) associated with increasing age, rural (vs. urban) residence, association with pigs (vs. no free-roaming pigs), progressively lower socioeconomic status (vs. highest status), unimproved drinking water source, and lack of toilet facilities. In multivariate analyses, increasing age, rural residence, association with pigs, and lower socioeconomic status remained significant risks for cysticercosis. For taeniasis, the highest socioeconomic status had lower odds of infection compared to the lowest (aOR=0.40, 95% CI 0.22-0.75). Adjusting for all the other variables noted above, the individual impacts of safe water and improved toilets were not associated with decreased risk for each disease; but, regression results suggested a lower risk for cysticercosis when both safe factors were present. To our knowledge, this is the first nationally representative survey providing data on *T. solium* prevalence in Nigeria. The results support prioritizing control and public health strategies such as simultaneous access to improved water and safe toilet facilities to prevent brain cysts and epilepsy.

6836

PULMONARY CYSTIC ECHINOCOCCOSIS TREATMENT OUTCOMES AMONG 280 PATIENTS AT TWO TERTIARY CARE CENTERS IN CUSCO, PERU

Roberto Pineda-Reyes[1], Maria L. Morales[2], Karen Mozo[2], Maria A. Caravedo[3], Angel Gamarra[4], Ramiro Hermoza[4], Rocio Cuaresma[4], Miguel M. Cabada[3]

[1]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [2]Cusco Branch - Alexander von Humboldt Tropical Medicine Institute/Universidad Peruana Cayetano Heredia, Cusco, Peru, [3]Infectious Disease Division, University of Texas Medical Branch, Galveston, TX, United States, [4]Department of Surgery, Hospital Regional del Cusco, Cusco, Peru

The management of pulmonary cystic echinococcosis (pCE) is influenced by local practice and center volume. Treatment recommendations are largely based on expert opinion and small single-center case series. We reviewed medical records of patients discharged with a diagnosis of pCE from two referral centers in the Cusco Region of Peru between January 2009 and December 2019. Adverse hospitalizations outcomes were defined as discharge condition recorded as 'unchanged', 'worse', or 'dead'. Two hundred eighty cases with pCE were identified, 45% were younger than 18 years and 43% were female. A single lung cyst was diagnosed in 56% while 16% had 2 cysts, and 16% had ≥ 3 cysts. In 41% of cases the diameter of the largest cyst was ≥10 cm. Ten patients (4%) received pre-surgical albendazole (ABZ), 57 (20%) post-surgical ABZ, and 4 (1%) pre- and post-surgical ABZ. In 163 (58%) surgery was performed without documentation of ABZ prescription. Eight patients (3%) received ABZ with no surgery. The type of treatment prescribed was not documented in 29 patients (10%) and 9 (3%) received surgery and ABZ but the exact order of the interventions was unknown. Multivariate backwards logistic regression found pre-surgical respiratory insufficiency (OR=3.12, 95%CI 1.03-9.47) as predictor for adverse hospitalization outcomes. Subjects referred from a healthcare center (OR=0.21, 95%CI 0.1-0.5) and those hospitalized ≥1 month (OR=0.07, 95%CI 0.01-0.4) were less likely to have adverse hospitalization outcomes. Subjects with documentation of "infected cyst" (OR=11.39, 95%CI 1.2-108.2) and those having a concomitant liver cyst (OR=6.34, 95%CI 3.01-13.35) were more likely to have at least one readmission. No statistically significant differences were found for pre- or post-surgical ABZ and hospitalization outcome or readmission. Further studies analyzing the appropriate timing of antiparasitic therapy in patients with pCE are needed.

6837

TAENIA SOLIUM FATTY ACID BINDING PROTEIN 1 INDUCES SUPPRESSES TLR4 SIGNALING AND DOWNREGULATE IRE-1α IN A PPAR-G DEPENDENT MANNER

Amit Prasad, Suraj S. Rawat

Indian Institute of Technology Mandi, mandi, India

Neurocysticercosis is a major neurological threat, accounting for over 30% of cases in endemic areas. *Taenia solium*, the causative agent, and its other helminthic counterparts lack key components of the cellular machinery required for endogenous lipid biosynthesis. This deficiency enables the parasite to obtain all required lipids from its host organism. To facilitate effective lipid transport, the cestode parasite employs Fatty Acid Binding Proteins (FABPs), which bind to lipid ligands and allow lipid transport across membranes and into the cytosol. *T. solium* expresses an abundance of FABPs. Apart from transporting ligands, FABPs interacts with the host immune system, however the functional aspect of *T. solium* FABP is still unknown. Elucidating the functional outcome of FABP on host immune system will contribute to understand the detailed immunopathology of cysticercosis infection. TsFABP1 is one of the members of *T. solium* FABP family, which is secretory in nature, interacts with neighbouring cells, potentially modulating their functions. We expressed TsFABP1 in the pET23a vector, purified it with Ni-NTA affinity chromatography, and measured the molecular weight at 15 kDA. TsFABP1 purified form induced anti-inflammatory gene expression in THP-1-derived macrophages in a dose-dependent manner. TsFABP1 inhibits the CD14-TLR4 pathway by binding to CD14 at the LPS binding site, reducing ROS and cleaved IL-1β production. Interestingly macrophages readily internalize the cyanine5-labelled TsFABP1 and in the cytosol the protein may play significant role in immunomodulation. Here for the first time, we report that the TsFABP1 play role in PPAR-γ pathway, which was previously unknown. TsFABP1 suppresses IRE-1α in a PPAR-γ-dependent manner. In conclusion, TsFABP1 is an anti-inflammatory molecule that also downregulate the endoplasmic stress response associated molecule and apart from that TsFABP1 can be explored for therapeutic potential.

6838

HIGH PREVALENCE AND HOUSEHOLD CLUSTERING OF LIVER CYSTIC ECHINOCOCCOSIS IN A RURAL COMMUNITY IN THE CENTRAL ANDES OF PERU: A POPULATION - BASED SURVEY

Saul J. Santivanez[1], Percy Soto-Becerra[1], Raul Enriquez[1], Luis Tello[1], Oswaldo G.E. Espinoza-Hurtado[1], Andreas Neumayr[2], Hector H. Garcia[3]

[1]Universidad Continental, Huancayo, Peru, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]Center for Global Health, Universidad Peruana Cayetano Heredia, Lima, Peru

Human cystic echinococcosis (CE), a zoonotic disease caused by the larval stage of the *Echinococcus granulosus* tapeworm, presents a significant public health challenge in the Peruvian central highlands. In this region, the disease's impact is profound, with some families reporting multiple infected individuals. The current study aimed to estimate the prevalence of CE in Corpacancha, a rural community in the Peruvian central highlands, utilizing abdominal ultrasound (US), electroimmuno transfer blot (EITB), and computed tomography (CT) scans for individuals with positive US or EITB results. Additionally, we explored household clustering of CE cases using the intraclass correlation coefficient (ICC) with 95% credibility intervals (CrI) estimated through Bayesian multilevel model, updating prevalence

data, and identifying risk determinants, particularly focusing on household clustering. The findings revealed a liver CE prevalence of 16.1% (95% CI: 11.1% - 22.7%) as detected by ultrasound and a seroprevalence of 24.1% (95% CI: 15.4% - 35.6%) using the EITB assay. Active liver CE was present in 11.9% (95% CI: 7.8% - 17.9%) of participants, predominantly in the CE1 stage, while inactive liver CE had a prevalence of 4.1% (95% CI: 2.3% - 7.4%). Lung involvement was identified in 30.6% (95% CI: 16.9% - 48.8%) of individuals undergoing CT evaluation. Our survey also indicated that approximately one quarter of households had at least one case of CE, with a third of these households reporting multiple cases. After adjusting by relevant predictors of liver CE and accounting by household as a random intercept, we found an ICC of 0.3334 (95% CrI 0.0025 to 0.7379). Overall, this study not only demonstrates hyperendemic levels of CE but also highlights significant household-level influences on disease prevalence, suggesting that intervention efforts may be more effective when targeted at the household level.

6839

DIAGNOSTIC PERFORMANCE OF A MULTIANTIGEN PRINT IMMUNOASSAY FOR ANTIBODY DETECTION IN HUMAN NEUROCYSTICERCOSIS

Luz M. Toribio Salazar[1], Carolina Guzman[1], Herbert Saavedra[2], Isidro Gonzales[1], Javier A. Bustos[1], Sukwan Handali[3], Hector Garcia[1]

[1]universidad Peruana Cayetano Heredia, Lima, Peru, [2]Instituto Nacional de Ciencias Neurologicas, Lima, Peru, [3]Division of Parasitic Diseases, Coordinating Center for Infectious Diseases, Centers for Disease Control and Prevention USA, Atlanta, GA, United States

Neurocysticercosis (NCC) stands as the most prevalent helminthic infection affecting the human central nervous system. Although neuroimaging is required for definitive diagnosis, the gold standard for serology is the antibody detection using the enzyme-linked immunoelectrotransfer blot assay (EITB, Western blot), which uses seven highly antigenic lentil-lectin purified parasite glycoproteins. EITB is poorly accessible due to is technical complexity and the requirement of sophisticated equipment and parasitic material. We recently developed a 3-antigen-multiantigen print immunoassay (MAPIA) based on recombinant/synthetic antigens (rGP50, rT24H and sTs14), corresponding to the three principal EITB diagnostic families, that effectively address many of the aforementioned barriers. We expanded the initial evaluation of performance of this MAPIA assay using a well-defined set of serum samples from NCC patients confirmed by imaging, including 73 individuals with subarachnoid NCC, 73 with more than 5 parenchymal cysts, 62 with 3-5 parenchymal cysts, 98 with 1-2 parenchymal cysts and 80 healthy controls devoid of neurological disease. The assay overall sensitivity was 97.71% and specificity 97.5%. Subgroup analyses by type of NCC demonstrated a sensitivity of 100% for subarachnoid and parenchymal NCC with more than 5 cysts, slightly decreasing for the groups with 3-5 cysts (96.77%) and 1-2 cysts (94.9%). Equivalent results were obtained when comparing its performance with that of the reference EITB, reaching a sensitivity of 100% for subarachnoid and parenchymal NCC for more than 3 cysts and 95.92% for 1-2 cysts. Our 3-antigen MAPIA is comparable to EITB and emerges as a simpler, reproducible, and available alternative for antibody diagnosis in NCC.

6840

COMPARISON OF THE ANTIBODY DYNAMICS IN TWO MODELS OF EXPERIMENTAL PIG CYSTICERCOSIS USING A MULTIPLEX BEAD ASSAY

Luz M. Toribio Salazar[1], Sukwan Handali[2], Gianfranco Arroyo[1], Javier A. Bustos[1], Hector Garcia[1]

[1]universidad Peruana Cayetano Heredia, Lima, Peru, [2]Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States

Cysticercosis is a parasitic infection caused by *Taenia solium* that can invade the brain causing Neurocysticercosis (NCC). Controlled experimental infections of pigs allow to accurately determine timepoints during cysticercosis infection. Antibody responses have been characterized using the traditional lentil-lectin enzyme-linked immunoelectrotransfer blot (LLGP-EITB) assay; however, this qualitative technique presents technical challenges and depend on parasite material. We have developed a Multiplex Bead Assay (MBA) coupled to six recombinant/synthetic antigens used for diagnosis (rGP50,rT24H,sTs14,sTs18,sTsRS1,sTsRS2). To simultaneously quantify the dynamics of the antibody responses against mentioned antigens during infection, and to explore differences in antibody responses in two different experimental porcine cysticercosis models, one using oral infection with eggs and the other using intracarotid injection of activated oncospheres, we analyzed 60 archived serum samples from pigs orally (n=6) and intracarotid (n=6) infected, who developed viable cysticercosis and that were sampled at five time points post-infection (PI). Cyst establishment in brain tissue was predominant in the carotid model. Our 6-antigens MBA determine significantly higher antibody responses against sTs14 and sTs18 for both models ($p<0.01$) and differences against rGP50 and rT24H antibody levels, which were higher only in pig orally-infected. Antibody dynamics in both models described a similar pattern in which rT24H and rGP50 responses were detected from day 28 onwards with a gradual increase throughout the infection course, while smaller antigenic peptides showed a stronger response from day 35PI. Pigs orally infected exhibited a significant decrease in antibody response from day 57PI until necropsy, while this decrease occurred by day 70PI in pigs carotid infected. Although, antibody dynamic is consistent in both models, differences in antibody levels could be explained by the route of infection; natural route that parasite must go through to stablish as a cyst in oral infection could stimulate more antibodies against anchoring antigens (rGP50).

CHARACTERIZATION OF THE ACUTE NEUROINFLAMMATORY RESPONSE INDUCED BY ANTIPARASITIC TREATMENT IN THE CAROTID PORCINE MODEL OF NEUROCYSTICERCOSIS

Gianfranco Arroyo[1], Lizzie Tello-Ccente[1], Rosa Diaz-Gongora[1], Yessenia Salas[1], Miguel A. Orrego-Solano[1], Javier A. Bustos[1], Manuela R Verastegui[1], Robert H Gilman[2], Hector H. Garcia[1]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Johns Hopkins University, Baltimore, MD, United States

Antiparasitic treatment (APT) in NCC causes cyst damage and activates the host's immune system, triggering early neuroinflammation. We evaluated the development of treatment-induced neuroinflammation in the experimental NCC pig model by intracarotid-oncosphere injection using histopathological, immunohistochemical, and molecular markers to provide evidence for the suitability of this model for studying neuroinflammation. Twelve NCC pigs by intracarotid-oncosphere injection were distributed as untreated (T1), treated with ABZ plus PZQ and sacrificed 48h (T2) and 120h (T3) after APT (n=4 pigs each). Before euthanasia, all pigs received intravenous Evans-Blue (EB) infusion to assess BBB disruption. EB-stained (blue) and non-stained (clear) cysts with adjacent tissue were stored in 10% formalin and paraffin-embedded; pericystic inflammation was assessed using histopathological scores (ISC, range: 0-400). Astrocytosis and microglia were assessed by IHQ using primary antibodies anti-GFAP and anti-IBA 1 and expressed as immunoreactive areas (percentages). Cysts with capsules were also assessed for gene-expression levels of cytokines (IFN-γ, TNF-α, IL6, IL10, and VGEF) by real time PCR. Almost all cysts from treated NCC pigs showed EB-disruption (94.3% [48h] and 100% [120h]) versus untreated pigs (50%, $P< 0.001$). EB-stained cysts showed increased ISCs 120h after APT (median: 400) versus 48h after APT and no-treatment (median: 283, and median: 275, $P<0.001$). Astrocyte and microglia immunoreactivity was higher in NCC pigs 120h after treatment versus 48h after treatment or untreated pigs ($P<0.05$). Increased expression levels of TNF-alpha, INF-gamma, IL-6, and VGEF were found in EB-stained cysts from NCC pigs 120h after APT compared to NCC pigs 48h after APT and untreated pigs ($P<0.005$); IL-10 levels increased 48h after treatment but decayed 120h after treatment ($P<0.005$). Acute pericystic neuroinflammation can be properly induced by 120h after treatment in the carotid model, thus providing a valuable tool to study neuroinflammation and evaluate pharmacological interventions to reduce pericystic neuroinflammation.

A CRISPR-CAS13A ASSAY FOR DETECTION OF CIRCULATING CELL FREE RNA (CCFRNA) IN ACTIVE *WUCHERERIA BANCROFTI* INFECTION

Carlos F. Ng[1], Sasisekhar Bennuru[2], Amy Lyden[1], Andres A. Dextre[1], Zaina L. Moussa[1], María Díaz De León Derby[1], Thomas B. Nutman[2], Daniel A. Fletcher[1]

[1]University of California, Berkeley, Berkeley, CA, United States, [2]National Institutes of Health, Bethesda, MD, United States

Detecting parasitic circulating cell free nucleic acids (ccfDNA/ccfRNA) in plasma is a promising approach for sensitive and specific detection of active helminth infection including *Wuchereria bancrofti* (Wb). To identify potential Wb RNA targets, we performed Plasma-RNAseq using plasma from 10 Wb microfilaria-positive (mf-positive) individuals and 10 healthy blood bank individuals and used bioinformatic tools to ensure specificity. Six targets were identified that were specific to Wb and/or *Brugia malayi* (Bm), the causative agents of lymphatic filariasis, and not found in *Loa loa* (Ll) or *Onchocerca volvulus* (Ov), two closely related filarial parasites. Reverse transcriptase-PCR (RT-PCR) assays for each of these six targets were developed and tested on RNA from extracted daytime plasma from mf-positive patients with Wb and shown to be variably positive. To improve the sensitivity of the detection of ccfRNA in Wb infection and to develop a possible point-of-care (POC) assay concurrently, guide RNAs for the set of six ccfRNA targets were designed and used in a CRISPR-Cas13a (RNA-directed RNA nuclease) assay. We first tested these guide RNAs against synthetic target RNAs in the presence of reporter molecules that fluoresce after cleavage by activated Cas13a. By combining the most active guide RNAs into a pooled assay, results showed a limit of detection of approximately 1000 copies/µL using synthetic targets. The Cas13a assay requires no RNA purification, reverse transcription, or amplification and can be detected by a simple fluorescent reader. To demonstrate this, we added fluorescence illumination to a compact mobile phone-based digital microscope known as the NTDscope (aka LoaScope) and were able to detect an increasing fluorescence signal in the presence of RNA biomarkers compared to a control reaction without them. These data suggest that molecular testing for ccfRNA for Wb at the POC with an amplification-free Cas13a assay is feasible. The assay will be optimized prior to assessing the sensitivity and specificity using cryopreserved plasma samples from mf-positive Wb patients and Wb-uninfected controls.

Loiasis is a disease caused by infection with the nematode *Loa loa*. Some people with high *L. loa* microfilaria counts develop serious adverse drug reactions after treatment with ivermectin. This poses a significant challenge for lymphatic filariasis and onchocerciasis elimination programs in Central Africa where loiasis is endemic, as these programs rely on mass distribution of ivermectin. To address this problem, improved methods are needed to efficiently identify individuals with loiasis who are at increased risk of ivermectin-related adverse events. We have previously reported detection of the *L. loa* protein Ll-Bhp-1 in the sera of people with loiasis. Here, we describe use of this antigen as an infection biomarker that may be especially useful for identifying people with high *L. loa* infection burdens. We developed a prototype antigen capture ELISA that detected Ll-Bhp-1 in 74 of 116 (63.8%) loiasis patient sera. Antigen levels were significantly correlated with *L. loa* microfilarial counts. Assay sensitivity was excellent in samples from people with microfilarial counts that would put them at risk for serious adverse events (sensitivities of 94% and 100% in samples from people with ≥20,000 and ≥50,000 *L. loa* microfilaria per milliliter of blood, respectively). The assay is highly specific and did not detect Ll-Bhp-1 in any of 112 sera from people with other filarial infections or in 34 sera from non-endemic controls. Thus, this antigen assay appears to be highly sensitive for identifying people with high *L. loa* microfilarial counts who are at increased risk of serious adverse events after ivermectin. Optimization of this prototype assay and use of a rapid diagnostic platform could facilitate loiasis mapping and efforts to eliminate lymphatic filariasis and onchocerciasis in Central Africa.

[1]Centre de Recherche en Maladies Tropicales Ituri, Rethy, Congo, Democratic Republic of the, [2]Ituri Provincial Health Division, Bunia, Congo, Democratic Republic of the, [3]Luxembourg Institute of Health, Strassen, Luxembourg, [4]World Health Organization Special Programme for Research and Training in Tropical Diseases (TDR), Geneva, Switzerland, [5]Forsythe and Bear, LLC, Los Angeles County, CA, United States, [6]Medicines Development for Global Health, Southbank, Australia

Long-term community-directed treatment with ivermectin (IVM) has reduced onchocerciasis prevalence and may have eliminated onchocerciasis in some foci in Africa, but alternative strategies are needed for accelerating elimination across Africa. The US Food and Drug Administration approved moxidectin (MOX) 8 mg for treatment of individuals ≥12 years old with onchocerciasis based on Phase 2 and 3 study data showing that a single MOX dose reduced skin microfilariae levels (SmfL) better and for longer than a single 150 µg/kg IVM dose. MDGH is seeking regulatory approval for children 4 to 11 years old. A double-blind trial, initiated in the Ituri province of the Democratic Republic of Congo in May 2021, is comparing the safety and effect on SmfL in individuals ≥12 years old randomized in a ratio of 3:1:3:1 to three annual MOX doses, three annual IVM doses, five 6-monthly MOX doses or five 6-monthly IVM doses. The primary efficacy endpoint is the percentage of participants who received a single or two 6-monthly MOX doses and had undetectable (0) SmfL both 6 and 12 months after the first treatment. Safety endpoints are vital signs and the incidence and severity of adverse events (AEs) to 36 months and liver function to 12 months after the first treatment. Secondary efficacy analyses include SmfL 6, 12, 18, 24, 30 and 36 months after the first treatment. A total of 8925 people from 45 villages in the Logo and Nyarambe Health Zones were screened. Enrolment was completed in July 2023 with 323 participants with ≥10 mf/mg skin (based on 4 skin snips, mean 23.1 ± 20.8 mf/mg, range 10.0 to 175.4 mf/mg skin) randomized and treated. To-date, treatments have been well-tolerated. The majority of participants reported no AEs. The types of AEs were similar to those in the Phase 2 and 3 studies. AEs occurred primarily within the first 5 days after treatment. The severity of 96% of AEs was mild or moderate. Details of the study design, including the cost- and time-effective nested recruitment and screening strategy with a concurrent single dose safety study, participant population and results of the 12-month efficacy and safety analyses will be presented.

MULTIPLEXING NOVEL BIOMARKERS TO AID POST-ELIMINATION SURVEILLANCE IN LYMPHATIC FILARIASIS

Rachel E. Pietrow[1], Belinda Jackson[2], Edward E. Mitre[2], Thomas B. Nutman[1], Sasisekhar Bennuru[1]

[1]Laboratory of Parasitic Diseases, NIAID, National Institutes of Health, Bethesda, MD, United States, [2]Microbiology and Immunology, School of Medicine, Uniformed Services University of Health Sciences, Bethesda, MD, United States

The success of mass drug administration (MDA) at reducing the prevalence of lymphatic filariasis (LF) in endemic areas has led to an increased need for diagnostic assays with high sensitivity and specificity. To be useful in post-elimination surveillance (PES) areas with low to zero prevalence, high test performance characteristics are required to enable the early detection of infection recrudescence without eliciting high numbers of false positive results. Antibodies to several *Wuchereria bancrofti* [*Wb*]- and *Brugia malayi* [*Bm*]-encoded antigens (e.g. Wb123, Bm33, BmR1) have been utilized to this end, but suffer either from sensitivity or specificity levels that fail to meet recently adopted target product profiles. Additional targets that could be used as confirmatory tests or in multiplexed assays could overcome these issues. From a screen of 12 targets (reported previously) we identified that immunoassays detecting IgG antibodies against Wb5 and Wb4 antigens were highly sensitive and specific for Wb and/or Bm infection and were associated with pre-patent (Wb5) or patent (Wb4) infection. Recombinant Wb4 and Wb5 proteins were generated for use in a variety of IgG4-based immunoassays. Screening of serum from *Brugia*-infected humans (n=19) revealed high prevalence of anti-Wb4 antibodies (14/19 positive) and minimal cross reactivity with other filarial infections. Using IgG4 based immunoassays at 100% specificity, Wb5 and Wb123 had individual sensitivities of 53.7% and 75.3%, respectively, while a combination resulted in 81.0% sensitivity in 381 samples (231 Wb-infected; 150 Wb-uninfected controls). Testing of prototype Wb5 IgG4-based lateral flow assays supports the finding that the addition of Wb5 to Wb123 increases sensitivity of LF detection. Moreover, kinetic studies of patients that were treated and followed longitudinally demonstrated a sharper decline in Wb5 titers compared to Wb123, suggesting the use of Wb5 as a marker of active infection. Ongoing studies to improve the detection of Wb4 and Wb5 paves the way for their use in combination with Wb123 (or other antigens) to increase the sensitivity of Ab-based assays for PES.

FIELD EVALUATION IN GHANA OF A NEW OVND5 REAL-TIME PCR METHOD FOR DETECTION OF *ONCHOCERCA VOLVULUS* DNA IN POOLED *SIMULIUM DAMNOSUM S.L.* BLACKFLIES

Jessica Prince-Guerra[1], Gifty Boateng[2], Rexford Adade[2], Andrew Abbott[1], Joseph Opare[3], Odame Asiedu[3], Ellen J. Doku[3], Kofi Asemanyi-Mensah[3], Ben Masiira[4], Thomson Lakwo[4], Ernest Kenu[4], Moukaram Tertuliano[1], Stephen Lindstrom[1], Paul Cantey[1]

[1]US Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, [2]National Public Health and Reference Laboratory, Ghana Health Service, Accra, Ghana, [3]Neglected Tropical Diseases Program, Ghana Health Services, Accra, Ghana, [4]African Field Epidemiology Network, Kampala, Uganda

Onchocerciasis is a parasitic disease transmitted by blackflies and targeted by the World Health Organization (WHO) for elimination. WHO guidelines for stopping treatment (MDA) require screening pools of *Simulium* blackflies for the presence of *O. volvulus* using the O150 PCR-ELISA. A new qPCR assay using the ND5 region (OvND5) was found to be more sensitive and species-specific than O150 molecular methods. It is also faster, easier to perform, lower cost, and uses room-temperature stable reagents. However, the OvND5 qPCR method has not been evaluated in *Simulium* blackflies collected in endemic regions. As part of a larger study evaluating serological thresholds to stop MDA in Northern Ghana, DNA extracted from pools of heads from 22,772 *Simulium damnosum s.l.* blackflies, collected from 10 capture sites in 4 districts, were tested by OvND5 and O150 qPCR assays. A sample was considered positive if both OvND5 and O150 qPCRs were positive. Samples with discordant qPCR results were repeated at a higher (1/20) dilution of DNA. Of 233 pools analyzed, 3 were positive, each from a different site. Cycle threshold (Ct) values ranged from 29-34 (OvND5) and 24-27 (O150). The prevalence calculated using the Poolscreen software was 0.013% (95% CI 0.003-0.038%), which met WHO criteria for stopping MDA. There were 9 pools of blackflies with discordant qPCR results (O150+/OvND5-), 7 of which were from sites with a positive pool. All discordant samples had O150 Ct values > 36. Repeat testing of these samples with diluted DNA did not reveal inhibition; no OvND5 result became positive. It is possible that the high O150 qPCR Ct value represents a small amount of *O. volvulus* DNA that does not indicate an L3 larvae in the head or cross-reaction with another *Onchocerca* species. Further evaluation of the samples is ongoing including genetic sequence analysis to verify species identity, which would help better understand how to use this new method to inform stopping decisions. This evaluation of the OvND5 qPCR provided information on how this test will perform programmatically. Additional evaluations, including those ongoing in Tanzania, Benin, and Malawi, will be important.

In 2018, the US FDA approved the macrocyclic lactone moxidectin (MOX) at 8 mg dosage for onchocerciasis treatment in individuals aged ≥12-year-old. Severe adverse reactions have occurred after ivermectin (IVM), also a macrocyclic lactone, in individuals with high *Loa loa* microfilaria density (MFD). This study compared the safety and efficacy of a 2 mg MOX dose and the standard 150 µg/kg IVM dose in individuals with low *L loa* MFD. A double-blind randomized, ivermectin-controlled, trial of a 2 mg moxidectin dose was conducted in Cameroon between May 2022 and May 2023. It enrolled 72 adult men with *L. loa* MFD between 5-1000 microfilaria/mL. Outcomes were occurrence of adverse events (AE) and *L. loa* MFD reduction rate during the first month off treatment. No serious or severe AEs occurred among the 36 MOX or the 36 IVM treated individuals. Forty-nine AEs occurred in the MOX arm vs 59 AEs in the IVM arm. Grade 2 AE incidence was higher among IVM than MOX treated participants (38.5% and 14.3%, respectively, p=0.043). Median MFD reduction rates were significantly higher after IVM than MOX at day 3 (D3) (70.2% vs 48.5%), D7 (76.4% vs 50.0%) and D30 (79.8% vs 48.1%). Efficacy results at D180 and D365 will be available in June 2024. A single 2 mg MOX dose is as safe as 150 µg/kg IVM in patients with low *L loa* MFD. Further studies with higher moxidectin doses and in patients with higher MFD are warranted.

NEXT GENERATION OV16-BASED RAPID TESTS: FIELD DATA

Marco Biamonte[1], Sam Marton[1], Lauren Boone[1], Justin Nueve[1], Rhea Perez[1], Lily Sullins[1], Jean Saunders[2], Matthias Schwarz[2], Adina Gerson-Gurwitz[2], Sasisekhar Bennuru[3], Rachel Pietrow[3], Yaya Coulibaly[4], Patrick N. Kpanyen[5], Kerstin Fischer[6], Peter U. Fischer[6], Sarah Sullivan[7], Lee Hundley[7], Yvonne Ashong[8], Dziedzom K. de Souza[8]

[1]Big Eye Diagnostics, Inc., San Diego, CA, United States, [2]DDTD, San Diego, CA, United States, [3]NIAID, Bethesda, MD, United States, [4]ICER Mali, Université des Sciences, des Techniques et des Technologies de Bamako, Bamako, Mali, [5]National Public Health Institute of Liberia (NPHIL), Monrovia, Liberia, [6]Washington University School of Medicine, St Louis, MO, United States, [7]COR-NTD, Task Force for Global Health, Decatur, GA, United States, [8]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Improved diagnostics are required to map onchocerciasis in low endemicity areas. In 2021 WHO issued a Target Product Profile (TPP) that calls for a sensitivity ≥ 60% and specificity ≥ 99.8%. To reach this stringent specificity requirement, we developed a prototype rapid diagnostic test that detects IgG4 antibodies to different recombinant *O. volvulus* proteins arranged as two different test lines. Both test lines must be visible to count the test positive. In the latest iteration, called “Biplex D”, the first test line (TL1) is made of Ov16 and the second test line (TL2) contains a mixture of OvOC3261 and Ov33.3. When evaluated in the laboratory against a panel of cryopreserved sera containing 86 microfilariae (Mf) positives and 234 other infections, the sensitivity of Biplex D was 79% (95%CI 69-86%) and its specificity 100% (99.95-100). An earlier test version, called “Biplex C” contains only OvOC3261 and no Ov33.3 at TL2. These two versions are being validated in the field using fingerstick blood. In Bong, Liberia, a preliminary dataset on 19 patients with onchocerciasis (all Mf and nodule positive before ivermectin 18 month ago) gave a sensitivity for Biplex D of 17/19 = 89% (69-97). Combining this with the specificity data obtained in the lab, we conclude that Biplex D meets the TPP sensitivity and specificity specifications, even at the lower bound of the 95% CI. The sensitivity of Biplex C was in Liberia 16/19 = 84% (62-94%), and in Nkwanta, Ghana 11/13 = 85% (57-97%). Combining the two data sets gives a mean sensitivity of 27/32 = 84 % (68-93%), above the 60% sensitivity threshold at the lower bound of the 95% CI. Antibody prevalence data were collected in Ghana with Biplex C. In Adaklu, which is not endemic for onchocerciasis and where no skin snip were Mf positive by microscopy, the seroprevalence in adult males was 3% (1.1-7.4), suggesting that at that level no MDA should be initiated. In adult males in Nkwanta, the Mf prevalence was 4% (1.9-7.9) and the seroprevalence 44% (37-51). Despite proven transmission, both the Mf prevalence and seroprevalence was 0% in children under the age of 10, suggesting that children would be an inadequate sentinel group post-MDA.

6849

IXOKALLIPIN, A NEW PLASMA KALLIKREIN INHIBITOR FROM *IXODES SCAPULARIS* BINDS TO THE CELL MEMBRANE AND IMPAIRS HEMOSTASIS AND THE SKIN WOUND HEALING

Markus Berger, Jan Kotal, **Lucas Tirloni**

National Institute of Allergy and Infectious Diseases, Hamilton, MT, United States

Besides its role in blood coagulation, plasma kallikrein (KLK) also induces keratinocyte migration accelerating wound healing process. Since ticks are blood pool feeders, we rise the hypothesis that KLK-kinin system components would have contact with keratinocytes from the skin and tick salivary proteins at the bite site. In this work we described for the first time an interesting molecule from *I. scapularis* saliva that binds to keratinocyte and endothelial cell membrane, blocking hemostasis and KLK-induced wound healing. We found a strong KLK inhibitory activity in *I. scapularis* saliva. This activity was purified, characterized and a new molecule from the serpin family, that was named ixokallipin, was identified. Ixokallipin inhibits the intrinsic pathway of blood coagulation targeting specifically KLK and factor XIIa. Ixokallipin inhibits the KLK generation on endothelial cell surface *in vitro* and the venous thrombosis *in vivo* without causing a significant bleeding effect. Ixokallipin binds to endothelial cell and keratinocyte surface mainly through phosphatidic acid. Keratinocyte surface supports high molecular weight kininogen-dependent plasma preKLK activation and production of active kallikrein. This event is modulated and completely blocked by ixokallipin. Ixokallipin inhibits keratinocyte migration by reducing cellular focal adhesions and membrane protrusions. The keratinocyte migration is dependent on PAR-1 but not PAR-2 activation. KLK cleaves PAR-1 at a non-canonical site generating a protective response associated with PKC-dependent calcium signaling which was down-regulated by ixokallipin. Looking in more details, ixokallipin inhibits kallikrein/PAR-1-dependent EGF/EGFR transactivation, down-regulating ERK1/2, AKT and paxillin activation, decreasing actin polymerization and consequently the cell migratory responses. Finally, using an *in vivo* model, we confirmed that ixokallipin causes a delay in the wound healing. Our results highlighted interesting new strategies used by the ticks to avoid host hemostasis and skin barriers at the same time.

TSETSE-ENDOSYMBIONT METABOLIC COMPETITION FOR ACYL-CARNITINES REGULATES FLY FECUNDITY BY SUPPRESSING THE VIABILITY OF STORED SPERM

Brian L. Weiss, Erick Awuoche, Serap Aksoy

Yale School of Public Health, New Haven, CT, United States

Competition between insects and their endosymbiotic bacteria for environmentally limited nutrients can compromise the fitness of both organisms. Tsetse flies, the vectors of pathogenic African trypanosomes, harbor a host species and population-specific consortium of vertically transmitted endosymbiotic bacteria that range on the functional spectrum from mutualistic to parasitic. Tsetse’s indigenous microbiota can include a member of the genus *Spiroplasma*, and infection with this bacterium causes fecundity-reducing phenotypes in the fly that include a prolonged gonotrophic cycle and a reduction in the motility of stored spermatozoa post-copulation. Herein we demonstrate that *Spiroplasma* and tsetse spermatozoa utilize fly-derived acyl-carnitines, which in animals are a component of the carnitine shuttle that transports fatty acids across the mitochondrial matrix for use in energy production. The fat body of mated female flies increases acyl-carnitine production in response to infection with *Spiroplasma*. Additionally, their spermathecae (sperm storage organs), and likely the sperm within, up-regulate expression of *carnitine O-palmitoyltransferase-1*, which is indicative of increased carnitine shuttle activity and thus increased energy demand and energy production in this organ. These compensatory measures are insufficient to rescue the motility defect of spermatozoa stored in the spermathecae of *Spiroplasma* infected females and thus results in reduced fly fecundity. Our results provide insight into the mechanisms that facilitate the maintenance of bacterial endosymbioses, and how these relationships impact sperm motility and host fecundity. In the case of pest insects, a better understanding of the metabolic mechanisms that underlie these associations can lead to the development of novel control strategies.

Scabies is a neglected tropical disease with a prevalence of 400 million cases annually. The disease is prevalent in tropical regions where there is an established link with secondary bacterial infections. The causative agent *Sarcoptes scabiei* is an obligate ectoparasitic mite that burrows into the superficial layers of the host skin. This action combined with a complex interaction between scabies mite excretory proteins and the host's immune system leave patients susceptible to secondary bacterial infections. It is these secondary complications that account for the disease burden that is estimated to be 0.21% disability-adjusted life years. Clinical research has shown a correlation between scabies infections and opportunistic pathogens. Despite this accepted correlation there is little molecular data to underpin this complex relationship. Our aim is to provide the fundamental molecular evidence of how scabies infections interfere with the host microbiome. We undertook a collaborative multi-national study that collected skin scrapings from scabies infected patients in India, France and Australia representing a diverse climate and socio-economic range. Microbial DNA was extracted and 16s full length rRNA and ITS[1-4] sequencing were performed using the PacBio sequel,utilising single molecule real-time technology to generate long read lengths. Using an established bioinformatics pipeline, a total of 22,678 amplicon sequence variant (ASVs) were identified from 751 samples. Community composition and microbial abundance was then analysed using the programing language R. Our data demonstrates that there is a significant increase in *Staphylococcus aureus* ($P<0.05$) in scabies infected lesions across all countries and in India and Australia there was a significant increase in *Streptococcus pyogenes* ($P<0.05$) in scabies infected lesions. We found no significant changes in the fungal microbiome and we found several commensal skin bacteria were significantly decreased. This study is the first to quantify the scabies associated microbiome at the molecular level, and address how it might differ globally.

LEISHMANIA TRANSMISSION IS DISRUPTED IN SANDFLIES COLONIZED BY *DELFTIA TSURUHATENSIS* TC1 BACTERIA

Pedro Cecilio[1], Luana A. Rogerio[2], Tiago D. Serafim[2], Kristina Tang[2], Laura Willen[2], Eva Iniguez[2], Claudio Meneses[2], Luis F. Chaves[3], Yue Zhang[4], Wei Huang[5], Pablo Castaneda-Casado[6], Marcelo Jacobs-Lorena[5], Jesus G. Valenzuela[2], Janneth Rodrigues[6], Fabiano Oliveira[2]

[1]Vector Biology Section, LMVR, NIAID, NIH, Rockville, MD, United States, [2]Vector Molecular Biology Section, LMVR, NIAID, NIH, Rockville, MD, United States, [3]Department of Environmental and Occupational Health, School of Public Health-Bloomington, Indiana University, Bloomington, IN, United States, [4]Integrated Data Sciences Section (IDSS), Research Technologies Branch, NIAID, NIH, Bethesda, MD, United States, [5]Department of Molecular Microbiology and Immunology, Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [6]Global Health Medicines R&D, GSK; Tres Cantos, Madrid, Spain

Most human pathogenic *Leishmania* species are zoonotic agents; therefore, sandfly-based control strategies are essential to prevent parasite circulation. Here, we used a *Delftia tsuruhatensis* strain that inhibits the development of *Plasmodium* in mosquitoes, but in the context of *Leishmania*-infected sandflies. Using GFP-expressing *D. tsuruhatensis* TC1, we show that this bacterium colonizes the midgut of *Phlebotomus duboscqi* sandflies. Such colonization impacts the development of *L. major* parasites in the vector, as per the significantly lower number of both total and infectious metacyclic parasites detected in the midguts of bacteria-fed *versus* control sandflies (90% reduction). This phenotype was consistently observed, regardless of the timing of bacterial feeding (from 1 week prior to infection to 8 days after infection), and was even stronger in sandflies given a second, uninfected, bloodmeal. Curiously, our data suggests this phenotype is likely an indirect effect of TC1 colonization, related with the induction of sandfly gut dysbiosis. These results have biological significance, since we observed that *Leishmania*-infected, bacteria-fed sandflies are less able to transmit *Leishmania major* parasites and cause disease in a mouse model of cutaneous leishmaniasis (parasites detected in 27% of animals bitten by bacteria-fed flies *versus* 100% of animals in the control group). Relevantly, modelling studies based on our results support the disruption of disease endemicity in the field. Altogether, these results highlight TC1 as a promising vector-based approach for the control of leishmaniasis in the field.

Tick salivary glands secrete a complex saliva into their hosts to facilitate blood feeding and pathogen transmission. Thousands of transcripts coding for structural and secreted protein have been identified in tick salivary glands. The transcriptomic profile changes over time during feeding, indicating a switch in the sialome. Bulk RNA-seq of *Ixodes scapularis* salivary glands revealed temporal differences in the transcriptomic profile as blood feeding progresses, confirming the "sialome switching" takes place. To uncover the cellular mechanisms behind this phenomenon, we performed single cell RNA sequencing (scRNA-seq) of salivary glands. Salivary gland cells exhibited hypertrophy throughout the feeding process. Clustering analysis identified a total of ten different cellular clusters. Four clusters were observed in unfed ticks; and one of them expresses genes related to cell signaling, signal transduction, and transcription factors, including genes related to the non-canonical Wnt signaling pathway. This suggests that it may represent salivary gland cells in an undifferentiated stage. The abundance of these putative cells presents in unfed ticks decreased as blood feeding progresses, while new clusters appear which express canonical salivary genes. The identity and distribution of the cell clusters and their apparent differentiation were validated by RNA *in-situ* hybridization. Sialome switching appears as a result from cell differentiation rather than cell proliferation. Furthermore, the pJNK is activated during the transition from unfed to fed stage. Based on these findings, we propose that blood feeding activates terminal differentiation of tick salivary gland precursor cells into cells that express subsets of salivary genes in a dynamic process involving the non-canonical Wnt signaling pathway. These findings provide new insights on the dynamic transcriptional response of salivary glands required for successful blood feeding. Disrupting this process may offer potential strategies for controlling tick feeding and, consequently, tick-borne diseases.

SEASONAL VARIATION IN TSETSE FLY APPARENT DENSITY AND TRYPANOSOMA SPP. INFECTION RATE AND OCCURRENCE OF DRUGRESISTANT TRYPANOSOMES IN LAMBWE, KENYA

Ivy S. Okello[1], Gillian Eastwood[2], Jahashi Nzalawahe[1], Eliakunda Mafie[1]

[1]Sokoine University of Agriculture, Morogoro, Tanzania, United Republic of, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, United States

Tsetse flies are major vectors of trypanosomes causing debilitating African animal trypanosomiasis. Emergence of drug resistant trypanosomes is a common problem in sub-Saharan Africa. This study aimed to identify tsetse flies' seasonal variation in apparent densities and their infection rates and occurrence of drug resistant trypanosomes. Tsetse flies were collected from Lambwe, Kenya in May and September 2021. Genomic DNA was extracted from them and *ITS1* gene amplified to detect *Trypanosoma* infection with subsequent species detection. Transporter genes *DMT*, *E6M6*, *TbAT/P2* and *TcoAde2* were targeted to detect polymorphisms associated with drug resistance using sequencing and comparison to drug sensitive species referenced in Genbank. A total of 498 tsetse flies and 29 non-tsetse flies were collected. Apparent density of flies was higher in wet season 6.2 fly per trap per density (FTD) than in dry season 2.3 FTD ($P = 0.001$). Male tsetse flies ($n = 311$) were numerous than females ($n = 187$) ($P = 0.001$). Non-tsetse flies included Tabanids and *Stomoxys* spp. *Trypanosoma* infection in tsetse was 5% (25/498) whereby *T. vivax* was 4% (11/25), *T. congolense* 36% (9/25) and *T. brucei* 20% (5/25) ($P = 0.186$ for species distribution) with infections being higher in females ($P = 0.019$) and during wet season ($P < 0.001$). Numerous polymorphisms and insertions associated with drug resistance were detected in *DMT* and *E6M6* genes in two *T. congolense* isolates while some isolates lacked these genes. *T. brucei* lacked *TbAT/P2* genes. *TcoAde2* in three *T. congolense* isolates were related to those in trypanosomes from cattle blood in our previous study, supporting tsetse fly involvement in transmission in the region. We report *Trypanosoma* associated with drug resistance in tsetse flies from Lambwe, Kenya. Female tsetse flies harbored more *Trypanosoma* infections than males. Tsetse transmission of trypanosomes is common in Lambwe. Risk of trypanosome infection seem higher in wet season when tsetse flies and *Trypanosoma* infections are more prevalent than in dry season. More efforts to control animal trypanosome vectors in the region are needed with particular focus on wet seasons.

CHANGES IN CYTOFORM (CYTOSPECIES AND CYTOTYPE) COMPOSITION OF VECTORS OF ONCHOCERCIASIS IN NORTHERN CAMEROON AND ITS POSSIBLE IMPLICATIONS FOR DISEASE ELIMINATION

Franklin Ayisi[1], Dziedzom de Souza[2], Jamie Tallant[3], Eric Bertrand Fokam[4], Daniel Adjei Boakye[3]

[1]African Regional Postgraduate Programme in Insect Science (ARPPIS), University of Ghana, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research (NMIMR), University of Ghana, Accra, Ghana, [3]The End Fund/Reaching the Last Mile Fund (RLMF), New York, NY, United States, [4]Department of Animal Biology and Conservation, University of Buea, Buea, Cameroon

Onchocerciasis, caused by *Onchocerca volvulus*, is the second leading cause of infectious blindness worldwide. Members of the *Simulium damnosum* species complex are the major vectors in Africa, host to over 99% of the global disease burden. Attaining the WHO goal of transmission elimination (TE) requires regular surveys of vector cytoform composition (as part of monitoring and evaluation), since cytoform composition may change over time. This is especially important because cytoforms of the vectors differ in their vectorial efficiency, ecological distribution and biting pattern, and therefore influence disease epidemiology. Northern Cameroon (NC) is a savanna area with varying success towards TE. Cytoforms previously reported in NC are *S. damnosum* sensu stricto, *S. squamosum* cytotype A, *S. sirbanum* and *S. mengense*. There is paucity of recent information on the cytospecies/cytoform composition in NC, with data available only for few selected sites, and most available data date decades ago. We sampled larvae from rivers in three administrative regions that constitute NC. Larvae were identified by cytotaxonomy of polytene chromosomes. Five cytoforms were identified: *S. damnosum* s.s., *S. sirbanum*, *S. squamosum* cytotype C, *S. yahense* and a cytotype that we call *S. damnosum/sirbanum* because it could not be placed under either cytospecies. This is the first report of *S. yahense* in NC, a restricted species known only in forest areas. *S. yahense* is a very competent vector, more than all previously known vectors in NC. Also, this is the first report of *S. squamosum* C from NC. The *S. squamosum* cytotypes have been associated with differences in biting pattern. In addition, *S. damnosum* s.s. was observed to possess high frequency of inversion 2L-st/2b; this inversion was only previously reported in Ethiopia. Hence, there have been significant changes in cytoforms composition in NC. This change may be due to adaptation of species like *S. yahense* to dryer environments, and possibly due to climate change whose impact is tangible in NC with recorded increase in mean annual temperature. The observed changes in cytoform composition may impact the drive toward TE in NC.

MATERNAL MICROCHIMERISM IS ASSOCIATED WITH AN ALTERED TRANSCRIPTIONAL PROFILE OF *PLASMODIUM FALCIPARUM*-SPECIFIC T CELLS IN MALIAN CORD BLOOD

Yonghou Jiang[1], John Houck[1], Marc Carlson[1], Almahamoudou Mahamar[2], Gaoussou Santara[2], Oumar Attaher[2], Robert Morrison[3], Sudhir Kumar[4], Blair Armistead[1], Irfan Zaidi[3], Stefan Kappe[5], Alassane Dicko[2], Patrick E. Duffy[3], Michal Fried[3], Marion Pepper[6], **Whitney E. Harrington**[5]

[1]Seattle Children's Research Institute, Seattle, WA, United States, [2]International Center for Excellence in Research, Bamako, Mali, [3]Laboratory of Malaria Immunology & Vaccinology, National Institute of Allergy and Infectious Disease, Bethesda, MD, United States, [4]Department of Biomedical Sciences, Iowa State University, Ames, IA, United States, [5]Seattle Children's Research Institute / University of Washington, Seattle, WA, United States, [6]University of Washington, Seattle, WA, United States

Plasmodium falciparum (Pf)-responsive T cells have previously been identified in cord blood from malaria-endemic settings, a phenomenon known as prenatal immune priming (PIP). We have found that maternal microchimerism (MMc) at delivery was associated with increased susceptibility to Pf infection in childhood, and we hypothesized that MMc modulates the quality of PIP. To investigate this hypothesis, we developed an approach to identify and characterize Pf-responsive T cells using single cell RNA sequencing (scRNAseq). Whole cord blood from Malian primigravidae living in a malaria endemic setting was first screened for MMc using qPCR assays targeting a maternal specific allele. Cord blood mononuclear cells (CBMC) from n=8 MMc+ and n=3 MMc- offspring were stimulated with purified Pf merozoite extract for 18 hours and CD3+ CD69+ cells were sorted by flow cytometry for scRNAseq using the 10X Genomics platform. Data from 31,792 T cells across 11 samples were normalized and aggregated for further analysis, including 19,882 CD4 T cells, 6,082 CD8 T cells, and 2,308 γδ T cells. To identify true antigen-specific vs. bystander activated T cells, we developed a T cell activation gene signature that included genes upregulated in the setting of T cell receptor (TCR) engagement (NR4A, IRF4, IL2RA, MIR155HG, CD40LG, TNFRSF4, and TNFRSF9). The gene signature identified 1,178 CD4 T cells, 184 CD8 T cells, and 375 γδ T cells with evidence of TCR engagement, suggesting antigen specificity. Within CD4 T cells, Pf-responsive vs. bystander cells had significantly increased expression of HLA-DR and HLA-DP genes, as well as IL1B, GZMB, IFI30, and CXCL8 (IL-8). Pf-responsive cells from MMc+ vs. MMc- cord bloods had significantly decreased expression of IL1B, GZMB, CXCL1, and CXCL2; and significantly increased expression of the immunoregulatory molecule CD52. Together, these data demonstrate the ability to identify Pf-responsive T cells in CBMC using modern, robust, single cell approaches and suggest the potential for differential function of these cells by MMc status.

Affiliation 2: CERPAGE (Centre d'Etude et de Recherche sur les Pathologies Associées à la Grossesse et à l'Enfance), Cotonou, Benin, [2]CERPAGE (Centre d'Etude et de Recherche sur les Pathologies Associées à la Grossesse et à l'Enfance), Cotonou, Benin, [3]Institut de Recherche Clinique du Bénin (IRCB), Cotonou, Benin, [4]Centre for Medical Parasitology at Department of International Health, Immunology and Microbiology, University of Copenhagen and Department for Congenital Disorders, Statens Serum Institut, Copenhagen, Denmark

The transplacental transfer of maternal antibodies to the fetus is crucial in protecting neonates in early life. However, several studies have shown that infants born from mothers with *Plasmodium falciparum* Malaria infection at Delivery (MiD) present a high risk of infection and constitute a particularly vulnerable population. Many studies have investigated the efficacy of maternal antibodies transfer in MiD whereas the functionality of those antibodies remains to be assessed. The study was carried out in a rural region of southern Benin and neonates were followed-up from birth to 18 months of age. The functionality of immunoglobulin G (IgG) against 5 *Plasmodium falciparum* antigens was determined using a bead-based opsonic phagocytosis assay (BPA) and THP1 monocyte line with available maternal and cord serum (n=355). IgG, IgG1 and IgG3 specific to *Pf*-antigens were quantified from the same samples using ELISA. We observed that phagocytosis in the maternal compartment is strongly dependent on the concentration of antibodies specific to each antigen (AMA1 p=0.002; MSP1 p=0.014; MSP3 p=0.017; GLURP-R0 p<0.001 and GLURP-R2 p<0.001) whereas maternal hypergammaglobulinemia (total IgG greater than 16g.L^{-1}) was negatively associated with phagocytosis (AMA1 p=0.014, MSP3 p=0.013). Functional antibody transfer was positively associated with maternal antibody concentration (AMA1 p<0.001, MSP1 p=0.025, MSP3 p=0.043, GLURP-R0 p=0.013, GLURP-R2 p<0.001) and negatively associated with maternal exposure to malaria vector (AMA1 p= 0.07, MSP3 p= 0.008). Taken together, our data suggest that maternal specific antibodies are strongly secreted during MiD. They are functional until total IgG reaches a high concentration which will reduce the capability of specific IgG to induce phagocytosis. The transplacental transfer of functional antibodies is impaired when mothers are exposed to malaria vectors.

ANTIBODY FC GLYCOSYLATION MODULATES NATURAL KILLER CELL-MEDIATED ANTIBODY-DEPENDENT CELLULAR CYTOTOXICITY (ADCC) IN MALARIA-EXPOSED PREGNANT WOMEN

Savannah N. Lewis[1], Adam S. Kirosingh[1], Kattria van der Ploeg[1], Kathleen D. Press[1], Felistas Namirimu Nankya[2], Kenneth Musinguzi[2], Evelyn Nansubuga[2], Stephen Tukwasibwe[2], Mary Lopez-Perez[3], Moses R. Kamya[2], Philip Rosenthal[4], Grant Dorsey[4], Lars Hviid[3], Prasanna Jagannathan[1]

[1]Stanford University School of Medicine, Stanford, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]University of Copenhagen, Copenhagen, Denmark, [4]University of California, San Francisco, San Francisco, CA, United States

Antibody-dependent cellular cytotoxicity (ADCC) mediated by natural killer "NK" cells has been associated with clinical immunity to malaria in both children and adults in several endemic settings. However, it remains unclear whether NK cell-mediated ADCC is also protective against malaria in pregnancy. To study the NK cell response in malaria-exposed pregnant women, we leveraged peripheral blood mononuclear cell (PBMC) samples from the DPSP Clinical Trial (ID: NCT04336189), in which participants living in Busia District, Uganda were randomized to receive sulfadoxine-pyrimethamine, dihydroartemisinin piperaquine, or a combination of these drugs for intermittent preventive treatment of malaria in pregnancy. We first observed that primigravid donors had a higher risk of malaria-related complications than multigravid donors, suggesting that adaptive immune mechanisms may confer protection in this context. When we profiled the ability of NK cells to perform ADCC against erythrocytes infected with VAR2CSA-expressing *Plasmodium falciparum* (CS2), we observed that the magnitude of ADCC was significantly enhanced when infected erythrocytes were opsonized with pooled plasma from multigravid compared to primigravid donors. VAR2CSA-specific IgG titers were similar in both plasma pools. NK cell degranulation and cytokine production was similar between primigravida and multigravida PBMC donors, leading us to hypothesize that NK cell-extrinsic factors present in plasma underlie this observation. Previous serology work has shown that afucosylation of VAR2CSA-specific antibodies increases with gravidity, which enhances Fc-dependent effector responses. When we opsonized CS2-infected erythrocytes with pooled plasma with high and low Fc fucosylation of VAR2CSA-specific IgG, we found that lowly fucosylated plasma induced significantly more NK cell degranulation than highly fucosylated plasma in DPSP donors. We are currently working to identify phenotypic features of NK cells that respond to afucosylated VAR2CSA-specific IgG and to search for correlations between these phenotypes and birth outcomes within the DPSP study cohort.

Chronic *Plasmodium falciparum* infections are the norm in endemic areas. While minimally symptomatic, these infections predispose individuals to secondary bacterial infections and reduce malaria vaccine efficacy. Thus, understanding how chronic infections alter the immunological landscape of infected individuals is needed. Here, we used samples collected from macaques infected with *P. coatneyi*, a model of *P. falciparum* malaria, to define host transcriptional changes and immunological responses that lead to the establishment of a chronic infection. Using whole blood RNA sequencing, we show that infections reach chronicity 50 to 80 days after inoculation with sporozoites. Based on transcriptional analysis of the host response, progression to chronicity is generally independent of parasitemia and, instead, related to time an infection has persisted. The transition from acute to chronic infections was defined by upregulation in gene signatures related to B cells and cytokine signaling and downregulation of interferon gamma signaling. Interestingly, Type I interferon signaling remained elevated from the acute to chronic phases. Inflammatory cytokine gene expression was upregulated during acute infection and decreased as the infection progressed to the chronic phase. However, some pro-inflammatory cytokines like TNFα remained elevated. Anti-inflammatory cytokines (e.g., IL-10) increased in the acute and returned to baseline when chronicity was reached. Flow cytometry analysis showed an increase in multiple B cell subsets, including CD21^{neg-} CD27^{neg-} B cells, and effector memory CD8^{+} T cells. Control of parasitemia was significantly correlated with the changes in B and T cell populations in addition to IgG and IgM against *P. coatneyi*, suggesting these responses are key for maintaining parasite control during chronic infections. In sum, this study defines the progression of a Plasmodium infection from acute to chronic and shows persistent derangements in the host immunological landscape that may influence malaria vaccine efficacy.

Reliable immune correlates of protection against *Plasmodium falciparum* (*Pf*) malaria remain elusive, in part because sustained protection from parasitemia through natural exposure is rarely observed. In a prospective cohort study of Malians living in an area of intense malaria transmission, we identified a subset of young children who remained aparasitemic during 7 months of biweekly active and passive surveillance. These children showed boosting of malaria-specific IgG during the season, suggesting evidence of malaria exposure despite remaining aparasitemic. To identify immune responses associated with apparent elite control of infection, we carried out CITE-seq of PBMCs from 7 pairs of age- and sex- matched aparasitemic and parasitemic children. We included *Pf* antigens MSP1- and AMA1- specific B cell tetramers in the CITE-seq cocktail and sequenced B cell receptors (BCRs) from these cells. To identify epigenetic changes that confer the aparasitemic phenotype, we performed scATAC-seq on cells from additional samples. Immune cell types from aparasitemic and parasitemic children exhibited markedly different transcriptional states and epigenetic landscapes. Notably, $CD14^+$ monocytes in aparasitemic children showed enrichment of inflammatory signatures including TNFα signaling via NF-κB along with differently accessible chromatin in the target genes of these pathways. We also identified 44 antigen-specific B cells, primarily from aparasitemic children, and cloned their BCRs into expression plasmids with the goal of producing *Pf*-specific monoclonal antibodies *in vitro* to assess their ability to control parasite growth and enhance the opsonophagocytosis capacity of monocytes.

PVDBP GENE AMPLIFICATION PROTECTS *PLASMODIUM VIVAX* IN VIVO AGAINST HOST NATURALLY ACQUIRED ANTI-PVDBP IMMUNITY

Lea Baldor[1], Brice Feufack-Donfack[1], Dynang Seng[1], Sokleap Heng[1], Nichole D. Salinas[2], Niraj H. Tolia[2], Chetan E. Chitnis[3], Ivo Mueller[4], Christopher L. King[5], Eugenia Lo[6], Benoit Witkowski[7], Claude Flamand[1], Jean Popovici[1]

[1]Institut Pasteur Cambodge, Phnom Penh, Cambodia, [2]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [3]Institut Pasteur Paris, Paris, France, [4]The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, [5]Center for Global Health and Diseases, Cleveland, OH, United States, [6]Department of Microbiology and Immunology, Drexel University, Philadelphia, PA, United States, [7]Institut Pasteur Madagascar, Antananarivo, Madagascar

The key ligand involved in *Plasmodium vivax* (Pv) invasion is the Pv Duffy Binding Protein (PvDBP) binding to the Duffy. Anti-PvDBP human monoclonal antibodies (Abs) can inhibit the PvDBP-Duffy binding and neutralize invasion of reticulocytes by parasites. However, parasites with multiple copies of the PvDBP gene are protected *in vitro* against neutralization. Here, we aim to determine if this gene amplification also protects parasites *in vivo.* We hypothesize that: (i) multi-*pvdbp* copy parasites are more frequent in areas with a high Pv prevalence compared to low prevalence areas and (ii) individuals with naturally-acquired binding inhibitory anti-PvDBP Abs (Blabs) are predominantly infected over time by multi-copy parasites. To test these hypotheses, we analyzed samples from a longitudinal cohort of individuals living in nine villages in Eastern Cambodia with low (~5%) to high (~30%) prevalence. Using a PCR assay targeting the boundaries of the *pvdbp* duplication, we show a significant association between Pv prevalence and proportion of multicopy parasites (35% in low prevalence villages to 47% in high prevalence ones, p=0.0246). Then, using a flow cytometry assay, we determined the presence of naturally-acquired Blabs in the plasma of 657 participants of the cohort. The more inhibitory the Abs in the hosts' plasma, the higher the proportion of multicopy parasites: 87% (40/46) from individuals with highly inhibitory Abs (>90% inhibition) while 38% (167/436) from individuals without any Blabs ($p<0.0001$). Finally, we compared the gene copy number of parasites over the 21-month follow-up in the cohort participants according to the presence of Blabs at month 0. We show that the frequency of multicopy parasites was consistently higher in participants with highly inhibitory Abs compared to those without any Blabs for the entire follow-up. Overall, these results demonstrate that *pvdbp* duplication protects parasites *in vivo* against hosts' anti-PvDBP immunity. These results warrant further investigations to determine if immunization of individuals with a PvDBP vaccine could overcome this new immune evasion mechanism.

IMMUNO-INFORMATIC APPROACH TO IDENTIFYING VARIANT-TRANSCENDENT NATURALLY-ACQUIRED PROTECTION AGAINST *PLASMODIUM FALCIPARUM*

Katherine Chew, Steve Taylor, Wendy O'Meara, Christine Markwalter

Duke University, Durham, NC, United States

Plasmodium falciparum antigenic diversity compromises the development of lasting immunity. Current available vaccines for malaria contain a single sequence of P. falciparum circumsporozoite protein (CSP), and protection following vaccination is variant-specific. Multi-variant vaccines may help to overcome antigenic diversity, but identifying a minimum set of variants that provide cross-protection against a broad range of CSP variants remains a challenge. We recently reported an epidemiologic signature of natural immunity to *P. falciparum* in which time to reinfection with parasites bearing homologous CSP T cell epitopes was delayed following symptomatic vs asymptomatic infections. We hypothesized that this delayed reinfection would extend to cross-protective 'epitope types' which are likely to be physiochemically similar. Thus, we applied 10 quantitative metrics of amino acid physiochemical properties (PCPs) to group CSP Th2R and Th3R epitope types via hierarchical clustering. Using *pfcsp* sequences (344 infections, 155 unique haplotypes) from a 14-month longitudinal cohort in Western Kenya, we evaluated PCP-based epitope clusters by assessing the phenotype of increased time to reinfection with parasites bearing physiochemically-similar epitopes after symptomatic vs asymptomatic infections. At Th2R, clustering epitope types by any of the PCP metrics reproduced the phenotype with >20 groups, but the Yampolsky and Stolzfus measure shows the phenotype in as few as 10 groups; no PCP metric displayed the phenotype with <10 groups. The Th3r epitope displayed the phenotype with 8 groups, but the PCP measures that meaningfully clustered epitypes were distinct from those identified for the Th2R locus. Overall, our study demonstrates that amino acid properties can identify immunologically-similar CSP epitopes that share recognition by naturally-acquired immune responses. This offers a path forward to exploiting parasite diversity and reducing the search space for variant-transcendent responses.

Novel vector control tools, such as Olyset®Plus ceiling net (2% permethrin+1% piperonyl butoxide), are needed to fight the malaria resurgence reported since 2016, especially in sub-Saharan Africa. We evaluated the protective effectiveness of adding Olyset®Plus ceiling net to existing control interventions on *Plasmodium falciparum* malaria prevalence and incidence. We conducted a two-arm, parallel group, superiority cluster randomized controlled trial with 10 clusters per arm during November 2021-May 2023 on Mfangano Island in western Kenya. Olyset®Plus ceiling nets were installed in eligible households in the intervention arm. The primary outcome, malaria prevalence in children (3-15 years old) at 12 months post-intervention, was measured during cross-sectional school surveys. The secondary outcome, cumulative malaria incidence in all age groups during a 12-month follow-up post-intervention, was tracked monthly for 12 months in a community cohort. Malaria infection was determined using malaria rapid diagnostic test (Paracheck-Pf® Orchid Biomedical Systems, India). Olyset®Plus ceiling nets were installed in 1006 houses (mean coverage: 93.4%). Eight hundred six eligible children were recruited in the control- and 831 in the intervention- arms to determine malaria prevalence. At 12 months post-intervention, malaria prevalence was 30.1% (95%CI: 27.1-33.3) in the control- and 16.4% (14.0-19.2) in the intervention- arms (prevalence ratio 0.55; 95% CI: 0.33-0.91, p = 0.056). Two hundred six eligible persons were recruited in the control- and 266 in the intervention-arms to determine malaria incidence. During the 12-month follow-up, malaria incidence was 0.11 per person-year (ppy) (0.07-0.15) in the control- and 0.05 (0.02-0.09) ppy (1.21-1.65) in the intervention- arms (incidence rate ratio 0.47; 95% CI: 0.24-0.95, p = 0.030). Olyset®Plus ceiling nets protected against malaria in addition to the effects of existing control interventions. Multi-county studies across different malaria transmission intensities are needed for wider adoption to complement existing vector control interventions.

6864

EFFECTIVENESS OF CHLORFENAPYR-PYRETHROID INSECTICIDE-TREATED NETS ON DECREASING MALARIA IN LIBERIA: AN OBSERVATIONAL ANALYSIS USING ROUTINE HEALTH FACILITY DATA, 2019-2023

Emily R. Hilton[1], D. Levi Hinneh[2], Chrispin Williams[3], Patrick Konwloh[2], Trokon Washington[2], Ibrahima Baber[4], Yemane Yihdego[5], Tuwuyor Belleh[4], Miriam Williams[5], Melissa Yoshimizu[6], Uwem Inyang[7], Sarah Burnett[8]

[1]PMI Evolve Project, PATH, Seattle, WA, United States, [2]National Malaria Control Program, Monrovia, Liberia, [3]National Malaria Control Program, Monrovia, Libya, [4]PMI Evolve Project, Abt Associates, Monrovia, Liberia, [5]PMI Evolve Project, Abt Associates, Rockville, MD, United States, [6]U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington, DC, United States, [7]U.S. President's Malaria Initiative, U.S. Agency for International Development, Monrovia, Liberia, [8]PMI Evolve Project, PATH, Washington, DC, United States

Dual-active ingredient (AI) chlorfenapyr-pyrethroid insecticide-treated nets (ITNs) were distributed nationwide in Liberia in June 2021 to address growing pyrethroid resistance in malaria vector populations. This retrospective observational study evaluated the post-intervention impact of the new ITNs on epidemiological and entomological indicators of malaria compared to the pre-intervention baseline period when pyrethroid-only ITNs had been distributed. A negative binomial Bayesian mixed effects interrupted time series model was used to estimate the effect of dual AI ITN distribution on reported confirmed malaria cases from July 2019 to June 2023 in all 15 counties of Liberia and the number of cases averted by dual AI ITNs, controlling for month, community health worker reporting, non-malaria outpatient attendance, precipitation, and vegetation. Trends in vector human biting rate (HBR) and indoor resting density (IRD) measured during the high transmission season (March to June) one year before and after dual AI ITN distribution were descriptively analyzed. During the two years post-dual AI ITN distribution, an estimated 87.6 malaria cases per 1,000 population (95%CI=65.0 - 112.9) were averted with an estimated case incidence decrease of 41.0% (95%CI=43.9% - 38.4%) overall (from an estimated 239.9 [95%CI=236.6 - 243.4] cases per 1,000 during the baseline to an estimated 170.1 [95%CI=167.6 - 172.6] cases per 1,000). Case incidence reductions compared to baseline were greater in the first year post-distribution (mean=49.0%; 95%CI=52.4% - 45.6%) than in the second year (mean=33.9%; 95%CI=37.4 % - 30.7%). Indoor HBR of *An. funestus* s.l. and *An. gambiae* s.l. decreased in the year following dual AI distribution, although only *An. funestus* s.l. experienced a decrease in IRD during the same period. Dual AI chlorfenapyr-pyrethroid ITNs appeared to substantially reduce malaria case rates following nationwide mass distribution in 2021 and were associated with declining trends in malaria vector HBR.

6865

REDUCTION IN MALARIA CASES AFTER DEPLOYMENT OF IG2 NETS IN AN AREA WITH KNOWN PYRETHROID RESISTANCE AND MARKED OUTDOOR BITING - AN INTERRUPTED TIME SERIES ANALYSIS.

Samuel Kweku Oppong[1], Otubea Owusu-Akrofi[2], Christian Atta-Obeng[2], Wahjib Mohammed[2], Punam Amratia[3], Nana Yaw Peprah[2], Peter Gething[4], Keziah L. Malm[2]

[1]Curtin University, Bentley, Australia, [2]National Malaria Elimination Programme, Accra, Ghana, [3]Malaria Atlas Project, Dar esalam, Tanzania, United Republic of, [4]Malaria Atlas Project, Telethon Kids Institute, PERTH, Australia

In 2019, the first-ever stratification for subnational tailoring was conducted using data routine health facility data from 2015-2018. Results showed that the Western North region had one of the highest malaria burden in the country. Notwithstanding the high rate of outdoor biting, reported pyrethroid resistance in the region warranted the distribution of new generation ITNs in all the 9 districts in July 2021 to help reduce the cases. In this study we assessed the effect of IG2 nets on malaria cases between 2019 and 2023. Monthly health facility data on reported suspected, tested, confirmed, and presumed malaria cases were aggregated for each district from 2019 to 2023. We conducted a trend analysis and an interrupted time series analysis of the confirmed malaria cases for the period January 2019 to December 2023. The auto ARIMA function in R was used to choose the best model and adjust for seasonality and other dependency. A total of 1,235,126 confirmed malaria cases were reported between 2019 and 2023. Confirmed malaria cases decreased from 317,495 in 2019 to 182,856 in 2023. The baseline confirmed cases (intercept) from the regression model was 25,025 (95% CI = 22, 672, 27,737). The time coefficient showed a declining trend but was not statistically significant (-21.7; 95% CI = -150.1, 106.6). We observed an immediate, statistically significant decrease of 6,130 malaria cases (95% CI = -9,441, -2,820) after the intervention compared to the period before the intervention. Assessing the trend that would have been expected in absence of the intervention, the results

showed a non-significant sustained decrease of 107 (95% CI = -298, 84) in the monthly number of confirmed malaria cases during the intervention period. The ACF plot of the residuals showed the autocorrelations were not significant. This study shows that deployment of next generation ITN may have contributed significantly to the reduction in malaria incidence in Western North. The findings will support IG2 deployment decision making in the country to complement other malaria control interventions ultimately to reduce malaria burden in the country.

6866

EFFECT OF ATTRACTIVE TARGETED SUGAR BAITS (ATSBS) ON MALARIA INCIDENCE IN CHILDREN IN WESTERN KENYA: A CLUSTER-RANDOMIZED CONTROLLED TRIAL

Caroline Ogwang[1], Alice Kamau[2], Kizito Obiet[1], Brian Seda[1], Daniel McDermott[2], Julia M. Janssen[3], Wycliffe Odongo[3], Julie R. Gutman[3], Jonathan Schultz[4], Frank Aduwo[1], Mercy Chepkirui[1], Oliver Towett[1], Maia Lesosky[5], Martin Donnelly[2], Simon Kariuki[1], Aaron Samuels[4], Feiko ter Kuile[2], Sarah G. Staedke[2]

[1]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [2]Liverpool School of Tropical Medicine, Liverpool, Liverpool, United Kingdom, [3]Division of Parasitic Diseases and Malaria, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Malaria Branch, National Center for Emerging and Zoonotic Infectious Diseases, US Centers for Disease Control and Prevention, Kisumu, Kenya, [5]Imperial College London, London, United Kingdom

Attractive Targeted Sugar Baits (ATSBs) are a novel malaria vector control tool designed to attract and kill mosquitoes outdoors. We conducted an open-label, cluster-randomised trial to evaluate the impact of ATSBs on clinical malaria incidence in Siaya County, western Kenya. Overall, 70 clusters (1-3 villages) were randomised 1:1 (35 per arm) to intervention (ATSBs) vs control (no ATSBs) using restricted randomisation. A 'fried egg' design was used for deployment of ATSBs (whole cluster) and evaluation of outcomes (core only), with a buffer zone of 600-1200m to limit contamination in the control arm. Two ATSB stations were hung on the outside walls all eligible structures and replaced every 6 months over 2 years. In total, 267,987 ATSBs were hung. All clusters received long-lasting insecticidal nets (LLINs) delivered by the Ministry of Health and supplemented by the study team, targeting a desired ratio of 1 net per every two people. From March 2022 to March 2024, three consecutive cohorts of children aged 1 to <15 years were enrolled and followed up sequentially over 2 years to assess the primary outcome of malaria incidence, aiming to accrue 1,260 person-years of follow-up time. Here, we present blinded results. Of 3,704 children screened, 217 declined, 525 were excluded, and 2,962 were enrolled into the cohorts, including 784 (26%) aged 1-4 years, and 2,178 (74%) aged 5 to <15 years. Cohort children completed 21,800 routine visits and 2,365 sick visits over the follow-up period. At 2,568 visits, children were tested for malaria by RDT; 1,766 (69%) were positive. Overall, 2,862 children were included in the endpoint analysis; 104 were excluded due to loss to follow-up (n=56), lack of at-risk person-time (n=31), and other (n=17). In total, 1,939 malaria cases over 1,435 person-years were captured, (1.35 malaria episodes per person-year). Complete unblinded results will be presented.

6867

SAFETY < EFFICACY OF INTERMITTENT PRESUMPTIVE TREATMENT IN PREGNANCY WITH SULFADOXINE-PYRIMETHAMINE USING RAPID DIAGNOSTIC TEST SCREENING < TREATMENT WITH DIHYDROARTEMSININ-PIPERAQUINE AT FIRST ANTENATAL CARE VISIT PRELIMINARY RESULTS

Jean-Bertin Bukasa Kabuya[1], Matthew Ippolito[2], Christine Manyando[1]

[1]Tropical Diseases Research Centre, Ndola, Zambia, [2]Johns Hopkins University, Baltimore, MD, United States

Intermittent presumptive treatment in pregnancy (IPTp) with sulfadoxine-pyrimethamine (SP) is a life-saving intervention for African pregnant women and their offspring, but increasing parasite resistance to SP has challenged its effectiveness. Alternative strategies are therefore being tested in clinical trials throughout Africa that include the incorporation of artemisinin-based combination therapy as an alternative to SP. We conducted a randomized controlled trial to assess the safety and efficacy of an IPTp approach that incorporates screening with RDT and treatment with dihydroartemisinin-piperaquine (DP) at the first antenatal care (ANC) visit. Asymptomatic pregnant women were randomized to IPTp-SP or hybrid IPTp-SP plus screening and treatment (IPTp-SP+). In the IPTp-SP+ arm, mothers testing positive by RDT were treated with DP at the first ANC visit, while those who screened negative received SP. In the control arm, IPTp-SP was administered per current guidelines. All received SP on days 35 and 63 and were followed biweekly up to day 63 then monthly until delivery. 393 pregnant women were recruited. Our results showed that the intervention was associated with 41% reduced odds of clinical malaria during pregnancy (OR = 0.59, 95% CI 0.38-0.92, P=0.019), adjusted for age, net use, indoor residual spraying, and gravidity. We found no significant difference in hemoglobin on day 63 (Hb 10.9±1.6 vs 11.1±1.4 g/dL, P=0.22), hemoglobin at delivery (Hb 10.9±1.6 vs 10.9±1.6 g/dL, P=0.77), congenital malaria (6% vs 3%, P=0.24), birth weight (3.0 ±0.4 vs 2.9±4.9 kg, P=0.092) or the prevalence of stillbirth (1% vs 3%, P=0.16) in the control compared to the intervention arm, respectively. The odds of low birth weight (LBW; OR 2.56, 95%CI 1.17 - 5.61, P=0.019) were higher in the IPTp-SP+ arm. However, no significant difference in LBW was detected between first-visit SP and DP in an IPTp-SP+ within-group analysis (61% vs 39%, P=0.94). IPTp-SP+ reduced the odds of malaria in pregnancy compared to the current standard of care and was shown to be safe and well-tolerated.

6868

THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON THE EDUCATIONAL OUTCOMES OF SCHOOL-AGED CHILDREN IN SUB-SAHARAN AFRICA

Mohammed Ndiaye[1], Donal Bisanzio[2], Amber Gove[2], Lauren Cohee[3], Richard Reithinger[2]

[1]University of Maryland, College Park, MD, United States, [2]RTI International, Washington, DC, United States, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Early childhood is a time of substantial growth and cognitive development—it is also the time when children are most at risk of malaria-related morbidity. Severe malaria, especially cerebral malaria, is associated with increased individual-level risk of adverse neurocognitive and behavioral outcomes. However, the population-level impact of repeated events of uncomplicated malaria on cognitive development and early learning is not known. Seasonal malaria chemoprevention (SMC) has led to substantial reductions in the burden of malaria in young children. To address this knowledge gap, we conducted a literature review to establish a foundational understanding of the nexus between health and educational outcomes, as well as define a set of harmonized malariometric, educational and other indicator data studies investigating the link between malaria and education should collect. This groundwork facilitated the use of ecological analyses to measure the impact of SMC on cognitive function and early learning. We identified countries (Gambia, Guinea, Senegal) in which cognitive and/or educational

assessments took place before/after SMC introduction and/or in areas with and without SMC. We used generalized additive mixed models (GAMMs) to investigate the relationship between SMC implementation and education indicators, and show that educational indicators have significantly improved in regions where SMC has been implemented over several years. Findings broaden our understanding of the potential educational and economic impacts of malaria prevention and may support further multi-sectoral investments in malaria control.

6869

URGENCY OF PHARMACEUTICAL SECTOR REFORM TO ACHIEVE UNIVERSAL HEALTH COVERAGE IN NEPAL

Pradip Lamsal, Krishna P Adhikary

Helping Hands Community Hospital, Kathmandu, Nepal

The Constitution of Nepal 2015 has established health as a fundamental right of the citizens. Both the National Health Sector Strategy and the National Health Policy were developed to realize the constitutional aspirations and are anchored to Nepal's commitment to Universal Health Coverage. The government cannot provide financial risk protection without equitable access to pharmaceuticals. Quality assured medicine are needed to expand health coverage and services. To fulfill the government's promise to improve public health, key policy reforms are required to unleash this potential. To discuss critical issues of Nepal's pharmaceutical sector, including the regulatory environment and domestic manufacturing, a high-level multispectral policy dialogue was organized in November 2021, and a series of intensive focus group discussions were carried out to encapsulate a vision for Nepal's pharmaceutical sector, outline the building blocks for pharmaceutical sector reform, and propose key reform priorities. The paper aims to provide a holistic view of the reform agenda and is mainly intended for the consumption of policymakers, development partners, and stakeholders directly or indirectly associated with Nepal's pharmaceutical sector. To unleash the full potential of Nepal's pharmaceutical sector, several critical challenges need to be addressed. The main buckets of issues and challenges are self-reliance, regulation, quality assurance, institutional restructuring, innovation, and strategic positioning of the pharmaceutical sector. The building blocks of the pharmaceutical sector fall under seven domains: policy coherence and harmonization, regulatory stewardship, local manufacturing promotion, institutional governance, pharmaceutical services, and technology and innovation. As Nepal transitions to federalism, the government shoulders the mandate of safeguarding the health of the citizens by espousing the principles of equality, prosperity, and social justice, the question "What should be the new vision for the pharmaceutical sector?" needs to be answered from the perspective of both consumers and providers.

UNDERSTANDING COVID-19 VACCINE HESITANCY AMONG KEY STAKEHOLDERS IN A CONFLICT AFFECTED AREA OF CAMEROON, A FOCUS GROUP DISCUSSION APPROACH

Henry Fomukong Nzozone[1], Ngwingnchi Belove Asaah[2], Joyce Amambo Nzozone[1], Oben Pamela epse Besong[3]

[1]konye Health District, Regional Delegation Of Public Health, Southwest, Cameroon, [2]panafrican Institude Of Development, West Africa, Southwest, Cameroon, [3]regional Coordination Unit Epi, Regional Delegation Of Public Health, Southwest, Cameroon

The COVID-19 vaccine hesitancy issue is a significant challenge in Africa, influenced by historical, cultural, and socio-political factors. Health workers play a crucial role in shaping public perceptions of vaccines, and understanding their perspectives is essential for informed decision-making. Focus group discussions (FGDs) can help uncover these factors and provide insights into regional variations, enabling targeted interventions in urban and rural areas. This qualitative survey explored perceptions and attitudes towards COVID-19 vaccination in the Kumba community, South West Cameroon. Ten focus groups representing diverse demographics were involved. Recorded Discussions lasted less than 60mins on 24 themes. The recordings were uploaded into Nvivo version 12, coded and transcribed during narration. Results revealed a lack of understanding about vaccines' preventive nature, with 68% initially welcoming the vaccine with fear due to social media misinformation. Seventy-three percent of participants, including health workers, had not been vaccinated, citing fear and misinformation. Despite acknowledging their ethical responsibility, 42.1% negatively influenced others' vaccination decisions. Only 37.5% believed measures against COVID-19 in Cameroon were effective. Unvaccinated participants stressed the need for clarification and rural outreach. Recommendations include culturally tailored communication, community engagement, health education, equitable vaccine distribution, and continuous research to address vaccine hesitancy. Addressing vaccine hesitancy in Cameroon demands a multifaceted approach. The findings underscore the urgency of combating misinformation on social media and involve health workers actively in vaccination campaigns. Continuous research and evaluation will guide adaptive strategies, ensuring a comprehensive and inclusive response to COVID-19 vaccination challenges in Cameroon

6871

THE INFLUENCING FACTORS OF QUALITY OF LIFE AMONG INDIVIDUALS RESIDING IN RURAL AND URBAN AREAS OF THAILAND DURING THE COVID-19 PANDEMIC

Wiriya Mahikul, Wisut Lamlertthon, Kanchana Ngaosuwan, Kornphaka Phatthanagumphol, Pisinee Narayam, Nattakitta Mektripop

Chulabhorn Royal Academy, Lak Si, Thailand

The COVID-19 pandemic has profoundly impacted individuals' quality of life worldwide. This cross-sectional study was designed to explore the factors influencing the quality of life among residents in rural (Ban Luang district, Nan province) and urban (Lak Si, Bangkok) areas of Thailand during the pandemic. Participants were selected using a stratified sampling method. Quality of life was assessed using the WHOQOL-BREF-THAI questionnaire. Descriptive statistical methods and logistic regression analysis were applied to analyze the collected data. Of the 867 survey participants, 420 individuals were from rural areas and 447 were from urban areas. The mean age of participants was 35.6 ± 10.2 years in rural areas and 38.2 ± 9.8 years in urban areas. In urban areas, a majority of participants were women, married, and had lower education levels (71.1%, 50.3%, 58.8%, respectively). The overall quality of life (QOL) score was 98.2 (SD = 10.8) in rural areas and 98.5 (SD = 14.5) in urban areas. In urban areas, living in a nuclear family was associated with approximately 3.3 times higher QOL compared to living in an extended family (AOR = 3.31, 95% CI [1.75-6.27]). Additionally, using social media was associated with approximately 3.3 times higher QOL compared to not using social media (AOR = 2.06, 95% CI [1.03-4.10]). In rural areas, having an average household monthly income over 10,000 THB was associated with approximately 3.7 times higher QOL compared to lower income levels (AOR = 3.68, 95% CI [1.39-9.72]). Similarly, drinking alcohol in rural areas was associated with approximately 2.1 times higher QOL compared to not drinking (AOR = 2.12, 95% CI [1.36-3.31]).This study emphasizes the differences in QOL and related factors between rural and urban areas of Thailand during the COVID-19 pandemic. To enhance QOL, it is important to address specific challenges unique to each setting, such as those living in extended families and the use of social media in urban areas, as well as among individuals in rural areas with lower income levels. Our findings can inform the development of public health policies aimed at improving QOL in these specific settings.

6872

MEASURING CLIENT EXPERIENCE OF CARE FOR PERENNIAL MALARIA CHEMOPREVENTION IN BENIN

Cyprien Zinsou[1], Paul Bouanchaud[2], Isidore Kikissagbe[1], Ghyslain Guedegbe[1], Maya Schane[3], Charlotte Eddis[3]

[1]ABMS, Cotonou, Benin, [2]PSI, Washington, DC, United States, [3]PSI, Abidjan, Côte D'Ivoire

The right to dignified, respectful health care is enshrined by WHO. Client experience in the health system is an important driver of health service attendance and treatment adherence. There is a lack of measurement of client experience of care in malaria chemoprevention and malaria service provision more broadly. The Plus Project (funded by Unitaid, implemented by ABMS/PSI) provides Perennial Malaria Chemoprevention (PMC) to children under 2 years in selected districts of Benin. This study aims to develop and test measures for client experience of care with respect to PMC in children in Benin and goes beyond measures of client satisfaction to centre clients' voices in defining the metrics. We conducted in-depth interviews (IDI) (N=30) to establish key domains of client experience and priorities among caregivers of children under 2 in the three project zones in Benin who have received PMC. We used these data to develop survey questions which were then piloted and improved through cognitive interviews (N=30) with the target population. Once finalised. the questions were fielded in a quantitative client exit survey (N=308). Data collection was between December 2023 and March 2024. IDIs revealed the importance of caregivers' interactions with health providers, including greetings, health center cleanliness and security, perceptions of fairness in service provision, quality of explanations from providers, and quality of products. Of the 22 questionnaire items developed from IDIs, six were significantly reformulated through cognitive interviewing. Quantitative data reveal mothers attending PMC with their child had a mean age of 27.5 years and over 55% had no formal education. We found overall good client experience across all domains, with variability by geographic zone and respondent demographics. The person-centered, iterative approach to questionnaire development enabled us to readjust the collection tools so that they are adapted to socio-cultural realities and participants' lived experiences and priorities. We demonstrate how client experience may be captured for PMC and can lead to actionable recommendations to improve service provision.

6873

THE WHO VACCINE INNOVATION FRAMEWORK: COUNTRY STAKEHOLDER DELIBERATIONS TO ASSESS THE PROGRAMMATIC NEED AND USE CASE FOR INNOVATIVE VACCINE PRODUCTS

Anna-Lea Kahn, Dijana Spasenoska

World Health Organization, Geneva, Switzerland

Insufficient understanding of country needs and preferences cam lead to development of vaccines and vaccine technologies that do not meet country requirements. This results in uncertainty in market demand and poor country uptake. To strengthen country-level engagement in product development for immunization, the World Health Organization (WHO) has developed the Vaccine Innovation Framework, with an objective to assess country needs and preferences. The Framework is conceived as a four-step inclusive process which fosters deliberation and communication between stakeholders from diverse levels and disciplines across national immunization systems. It aims to evaluate vaccine product innovations that facilitate vaccine storage, delivery or handling, or improve acceptability. Multi-stakeholder discussions occur in a workshop setting, enabling participants to compare current practices with novel innovations and express their opinion on perceived value and acceptability in the context of country-level immunization challenges and priorities. This allows for the identification of criteria and evidence needed for decision-making processes. To date, the Vaccine Innovation Framework has been used by the WHO as a platform for engagement with relevant country stakeholders from 14 countries in the African, Southeast Asian and American Regions. It has been adapted for three innovations: Microarray Patches (MAPs), thermostable vaccines and oral cholera vaccine capsules. In this presentation, we provide an overview of how this Framework generates evidence, promotes equity, informs research agendas, optimizes product development and implementation, and has the potential for still broader applicability.

6874

EQUALITY IN AJTMH PUBLICATIONS FROM 1952 TO 2024: WHAT CAN WE LEARN TO MAKE GLOBAL HEALTH RESEARCH PUBLISHING MORE EQUITABLE? PROTOCOL FOR A BIBLIOMETRIC ANALYSIS

Nabila F. Youssouf[1], Rebecca L. Luckett[1], Sara Schwanke Khilji[1], Pooja Gala[2]

[1]Botswana Harvard Health Partnership, Gaborone, Botswana, [2]New York University, New York City, NY, United States

The long overdue focus on decolonising global health has prompted various institutions to assess existing inequities in global health research partnership and resulting publications. Recent reviews have demonstrated inequities in published global health research between researchers from high-income countries and low- and middle-income countries in terms of authorship, gender and academic affiliations, among others. Reflecting the American Society of Tropical Medicine and Hygiene's aim to advance health equity globally, we propose to conduct a bibliometric analysis of the American Journal of Tropical Medicine and Hygiene (AJTMH) publications between 1952 and 2024. Specifically, we propose to assess the following: -Author order-Author affiliation(s), classified using World Bank country income classifications-Author gender, when available-Funding source-Study type-Study topic-Region of publication-Year of publication.Funding sources will be recorded primarily to identify main stakeholders for further dissemination of our findings. Data will be analysed using Student's t-tests and Chi-square, followed by logistic regression. Results from this review will 1) inform a widening participation strategy launched by the ASTMH in 2022, to reflect the current make-up of global health researchers worldwide and 2) strengthen the record of AJTMH as an innovative publication with not only its finger on the pulse of change, but also actively seeking to equalise the field of global health reporting. Finally, the authors will propose further direct collaboration with the AJTMH and its affiliates to update guidelines and prepare authorship guidelines describing the Journal's commitment to inclusivity, equality and fairness.

6875

FINANCING LANDSCAPE FOR KEY POPULATIONS HIV/AIDS IN UGANDA: MARCH 2022

Arnold Taremwa[1], Charlotte Muheki[2], Felix Rutaro[3]

[1]Ministry Of Health, Kampala, Uganda, [2]Healthnet Consult, Kampala, Uganda, [3]HealthNet Consult, Kampala, Uganda

Uganda, a low-income country with a growing population of 45.74 million, faces challenges in healthcare financing. Amidst economic fluctuations and the COVID-19 pandemic, Uganda's health sector struggles with inadequate funding, especially for key populations affected by HIV/AIDS. HIV prevalence remains high at 6.2%, necessitating targeted interventions. This study examines Uganda's health financing and its implications for key populations affected by HIV/AIDS. It reviews government expenditure, donor contributions, and out-of-pocket spending. The study also assesses funding trends for HIV/AIDS response, particularly for key populations. Uganda's health expenditure constitutes 9.5% of the GDP, with public, private, and donor contributions. Notably, donor funding comprises 42% of total health financing. HIV/AIDS intervention expenditures peaked in 2016/17 and then declined. While the government's domestic public expenditure on the HIV/AIDS response increased significantly, it remains below recommended levels. Key populations, disproportionately affected by HIV/AIDS, receive less than 1% of HIV prevention funding, with sex workers receiving the majority. Uganda's health sector faces financial challenges, with HIV/AIDS interventions for key populations requiring urgent attention. Donor reliance raises sustainability concerns, and declining

funding threatens progress. Sustainable financing strategies, innovative resource allocation, and increased government commitment are crucial for addressing HIV/AIDS in key populations. Without addressing these financial gaps, achieving the 90-90-90 goals and mitigating the HIV epidemic's impact will remain challenging.

6876

EXPLORING ROLES, POWER DYNAMICS, AND CULTURAL SIGNIFICANCE OF ELDERS' AUTHORITY DURING DEATH IN RURAL SOUTH AFRICA

Zokwane L. Mondlane[1], Laura-Lynne Brandt[1], Gift Mathebula[1], Sara Jewett[2], Kathleen Kahn[1], Jessica Price[1], Ryan G. Wagner[1]

[1]MRC/Wits Rural Health and Health Transition Unit, Agincourt, University of the Witwatersrand, Bushbuckridge, South Africa, [2]University of the Witwatersrand, Health & Society Division, School of Public Health, Johannesburg, South Africa

In rural South African villages, the authority of elders during the process of death holds profound significance. An elder typically refers to an older person who holds a position of respect and authority within their community or family. They are valued for their wisdom, experience, and role in preserving cultural traditions and values. Elders may certify deaths, guide mourning, organize funerals, and transmit cultural knowledge surrounding death. We thematically analysed 20 in-depth interviews of community members who experienced a death in the past 2 years within the Agincourt Health and socio-Demographic Surveillance System site and 6 focus group discussions from different stakeholders to investigate the role of elders in managing the challenges of death rituals in distinct cultural contexts. Determinants sustaining the elder's authority included age, gender, and familial hierarchy. In some families, elders believe in miraculous resurrections and wait 2-6 hours to confirm the death before notification. Additionally, reflecting cultural values, infants are typically buried by elderly women at sunset. These practices underscore the deep-rooted cultural significance and reverence for rituals surrounding death within these communities. Elders' knowledge of traditional customs is often unfamiliar to younger generations and their absence results in incomplete traditional customs, with subsequent misfortunes that befall families often attributed to not following burial rituals. Elders hold considerable authority within the family structure, giving them influence over decision-making processes, including whether to participate in Minimally Invasive Tissue Sampling in research studies. Our work underscores the role of elders in rural communities as primary decision-makers in death rituals. We emphasize their authority and contributions in shaping communal responses to death, offering valuable cultural insights and wisdom. Recognizing elders' significance in future studies is crucial for understanding traditional customs and coping mechanisms related to death.

6877

CENTRING LIVED EXPERIENCE WITHIN HEALTH SYSTEMS REFORM CO-PRODUCED APPROACHES AMONG PEOPLE AFFECTED BY SKIN NEGLECTED TROPICAL DISEASES IN LIBERIA

Emmanuel Zaizay[1], **Hannah Berrian**[2], Laura Dean[3], Shahreen Chowdhury[3], India Hotopf[3], Wede Tate[2], Jerry Kollie[2], Colleen Parker[4], John Solunta Smith Jr.[2], Karsor Kollie[4], Zeela Zaizay[5], Tia Akpan[6], Rosalind McCollum[3], Sally Theobald[3]

[1], Monrovia, Liberia, [2]UL-PIRE Africa Center, Monrovia, Liberia, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Ministry of Health, Monrovia, Liberia, [5]Actions Transforming Lives (ACT), Monrovia, Liberia, [6]American Leprosy Missions (ALM), Greenville, SC, United States*

Persons affected by skin Neglected Tropical Diseases (NTDs), are one example of a vulnerable population who often experience stigma and discrimination due to supernatural beliefs aboutcausation. Discrimination often leads to barriers accessing timely, quality health services,limiting participation and within their community contributing to worsening physical andmental morbidities. Involving persons affected by skin NTDs in health systems and policyreform is essential, yet there is limited evidence surrounding best practices for equitable co-production. Persons affected by skin NTDs, together with academic researchers, presentlearnings from co-produced research study (REDRESS) in Liberia guided by Gaventa's powercube analysis, which aimed to focus on our lived experience and perspectives to support thedevelopment of more person-centred care. We carried out in-depth interviews with Ministry of Health at county and national levels (17),persons affected (12), paired in-depth interviews (3) and ripple effect mapping with co-researchers (2) to reflect on the value of their participation and the impact of co-production onhealth systems reform for persons affected.When underlying power dynamics are considered, with co-produced activities shaped toencourage engagement e.g. using world café small group discussions to prompt contributionsfrom all, these approaches bring value for both the individuals and the wider community andhealth system. Involving persons affected to shape the proposal, and as co-researchers broughtstronger advocacy and awareness raising within community, national and global levelsgenerating awareness of the needs and priorities of persons affected, with stronger relationshipsand ability to engage with policy actors. Persons affected placed greater trust in those withshared lived experience strengthening referral pathways.Using co-produced research approaches promotes inclusion and belonging for persons affectedwithin decision-spaces, contributing to greater capacity and advocacy roles by those directlyinvolved as co-researchers, as well as more inclusive health services.

EMPOWERING EARLY-CAREER WOMEN IN BIOSCIENCES: A PILOT MENTORSHIP INITIATIVE AT NNAMDI AZIKIWE UNIVERSITY, NIGERIA

Ogechukwu Benedicta Aribodor[1], Eneyi E. Kpokiri[2]

[1]Department of Zoology, Nnamdi Azikiwe University, Awka, Nigeria, [2]Department of Clinical Research, Faculty of Infectious and Tropical Diseases London School of Hygiene and Tropical Medicine, London, United Kingdom

Female early-career academics often face gender biases and stereotypes that hinder their professional growth. This pilot mentorship program aims to equip women with the skills for effective leadership, drawing inspiration from the WHO TDR Health Research Mentorship in low- and middle-income countries (HERMES) Practical Guide for institutionalizing health research mentorship. The absence of a formal mentorship program at the University since its inception in 1991 underscores the significance of this initiative, which seeks to institutionalize mentorship, and enhance diversity, inclusivity, and excellence within the biosciences faculty. To address this gap, a needs assessment survey was conducted in March 2024 to identify the challenges and needs of early-career women in biosciences, recruiting participants through the university networks using an online platform. All 19 participants were women aged 25-44 years, with 85% having 1-10 years of academic experience. Most (90%) were married, with 65% having children aged 3 months to 10 years. Challenges included balancing family and career, lack of mentorship, and financial support. All participants expressed the need for mentorship programs, implicit bias training, and family-friendly policies for academic career support. Of the participants, 36.8% (7/19) had prior mentorship experience, while 63.2% (12/19) had not. Among those with prior experience, 42.9% (3/7) reported mixed experiences or challenges, and 28.6% cited a lack of follow-up or short program duration. Respondents suggested promoting gender equity initiatives, providing mentorship and sponsorship programs, creating inclusive and supportive environments, offering professional and leadership development opportunities, encouraging work-life balance, effective time management skills, celebrating achievements and visibility, addressing implicit bias and stereotypes, and supporting networking and collaboration. The findings underscore the critical role of tailored support in advancing early-career women's careers in biosciences, emphasizing the importance of mentorship and inclusive policies.

NAVIGATING HEALTHCARE HURDLES IN LORETO: EVALUATING BARRIERS TO ACCESS

Maribel Paredes Olortegui[1], Karin F. Perez Garcia[1], Mario Güimack Fajardo[1], Loida F. Zegarra Paredes[1], Francesa Schiaffino[2], Josh M. Colston[3], Pablo Peñataro Yori[3], Patricia Pavlinac[4], Margaret N. Kosek[3]

[1]Asosciacion Benefica Prisma, Iquitos, Peru, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]University of Virginia, Charlottesville, VA, United States, [4]University of Washington, Seattle, WA, United States

Covering nearly one-third of Peru's territory, Loreto faces a complex healthcare landscape with significant challenges that hinder healthcare-seeking behavior. Barriers to healthcare seeking are generally attributed to the lack of healthcare facilities and, consequently, long travel time to the facility, as well as limited economic resources. However, it is yet to be determined if discrimination in healthcare settings is perceived as a barrier in Loreto. This study was implemented as a sub-study of The Enterics for Global Health study and utilized an already validated survey to measure discrimination in health establishments. Its aim was to determine if discrimination was a barrier to seeking care among children with acute diarrheal illness and to determine if structural deficiencies were prevalent among health posts, including the presence of health care providers, treatment options, and basic services, such as potable water and electricity. The survey was deployed in the area of influence of 5 health care centers in Iquitos, Loreto, and the availability of services was evaluated using spot checks by health care workers once a week. Between June and December 2023, 2183 participants completed the questionnaire. Of these, 67.9% (1483/2183) attended a health post in the last year, of which 8.3% (82/977) had a child under 5 with diarrhea. 38.3% (836/2183) of participants indicated they felt mistreated or discriminated against in a health center. Additionally, each healthcare center was surveyed on 190 days on average. It was identified that services, including electricity and water, were generally available in all 5 health centers, yet piped water was only available in one. Healthcare personnel worked on over 90% of the days in which spot checks were performed. Diarrhea treatment options, including antibiotics, were available in over 90% of days surveyed. However, zinc was not available on 37% of days and ORS in 18% of days surveyed.

6880

ADDRESSING STRUCTURAL BARRIERS AND HUMAN RIGHTS IN MALARIA SERVICES IN UGANDA AND KENYA

Joseph J. Amon[1], Megan McLemore[1], Alistair Shaw[2], Alexandrina Iovita[2]

[1]Drexel University, Philadelphia, PA, United States, [2]Global Fund Against HIV, TB and Malaria, Geneva, Switzerland

The Global Fund's Breaking Down Barriers (BDB) initiative provides support in Uganda and Kenya for the scale-up of evidence-based programs to remove equity-, rights-, and gender-related barriers to malaria services, with the aim to increase the effectiveness of Global Fund grants and ensure that health services reach those most affected. An evaluation of these efforts was conducted in both countries in 2023, and findings were compared with an earlier 2017 baseline assessment which found in both countries few or no formalized programs to address these barriers. By 2023, both countries had created programs seeking to better understand and strengthen availability and accessibility of services. For example, Malaria Matchbox assessments identified populations most at risk, as well as those underserved by existing interventions. Both countries integrated human rights and gender into their national strategies, and in policy and program implementation. Community leadership - through, for example, community dialogues - led to increased resources closer to communities, allowing for timely identification of challenges and locally driven solutions to drive a more effective malaria response. The evaluation also found that there has been a renewed focus within both countries on understanding gender norms and their influence on the effectiveness of malaria programming, and increased collaboration across health sectors, for example in mapping vulnerable populations and implementing some malaria activities. Nonetheless, significant challenges remain. Many malaria stakeholders lack the training, staff and technology for integrating human rights principles and approaches into service delivery. A dearth of disaggregated data by age, gender and other factors related to risk and vulnerability impedes the ability to effectively tailor approaches to subnational levels, and remove structural barriers that exist. Advocacy to reduce law and policy-related barriers to malaria services remained in early stages. Local capacity for effective monitoring and evaluation related to malaria and human rights programs needs to be strengthened.

6881

ADVANCING GENDER EQUALITY WILL STRENGTHEN INTERVENTIONS FOCUSED ON ENDING THE MALARIA EPIDEMIC

Alistair Shaw[1], Emilomo Ogbe[1], Thea Willis[1], Tara Talvacchia[2], Kirsten Gagnaire[2]

[1]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland, [2]Kati Collective, Vashon, WA, United States

Gender equality is increasingly recognized as a crucial element in the fight against malaria. Drawing from evidence-based approaches and experiences gleaned from Malaria Matchbox assessments conducted in over 20 countries receiving Global Fund funding, and other interventions, three programmatic entry points for advancing gender equality have demonstrated to be contributory to the malaria response. Firstly, women's economic empowerment ensures women's participation in markets, control over resources, access to decent work, and agency in decision-making processes. Evidence suggests that integrating activities to enhance women's economic agency accelerates the malaria response, resulting in greater net use within households and improved health seeking behaviors. Second, ANC promotes healthy behaviors such as the use of insecticide-treated bed nets and intermittent preventive treatment of malaria during pregnancy. However, barriers such as poverty, mobility constraints, and power dynamics within households impede women's access to and utilization of ANC services. Strengthening access to and utilization of ANC services not only improves maternal and child health, but also provides opportunities to reach more people with malaria prevention commodities and services. Furthermore, addressing gender disparities within the malaria health workforce is imperative. Women are disproportionately represented in lower-paid roles and face discrimination and exploitation. Women are often inadequately compensated and lack opportunities for professional advancement. Achieving gender equality within the health workforce is essential for ensuring equitable access to malaria care and improving program effectiveness. Strategies aimed at challenging gender inequalities and norms enhance the effectiveness of investments and contribute to long-term program outcomes. In 2024, the Global Fund has newly committed at least US $2 million to specifically advance gender equality and thereby accelerate progress towards ending the malaria epidemic.

6882

LEVERAGING GLOBAL FUND INVESTMENTS: PROTECTING THE RIGHT TO HEALTH AND LIMITING FINANCIAL HARDSHIP

Alistair Shaw, Michelle Remme, Alexandrina Iovita

The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Financial barriers to healthcare, rooted in economic disparities, structural inequalities and health system financing models, can significantly impede accessibility to essential health services. These barriers manifest in many forms including out-of-pocket expenditure, lack of adequate health insurance coverage, costs of additional medicines, transportation costs to reach a clinic or care provider, lost income, informal payments, and intra-household decision making on family finances. For many individuals and families, particularly those living in low-income communities or rural areas, these financial barriers can be prohibitive, keeping people away

from essential health services, causing financial hardship, and deepening poverty. Addressing financial barriers to healthcare is more than an issue of affordability, it is a fundamental imperative for ensuring equitable access and for protecting the right to health for all. Global Fund resources have been instrumental in driving change in this area. It has supported health financing and insurance schemes to prevent catastrophic financial impact as a result of severe malaria; strengthened community-based service delivery models to reduce transport costs incurred by patients; subsidized malaria commodities to ensure they are provided at no cost to users; enabled the use of non-malaria medications for integrated community case management of childhood illness, reducing indirect costs to families that may have prevented them seeking care; and supported ongoing monitoring of financial barriers through community-led monitoring (CLM). By working to reduce financial barriers to health services, and prioritizing high risk and underserved populations, the Global Fund partnership has accelerated progress towards malaria elimination and realizing a world free of the burden of malaria with better, equitable health for all.

6883

CITIZENS AS INFLUENCERS OF HEALTH SERVICE AVAILABILITY AND NOT AS CONSUMERS ONLY

Alex Mukembo, Alex Mukembo

World Vision International, Kampala, Uganda

Advocacy for health services is critical for availability of health services in resource limited settings. Availability of health services influences utilization and ultimately the health status of the community. While advocacy for health service has been recognized as a major tool to influence service, often advocates focuses on service providers or duty bearers with limited engagement of service citizens in influencing availability of health services. It is oftentimes led by external, leaving the citizens as consumers of services and not influencers. World Vision adopted Citizen Voice and Action advocacy approach which is a social accountability methodology that empowers communities to monitor the performance of local governments in providing essential services like health care at the local level. It empowers citizen to monitor actual availability, quality and quantity of health services in their community against the government standards and use the identified gaps to engage and influence through dialogues. Communities were first sensitized on the health facilities (HFs) monitoring standards and relevant health policies, like patient charters. This was followed by gatherings at HFs, involving about 50 community members, grouped according to sex and age. During the gathering, communities scored availability, quantity and quality of services against government standards. Based on identified gaps, dialogues were created between the citizens, health workers and duty bearers to close the identified gaps. This resulted in actions to closing the identified gaps. Implementation of actions was monitored by the CVA for 18 months. Improvement in staffing in HFs, from 54% to 72%, and recruitment of more critical staffs. The district allocated 500 million in additional funding for infrastructure development. Absenteeism among health workers reduced, while blood transfusion services were operationalized at Nankoma H/CIV. Citizens are critical influencers of service availability, when considered as being more than consumers.

LESSONS LEARNED FROM GEOGRAPHIC INFORMATION SYSTEMS FOR INFECTIOUS DISEASES RESEARCH AND SURVEILLANCE

Tippa Wongstitwilairoong[1], Darunee Buddhari[2], John Mark Velasco[3], Diones Paula Corazon[3], Alera Maria Theresa[4], Sanjaya Kumar Shrestha[5], Tipawan Kangvanrattana[1], Kathryn McGuckin Wuertz[1], Aaron Farmer[1]

[1]WRAIR-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Kamphaeng Phet/AFRIMS Virology Research Unit, Kamphaeng Phet, Thailand, [3]Philippines/AFRIMS Virology Research Unit, Manila, Philippines, [4]Philippines/AFRIMS Virology Research Unit, Cebu, Philippines, [5]Walter Reed/AFRIMS Research Unit, Kathmadu, Nepal

WRAIR-Armed Forces Research Institute of Medical Sciences (WRAIR-AFRIMS) collaborates closely with public health partners in Nepal, the Philippines, Thailand and other areas in Southeast Asia, forming an infectious disease research and surveillance network. Medical research and surveillance often entail the collection of vast amounts of data, which are then analyzed for clinical and statistical significance, as well as for generating hypotheses. Geographic Information Systems (GIS) technology emerges as a valuable tool for researchers and epidemiologists, facilitating the graphical representation of infectious disease outbreak results in a universally understandable manner, displaying both temporal and spatial aspects. WRAIR-AFRIMS utilizes GIS-based procedural visualization for conducting infectious disease research and surveillance, generating crucial insights necessary for decision-making at local, national, and international levels. WRAIR-AFRIMS' Virology department integrates clinical and laboratory data related to respiratory illnesses, SAR-CoV2, febrile and vector-borne infections (FVBI) including geolocation data on thousands of samples collected annually. Employing GIS software such as ArcGIS and QGIS, they create visual maps illustrating the spread of infectious diseases over time and surveillance areas such as FVBI and respiratory surveillance. These maps facilitate the analysis of spatial patterns encompassing disease incidence, prevalence, and distribution. The resulting data enables authorities to monitor disease trends, detect anomalies, and allocate resources effectively for targeted interventions. Through collaborations facilitated by WRAIR-AFRIMS, GIS technology has advanced in monitoring infectious diseases in real-time, enhancing the accuracy of disease risk assessments, and supporting decision-making processes. These efforts contribute to improved communication of surveillance findings to stakeholders and the public, ultimately bolstering public health responses and outcomes.

SYNDEMIC MODELLING: A NOVEL MATHEMATICAL MODELLING FRAMEWORK FOR SIMULATING MULTIPLE PATHOGENS DYNAMICS IN CONTEXT

Caroline Franco[1], Lisa J. White[2], Sheetal Silal[3]

[1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]University of Cape Town, Cape Town, South Africa

Mathematical models have historically been used to understand and predict disease transmission dynamics, slowly evolving along with our understanding of the underlying biology of disease spread. Knowledge of disease dynamics and interactions can be combined with socio-economic considerations to produce models robust enough to simulate and compare control strategies, thus becoming useful tools to inform health policy making. It is still a challenge, however, to produce robust mathematical models that can concomitantly address the dynamics and interactions among multiple etiological agents. Models for multiple strains or species of pathogens are challenging due to the number of equations required to accurately account for the inter-species interactions, which increases exponentially with the number of species, making numerical and structural identifiability increasingly improbable.We have developed a mathematical approximation which allows the dimension of the resulting model to increase linearly with the number of species (instead of exponentially). For a two-species SIRS model, we have shown through mathematical analysis that this approximation is appropriate for species with low levels of interaction. We have recently been working on generalising this framework through further analysis and numerical simulations, and exploring less analytically tractable examples of multi-species malaria and multi-pathogen epidemics (e.g. COVID-19 and flu syndemics). Our overarching aim is to use the proposed framework to develop better context-informed models with policy-making impact at local, national and international levels.

6886

MALARIA IN THE REPUBLIC OF GUINEA: COSTS ASSOCIATED WITH THE CARE PATHWAY FROM THE PATIENT'S PERSPECTIVE, 2022 - 2023

Elhadj Marouf Diallo[1], Fatoumata Bintou Traore[1], Alice Langlet[2], Marie Blanquet[2], Bienvenu Salim Camara[3], Alioune Camara[4], Laurent Gerbaud[2]

[1]African Center of Excellence for the Prevention and Control of Communicable Diseases, Faculty of Health Sciences and Techniques, University of Conakry, Dixinn, Conakry, Guinea, [2]CHU Clermont-Ferrand, UFR Medicine & Paramedical Professions, University Clermont Auvergne, CNRS, Sigma Clermont Institute Pascal, Clermont-Ferrand, France, [3]Centre National de Recherche et de Formation en Santé Rurale de Maferinyah Guinée (CNRFSR), Maferenya, Forecariah, Guinea, [4]National Malaria Control Program, Dixinn, Conakry, Guinea

Access to safe, affordable healthcare is crucial for reducing health disparities. In Guinea, malaria is a major public health issue with significant economic consequences. In 2010, the country introduced free healthcare services for malaria to control the endemic disease. This paper analyzes the costs (out-of-pocket expenses) associated with the care of malaria patients in the Republic of Guinea. An economic analysis of the costs of managing malaria in Guinea was conducted using data from a cross-sectional survey on the determinants of malaria prevention. Data were collected between December 2022 and March 2023 in health facilities and at the community level. The Time-Driven Activity Based Costing approach and micro-costing were used to evaluate the costs associated with care-seeking, management, and related costs. The study enrolled a total of 3,300 patients from 60 healthcare facilities, predominantly in urban areas (65%), with one-third being children under 5 years of age (mean age 27 months). Most patients were accompanied by their mothers, had no formal education, came from households led by husbands, and had a median monthly income of $115.95. Around 41% were seeking care for the first time. The costs of seeking care varied based on the type of malaria, with $3.48 for uncomplicated cases and $13.45 for severe cases. The median direct care costs in healthcare facilities for uncomplicated malaria were $7.30, and $30.84 for severe cases. Overall costs associated with malaria varied by type and age group, with median costs borne by patients estimated at $17.57 for uncomplicated malaria and $44.87 for severe cases. Delay in seeking care accounted for 19% of the costs incurred by malaria patients in Guinea ($p < 0.001$). Despite the implementation of free malaria prevention services, patients continue to experience costs and income loss. An approach based on selective free access and affordable flat-rate costs could ensure the financial sustainability of healthcare facilities and reduce out-of-pocket expenses for patients.

6887

EXPLORING THE MIGRATION PATTERNS AND POPULATION HEALTH OUTCOMES IN URBAN AFRICA: A CASE OF NAIROBI CITY

Evans Omondi, Samuel Iddi, Steve Cygu, Abdhalah Ziraba, Damazo Kadengye, Agnes Kiragga

African Population and Health Research Center, Nairobi, Kenya

Understanding the dynamics of transitions between different residency states is essential for informing effective population management strategies. Our aim is to characterize the trajectories of residency events within the Nairobi Urban Health and Demographic Surveillance System (NUHDSS), encompassing key residency events. Thus, we intend to unravel patterns and trends that can guide the development of targeted policies and interventions to address the evolving needs of the population. We proposed a continuous time homogeneous multi-state Markov model for the NUHDSS longitudinal residency data collected from 223,350 individuals in Korogocho and Viwandani slums in Nairobi. The model is used to effectively capture and model residency events; births, deaths, in-migrations, and out-migrations that directly impact the population dynamics including population growth, and population decline. However, exit and entry are included in the descriptive analysis to offer some insights into the magnitude and patterns of internal population movements over time. From the findings the hazard ratio (HR) of 0.7684 suggests that adjusting for the effects of gender, ethnicity, area of birth and age, the transition of individuals in Viwandani from birth to death is associated with a 23.16% lower than those in Korogocho. Same results are seen for the individuals in Viwandani for the transitions from enumeration to death, and in-migration to death. Our findings provide unique insights into the frequency of events, their transition rates, and the impact of gender, slum area, age, ethnicity, and area of birth. These results have implications for preventive health interventions and planning for appropriate levels of residential care. Moreover, modelling the residency events helps in understanding the expected burden of the migration and population growth.

6888

WHATSAPP MESSAGING AND USE OF MALARIA SERVICE GUIDES AND FEVER MANAGEMENT TOOLS IN CROSS RIVER STATE, NIGERIA

Oluwatobiloba Akerele[1], Uchenna Nwokenna[2], IniAbasi Nglass[2], Aniefiok Akpasa[3], Etieno Etuk[1], Victor Bassey[1], Udeh Phillip[1], Damola Abikoye[1], Olayemi Abimbola[2], Rudi Thetard[4], Arja Huestis[4], Thomas Hall[4], Dorathy Iwasam[3], Grace Nwankwo[5], Erkwagh Dagba[6], Veronica Momoh[6], Jules Mihigo[6], Chukwu Okoronkwo[7], Nnenna Ogbulafor[7], Godwin Ntadom[7]

[1]Management Sciences for Health, Cross River, Nigeria, [2]Management Sciences for Health, Abuja, Nigeria, [3]Cross River State Malaria Elimination Programme, Cross River, Nigeria, [4]Management Sciences for Health, Arlington, VA, United States, [5] United States Agency for International Development, United States President's Malaria Initiative, Abuja, Nigeria, [6]United States Agency for International Development, United States President's Malaria Initiative, Abuja, Nigeria, [7]National Malaria Elimination Programme, Abuja, Nigeria

Appropriate and timely fever management are crucial to prevent severe malaria (Agunbiade et al, 2022). The U.S. President's Malaria Initiative for States project (PMI-S) aimed to improve fever case management in 165 health facilities (HFs) in Cross River State using Behavioral Economics Prototypes (BEPs), a set of tools and processes designed to guides appropriate fever management. In March 2023, BEP monitoring teams observed that the tools were not adequately used or accessible on request. PMI-S addressed this poor BEPs use by sharing them across four relevant WhatsApp groups with 32, 66, 43 and 36 participants. The BEPs were disseminated twice a week from July to September 2023: (1) "Is it malaria?" An interactive group discussion guide, (2) Whole Site Counseling Tool, (3) Performance-Tracking Poster, (4) Malaria Testing and Treatment Tally Form, (5) Fever Evaluation Tool, and (6) Pediatric Evaluation Form. Netnographic and conversation analyses were conducted on the WhatsApp platforms where the BEPs were shared. This revealed that more than 50% of participants downloaded the tools over a three-month period (July to September 2023). Conversational analysis of the WhatsApp response thread showed that sharing BEPs enabled discussion on their application, including challenges. District Health Information System data analyzed found that malaria test positivity rate (TPR) reduced across 165 HFs from an average of 64% from July to September 2022 to 58% with BEP implementation in the same period in 2023. TPR reductions rely on improved testing, which may have been aided by the shared BEPs being made immediately available on WhatsApp. Additional studies could further explore the utility of sharing BEPs through mobile messaging platforms, the uptake of tools, and the resulting changes in key malaria case management indicators.

6889

COMPARATIVE ANALYSIS: USING A HYBRID ICF VERIFICATION TOOL IN A 28,000-PARTICIPANT CLINICAL TRIAL AT COMMUNITY LEVEL IN MOZAMBIQUE AND KENYA

Eldo Aly Elobolobo[1], Lisa Collins[2], Leslie Sam[2], Jamal Salim[3], Paula Ruiz-Castillo[2], Mary Mael[2], Isaac Ringera[3], Mercie Kariuki[3], Shadrack Karisa[3], Vegovito Vegove[4], Patricia Bellot[2], Isaiah Omondi[3], Carlos Chaccour[2], Regina Rabinovich[2], Marta Maia[3]

[1]Databrew, Manica, Mozambique, [2]Isglobal, Barcelona, Spain, [3]Kenya Medical Research Institute - KEMRI, Kwale, Kenya, [4]Centro de Investigação em Saúde de Manhiça - CISM, Manhiça, Mozambique

Clinical trials in low- and middle-income countries (LMICs) face unique challenges when adapting traditional methodologies to comply with Good Clinical Practice (GCP) standards and ensuring participant safety. The BOHEMIA trial in Mozambique and Kenya assessed the impact of mass ivermectin distribution on malaria transmission, enrolling over 58,000 participants. Handling 50,000+ paper-based informed consent forms (ICFs) per country was risky and inefficient. In Mozambique, paper reliance and manual tracking led to potential compliance issues with ICH E6 (R2) standards due to cumbersome systems and disconnection from the main database. Conversely, the Kenyan team implemented a hybrid approach, integrating paper ICFs with an electronic registry, enhancing real-time management, data security, and stakeholder collaboration. This system streamlined verification, query resolution, and archiving, also enabling prompt identification and correction of missing ICFs, ensuring data integrity. The digital tool developed in Kenya outperformed traditional methods, improving transparency, efficiency, and safety in participant management. Its potential integration with machine learning and AI, and compatibility with existing electronic data capture systems (EDC), exemplifies innovative approaches in clinical trial methodologies, particularly suitable for LMIC settings where resources are limited. The BOHEMIA study's success demonstrates the effectiveness of this approach in overcoming traditional research barriers.

6890

NETWORKING OF MEDICAL LABORATORY DATA IN MADAGASCAR

Omega Raobela[1], Tovonahary Rakotomanga[1], Freddy Lokossa[2], Sandy M. Ralisata[2], Andry Patrick Raoiliarison[2], Daniella Randriamanana[2], Sandratra Harizaka Rakotoarisoa[2], Davida Natolotra Razafindratsaravahy[2], Tolotriniaina Eric Rafanomezantsoa[2]

[1]Madagascar Ministry of Health, Antananarivo, Madagascar, [2]Population Services International Madagascar, Antananarivo, Madagascar

The Ministry of Health (MOH) in Madagascar, through the Directorate of Pharmacies, Laboratories and Traditional Medicine (DPLMT), the Malagasy Medical Analysis Laboratory (LA2M) and the Directorate of Studies, Planning and Information System in Health (DEPSI) is strengthening its data reporting system of medical analysis laboratories, through the digitalization of an electronic laboratory register. To date, each health program has its own laboratory reporting system, making compilation and monitoring difficult for an integrated approach to communicable disease control. This strengthening of the electronic reporting system meets the MOH's digitalization objective for the surveillance of malaria, tuberculosis, HIV and COVID. 19.73 (37%) of the 198 analysis laboratories in Madagascar with internet connection have benefited from training and provision of electronic tablets for this electronic register. Laboratories were selected to represent the 12 TB and HIV priority districts, those with the highest malaria risk level and those in pre-elimination, alongside public and private facilities. Among the 73 laboratories supported for this intervention between October 2023 and January 2024, 77% (56/73) reported data electronically, including 47% (34/73) on diagnosed malaria cases diagnosed, 52% (38/73) on detected tuberculosis cases, 47 % (34/73) for HIV testing and 3% (2/73) for COVID19 cases. The 23% of laboratories not reporting was due to the poor-quality connectivity, non-daily data entry, the absence of post-training monitoring for the period, and a reported lack of willingness for some. Future supportive supervision by regional laboratory managers will aim to resolve these obstacles. Laboratory data, training curricula and modules are currently available in the Ministry of Health's DHIS2 server, under the responsibility of DEPSI.

6891

PHYSICIANS' PERSPECTIVES OF INFORMAL HEALTH PRACTITIONERS IN BANGLADESH AND POTENTIAL FOR ENGAGEMENT

Zahid Hasan Khan[1], Olivia R. Hanson[2], **Sarah A. Dallas**[2], Mohammad Ashraful Amin[1], Ishtiakul Islam Khan[1], Debashish Biswas[1], Md. Taufiqul Islam[1], Eric J. Nelson[3], Firdausi Qadri[1], Melissa H. Watt[2], Daniel Leung[2], Ashraful Islam Khan[1]

[1]icddr,b, Dhaka, Bangladesh, [2]University of Utah, Salt Lake City, UT, United States, [3]University of Florida, Gainesville, FL, United States

The healthcare landscape of rural Bangladesh faces various complex challenges, including limited resources and a shortage of qualified healthcare professionals. Informal healthcare providers, locally termed village doctors, fill this void and provide the majority of primary care, especially in remote villages and hard-to-reach areas. In many parts of Bangladesh, patients who present to formal healthcare facilities have first been to see a village doctor for assessment and treatment. This study aimed to qualitatively explore the perspectives of formally trained physicians on the role of village doctors in Bangladesh's healthcare system. This study was conducted in the Sitakunda Upazila subdistrict of Southeast Bangladesh. We recruited twelve formally trained physicians through a purposive sampling technique. Individual in-depth interviews were conducted by an ethnographic research team in Bangladesh. Interviews were transcribed and thematically coded to examine both positive and negative opinions of village doctors. The interviews unveiled three prominent themes highlighting the perceived positive contributions of village doctors: 1) provision of essential services and resources in isolated areas, 2) enhanced accessibility and familiarity with the community, and 3) active involvement in public health education. Additionally, the interviews revealed five themes related to physician's perspectives of the negative impacts of village doctors in the healthcare system: 1) insufficient education and training, 2) use of inappropriate treatments, 3) inappropriate referral practices, 4) the misuse and overuse of antibiotics, and 5) prioritization of financial gain. This study sheds light on the complex relationship between formal and informal healthcare providers in the larger healthcare system and emphasizes both the contributions and impedance of village doctors to rural healthcare settings. Coordination between formal and informal healthcare providers is necessary to meet the needs of rural patients in Bangladesh.

6892

MODELING THE IMPACT OF CORE AND SUPPLEMENTARY TOOLS ON PYRETHROID RESISTANCE AND MALARIA TRANSMISSION DYNAMICS

Hamenyimana Emanuel Gervas

Ifakara Health Institute, Morogoro, Tanzania, United Republic of

Significant investments in malaria vector control during the previous 20 years have led to a 40% decrease in the number of clinical cases of malaria and the anticipated prevention of 663 million cases in sub-Saharan Africa. Vector control methods such as indoor residual spraying (IRS), larval source management (LSM), insecticide-treated nets (ITNs) have been credited with these results. The unexpected increase in malaria incidence and prevalence in Africa is concerning, even if there has been a decrease in malaria cases and fatalities as a result of ITNs and IRS deployments. A number of factors have led to the decline in these achievements, including changes in the behavior of the malaria vector species and, most importantly, insecticide resistance in the malaria vectors. The most dependable instruments in Tanzania for controlling malaria vectors, IRS and ITNs, are seriously threatened by the outbreak of insecticide resistance. For example, by 2020,

more than 80% of sentinel sites had pyrethroid resistance, up from 0% in 2004. Therefore, a new mathematical model for the dynamics of malaria transmission has been developed and thoroughly examined in this study in order to assess the effects of ITNs, IRS, and Attractive Sugar Baits (ATSB) on pyrethroid resistance in the context of Tanzania. This model takes into account the susceptible and resistant *Anopheles gambiae s.l.* and *An. funestus* species and the fact that the effectiveness of vector control measures deteriorates with time. Once more, the model takes into account the varying resistance levels of the resistant *An. funestus* and *An. gambiae s.l.* species. Using secondary data from previously published studies and datasets, a number of simulations using the Python programming language are being run to assess the effects of combining various forms of ITNs with IRS and ATSB. The preliminary findings demonstrate the substantial impact of supplementing ITNs with IRS and ATSB. Additionally, the study plans to evaluate the impact of these vector control methods on the allele frequencies of the mosquito species using the Epidemiological Modeling Software (EMOD).

6893

THE EFFICACY OF MOBILE SERIOUS GAMES (SWAZIYOLO) IN INCREASING HIV RISK PERCEPTION IN ESWATINI: A RANDOMIZED CONTROL TRIAL.

Bhekumusa Lukhele[1], Mac Delay[1], Fortunate Shabalala[2], Mfundi Motsa[3], Alexander Kay[4], Christina El-saedi[5], Bongani Masango[3], Gregory Pavela[1], Katia Bruxvoort[1]

[1]University of Alabama at Birmingham, Birmingham, AL, United States, [2]University of Eswatini, Mbabane, Eswatini, [3]Ministry of Health, Mbabane, Eswatini, [4]Baylor College of Medicine, Houston, TX, United States, [5]City of San Antonio Metropolitan Health District, San Antonio, TX, United States

Eswatini has one of the highest HIV prevalence rates globally (24.8% among people ≥15 years of age). Unprotected heterosexual transmission accounts for more than 90% of new HIV infections in the country. Mobile phone technology is growing rapidly, offering opportunities for technology-driven interventions for HIV prevention. Our team developed SwaziYolo, a smartphone, interactive, educational story game that places the player in the role of a young adult looking for love in Eswatini's capital city. We conducted the Serious Games HIV Prevention Trial (SGPrev-Trial), a 4-week, 2-arm, 1:1 randomized controlled trial of SwaziYolo among people 18-25 years of age in Eswatini. The main outcome was HIV risk perception scores (10-item index and a subscale 8-item index), assessed using intention-to-treat and per-protocol difference-in-difference (DID) analysis. Secondary analyses examined differences in reported sexual behavior and serious game acceptability. Of 380 people who agreed to participate in this study, 130 in the control arm and 127 in the intervention arm completed follow-up. Among the 79.5% (101/127) of intervention arm participants who completed at least one game (per-protocol analysis) we observed an increase in the 10-item HIV risk perception index compared to control arm participants (DID mean score of 1.63, p-value 0.048) and a borderline increase for the 8-item HIV risk perception index (DID mean of 1.37, p-value 0.060). In intention to treat analysis, there were no significant differences between arms in both the 10-item and 8-item indices. Nearly all (96.1%) participants strongly agreed or agreed that they would recommend SwaziYolo to their peers. The high retention rate observed in this study demonstrates the feasibility of online technology-based interventions for HIV prevention in Eswatini. Our preliminary results suggest that serious game interventions can be effective at increasing HIV risk perception. Future research will explore how to optimize SwaziYolo to promote and sustain HIV prevention among young people in Eswatini and adapt the intervention to other settings.

6894

DIGITIZATION OF COMMUNITY HEALTH IN BURKINA FASO: CONSIDERING THE PERSPECTIVES OF COMMUNITY WORKERS THROUGH USER ACCEPTABILITY TESTING

Alain Kabore[1], Assetta Bara /Compaore[1], Fatou Fall[2], Bry Sylla[3], Adama Yameogo[1], William Ouango[3], Jean Serge Dimitri Ouattara[3]

[1]PATH, Ouagadougou, Burkina Faso, [2]PATH, Dakar, Senegal, [3]Ministry of health and public hygiene, Ouagadougou, Burkina Faso

Malaria remains a major public health burden in Burkina Faso. With an incidence of 525.4 per 1000 inhabitants (2022), it is the leading cause of morbidity and mortality. The government of Burkina Faso implemented a 2019-2023 community health strategy, with digitization of service delivery as a priority intervention. The aim was to set up a digital solution to provide decision support to community health workers to improve the quality of services, the quality of data and the performance of these players. One of the fundamental principles of digitization is the end-user-centered approach. To comply with this principle, Digital Square at PATH with funding from the US Presidential Malaria Initiative, provided technical support to the Ministry of Health to conduct a training of 58 community health workers and 15 supervisors, followed by user acceptance tests in the Boromo health district. The training consisted in showing the participants how to use the Android mobile phone and the decision-support application developed on Commcare platform. An evaluation using interview and observation gathered feedback and suggestions from the participants. Although a good satisfaction (70%) about application accessibility, user-friendliness and stability, concerns about the applications were raised by 35% of participants, including data not being transmitted via SMS, certain modules not being displayed, discrepancies between the content of the modules and actual actions in the field, and the need for the supervisor to have controlled access to the CHW's telephone. In addition, concerns were raised about the system in general, particularly the security of the devices in the hands of CHWs, maintenance/updating, renewal, and the availability of an energy source for recharging at the community level. Overall, the UATs make it possible to check that applications and devices are working in real time on the ground, to assess the ability of stakeholders to use them, and to gather concerns and worries, with a view to improving the system so that it meets the expectations of the first users as well as the goals of community health digital transformation.

6895

EXPLORING PERSPECTIVES ON THE SCANNABLE MATERNAL & CHILD HEALTH HANDBOOK IN SIAYA, KENYA: A QUALITATIVE ASSESSMENT OF HEALTHCARE PROVIDERS & ANC CLIENTS

Fredrick omiti[1], Wycliffe Odongo[2], Mevis Omollo[1], Kizito Obiet[1], Brian Seda[1], , Victoria , Seffren[2], Jonathan Schultz[3], Simon Kariuki[1], Feiko terKuile[4], Gutman Julie R[2]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]4Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, kisumu, Kenya, [4]3Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

A scannable version of the Kenyan Ministry of Health (MOH) Maternal and Child Health (MCH) handbook was piloted to assess impact on data quality and utility in Siaya, western Kenya. Acceptance by healthcare providers and antenatal care (ANC) attendees is crucial for successful implementation and adoption of such a tool. We conducted a qualitative assessment to explore the perspectives of healthcare providers and ANC clients on implementation and associated challenges. From the pilot, 36 ANC clients were purposively identified and split into 3 focus groups by number of contact visits: a) 2-3, b) 4-5, and c) 6-8. Additionally, 10 key informant interviews (KIIs) were conducted individually with 8 service providers and 2 county health officials. Interviews were transcribed, coded, and thematically analyzed in NVivo v.12. The results showed that the scannable handbook's resemblance to

the standard handbook made it familiar and user friendly, with its revised structure and flow simplifying data entry. Digitization of individual data from the handbook facilitates tracking ANC services individual women received across multiple facilities. Results also suggested that the books' design, size, material quality, spiral binding and hard cover provided extra protection, making it durable, aesthetically pleasing, easier to handle and minimized chances of misplacement or loss. Possible barriers identified included scanning (photographing) difficulties to abstract data with some providers finding it time-consuming. ANC clients faced difficulties at non-pilot facilities with providers unfamiliar with the handbook emphasizing the need for sufficient sensitization and training before implementation. The scannable MCH handbook is widely accepted in Siaya county due to several advantages including its user-friendliness, durability, and the ability to digitally abstract data and track ANC clients across multiple health facilities. Addressing the challenges such as scanning, training, and orientation are crucial to improving negative experiences before potentially scaling up.

6896

EXPLORING EXPERTS' PERSPECTIVES ON THE ADOPTION AND USE OF MULTIPLEX BEAD ASSAYS FOR INTEGRATED SEROSURVEILLANCE IN LOW- AND MIDDLE-INCOME COUNTRIES

Alex C. Kong, Andrea C. Carcelen, William J. Moss

Johns Hopkins Bloomberg School of Public Health International Vaccine Access Center, Baltimore, MD, United States

Serological surveillance ('serosurveillance') enables health systems and researchers to estimate a community's level of exposure or immunity to various pathogens and guide the implementation and monitoring of public health interventions. The use of multiplex bead immunoassays (MBAs) can streamline this approach by allowing for the simultaneous detection of several antibodies to different antigens and pathogens in a single reaction. However, this technology has not been universally adopted, particularly in low- and middle-income countries (LMICs). To understand experts' perceptions on the value of MBAs for integrated serosurveillance, and challenges to adoption and scale-up in LMICs, we conducted 20 semi-structured interviews with key informants working in LMICs and high-income countries (HICs) who were familiar with MBAs. These experts came from academia, funding agencies, implementing organizations, and the private sector. We recorded and transcribed the interviews and used inductive and deductive coding to support thematic analysis of the data. Although MBAs can serve as powerful tools for integrated serosurveillance and have demonstrated value in several settings, not all countries are well-positioned to adopt this technology. Some prioritize other investments, including those which could support the use of these assays in the future, like improvements to maintain stable electricity supplies and controlled laboratory environments. The immense amount of data that MBAs produce can be a double-edged sword as analytical bottlenecks can impede the use of data to guide public health responses. Amid these challenges, the LMICs which have been best prepared to adopt and scale the use of this technology are often those which possess comparably strong laboratory networks. Many of these countries have longstanding relationships with laboratories in HICs. Commercialization and standardization of some assays could support the adoption and expansion of this technology to other LMICs, but maintaining a country's ability to decide what they monitor is critical for establishing buy-in.

6897

DETECTION OF RECURRENT MALARIA BY IMPROVING THE ACCURACY OF UNIQUE PATIENT IDENTIFICATION WITH BIOMETRICS IN PAPUA, INDONESIA

Liony Fransisca[1], Reynold Rizal Ubra[2], Enny Kenangalem[1], Benedikt Ley[3], Ric N. Price[3], Nicholas M. Douglas[3], Jeanne Rini Poespoprodjo[1]

[1]Papuan Community Health and Development Foundation, Timika, Indonesia, [2]Mimika Regency Health Office, Timika, Indonesia, [3]Menzies School of Health Research, Charles Darwin University, Darwin, Australia

Detection of malaria recurrence requires unique identification of patients through multiple presentations to a health facility. This can be challenging in resource-limited settings. The impact of adding fingerprint identification to an existing physical "malaria card" identification system was assessed at two remote clinics in Papua, Indonesia. A three-stage approach was taken with one clinic serving as a control. In Stage 1 (3 months), standard patient identification practices using the malaria card system for malaria patients were observed at both clinics. In Stage 2 (6 months), fingerprint scanning using the Flexcode 4500™ system was added to standard patient identification procedures for suspected malaria patients at the intervention clinic. In Stage 3 (6 months) fingerprint scanning continued at the intervention clinic but with the addition of linkage to prior fingerprint registrations. At the intervention clinic, the proportion of malaria patients carrying a malaria card rose from 24.3% (467/1,925) in Stage 1 to 44.0% (3,566/8,103) in Stage 3 ($p<0.001$), compared to a more modest increase from 18.2% (397/2,187) to 25.1% (1,019/4,067, $p<0.001$) at the control clinic. Detection of duplicate (1 number assigned to multiple patients) or multiple (1 patient assigned multiple numbers) malaria card numbers increased from 0.3% (6/1,925) in Stage 1 to 4.1% (246/5,939) in Stage 2 with no corresponding increase at the control clinic. The proportion of repeat visit increased from 42.4% (816/1,925) in Stage 1 using standard patient identification practices, to 44.0% (2,612/5,939) in Stage 2 and 56.0% (4,556/8,103) in Stage 3 after adding fingerprinting to the patient verification process. In Stage 3, 99.8% of patients attending the intervention clinic could be definitively linked to a unique malaria card identification number versus 88.9% at the control clinic. Very few patients refused fingerprinting. The use of biometric fingerprinting was well-accepted and was associated with improved patient identification through multiple presentations to a healthcare facility.

6898

THE ROLE OF DIGITIZATION IN IMPROVING DATA QUALITY FOR ITN DISTRIBUTION CAMPAIGNS IN MALI

Boubacar Sidiki Maiga[1], Alassane Bangoura[1], Jean Yves Mukamba[2], Chrestien Yameni[3], Fatoumata Keita[1]

[1]Catholic Relief Services - CRS, Bamako, Mali, [2]Catholic Relief Services - CRS, Congo, Congo, Democratic Republic of the, [3]Catholic Relief Services - CRS, Dakar, Senegal

From 2011 to 2020, Mali made efforts to provide universal coverage of Insecticide-Treated Nets (ITN) through campaigns. The campaigns covered all regions an average of three times, except for the northern regions, which were not covered as much. However, these campaigns faced challenges such as poor data quality, complex stock management, uncovered areas, and long wait times for beneficiaries. NMCP is partnering with other organizations to digitize data for ITN distribution campaigns. The aim is to improve data quality and support evidence-based decisions. This study aims to compare the benefits of digitization using two different approaches. The ITN campaign was conducted in 29 health districts using digital means, while 17 health districts used non-digitized methods. All villages in the health areas were mapped and integrated into DHIS2 to allow for comprehensive analysis of ITN campaign data at all levels of the health system, including the distribution sites. ITN enumerators and distributors collected data at the community level using smartphones and unique QR code coupons in digitized areas. Non-digitized areas used paper collection and an Excel file as the database. However, data collection in non-digital

zones was slow and often riddled with errors. Digitization has highlighted the many challenges posed by traditional distribution methods. It also enabled us to identify non-covered areas and ensure household traceability for better decision-making. According to the report, out of the planned 10,878,186 ITNs, 10,673,108 ITNs have been distributed at an impressive rate of 99.26% for the 46 districts. This distribution rate represents 98.8% for the 29 digitized districts and 99.2% for the 17 non-digitized districts. Regarding household and population coverage rates, 2,067,913 households were served out of 2,106,140, meaning a household coverage rate of 98.17%. Additionally, 21,285,182 people were covered out of 22,048,413, resulting in a coverage rate of 97%. 638. In short, digitization optimizes net distribution and combined with recommended practices, effectively reinforces malaria prevention.

6899

SUCCESSFUL TASK SHIFTING: CROSS-SECTIONAL STUDY OF AN EMERGENCY OBSTETRIC CARE PROGRAM IN AN LMIC SETTING

Rita Thapa[1], **Abigail Knoble**[2], Suresh Tamang[1], Bal Sundar Chansi Shrestha[1], Arpana Kalaunee[1], Indra Rai[1], Bikash Shrestha[1], Pravin Paudel[1], Archana Amatya[1], Ruma Rajbhandari[2]

[1]Nick Simons Institute, Kathmandu, Nepal, [2]Mass General Birgham, Boston, MA, United States

Direct obstetric causes of maternal mortality still account for approximately 86% of all global maternal deaths, the majority of which are preventable. In Nepal, 12% of all deaths for women of reproductive age are due to preventable obstetric complications. However, the distribution of human resources (HR) and availability of healthcare workers capable of providing CSs in LMICs is a significant limiting factor to reducing MMR. To address this disparity the Advanced Skilled Birth Attendant (ASBA) task-shifting initiative was developed to train medical officers to perform Cesarean sections (CSs) to manage obstetric emergencies. Until now, there has been limited study of the program's efficacy. A survey targeting all 234 ASBA graduates resulted in 93 usable surveys. Additionally, 7 rural CEONC government hospitals with posted ASBAs were selected for 13 in-depth interviews and 6 focus group discussions with Operation Theater (OT) staff. Results were then triangulated. Immediately after the training, 92.7% of ASBA graduates reported performing CSs at their hospital with the majority (65.6%) continuing to perform CSs today. Of the ASBAs not performing CSs, 51.7% could be explained by the lack of a functional operating theater, underscoring the need for a holistic approach to clinical service provision. ASBAs were significantly more likely to be performing CSs if a family physician or another ASBA was present at their current hospital ($p < 0.001$; $p < 0.001$). Their work was perceived to increase the use of services by the community, facilitate a positive working environment, improve healthcare access, reduce referrals, and reduce the burden of CSs on any one staff member. Staff were motivated to provide CSs when they otherwise might not have been able to and perceived the hospital to be in better standing with the community. The ASBA program is a successful task-shifting initiative that reduces human resource shortages, expands the provision of CSs, and improves the working conditions in rural hospitals within the LMIC setting. The program should be continued to further increase access to CSs in rural hospitals with a functioning operating theater.

6900

COMMUNITY-BASED PARTICIPATORY INTERVENTION TO FIGHT DENGUE FEVER IN CÔTE D'IVOIRE

Véronique Koffi[1], Julien Zahouli[2], Carelle Brika[1], Larissa Angoua[3], Claver Adjobi[4], Pélagie Aboa[2], Sarah Ruel-Bergeron[5], Laura Vavassory[6], Giovanfrancesco Ferrari[7], Pie Müller[7]

[1]Centre Suisse de Recherches Scientifiques- Côte d'Ivoire, Abidjan, Côte D'Ivoire, [2]Centre d'Entomologie Médicale et Vétérinaire de l'Université Alassane Ouattara, Bouaké, Côte D'Ivoire, [3]univerty Felix Houphouet Boigny, Abidjan, Côte D'Ivoire, [4]Université Félix Houphouet-Boigny, Abidjan, Côte D'Ivoire, [5]ARCHIVE Global, Washington, WA, United States, [6]Swiss Tropical Institute of Tropical and Public Health Institute, Allschwill, Switzerland, [7]Swiss Tropical Institute of Tropical and Public Health Institute, Basel, Switzerland

Dengue fever is the most widespread mosquito-borne viral infection. Abidjan has a population of nearly 6 million, and Aedes breeding sites are ubiquitous. Given that people's knowledge, attitudes, practices and beliefs play an important role in the resurgence of mosquitoes, it is therefore important to carry out a community-based participatory intervention to sustain mosquito control actions, as mosquito control is essential for effective dengue prevention. Measure the population's knowledge, attitudes, practices and beliefs (KAPB) related to dengue fever in the Cocody-Bingerville health district. Probability sampling was used and a questionnaire survey was carried out among heads of households or their representatives in 40 clusters, with 11 households visited per cluster. Individual interviews were also conducted with community leaders. A participatory photovoice approach, as already implemented in the context of malaria vector control (Makungu et al., 2017) was used. The results showed that communities are not aware of dengue fever. Only 40% know about it. Those who have heard of it have little information about the disease. Admittedly, the populations do not strictly refute the thesis of the existence of a link between dengue fever and dengue fever. For an effective fight against dengue, we need to improve the population's knowledge of this emerging disease in our country.

6901

METHODOLOGICAL INSIGHTS FROM REFLEXIVE VIDEO ETHNOGRAPHY: A CASE STUDY OF LEPROSY PATIENTS IN MALAYSIA

Norana Abdul Rahman[1], Vaikunthan Rajaratnam[2]

[1]Athena Institute, Vrije University, Amsterdam, Netherlands, [2]Khoo Teck Puat Hospital, Yishun, Singapore, Singapore

This methodological review presents reflexive video ethnography (RVE) as a novel approach to exploring health-related social phenomena, illustrated through a case study of six leprosy patients in Malaysia. The study's core methodology integrates video ethnography with reflexive practices to capture and analyse the complex experiences of individuals affected by leprosy, living both within a leprosarium and in community settings. Our approach is distinguished by its emphasis on the participatory analysis of video data, facilitating deep engagement with the lived realities of participants. The research process was structured around three principal phases: extensive video documentation of participants' daily interactions and environments, reflexive review sessions involving researchers and participants, and a thematic analysis rooted in reflexive discussions. Ethical considerations were paramount, guiding the informed consent process and ensuring the confidentiality and dignity of all participants. This reflexive process enabled a contextual understanding of leprosy's social, emotional, and physical impacts, revealing insights into patient resilience, community integration, and the stigma associated with the disease. Our findings demonstrate the efficacy of RVE in uncovering the depth and breadth of patient experiences, emphasizing the methodology's capacity to elicit rich, participatory insights beyond traditional qualitative research methods. The case study of leprosy patients in Malaysia is a compelling example of RVE's potential to contribute to health sciences research, offering a comprehensive framework for researchers seeking to adopt a similar approach. This review argues for adopting RVE in the health sciences to enhance our understanding of patient experiences and inform the development of more empathetic and effective health interventions. By detailing the methodological execution and outcomes of our study, we aim to contribute to the broader discourse on qualitative research methodologies, advocating for reflexivity as a catalyst for methodological innovation and deeper social understanding.

6902

REASONS FOR NON-PARTICIPATION IN AZITHROMYCIN MASS DRUG ADMINISTRATION TO REDUCE MORTALITY AMONG CHILDREN 1-11 MONTHS OLD IN NIGER: A CROSS-SECTIONAL COVERAGE EVALUATION SURVEY

Carolyn Brandt[1], Ahmed M. Arzika[2], Ramatou Maliki[2], Alio Karamba[2], Nasser Galo[2], Naser Harouna[2], Diallo Beidi[2], Elodie Lebas[1], Brittany Peterson[1], Benjamin F. Arnold[1], Thomas M. Lietman[1], Kieran S. O'Brien[1]

[1]Francis I. Proctor Foundation, University of California, San Francisco, San Francisco, CA, United States, [2]Centre de Recherche et Interventions en Santé Publique, Birni N'Gaoure, Niger

The World Health Organization recommends biannual azithromycin mass drug administration (MDA) among infants aged 1-11 months to reduce mortality, following promising results of trials in Africa. However, with less resources than trials, coverage may decline during programmatic delivery, with the children missed likely at a higher risk of mortality. We aimed to understand reasons for participation and non-participation, how the intervention was received, and adverse events following azithromycin MDA in Niger by utilizing a coverage evaluation survey. In August 2023, trained community health workers delivered oral azithromycin MDA to children 1-11 months of age across 2,028 communities (42 integrated health centers [CSI]) in Tahoua, as a part of the AVENIR trial. Within 4 weeks of receiving the MDA, a separate data collection team conducted the survey. Separate mixed effects logistic regression models were used to analyze community-, household-, and child-level predictors associated with non-participation in azithromycin MDA, with random effects for community to account for clustering. A total of 3,848 households across 57 communities (7 randomly selected CSIs) were surveyed. Among children who were eligible for the distribution, 69% (n=721) received treatment based on caregiver self-report, compared to 92% community-health worker reported coverage. When asked why the treatment was not taken, the most frequently stated reasons were; not being in the age range (26.4%), someone not coming to the house (26.1%), absence (23.9%), and not receiving enough information (14.3%). In unadjusted models, factors that increased the odds of a child receiving treatment included being older (OR: 1.41, 95% CI: 1.33-1.49, p<0.0001) and receiving information about the program before (OR: 33.06, 95% CI: 21.82-50.07, p<0.0001, REF=did not receive information or do not know). Adverse events were reported among 6.5% of children who received treatment, and fever was the most reported symptom. Strengthening community preparation activities and understanding why younger children were less likely to be included may help to increase treatment coverage.

6903

TRENDS IN ANTENATAL CARE (ANC) CONTACTS AND EXCLUSIVE BREASTFEEDING IN SUB-SAHARAN AFRICA

Bolanle Olapeju[1], Michael Bride[2]

[1]Uniformed Services University of the Health Sciences, Bethesda, MD, United States, [2]Johns Hopkins University Center for Communication Programs, Baltimore, MD, United States

Exclusive breastfeeding is the safest and healthiest option for the first six months of life recommended by the World Health Organization (WHO), particularly in low resource settings. It is associated with reduced risk of malaria, diarrhea and other tropical health outcomes. The WHO 2016 ANC policy recommends at least eight (8+) ANC contacts during pregnancy and frequent antenatal care (ANC) contacts is correlated with exclusive breastfeeding. This study explores trends in breastfeeding practices in sub-Saharan Africa since the roll-out of the WHO 2016 ANC policy. A secondary analysis of data from 19 countries with available Demographic Health surveys from 2018 to date was performed. Key variables include exclusive breastfeeding, early initiation (within one hour of birth) of breastfeeding and number of ANC contacts (0-3, 4-7, 8+) in the most recent pregnancy in the two years prior to the survey. Exclusive breastfeeding ranged from 19% in Gabon to 81% in Rwanda (median=53%) while early initiation of breastfeeding ranged from 32% in Senegal to 85% in Rwanda (median=60%). Minimal women had 8+ ANC contacts, ranging from 0.3% in Rwanda to 39% in Ghana (median= 4%). The overall number of ANC contacts was positively associated with exclusive (AOR: 1.06, 95% CI: 1.05-1.08) and early initiation (AOR: 1.02, 95% CI: 1.01-1.03) of breastfeeding. However, women with 8+ ANC contacts were not more likely to exclusively or quickly initiate breastfeeding compared to women with 4-7 contacts. Study findings highlight the abysmally low rates of eight or more ANC contacts amidst a backdrop of suboptimal breastfeeding rates across sub-Saharan Africa. Findings also suggest a limited utility of eight compared to four ANC contacts and the WHO 2016 ANC policy in the context of exclusive and early breastfeeding. Behavior change efforts to improve the quantity of ANC contacts and complementary health service delivery interventions to improve the quality of ANC contacts are sorely needed and should remain a priority for sub-national and global stakeholders.

6904

ASSOCIATIONS BETWEEN IMMUNE STATUS AND CHILD DEVELOPMENT IN RURAL BANGLADESH

Sophia T. Tan[1], Andrew N. Mertens[2], Md. Ziaur Rahman[3], Fahmida Tofail Tofail[4], Helen O. Pitchik[2], Da Kyung Jung[2], Caitlin Hemlock[5], Benjamin F. Arnold[6], Lisa Hester[7], Mohammed Rabiul Karim[4], Sunny Shahriar[4], Shahjahan Ali[8], Abul K. Shoab[4], Md. Saheen Hossen[4], Palash Mutsuddi[4], Syeda L. Famida[4], Salma Akther[4], Mahbubur Rahman[4], Leanne Unicomb[4], Patricia Kariger[2], Alan E. Hubbard[2], Christine P. Stewart[9], John M. Colford Jr.[2], Stephen P. Luby[1], Firdaus S. Dhabhar[10], Lia C. H. Fernald[2], Audrie Lin[3]

[1]Division of Infectious Diseases and Geographic Medicine, Stanford University, Palo Alto, CA, United States, [2]School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [3]Department of Microbiology and Environmental Toxicology, University of California, Santa Cruz, Santa Cruz, CA, United States, [4]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [5]School of Public Health, University of Washington, Seattle, WA, United States, [6]Francis I. Proctor Foundation, University of California, San Francisco, San Francisco, CA, United States, [7]Department of Medicine, University of Maryland, Baltimore, MD, United States, [8]Colorado School of Public Health, University of Colorado, Denver, CO, United States, [9]Institute for Global Nutrition, University of California, Davis, Davis, CA, United States, [10]University of Miami, Miami, FL, United States

A healthy immune system will mount controlled inflammatory responses to physiological stressors. High levels of inflammation are known to disrupt memory and learning, which has detrimental implications for child development. Here, we conducted observational analyses on the association between immune status, including markers of protective, regulatory, and pathological responses, and development in the first two years of life among participants in the WASH Benefits trial. We used Cox proportional hazard models to assess differences in the rate of attainment of motor milestones at the 75th and 25th percentiles of exposure. We used generalized additive models to assess the relationships between immune markers and scaled development measures and reported the mean difference in predicted outcomes. We found that children with a larger concentration of Th1 cytokines relative to Th2 cytokines at 14 months were more likely to be crawling [Hazard ratio (HR) 1.15 95% CI (1.02, 1.29)] and standing alone [HR 1.19 (1.03, 1.39)] by 14 months. An increased ratio of Th1/Th2 was also predictive of improved development at 28 months, though these results were marginally significant. Previously, we reported on a high prevalence of intracellular pathogens at 14 months and evidence of chronic gut inflammation in the study population; elevated levels of Th1 cytokines, which respond to intracellular pathogens, may therefore reflect a robust protective immune response to the environment. In contrast, C-reactive protein (CRP) and alpha-1-acid glycoprotein (AGP), markers of systemic inflammation, were negatively associated with early development. CRP at 14 months was negatively associated with the number of motor milestones achieved by 14 months [-0.26 (-0.5, -0.02)]. AGP at 28 months was negatively associated with EASQ communication scores [-0.24 (-0.44, -0.04)] and the CDI expressive language score [-0.34 (-0.57, -0.11)] at 28 months. Our results suggest that in early life, regulated protective immune

responses may be key for healthy development, but development may be impaired by systemic inflammation and unregulated pathological immune response.

6905

CONTRIBUTION OF VACCINE PREVENTABLE DISEASES TO CHILD MORTALITY IN AFRICA AND ASIA - CHILD HEALTH AND MORTALITY PREVENTIONS SURVEILLANCE (CHAMPS)

Rosauro Varo[1], Ikechukwu U. Ogbuanu[2], Elisio Xerinda[3], Marcelino Garrine[3], Jaime Fanjul[1], Sara Ajanovic[1], David Torres-Fernández[1], Kyu Han Lee[4], Dianna Blau[4], Cynthia Whitney[4], Inácio Mandomando[3], Quique Bassat[1], Portia Mutevedzi[4]

[1]Barcelona Institute for Global Health, Barcelona, Spain, [2]Crown Agents in Sierra Leone, Freetown, Sierra Leone, [3]Manhiça Health Research Center, Manhiça, Mozambique, [4]Emory Global Health Institute, Emory University, Atlanta, GA, United States

Despite significant reductions in child mortality, children under five years of age remain disproportionately at-risk in Africa and Southern Asia. This is mainly attributed to uneven immunization, with over 30 million infections and 500,000 deaths annually estimated as due to vaccine-preventable diseases (VPD). We aimed to describe deaths attributed to VPDs using data from the Child Health And Mortality Prevention Surveillance network (CHAMPS). Cause of death determination was carried out through minimally invasive tissue sampling for microbiological and histopathological assessments, and determination of the chain of events leading to death using an expert panel at each CHAMPS site. During the study period, 6119 deaths had a COD determined through a DeCoDe panel on time for the analysis. Not considering stillbirths and neonates, 1459 deaths were counted: VPD deaths were responsible for 617 (42.28%) of deaths, of which 267 (18.3%) were included in the EPI schedules (*VPD-EPI* deaths: diphtheria, hepatitis B, Haemophilus influenzae type B infection (Hib), measles, whooping cough or pertussis, pneumococcal disease (PND), poliomyelitis, rotavirus diarrhea (Rota), rubella, tetanus or tuberculosis); and 350 (23.9%) were not (*VPD-non-EPI* deaths). Considering VPD-EPI deaths, the main etiology in was PND, being present in around 4 out 5 of deaths; followed by Rota (10%) and Tuberculosis (6.7%). Malaria accounted for vast majority of *VPD-non-EPI* deaths (90.6%). The second leading cause was Influenza and there were also cases reported of cholera, meningococcal meningitis, COVID-19, and rabies. A number of deaths presented with more than one VPD, and both, *VPD-EPI* and *VPD-non-EPI*, also presented with other pathologies in the casual chain. Malnutrition was especially important but also infectious diseases like HIV, LRTIs, malaria and sepsis. Updating the documented role of VPD's through postmortem sampling information on the subject is a strong and reliable tool to monitor vaccine delivery and uptake and surveillance of VPD remains crucial to improve vaccination programs and reduce child mortality due to VPDs.

6906

ENHANCING DATA AVAILABILITY AND QUALITY WITH AN EASY-TO-USE TOOL DURING THE LOGISTICS MANAGEMENT INFORMATION SYSTEM REFORM IN MADAGASCAR, 2022-2023

Maherison Jaona Andrianaivoravelona

PSI - Madagascar/ Impact, Antananarivo, Madagascar

The logistics management information system (LMIS) in Madagascar faced significant challenges for years, including low reporting rates, poor data quality, and lack of data visualization. To address these issues, the Ministry of Public Health (MOPH) decided to replace the offline national LMIS software (CHANNEL) with the online and open-source system, OpenLMIS, but this has been extensively delayed. During the wait, a reliable data tool was needed to maintain data quality and reporting. In October 2022, the PMI-funded Improving Market Partnerships and Access to Commodities Together (IMPACT) program supported the MoPH to develop e-LMIS (an Excel-based web, easy-to-use tool) and deploy it in all 115 districts beginning in January 2023. IMPACT conducted quarterly supportive supervision visits and routine data quality assessments (RDQA) at district pharmacies with reports from January to December 2022 for CHANNEL and January to December 2023 for e-LMIS. RDQA data were used to evaluate changes in quality of data on malaria commodities during the transition from CHANNEL to e-LMIS, comparing results from the 78 supported pharmacies in 2022 and 2023; we focused on completeness, timeliness, and accuracy. For malaria commodities, of 936 reports expected each year, 847 (90%) were submitted in 2022 and 907 (97%) in 2023 ($p<0.001$). In the same period, the on-time reporting rate increased from 579 (68%) of the 847 reports received in 2022 to 807 (89%) of 907 reports received in 2023 ($p<0.001$). Accuracy scores for three malaria products (rapid diagnostic tests and artemisinin-based combination therapy [1- to 5-year-old formulation and adult formulation] were 80% in 2022 and 96% in 2023.The use of e-LMIS tool was helpful and will continue to be used while awaiting deployment of Open-LMIS to generate quality data for commodity quantification, supply planning, and optimize availability of malaria commodities where and when needed.

6907

INTEGRATED DISEASE SURVEILLANCE AND RESPONSE SYSTEM: NEED FOR LABORATORY CONFIRMATION OF CASES IN BONO REGION, GHANA

Samara Ansata Mohammed[1], Kofi Amoh Kodie[1], Prince Quarshie[1], Jane Addae Kyereme[1], Bernice Konadu[1], George Asare Tarbi[1], Emmanuel Bachan[1], Joshua Asare[1], Daniel Konka[2], Dennis Adu-Gyasi[3]

[1]Ghana Health Service, Sunyani, Ghana, [2]Ghana Health Service - Sunyani West Municipality, Sunyani West, Ghana, [3]Kintampo Health Research Centre and University of Energy and Natural Resources, Kintampo North, Ghana

The Bono Regional Health Directorate with focus on one health, uses the various programs in the surveillance systems adopted by Ghana to identify and contain disease outbreaks and pandemics. Laboratory confirmation of identified cases is key in control and preventive measures in IDSR. We undertook a review of the IDSR records in the Bono Region to assess laboratory infrastructure necessary for commonly identified pathogens. This review of IDSR data from 2015-2024 in the Bono Region of Ghana considers weekly IDSR summaries from the District Health Information Management System (DHIMS2). The summaries include cases of diseases, recorded deaths from the diseases and the number of the cases that are confirmed by the laboratory, collated from the respective health system units and uploaded by public health officers. The data was organized and analyzed basically with Microsoft Excel version 2020. Permission for use of the data was sought from the Regional Director of Health Service. The diseases that were highlighted in the surveillance with laboratory confirmation were acute watery diarrhoea, cholera, COVID-19, diarrhoea by shigella, Measles, Meningococcal meningitis, Rabies, and Yellow Fever. With the exception of Rabies that had 100% of identified cases being confirmed by the laboratory in 2018, and Cholera with 90% in 2015, none of the cases identified for all the diseases had more than 25% laboratory confirmation. Even though Meningococcal meningitis consistently had some of the identified cases confirmed by the laboratory from 2015 to 2024, it was only in 2024 that a highest of 21% of the cases recorded was confirmed in the Bono Region. Considering COVID-19, less than 20% of the cases were confirmed by the laboratory.Laboratory confirmation of diseases earmarked for surveillance is low in the Bono Region of Ghana. Availability and access to laboratory facilities play critical role in laboratory confirmation. Adequate logistics and laboratory consumables hinder the ability of the health systems to confirm identified cases. Laboratory facilities are required foundations for effective IDSR implementation.

6908

RECURRENT ADMISSIONS AND MORTALITY RATE IN CHILDREN LESS THAN TWO YEARS OLD IN RURAL GAMBIAN SETTING

Abdoullah Nyassi, Isaac Osei, Yekini A. Olatunji, Golam Sarwar, Grant Mackenzie

Medical Research Council Unit The Gambia at London School of Hygiene & Tropical Medicine, Fajara, Gambia

Diseases resulting from hospital admission contribute to a significant clinical and economic burden globally. Some of these are reported to be recurring. Recurrent hospital admissions may have negative developmental effects, particularly in chronically ill children. The cost of hospitalization for serious medical problems can be up to 60 times higher than that of a mild or moderate condition managed by primary care services. In the Gambia, the direct cost of inpatient admission is $9.19, and indirect costs are $4.07 per visit. There have been no studies that looked at longitudinal data to provide more insight into readmission and death in a rural sub-Saharan environment. This calls for action to better understand and, therefore, contribute to the design of interventions to reduce recurrent admissions in young infants. We assessed the proportion of children less than 2 years of age readmitted, predictors associated with readmission, and the incidence of mortality in health facilities within the Basse Health and Demographic Surveillance System (BHDSS). A retrospective analysis of admitted patients that are less than 2 years of age with medical problems as the principal diagnosis at health facilities in BHDSS between January 2011 and December 2017 was performed. We calculated risk-standardized mortality rates at the first admission, risk-standardized readmission rates, and in-hospital mortality at 30 days, 90 days, and 2 years of readmission by using a multivariate mixed model. We included 4773 patients admitted with medical problems. The mean age was 7.6±5.5 months, and 56.9% were male. A total of 588 (12.3%) experienced at least a single episode of readmission. The number of readmissions for 30 days, 90 days, and 2 years is 103 (17.5%), 170 (28.9%), and 15 (53.6%). In-hospital mortality during the readmission episode was 128 (2.7%) throughout the years of follow-up. Readmissions are a significant contributor to the burden on the healthcare system, and early detection of patients who are at risk can help launch efficient interventions that lower costs and boost the standard of care.

6909

UTILIZING GEOSPATIAL DATA FOR TARGETED ADVOCACY TO ENHANCE MINIMALLY INVASIVE TISSUE SAMPLING (MITS) COLLECTION FOR CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) IN PAKISTAN

Hannah Melchinger[1], Sameer Belgaumi[1], Nazia Ahsan[2], Raheel Allana[2], Fauzia Malik[1], Saad B. Omer[1], Momin Kazi[2]

[1]Peter O'Donnell Jr. School of Public Health, UT Southwestern, Dallas, TX, United States, [2]Aga Khan University, Karachi, Pakistan

The Child Health and Mortality Prevention Surveillance (CHAMPS) project is focused on understanding and preventing child mortality through comprehensive data collection, including post-mortem minimally invasive tissue sampling (MITS). However, MITS can be challenging to perform in resource-constrained settings with limited community engagement. Geographic Information Systems (GIS) offers the opportunity to improve MITS collection by informing targeted CHAMPS advocacy, which can increase the number of death alerts received from the community and improve awareness and acceptability of MITS within the catchment area. In Pakistan CHAMPS, we started by collecting and cleaning data on child mortality rates, healthcare facilities, and MITS collection sites. We then analyzed this data using GIS techniques to identify hotspots of child mortality: these areas were then targeted for increased MITS collection and optimized resource allocation. The integration of geospatial data is crucial to creating an accurate picture of community needs: we combined population demographics, healthcare accessibility, and environmental factors onto one database. Preliminary findings from GIS data revealed a direct correlation between increased advocacy efforts and an increased number of death alerts, thereby improving potential effectiveness of MITS. Furthermore, targeting areas of high mortality with decreased MITS consent allowed us to make our advocacy and MITS efforts more effective overall. By mapping areas with lower advocacy coverage, we identified gaps in community engagement and targeted these areas with intensified advocacy campaigns to improve child mortality surveillance. GIS-driven targeted advocacy has revolutionized MITS collection in Pakistan, bridging gaps in community engagement and maximizing study impact. This innovative approach highlights the power of data-driven strategies to enhance public health interventions.

6910

PERCEPTIONS TO AND DECISION-MAKING DYNAMICS OF ANTENATAL CARE DURING PREGNANCY: A QUALITATIVE EXPLORATION IN RURAL BANGLADESH

Shahana Parveen[1], Dalia Yeasmin[1], Farhana Hasnat Khan[1], Syead Tamim Mahmud[1], Faruqe Hussain[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1], Emily S. Gurley[2]

[1]icddr,b, Dhaka, Bangladesh, [2]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Antenatal care (ANC) visits can identify pregnancy complications and promote optimal birth outcomes. The Child Health and Mortality Prevention Surveillance project in Bangladesh, uses minimally invasive tissue sampling (MITS) to determine the cause of death for stillbirths and deaths of children aged <5 years. Among the deaths enrolled in MITS, 94% were perinatal deaths and perinatal asphyxia was the leading cause of these deaths. In the catchment area rural Baliakandi, 90% of women received at least one ANC, but care was often sought late and from non-qualified providers. We explored the pregnant women's ANC perceptions and practices, aiming to design a culturally credible intervention to increase the uptake of timely and quality ANC. We interviewed 41 women between May and October 2022, who experienced a child loss and a subsequent pregnancy with a birth outcome to understand if any changes in ANC practices between their first and second pregnancy. Women perceived pregnancy is a normal physiological phenomenon in a woman's life and 46% believed that ANC is only required if they experienced a complication. Thirty-seven percent said that they should visit a qualified physician for an ultrasonogram between 5-7 months of the pregnancy to identify the sex, health condition and position of the fetus, so their family could plan for a home delivery if no complications were found. Fifty-three percent of women did not receive any ANC during the pregnancy where the child died, but did receive one to three ANC during the subsequent pregnancy; they stated that the child loss increased their interest in ANC. However, only 7% of these women met the guideline for at least 4 ANC visits in their subsequent pregnancy and were unaware about possible danger signs. Unfortunately, 23% of the women experienced a miscarriage or early neonatal death during their subsequently pregnancy. The existing practices of not seeking timely and quality ANC suggested the gap between perceived risks during pregnancy and required action points. Counseling women and families for quality ANC, outcome of the danger signs and ensuring quality care could promote care seeking during pregnancy.

6911

HOW SUPPLY CHAIN SHAPES LABORATORY PERFORMANCE IN SEROSURVEILLANCE BEFORE, DURING, AFTER COVID-19

Shahjahan Ali[1], Ibrahim Swaray[2], Wilhelmina Strasheim[3], Daniel Mumba[4], Oscar Kai[5], May Chu[1]

[1]Colorado School of Public Health, Aurora, CO, United States, [2]Centre for Global Health Research, Toronto, ON, Canada, [3]National Institute for Communicable Diseases, Johannesburg, South Africa, [4]Malawi Liverpool Wellcome Programme, Blantyre, Malawi, [5]Kenya Medical Research Institute, Kilifi, Kenya

The importance of the supply chain (SC) in effectively supporting laboratory-based serosurveillance is often overlooked. We identified the

SC pain points before, during, and after the COVID-19 pandemic to extract lessons learned for Sierra Leone, Kenya, Malawi, South Africa and beyond. SC bottlenecks contributed to months- and even year-long delays in receiving deliveries resulting in low efficiency/higher costs and impacted evidence-based decisions. We used a mixed-methods approach, reviewed 52 papers (published 2006-2023), conducted 12 interviews and surveyed 8 key SC principals: researchers/staff, manufacturers, and SC professionals. Transcribed data were coded using inductive and emergent coding methods then analyzed by narrative synthesis and thematic analytic processes. Sites (75%), before COVID-19, dealt with delayed and incomplete shipments and deliveries, did not have procurement planning/ forecasting capabilities, lacked SC resource allocation, lacked inventory management systems and transportation logistics. During COVID-19, all SCs were severely disrupted: non-alignment of customs procedures and regulations between countries, disrupted shipping and inconsistent cold-chain handling instructions added to the challenges suppliers and users had to navigate. After COVID-19 customs-related issues improved for half of the sites with differing issues that will require both general and context-specific solutions. Many researchers tell us that they find "off-book" SC alternatives to ease their pain points. We will discuss the potential solutions tailored to fix infrastructural and systematic needs: adopting model regulations, personnel SC training, inventory management, one-stop serosurveillance bundles and fostering collaboration among stakeholders. During and post-COVID-19, the SC for genomics has paved a way for solutions by bundling purchases and improved logistics processes that have not been reflected for serosurveillance activities. These efforts should be better coordinated and funded. Innovations in product design and one-stop bundle packaging could ameliorate key barriers.

6912

ASSESSING THE QUALITY OF CARE PROVIDED TO WOMEN ATTENDING ANTENATAL CLINIC IN SIAYA COUNTY WESTERN KENYA

Kizito O. Obiet[1], Wycliffe Odongo[2], Fredrick Omiti[1], Brian Seda[1], Victoria Seffren[2], Feiko O. ter Kuile[3], Sarah G. Staedke[4], Jonathan Schultz Schultz[5], Simon Kariuki[1], Julie Gutman[2]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Department of Vector Biology, Liverpool School of Tropical Medicine, Kisumu, Kenya, [5]4Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Kisumu, Kenya

In Kenya, up to 52% of women do not reach the minimum 8 antenatal care (ANC) visits recommended by the Ministry of Health (MOH). While ANC plays a crucial role in the well-being of both mother and child from pregnancy through postpartum, the quality of care (QoC) can vary significantly across healthcare settings, impacting maternal and neonatal outcomes. To evaluate this, we assessed the QoC of ANC in Siaya County, western Kenya. Women aged 13-49 attending any ANC visit from Aug-Oct 2023 in 7 health facilities (HF); level 2 (n=4), 3 (n=2), and 5 (n=1) participating in a scannable maternal and child health (MCH) handbook feasibility pilot were included. Each woman was issued a scannable handbook and followed for six months. If women were enrolled after the first ANC visit, data from previous visits were copied into the scannable book. Data on services, including physical examination, ANC profile, ultrasound, and intermittent preventive treatment (IPTp) of malaria, were electronically abstracted. QoC was evaluated using 19 MOH recommended services, 11 of which were scored per pregnancy (once), while 8 were scored at every routine ANC visit; scores >75% were considered high quality, 50-74% moderate, <50% low. 567 women participated in the pilot. Most underwent both physical exam and ANC profile tests 97%(n=549), but fewer received deworming (36%) or ultrasound (12%) at any visit. The average QoC score per the national guideline was 71.9% (SD=7.6). Most women received moderate (64%) or high (34%) quality care. Primigravida women (aOR=0.6, 95%CI=-0.9-0,01, p=0.03) and those attending HF level 3 or higher (vs level 2) (aOR=0.5, 95%CI=-1.1-0.3, p=0.002) were less likely to receive higher QoC. While the average QoC score was moderate, indicating a reasonable adherence to MOH guidelines, there is need to ensure the highest standard of care for all women. The relationship between gravidity and HF level and QoC suggests the need for targeted efforts to improve ANC service quality. Using a scannable handbook to track women longitudinally across facilities provides a robust framework for assessing and potentially improving ANC quality over time.

6913

COMMUNITY-BASED ASSESSMENT OF SOCIAL BEHAVIOR AND INTERACTION PATTERNS USING WEARABLE PROXIMITY SENSORS AND CONTACT DIARIES IN PAKISTAN: A QUALITATIVE STUDY

Noureen Ahmed[1], Hannah Melchinger[1], Nazia Ahsan[2], Raheel Allana[2], Tehreem Maqsood[2], Najeeb ur Rehman[2], Benjamin A. Lopman[3], Saad B. Omer[1], Fauzia A. Malik[1], Abdul Momin Kazi[2]

[1]Peter O'Donnell Jr. School of Public Health at UT Southwestern Medical Center, Dallas, TX, United States, [2]Aga Khan University, Karachi, Pakistan, [3]Rollins School of Public Health, Emory University, Atlanta, GA, United States

In Pakistan, cultural norms, and community dynamics - including complex social hierarchies, traditional practices, and close-knit family structures - play a crucial role in shaping contact behaviors. Moreover, there are significant differences in contact behaviors between urban and rural areas due to varying lifestyles, population densities, and access to resources. Exploring a community's structure through innovative and direct methods can provide valuable insights. We completed a qualitative study in Karachi, Pakistan, to understand the social dynamics in urban vs. rural areas and assess the feasibility and acceptability of tracking community social interactions through contact diaries and proximity sensors. We conducted 24 focus group discussions (12 rural/ 12 urban) and 36 cognitive interviews (17 rural/ 19 urban) and analyzed data using thematic analysis. In analysis, key themes emerged, including gender preference, pre-appointment permission, and privacy concerns related to the documentation of daily interactions. Both urban and rural participants considered contact diaries to be important tools for interaction documentation, while rural participants emphasized the need to record interactions within extended families due to shared living spaces, the urban participants highlighted the need to document diverse interactions with individuals both within and outside of the household. The community overall identified the proximity sensors as new and unfamiliar. The urban participants were particularly concerned about privacy when wearing the sensors, while rural participants were concerned about wearability. Potential solutions brainstormed with the community included using Ajrak (Sindhi block-print fabric) pouches for rural wearers, blue pouches for urban adults, and T-shirts with concealed pockets for urban children. These results gave valuable insight into how cultural factors impact the acceptability of contact tracking tools. These findings laid the groundwork for successful implementation of a social behavior study in both rural and urban settings of low- and middle-income countries.

6914

ENGAGING PRIVATE PROVIDERS FOR ROUTINE IMMUNIZATION (RI) -INTEGRATED HEALTH SERVICES IN URBAN SLUMS OF HIGH-RISK UNION COUNCILS IN KARACHI, PAKISTAN

Zahid A. Memon[1], Shifa Habib[1], Ammarah Ali[1], Ahsanullah Bhurgri[2], Shehla Zaidi[3]

[1]Aga Khan University, Karachi, Pakistan, [2]Technical Focal Person, Karachi, Pakistan, [3]University College of London, London, United Kingdom

Fully Immunized Children coverage is low (39%-48%) in Karachi's high risk urban areas due to sparse government health infrastructure and lack of engagement of private sector in providing preventive health services. An implementation research project to integrate RI and nutrition counseling, screening, and management through private sector health care providers

in collaboration with the Expanded Program of Immunization, Department of Health, Sindh, and the Aga Khan University is underway in 8 high risk urban areas of Karachi. Through private provider engagement model, RI-integrated health service corners have been established at 18 private clinics enrolled on criteria including registration with the health care commission, lack of public health facility in the geographical proximity, adequate maternal deliveries or child OPD volumes and agreement for no charging policy for immunization. The child friendly corners have been supplemented with two vaccinators and one female counselor to provide vaccination, nutrition screening, and counseling (nutrition, breastfeeding, balanced diet, and WASH) services at no service charge. The project uses an innovative social mobilization and digital communication approach for community awareness and engagement, ensuring active participation through social gatherings planned in collaboration with local community influencers. We present retrospective data collected from the Sindh Electronic Immunization Registry for percentage coverage against quarterly 0-11 month vaccination target for 2023 at the 18 private immunization centers. Continuous improvement in vaccination coverage was seen, exceeding targets in Q4 of 2023. The coverage of Penta-1 improved from 74% in Q1 to 108% in Q4 of 2023. Similarly, Penta-2 increased from 64% to 98% , Penta-3 went from 70% to 105%, while IPV-1 rose from 74% to 104%. The MR-1 increased from 47% to 83% in the Q4 of 2023. BCG's trend was similar, increasing from 56% to 86% in Q4 of 2023. Private sector involvement is crucial for addressing immunization gaps and the inequities developed due to inaccessibility to government health infrastructure and services.

6915

UNDERSTANDING COMMUNITY PERSPECTIVES AND DECISION MAKING TO INFORM CHILD MORTALITY SURVEILLANCE AND MINIMALLY INVASIVE TISSUE SAMPLING (MITS) STRATEGIES IN KARACHI PAKISTAN: ESTABLISHING A NEW SITE

Nazia Ahsan[1], Shaheen Sarfraz Sarfraz[1], Sameer Mohiuddin Belgaumi[2], Hannah Melchinger[3], Saima Jamal[1], Sania Ali[1], Saad Bin Omer[3], A Momin Kazi[1], Fauzia A. Malik[3]

[1]Aga Khan University, Karachi, Pakistan, [2]UT South western, Dallas, TX, United States, [3]UT Southwestern, Dallas, TX, United States

Under-five child mortality is of major concern in Pakistan.[1] The CHAMPS Network collects data globally to understand these deaths using minimally invasive tissue sampling (MITS). A CHAMPS site in Karachi, Pakistan, presents the opportunity to understand regional causes of child mortality, but MITS in this setting can be challenging without a culturally nuanced approach. To assess CHAMPS implementation feasibility, we conducted a five-month-long qualitative investigation with community leaders and members. This included eight focus group discussions, 43 in-depth interviews in three low-income peri-urban communities with diverse categories of stakeholders. Major themes were derived from coded data to identify patterns and were analyzed using thematic analysis framework. We examined study acceptability, practicality, and ease of implementation. Most perspectives aligned with study goals: primary motivators of acceptance included understanding cause of death and a desire to prevent future deaths. Grief counseling was supported as an additional incentive for participation. Challenges to acceptability included worry about MITS invasiveness and discomfort a child's spirit might feel during MITS; belief that death is predetermined, and therefore cause of death is irrelevant; and social pressure during consent. Logistical challenges included the narrow window between death and ritual bathing/shrouding during which samples can be collected. Considering this, we implemented key strategies to improve study feasibility. These include strong community and religious advocacy to increase awareness and reduce stigma of participation; a robust network of key informants to encourage early death alerts for timely MITS sample collection; using a MITS van to assist families with rituals after conducting post-mortem sampling; and strengthening relationships between staff and community through transparency, targeted advocacy, and communication in local languages. These strategies have helped improve community acceptance, enhance community-based mortality surveillance, and successfully implement MITS in Pakistan.

6916

HEALTHCARE SEEKING BEHAVIOR AND DISEASE PERCEPTION ASSOCIATED WITH CHOLERA AND DIARRHEAL ILLNESSES AMONG POPULATIONS IN CHOLERA ENDEMIC REGIONS IN NAMPULA PROVINCE, MOZAMBIQUE

Yeonji Jeon[1], Liliana Dengo Baloi[2], Saemna Park[1], Sofião Manjor[2], Hyoryoung Lee[1], Ju Yeon Park[1], Geun Hyeog Jang[1], Young Ae You[1], Deok Ryun Kim[1], Nelmo Manjate[2], Aurea Tovele[2], Madalena Zacarias[3], Jamilo Chabane[3], Américo Barata[3], Julia Lynch[1], José Paulo Langa[2], Se Eun Park[1]

[1]International Vaccine Institute, Seoul, Korea, Republic of, [2]National Institute of Health, Maputo, Mozambique, [3]Provincial Delegation, National Institute of Health, Nampula, Mozambique

Healthcare seeking behavior and knowledge on cholera and diarrheal diseases in local populations influence disease control and prevention strategies. During November 10-19, 2023, we conducted a cross-sectional household survey in Nampula province, one of the most cholera affected regions in Mozambique. Households were selected using a two-stage cluster random sampling in cholera endemic and high priority hotspots in Nampula city and Meconta and Monapo districts of the province. A total of 838 households participated in the survey using tablet-based data collection and Electronic Data Capturing (EDC) system (REDCap). Age-group stratified healthcare seeking behavior associated with cholera and diarrheal diseases are being analyzed, which will support tailored community engagement for cholera control and serve as an adjustment factor in cholera incidence estimation. Accessibility to healthcare facilities by local populations is investigated by looking into various types of healthcare options near household, mode of transportation, travel distance, travel time, and travel cost to visit healthcare facilities. Socio-economic and demographic factors such as wealth and education level of household heads and history of symptoms related to acute watery diarrhea are analyzed to explore the potential association with healthcare seeking behavior for cholera and diarrheal diseases. Vaccination history of household members in each surveyed household and the community perception towards the oral cholera vaccine are being analyzed. These analyses will be ready for presentation at the upcoming ASTMH conference. Our study findings will fill the basic knowledge gap on the population-level risk factors associated with cholera, contributing to formulating more practical and appropriate community interventions to better control and prevention the disease in areas affected by periodic and persistent cholera epidemics.

6917

PROGNOSTIC PREDICTION MODELS FOR ADVERSE BIRTH OUTCOMES: A SYSTEMATIC REVIEW

Achenef Asmamaw Muche[1], Yifru B. Mitke[2], Likelesh L. Baruda[3], Clara Pons-Duran[4], Bezawit M. Hunegnaw[2], Kassahun A. Gelaye[1], Alemayehu W. Yalew[5], Sebastien Haneuse[4], Lisanu Taddesse[6], Delayehu Bekele[2], Grace J. Chan[4]

[1]University of Gondar, Gondar, Ethiopia, [2]Saint Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, [3], Federal Ministry of Health, Addis Ababa, Ethiopia, [4]Harvard T.H. Chan School of Public Health, Boston, MA, United States, [5]Addis Ababa University, Addis Ababa, Ethiopia, [6]HaSET Maternal and Child Health Research Program, Addis Ababa, Ethiopia

Despite progress in reducing maternal and child mortality globally, adverse birth outcomes have been observed to be disproportionately high in low- and middle-income countries (LMICs). Developing and validating a prediction model for adverse birth outcomes allows for early risk detection and prevention strategies. This systematic review aimed to assess the performance of existing prediction models for adverse birth outcomes and provide a comprehensive summary report of their findings. We used the Population, Index prediction model, Comparator, Outcome, Timing, and Setting (PICOTS) approach to retrieve studies PubMed/MEDLINE, Scopus, CINAHL, Web of Science, AJOL, EMBASE, and the Cochrane library.

We searched for grey literature using WorldCat, Google, and/or Google Scholar. Data were extracted using the CHecklist for critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies (CHARMS), and analyzed for risk using the Prediction model Risk of Bias Assessment Tool (PROBAST). We descriptively reported results in tables and graphs**.** We included 115 prediction models: composite adverse birth outcomes (6), low birth weight (17), small for gestational age (23), preterm birth (71), and stillbirth (9). Maternal clinical and medical characteristics were the most widely used prognostic factors for preterm and low birth weight prediction, while uterine artery pulsatility index was used for stillbirth and small for gestational age prediction. The discrimination performance of preterm birth prediction ranged from an area under the curve of 0.51 to 0.83. Only 6% of the models reported model calibration. Current adverse birth outcome prediction models have poor to very good discrimination performance, but most did not report calibration performance. Inconsistent prognostic factors were included for each adverse birth outcome prediction. Prediction models with consistent prognostic factors that warrant external validation should be accessible to practitioners.

6918

UNDERLYING CONDITIONS AND CONTRIBUTORS OF PERINATAL ASPHYXIA AMONG STILLBIRTHS AND EARLY NEONATAL DEATHS ENROLLED IN THE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS), WESTERN KENYA, 2017 TO 2022

Joyce Akinyi Were[1], Richard Omore[1], Aggrey Igunza[1], Dickson Gethi[1], Harun Owuor[1], Kephas Otieno[1], Edwin Kiplagat[1], Fredrick Onduru[1], Broline Asuma Sagini[1], Beth Tippett Barr[1], Victor Akelo[2]
[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Liverpool School Of Tropical Medicine, London, United Kingdom

Perinatal asphyxia (PA) describes neonatal encephalopathy resulting from severe oxygen deprivation during childbirth, largely due to pre-existing maternal or fetal conditions and events around labor and delivery. We describe conditions and contributors of PA among stillbirths and early neonatal deaths enrolled in the Kenya Child Health and Mortality Prevention Surveillance (CHAMPS). CHAMPS investigates causes of death (CoD) in children under-five years (U5) in defined catchment areas in 9 countries in Sub-Saharan Africa and South Asia. CoDs are determined by an expert panel using data from post-mortem minimally invasive tissue specimen testing, child and maternal clinical records, and verbal autopsy. Designated immediate, intervening, and underlying conditions are considered to be in the causal chain (CA) leading to death. Between 2017 and 2022, CHAMPS-Kenya enrolled 911 U5 deaths, of which 27.9%(254) were stillbirths and 25.0%(228) early neonates. Two thirds (64.1%) of the stillbirth and <7-day decedents had PA in the CA; 304 (63.1%) as underlying CoD and 5(1.0%) as immediate CoD. Nearly all deaths (296,95.8%) occurred in a health facility. The 5 cases with PA as immediate CoD all had other underlying conditions that likely increased the risk of asphyxia. Underlying maternal conditions were identified in most asphyxia deaths (264,85.4%), including hypertension (61,23.1%), HIV (57,21.6%), antepartum hemorrhage (39,14.8%), multiple pregnancy (27,10.2%), chorioamnionitis (27,9.5%), anemia (21,8.0%) and malaria (14,5.3%). Nearly all deaths (302,97.7%) were determined to be preventable and recommended public health actions to the deaths included improvement in obstetric care and management (34.6%), infection prevention and control (31.3%), maternal health education (21.1%) and emergency transportation (17.8%). HIV disease, hypertensive disorders and antepartum hemorrhage accounted for >65% of all maternal conditions underlying PA. A high index of clinical suspicion with appropriate antenatal and labor management should be encouraged to aid in diagnosis and management of high-risk pregnancies likely to result in PA

6919

SOCIO-DEMOGRAPHIC AND OBSTETRIC RISK FACTORS ASSOCIATED WITH LATE INITIATION OF ANTENATAL CARE (ANC) IN RURAL BANGLADESH: FINDINGS FROM THE CHAMPS PROJECT

Taukir Tanjim[1], Shovo Debnath[1], Emily S. Gurley[2], Kazi Munisul Islam[1], Rajib Biswas[1], Maria Rahman Mim[1], Qazi Sadeq-ur Rahman[1], Md. Abdus Salam[1], Md. Atique Iqbal Chowdhury[1], Sanwarul Bari[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1]
[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Johns Hopkins University, Baltimore, MD, United States

Antenatal care (ANC) is important for ensuring optimal pregnancy outcomes by detecting and managing pregnancy complications. Late initiation of ANC, defined as receiving the first ANC visit after 12 weeks of gestation, can have major adverse impacts on maternal and child health. To improve timely ANC utilization in rural Bangladesh, we aimed to identify the socio-demographic and obstetric risk factors associated with delayed ANC initiation. Child Health and Mortality Prevention Surveillance (CHAMPS) has been conducting pregnancy surveillance in Baliakandi, a rural sub-district of Bangladesh, monitoring each pregnancy, including antenatal care utilization. A cross-sectional study was conducted among women from Baliakandi who were pregnant in 2022 and received at least one ANC visit. The association between socio-demographic and obstetric characteristics and late ANC initiation was analyzed using multivariate logistic regression. Out of 7085 pregnancy events, in 2317 pregnancies, mothers did not take any ANC. A total of 4768 pregnancies with ≥1 ANC were recorded; ANC was delayed in 44% (n=2081) of these cases. Women who received delayed ANC were younger in age compared to women who sought ANC on time (37% were aged ≤20 years, compared to 34.5%). In our study population, 81% of the mothers had educational attainment only up to 10 years. Women who sought care on time were more educated than those who initiated ANC late (24% vs 13% with more than 10 years of education). In multivariate logistic regression, age ≤20 years (adjusted odd ratio [aOR]: 1.79, 95% CI: 1.36-2.36), maternal education ≤10 years (aOR: 1.40, 95% CI: 1.13-1.73), and spousal education ≤10 years (aOR: 1.41, 95% CI: 1.17-1.71) were significantly associated with delayed ANC initiation. With each living child, the risk of late initiation of ANC was increased (aOR: 1.40, 95% CI: 1.26-1.55). Whereas a history of miscarriage (aOR: 0.75, 95% CI: 0.63-0.90) showed higher chances of timely ANC. Our study suggests that younger women with lower levels of education tend to receive their first ANC later. Interventions designed to target this group may help minimize the gap.

IMPACT OF TWO-DOSE ORAL CHOLERA VACCINE IN CHOLERA ENDEMIC AND HIGH PRIORITY HOTSPOT IN CUAMBA DISTRICT IN CONTEXT OF THE 2023 CHOLERA OUTBREAK IN MOZAMBIQUE: FIVE YEARS AFTER A PREEMPTIVE MASS VACCINATION CAMPAIGN

José Paulo Langa[1], Cynthia Semá Baltazar[1], Liliana Dengo Baloi[1], José Alberto Manuel[2], Ramos B. J. Mboane[2], Sadate Assane[2], Alide Omar[3], Mariana Manso[3], Jucunú J. Elias Chitio[1], Naira Luiz Kanje[4], Saemna Park[4], Yeonji Jeon[4], Julia Lynch[4], **Se Eun Park**[4]
[1]National Institute of Health, Maputo, Mozambique, [2]Provincial Health Directorate, Niassa, Mozambique, [3]District Health Directorate, Cuamba, Mozambique, [4]International Vaccine Institute, Seoul, Korea, Republic of

Cholera remains a major public health concern in Mozambique with outbreaks occurring almost every year since 1989 with a marked seasonal pattern. Mozambique has experienced several large cholera outbreaks over the past four decades with more than 35,000 cases reported between 2022 and 2023 alone, the largest in last 20 years. The Northern and Central regions, particularly Nampula, Niassa, and Zambezia Provinces have been disproportionately affected, compared to the South region. Cholera outbreaks occurred across multiple districts in Niassa province in 2023 with 3,500 cholera cases (clinically suspected with a sub-set of patients positive

with rapid diagnostics test and culture confirmed with *V. cholerae)* and case fatality rate (CFR) of 0.71% (25/3500). Here we describe the impact of a two-dose OCV mass vaccination campaign we had conducted in Cuamba district located in Niassa province in 2018 (two-dose coverage of 60.4% (±3.4%)); in context of the recent cholera outbreaks in Niassa province. Routine epidemiological data from the local government were analyzed. During the cholera outbreaks in 2022-2023, 69% (11/16) of all districts in Niassa province were affected. Cuamba district was unaffected (no cases reported) and the remaining four districts minimally affected. The most affected districts were Lichinga (1,719 cases, 8 deaths, 4.4 attack rate (AR), 0.47% CFR), followed by Lago (652 cases, 7 deaths, 9.5% AR, 1.07% CFR) and lake region of Mecanhelas bordering Cuamba District (392 cases, 3.95 AR, 0.26% CFR, mainly fishermen aged 20-29 years) districts. These areas and Cuamba district are considered traditional cholera hot zones in Niassa province but had no history of OCV vaccination in the past five years, except for Cuamba. Two of the five unaffected or minimally affected districts also border Cuamba district, which were Mandimba (11 cases, 0.1% AR, no deaths) and Metarica (no cases) districts. Our findings suggest a preventive OCV use in cholera endemic and high priority hotspots with at least 60.4% coverage rate demonstrated the direct and indirect protection against cholera outbreaks at five years post-vaccination timepoint.

6921

ASSESSMENT OF HEALTHCARE WORKERS AND COMMUNITIES BEHAVIORS TOWARDS ANTIBIOTICS IN YIRIMADIO, MALI

Lazare Coulibaly[1], Demoutiery J. Sanou[1], Mamadou M. Teketé[1], Antoine Dara[1], Ibrahim Cissé[2], Bintou Diarra[1], Boi koné[1], Lassina Timbiné[1], Abdoulaye A. Djimdé[1]

[1]PDNA, Bamako, Mali, [2]Yirimadio health Center, Bamako, Mali

Antibiotic resistance is becoming a public health problem worldwide. A systematic analysis estimated 4.95 million deaths associated with bacterial AMR in 2019. A study in Mali has observed 93.8% and 92.6% of *E. coli* resistance to some of the antibiotics widely used in Mali, amoxicillin and cotrimoxazole, respectively. To better understand this problem there is a need for scientific information at the community and healthcare personnel levels regarding antibiotics. This study aims to assess the knowledge, attitude, and practices of antibiotics use and prescriptions in the Yirimadio health district in Mali. The population aged more than 18 years and health workers of Yirimadio health district was surveyed between 07 to 13 September 2023 and the survey was carried out in 11 sectors of the Yirimadio health area. Community permission was obtained from sector heads and interviewers were trained to collect data from the population, health workers, and focus groups. A total of 300 people were quantitatively surveyed, 100 health workers were interviewed and 6 in-depth interviews were carried out. Of those surveyed, 61% were women and 82% were aged between 24 and 65 years. In the general population, 57% declared that they had heard about antibiotics, 84% said they obtained antibiotics without a prescription, and 75% confirmed that they self-medicated with antibiotics. In our study, 61% of health workers surveyed were women, 81% prescribed antibiotics without requesting a bacteriological test, 83% prescribed without antibiogram testing. Moreover, 47% of health workers advised antibiotics without a prescription, 31% advised by phone, and 22% advised using social media. This study revealed that, in addition to the general population, some health workers need more training, awareness-raising, advice, and education on the optimal use of antibiotics.

6922

HAPPY FEET: UNDERSTANDING THE PREVALENCE OF PODOCONIOSIS AND ASSOCIATED RISK FACTORS IN SODO ZURIA AND OFFA DISTRICTS, SOUTHERN ETHIOPIA.

Tedila Habte Memera[1], Hannah Margaret Edwards[2], Esey Gabore[1], Helen Hawkings[2]

[1]Malaria Conssortium, Hawassa, Ethiopia, [2]Malaria Conssortium, London, United Kingdom

Podoconiosis is non-infectious lymphedema caused by barefoot exposure to irritant volcanic red clay soil. An estimated one-third of the 4 million global cases are reported in Ethiopia. However, reliable data on prevalence and risk factors associated with the disease are scarce. We investigated the prevalence and risk factors of podoconiosis in two districts of southern Ethiopia to provide evidence for policy and control programme planning. A mixed methods study was conducted in Sodo Zuria and Offa districts. Cross-sectional surveys were conducted with household heads in 968 households, including 116 household members with podoconiosis. In addition, four focus group discussions (FGDs) were carried out, two with community members with the disease and two without. Each FGD included eight female or male participants, totalling 32 community members (16 female and 16 male). Our results show the prevalence of podoconiosis among in the study districts was 3.95% with prevalence twice as high in women (5%) than men (2.5%). Although knowledge of podoconiosis and the prevention methods was high among community members, 29.7% were observed without shoes and 50% reported regularly walking to work barefoot. In addition, the mean age for first shoe-wearing among participants was 13.44 (± 9.4) years. Furthermore, among participants with podoconiosis, only 32% had clean and intact feet, and 71% reported seeking treatment for swelling from health facilities. FGD participants reported financial limitations and cultural barriers as reasons for not wearing shoes. FGD participants also reported men have greater access to shoes, are more likely to be able to afford shoes and spend more time outside which may be reasons for higher rates of shoe wearing among men. This study found a high prevalence of podoconiosis in Sodo Zuria and Offa districts in Ethiopia. Women were most affected by the disease and were reported to have lower access to shoes. To improve access to shoes and other preventative measures and encourage treatment-seeking behaviour we are implementing contextualized social behaviour change and healthcare interventions in these communities.

6923

ALL-CAUSE MORTALITY ATTRIBUTABLE TO THE COVID-19 PANDEMIC IN THE CONTEXT OF URBAN POVERTY: INSIGHTS FROM A COHORT IN PAU DA LIMA IN BRAZIL

Homegnon Antonin Ferreol Bah[1], Ana Paula Medeiros Pereira[2], Juan Pablo Aguilar Ticona[1], Nivison Nery Jr[1], Mariam O. Fofana[3], Murilo Enrique Dorion Nieto[3], Renato Victoriano[4], Cristiane Wanderley Cardoso[2], Federico Costa[1], Mitermayer G. Reis[4], Derek A. T. Cummings[5], Albert I. Ko[3]

[1]Instituto de Saúde Coletiva, Universidade Federal da Bahia, Salvador, Brazil, [2]Centro de Informações Estratégicas em Vigilância em Saúde do município de Salvador, Salvador, Brazil, [3]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, [4]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Ministério da Saúde, Salvador, Brazil, [5]Department of Biostatistics, University of Florida, Gainesville, FL, United States

There is limited evidence on the direct and indirect health burdens of the COVID-19 pandemic on the vulnerable populations. The aim of this study was to identify the causes of mortality in a cohort of residents of an urban informal settlement in the city of Salvador, Brazil and estimate excess mortality attributable to COVID-19 in comparison to trends before (2017-2019) and after (2020-2023) the pandemic. We extracted information on the primary causes of death (ICD-10 codes) from the Brazilian Mortality Information System (SIM) to identify for individuals ≥5 years old who participated in the cohort from 2016 to 2023. We computed the P-score (percentage difference between reported and expected number of deaths)

to estimate pandemic-related excess mortality. Among 4538 cohort participants, we identified 124 deaths from 2016 to 2023. We estimated the expected number of deaths to be 13 based on mortality date from 2017-2019. The reported number of deaths was 17 (P-score 31%) in the first two years of the pandemic period, rose to 27 (P-score 108%) in 2022, and was 20 (P-score 54%) in 2023. Men who died during the pandemic were younger than women (40 vs. 55 years; p<0.001). Among men, the most frequent cause of deaths were external causes (EC, 44%), such as accidents and assault, and non-communicable diseases (NCD, 40%). In contrast, the most frequent case of death among women were NCDs (68%). Overall, infectious diseases, including COVID-19, accounted for 10% of deaths throughout the study period. Compared to the pre-pandemic period, the proportion of deaths attributable to infectious diseases and EC increased by 1.6- and 1.9-fold, respectively, during the pandemic. In this vulnerable and marginalized urban population, the COVD-19 pandemic was associated with increased mortality due to NCD and EC in addition to infectious causes, suggesting that the pandemic was associated with a significant indirect burden with respect to mortality. This finding highlights the critical importance of structural interventions to address the social determinants of health during periods of major social and economic disruption that occurred during the pandemic.

6924

IMPACT OF LADY HEALTH WORKER VISITS IN THE PRENATAL AND POSTNATAL PERIOD ON THE UPTAKE OF CONTINUUM OF CARE INTERVENTIONS AND MORTALITY IN PAKISTAN

Shah Muhammad[1], zahid Ali Memon[1], Abeer Mian[1], arjumand Rizvi[1], Sajid Bashir Soofi[1], Simon Cousens[2], Zulfiqar A. Bhutta[1]
[1]Aga Khan University, Karachi, Pakistan, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom

In Pakistan, Lady Health Workers (LHWs) play a crucial role in bridging the gap between communities and healthcare facilities since the inception of the LHW initiative in 1994. However, the quality of care offered, and their impact on population level coverage of key maternal, newborn, and child health (MNCH) interventions, as well as mortality are not yet fully understood. We used household survey data from eight districts across Pakistan with each household having at least one woman of reproductive age (WRA) with a child under the age of five. The study aimed to quantify the uptake of MNCH interventions by examining the association between a woman's interactions with LHWs, measured by coverage of antenatal and postnatal visits, and MNCH intervention coverage and mortality. We classified interaction with LHWs into three groups: no contact, contact during the antenatal period or the postnatal period, and contact during both the antenatal and postnatal periods. Logistic regression, accounting for survey design, determined the odd ratios of receiving each intervention at each LHW contact level. After adjusting for apriori confounders, it was found that compared to households who had received no LHW visits, there was a statistically significant difference in key interventions across the continuum of care including antenatal care visits, skilled birth attendance, postnatal checkups for mother and newborn. Similarly, among households that had reported receiving antenatal or postnatal visits by LHW, or both, there was significant improvement seen in childhood health interventions such as BCG vaccinations, care-seeking for diarrhea and full immunization (p-value<0.001). No statistically significant differences were observed in neonatal, post neonatal, or under-5 mortality in LHW-covered areas. This study provides evidence for the impact of LHW contact towards improving maternal and child health. Thus, the work of LHWs remains critical to empowering communities, specifically within the rural context of Pakistan.

ETIOLOGY OF POSTPARTUM SEPSIS AMONG RECENTLY DELIVERED WOMEN IN PAKISTAN

Shabina Ariff
Aga Khan University, Karachi, Pakistan

ETIOLOGY OF POSTPARTUM SEPSIS AMONG RECENTLY DELIVERED WOMEN IN PAKISTAN Type: Abstract SubmissionShabina Ariff1, Uswa Jiwani2, Tooba Jawed Khan2, Muhammad Jawwad1, Sajid Soofi1*1The Aga Khan University Hospital, Pediatrics & Child Health, Karachi, Pakistan, 2The Aga Khan University, Centre of Excellence in Women and Child Health, Karachi, Pakistan*

Untreated postpartum-endometritis escalates to postpartum-sepsis, with a 17% fatality rate. This study aimed to provide the first population-level data on the epidemiology and microbiology of endometritis in Pakistan. A prospective-observational-cohort-study was conducted in Matiari and peri-urban areas of Karachi. Surveillance-system instituted in the study areas was utilized to recruit women within-14 days of delivery. Participants were followed on postpartum-days 0, 2, 6, 13, 20, 27, 34, 41, 48, and 59 by trained Community-Health-Workers (CHWs) after obtaining informed-consent. All women with physician-confirmed sepsis were referred for endometrial sample collection and treated according to WHO-recommendations. CHWs suspected sepsis in 1762(14.1%) of the 12509 eligible and consenting women. Physicians assessed 1451(82.34%) of the suspected sepsis cases and 1919 healthy women. CHWs identified sepsis with a sensitivity and specificity of 86% and 72%, respectively. Altogether, 466(52.1%) of the 894 women with physician-confirmed sepsis provided endometrial cultures. The most common pathogens were*; E. coli* (40.5%), *G. vaginalis*(15.3%), *S. pyogenes*(11.5%), and *S. aureus* (9.2%). Of the 10 most common pathogens, 67.6% were sensitive to combined clindamycin and gentamycin, 53.2% were sensitive to imipenem, 35.6% were sensitive to combined amoxicillin-clavulanic acid and metronidazole, and 19.4% were sensitive to combined ampicillin and metronidazole. Pakistan's high postpartum sepsis rates necessitate treatment guidelines based on common pathogen susceptibility, preventive strategies are imperative to improve the outcomes of postpartum women and reduce maternal mortality in Pakistan.

6926

RETROSPECTIVE ANALYSIS OF CHOLERA/ACUTE WATERY DIARRHEA (AWD) OUTBREAKS IN ETHIOPIA FROM 2001 TO 2023: INCIDENCE, CASE FATALITY RATE (CFR), AND SEASONAL AND MULTI-YEAR EPIDEMIC PATTERNS

Yeshambel Worku Demlie[1], **Abel Gedefaw**[2], Yeonji Jeon[2], Dejene Hailu[2], Tomas Getahun[3], Ondari D. Mogeni[2], David Mukasa[2], Geun Hyeog Jang[2], Gi Deok Pak[2], Deok Ryun Kim[2], Edlawit Mesfin Getachew[3], Biruk Yeshitela[3], Samuyel Ayele Abebe[3], Moti Edosa[1], Mesfin Wossen[1], Mekonnen Teferi[3], Se Eun Park[2]
[1]Ethiopia Public Health Institute, Addis Ababa, Ethiopia, [2]International Vaccine Institute, Seoul, Korea, Republic of, [3]Armauer Hansen Research Institute, Addis Ababa, Ethiopia

Ethiopian government has developed the multi-sectoral cholera elimination plan with an aim of reducing cholera incidence and case fatality rate (CFR). To better understand and monitor the progress of this plan, a comprehensive review of national cholera epidemiology was needed. Reported data on cholera/acute watery diarrhea (AWD) cases in the recent 20 years were extracted from Ethiopian Public Health Institute and World Health Organization databases. Descriptive statistics, Pearson's chi-square, and logistic regression analyses were conducted. From January 2001 to November 2023, total 215,205 cholera/AWD cases, 2,355 deaths with a cumulative CFR of 1.094% (95% CI: 1.092-1.095) and a mean annual incidence rate of 8.9 (95% CI: 6.5-11.3) per 100,000 population were reported. Cholera outbreaks peaked in 2006-7, 2009 and 2016-2017 with over 20,000 cholera/AWD cases per year; followed by the 2020 outbreak (over 15,000 cases). In 2023, nearly 30,000 cases were reported. During

2015-2023, around 54.0% (53,990/99,945) of cases were those aged 15-44 years. In 2019-2022, cholera outbreaks largely hit the southern and eastern regions. Cholera CFR has increased in recent years; highest CFR (3.13%; 95% CI: 2.1-4.5%) in 2022. During the cholera outbreak years, cases sharply increased in major rainy season (June-August). Regional distribution of cholera CFR showed a significant variation during 2015-2023; B/Gumz region (5.2% CFR) with the highest CFR, followed by Sidama (2.3%) region. Cholera cases and attack rates peaked during the El Niño years, indicating the potential impact of climate change on the magnitude of cholera outbreaks. Cholera/AWD patients in older adults (45 years and above), severe dehydration, peak outbreak season, patients treated at outpatient level were associated with higher risk of deaths. Upsurge of cholera cases and deaths in 2023 signals a critical need for reactive and preemptive cholera vaccinations in cholera hotspots. Continued systematic cholera surveillance, early case detection and adequate case management are critical for reducing deaths and controlling cholera transmissions in communities.

6927

THE TROPICAL MEDICINE IN THE GULF OF MEXICO (TROP-G) NETWORK AS A MODEL TO BRIDGE RESEARCH GAPS, FACILITATE COLLABORATION, AND EMPOWER THE NEXT GENERATION OF NTD SCIENTISTS

Claudia Herrera[1], **Leroy Versteeg**[2], Priscila Silva Farani[3], Antoine Amblard-Rambert[4], Norman Beatty[5], Maria Elena Botazzi[2], Pierre Buekens[6], Eric Dumonteil[1], Angel Ramos-Ligonio[7], Peter Hotez[2], Rachel Clear[1], Bridget Knudson[1], Etienne Waleckx[8], Idalia Paredes Sotelo[9]

[1]Department of Tropical Medicine and Infectious Disease, Tulane University,, New Orleans, LA, United States, [2]Texas Children's Hospital Center for Vaccine Development, Baylor College of Medicine; Texas Children's Hospital Center for Vaccine Development, Baylor College of Medicine, Houston, Texas, USA, Houston, TX, United States, [3]Department of Biological Sciences, Border Biomedical Research Center, The University of Texas at El Paso, El Paso, TX, United States, [4]Universidad Atonoma de Yucatan, Merida, Mexico, [5]Division of Infectious Diseases and Global Medicine, Department of Medicine, University of Florida College of Medicine, Gainesville, FL, United States, [6]Department of Epidemiology, Tulane University,, New Orleans, LA, United States, [7]LADISER Inmunología y Biología Molecular, Facultad de Ciencias Químicas, Universidad Veracruzana, Orizaba, Mexico, [8]Laboratorio de Parasitología, Centro de Investigaciones Regionales Dr. Hideyo Noguchi, Universidad Autónoma de Yucatan, Merida, Mexico, [9]Department of Chemical and Biological Sciences, University of Sonora, Hermosillo, Mexico

Neglected Tropical Diseases (NTDs) affect people primarily in low- and middle-income regions. The Gulf of Mexico region has been identified as a vulnerable and "hot zone" for emerging NTDs. Amidst these challenges, researchers in global health and NTDs navigate a path full of obstacles, such as scarcity of funding opportunities, limited access to critical samples or data, and lack of public support due to a low priority of global health on the political agenda. To address these challenges, the Tropical Medicine in the Gulf of Mexico (Trop-G) collaborating network (https://trop-g.org/) was established. Trop-G brings together doctoral candidates, postdoctoral scholars, and academics to collaborate on NTD research in the Gulf of Mexico region. The Trop-G goals include A) providing networking opportunities and events to build professional relationships, B) promoting interdisciplinary collaboration between people from diverse backgrounds, C) sharing knowledge by hosting regular discussions and presentations, and D) raising awareness on NTDs by engaging with the academic community and planning public outreach strategies. As part of its activities, Trop-G leads a 'Journal Club' to promote teamwork and networking, increasing awareness of NTDs. Trop-G Journal emerged through collaboration with Universidad Veracruzana, Universidad Autonoma de Yucatan, Baylor College of Medicine, and Tulane University. Today, our community counts 18 PhD students, 2 Postdocs, and eight researchers, with three additional institutions—the University of Florida, the University of Texas at El Paso, John Hopkins University, Universidad Autonoma de Nuevo Leon, and Universidad de Sonora. We have discussed 16 papers, showcased seven research project presentations, and hosted three guest talks. By organizing biweekly gatherings and showcasing the work through seminars and conferences, Trop-G fosters a dynamic forum for discussion and discovery and significantly boosts the visibility of NTDs research. This increased visibility can potentially lead to more opportunities for resources to be allocated toward NTDs research and improved public support.

6928

VACCINATION EXPERIENCE IMPACTS ON VACCINE CONFIDENCE AND FUTURE VACCINE BEHAVIORS IN KENYA, NIGERIA, AND SOUTH AFRICA

Alee Lockman[1], Tim Callaghan[2], Christine Blackburn[1], **Brian Colwell**[1]

[1]Texas A&M School of Public Health, College Station, TX, United States, [2]Boston University School of Public Health, Boston, MA, United States

We conducted large surveys as part of a larger project examining vaccination attitudes in three African countries (Kenya, N=1,545, Nigeria, N=1,557, and South Africa, N=1,588). We examined COVID-19 vaccination experiences & impressions in each country and the spillover of COVID-19 vaccine experiences on confidence in the safety, efficacy & importance of all vaccines approved for use in each country. We also asked about likelihood of self- and child vaccination in the future resulting from COVID-19 vaccine perception spillover. Majorities in all 3 countries indicated that, because of positive experiences with COVID-19 immunizations, they were more confident in the safety of other vaccines (72% in Kenya, 58.9% in Nigeria & 48.6% in South Africa), more confident of vaccine effectiveness (64.3% in Kenya, 55.9% in Nigeria & 49.2% in South Africa), & increased their beliefs that vaccines are important (71.7% in Kenya, 55.6% in Nigeria, 53.8% in South Africa). Other evidence of positive spillover was reflected in an increased likelihood of respondents indicating that they were more likely to vaccinate themselves & their children in the future because of positive experiences with the COVID-19 vaccination process. Among Kenyans, 71.5% were more likely to vaccinate themselves and 78.5% were more likely to vaccinate their children, 60,1% of Nigerians were more likely to get vaccinated in the future, and 64.6% were more likely to vaccinate their children. Fewer South Africans were more likely to vaccinate themselves (60.1%) and 64.6% were more likely to vaccinate their children in the future. In all 3 countries, about 25% of respondents expressed less confidence in vaccine safety and effectiveness after the COVID-19 vaccination process. Multivariate modeling found varying drivers of spillover effects in each country, but misinformation and confidence in government were stable predictors. Personal experiences with the COVID-19 vaccination process appear to be key drivers of generalized vaccination perceptions and predict self- and child vaccination in the future. The discussion will focus on improving vaccine acceptance among varying populations.

6929

INTESTINAL INFLAMMATION AND ENTERIC PATHOGENS CARRIAGE IN POST COVID-19 PATIENTS

Cinthia Copeticona-Callejas, Lucia Isabel Mendieta Elena, Sonia Guadalupe Jiménez Pacohuanca, Volga Ana Iñiguez Rojas

Instituto de Biologia Molecular y Biotecnologia, La Paz, Bolivia, Plurinational State of

The COVID-19 pandemic has affected millions of people. As a result of the SARS-CoV-2 infection, a broad array of sequelae have been observed, affecting one or multiple organs, including gastrointestinal inflammation. In developing countries, intestinal inflammation triggered by SARSCOV2 infection should be considered in the context of chronic or recurring infections by enteric pathogens. The main objective of this study was to evaluate the presence of intestinal inflammation and enteropathogenic carriage in post-COVID-19 patients. To this end, a total of 201 fecal samples were collected from post-COVID-19 patients (1-24 years of age) in the period of at least 2-4 weeks following their recovery from the disease. Intestinal inflammation was evaluated by the quantification of fecal calprotectin using an ELISA kit (ORG 580 kit). 14 enteric pathogens were

analyzed by real-time PCR. Pathogens included viruses (rotavirus, norovirus GI and GII, astrovirus, sapovirus, and adenovirus), bacteria (*Salmonella*, *Shigella*, ETEC (estA, eltB) and EPEC (eae, bfpA), *Clostridium difficile* (tcdA, tcdB), *Helicobacter pylori*, and *Campylobacter*), and parasites (*Giardia lamblia* and *Entamoeba histolytica*).In general, levels of calprotectin varied broadly from 6.1 ug/g to 2257.4 ug/g. 94% of the study population displayed levels above the normal range (50 ug/g), and 54% displayed high levels of calprotectin (>200 ug/g), suggesting inflammation. Regarding enteric pathogen infections, 21% carried at least one of the tested pathogens. The most frequently found pathogens were EPEC (34%), ETEC (20%), and *Shigella* (17%). No association was found between COVID-19 severity and inflammation. Overall calprotectin levels correlated positively with a higher number of pathogens (ANOVA, P = 0.012). The data obtained throughout this study indicates that pathogenic bacterial infections and inflammation are common in the study population.

6930

LESSONS FROM COVID-19 VACCINATION IMPLEMENTATION IN 52 AFRICAN COUNTRIES: IMPLICATIONS FOR FUTURE PANDEMIC PREPAREDNESS

Muhammed Olanrewaju Afolabi[1], Oghenebrume Wariri[2], Christinah Mukandavire[1], Yauba Saidu[3], Emmanuel A. Okpo[4], Olalekan Uthman[5], Beate Kampmann[1]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]MRC Unit The Gambia at the London School of Hygiene & Tropical Medicine,, Banjul, Gambia, [3]Clinton Health Access Initiative, Yaounde, Cameroon, [4]UK Health Security Agency, Newcastle, United Kingdom, [5]University of Warwick Medical School, Coventry, United Kingdom

Driven by the global imperatives to end the COVID-19 pandemic, the WHO set a goal in 2021 to fully vaccinate 70% of the global population by mid-2022. We projected the COVID-19 vaccination trajectory in 52 African countries and compared the projected to the 'actual' or 'observed' coverage as of December 2022. We also estimated the required vaccination speed needed to have attained the WHO 70% coverage target by December 2022. We obtained publicly available, country-reported daily COVID-19 vaccination data, covering the initial 9 months following the deployment of vaccines. We used a deterministic compartmental Susceptible-Exposed-Infectious-Recovered-type model and fit the model to the number of COVID-19 cases and vaccination coverage in each African country using a Markov chain Monte Carlo approach within a Bayesian framework. Only nine of the 52 African countries were on track to achieve full COVID-19 vaccination coverage rates ranging from 72% to 97% by the end of December 2022, based on their progress after 9 months of vaccine deployment. Of the 52 countries, 26 (50%) achieved 'actual' or 'observed' vaccination coverage rates within ±10 percentage points of their projected vaccination coverage. Among the countries projected to achieve <30% by December 2022, nine of them achieved a higher observed coverage than the projected coverage, ranging from 12.3 percentage points in South Sudan to 35.7 percentage points above the projected coverage in Tanzania. Among the 52 countries, 83% (43 out of 52) needed to at least double their vaccination trajectory after 9 months of deployment to reach the 70% target by December 2022. Our findings can guide countries in planning strategies for future global health emergencies and learning from each other, especially those that exceeded expectations and made significant progress towards the WHO's 2022 COVID-19 vaccination target despite projected poor coverage rates.

6931

UNIQUE AND ADAPTIVE PANDEMIC PREPAREDNESS IN LMIC HEALTH SYSTEM- AN INTEGRATED SURVEILLANCE POTENTIAL OF A RAPID TB AND COVID-19 DIAGNOSTIC IN BANGLADESH

Farzana Zaman[1], Muhammad Asaduzzaman[2]

[1]Directorate General of Health Services (DGHS), Dhaka, Bangladesh, [2]University of Oslo, Oslo, Norway

The COVID-19 pandemic with continuous emergence of its new variants largely affected the aviation system and international travel. Quarantine and proper testing of incoming travelers were considered as the most important preventive strategy. However, many unprecedented challenges were observed at the resource poor settings such as inadequate airport quarantine facilities, lack of highly sensitive but rapid testing and cost-effective management system. In this current study, we present a cost-effective and timely alternative diagnostic and quarantine facility for the incoming impoverished travelers in Bangladesh during the pandemic. We conducted a cross-sectional serosurvey from December 15, 2020 to November 30, 2021 for inbound travelers to Bangladesh. These impoverished travelers (unable to afford hotel quarantine) were quarantined in Hajj camp (a government facility near the airport reserved for muslim pilgrims) with full coverage of food and lodging at subsidized cost and free testing by GeneXpert, which is capable of Nucleic Acid Amplification Test (NAAT) for both COVID-19 and Tuberculosis (TB). Among 1328 participants, SARS-COV-2 positive patients were 106 (7.98%), out of which 72 were male. The highest infection rate was observed in travelers from Singapore (n=16/71, 22.53%) followed by USA and Malaysia. The result processing time was only 1 hour for the NAAT and 1222 participants (92%) were able to travel to their destinations on the same day. The positive cases were kept in quarantine for further assessment. Majority of the participants (95%) were satisfied with the service and processing time. This study is a scalable example of implementation research in resource poor settings which supports the equitable access to COVID-19 diagnostics for disadvantaged group and emergency preparedness for similar pandemics. Due to high sensitivity and specificity, NAAT is also recommended by WHO for diagnosis of acute COVID-19 cases. Our research also emphasizes on the potential to equip hard to reach laboratory facilities by GeneXpert for both TB and COVID-19 diagnostics specially where the double burden exists.

6932

RAPID RESPONSE MOBILE SUITCASE LABORATORY AS A TOOL FOR COMBATING INFECTIOUS DISEASE OUTBREAKS

Paula Emily Schweizer[1], Rea Maja Kobialka[1], Arianna Ceruti[1], Prakash Ghosh[1], Martin Faye[2], Oumar Faye[2], Andy Mahine Diouf[2], Soa Fy Andriamandimby[3], Dinesh Mondal[4], Sarah Schurig[1], Manfred Weidmann[5], Julius Boniface Okuni[6], Kamal H Eltom[7], Sheila Makiala-Mandanda[8], Mitali Chatterjee[9], Michael Frimpong[10], Ndongo Dia[2], George Olusegun Ademowo[11], Mohamed A. In times of emerging pathogens, point-of-need diagnostics represent the first line of defense. In the last two decades, there have been six pandemics and numerous outbreaks of infectious diseases worldwide. Especially in low- and middle-income countries, healthcare facilities are inadequate to manage and control outbreaks. The Mobile Suitcase Lab (MSL) provides a highly functional minimalist work unit that enables capacity development in remote settings in addition to the ease of delivery and deployment. The molecular methods used in the MSL are isothermal amplification (recombinase-aided amplification or recombinase polymerase amplification assay), rapid real-time PCR, and nanopore sequencing. Nucleic acid extraction can be performed within 15 min using simple and rapid reverse purification extraction methods. The MSL operates with a glove box for working with highly contagious pathogens. All reagents needed are cold chain independent and stable at ambient temperature of tropical areas. Independent power supply is achieved via solar power batteries. Members of the research group have released the first mobile Next Generation Sequencing protocol, where all necessary steps can be performed in a suitcase lab, enabling truly mobile use of this technology including offline data basecalling and analysis.The MSL team is working as an international consortium, consisting of 38 members from 17 countries, including public health, academic and governmental institutions. The MSL has been deployed to outbreaks of Ebola, SARS-CoV-2, Dengue, Zika, Avian Influenza and Marburg. As participants in the WHO's simulation exercise programme for Rapid Response Mobile Laboratories, the team contributed to the establishment of Minimum Operational Standards and the improvement of interoperability with other response forces. The MSL Consortium enables disease outbreak investigation and pathogen detection directly at the point-of-need, while strengthening international collaboration and local capacity building.

ADAPTING RAPID LABORATORY BIORISK SELF-ASSESSMENTS TO BETTER INCORPORATE CYBER-BIOSECURITY RISKS

Ming Yang Ong[1], Emilie Ryan-Castillo[1], Lauren Miller[1], Brian Samuelson[1], Claire Standley[1], Kaitlin Sandhaus[2], Kevin Omondi[3], Tura Galgado[3]

[1]Georgetown University Center for Health Science and Security, Washington D.C., DC, United States, [2]Global Implementation Solutions, Chicago, IL, United States, [3]Global Implementation Solutions, Nairobi, Kenya

Recent technological advances have highlighted the global catastrophic biological threat that generative AI could pose. A key building block of this threat is the ease of access to sensitive genetic and diagnostic material stemming from laboratories working with high-consequence pathogens. It is vitally important to secure critical high-containment laboratories and biorepositories from physical and digital biosecurity threats that could contribute to heightening AI and biotechnology risks. Since 2017, the Georgetown University Center for Global Health Science and Security has engaged with laboratory systems to identify gaps and strengthen biosecurity and biosafety capacities using the Laboratory Self-Assessment Tool (S-LAT). In light of rising cyber-biosecurity threats, we have developed an adaptation of the S-LAT including components specifically targeted at identifying and mitigating gaps in cyber-biosecurity capacities. The cyber-biosecurity component focuses on building biosecurity capacities across synthetic biology, toxicology, and genomic research communities, especially those deploying biotechnologies. It also establishes measures for biological and genomic data security, including capacities supporting oversight, enforcement, and/or reporting mechanisms. This presentation will examine the process of developing and incorporating the cyber-biosecurity component of the S-LAT, and provide an update on key considerations in mitigating the cyber-biosecurity threat of high-consequence pathogens from a laboratory perspective.

6934

AGRICULTURAL WORKERS IN GUATEMALA WITH CHRONIC KIDNEY DISEASE ARE AT HIGHER RISK OF ACUTE RESPIRATORY ILLNESS: FINDINGS FROM THE AGRICULTURAL WORKERS AND RESPIRATORY ILLNESS IMPACT (AGRI) STUDY

Molly M. Lamb[1], Diva M. Calvimontes[2], Neudy Rojop[2], Kareen Arias[2], Jenae Stutzman[3], Wanda Mejia[2], Melissa Gomez[2], Chelsea Iwamoto[4], Ian D. Plumb[4], Julio del Cid-Villatoro[2], Claudia Paiz[2], Lyndsay Krisher[5], Jose C. Monzon[6], Guillermo A. Bolanos[2], Ashley Fowlkes[4], Emily Zielinski-Gutierrez[6], Eduardo Azziz-Baumgartner[4], Lee S. Newman[5], Edwin J. Asturias[3], Daniel Olson[3]

[1]Colorado School of Public Health, AURORA, CO, United States, [2]Fundacion para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala, [3]University of Colorado School of Medicine, Aurora, CO, United States, [4]Center for Disease Control and Prevention, Atlanta, GA, United States, [5]Colorado School of Public Health, Aurora, CO, United States, [6]Center for Disease Control and Prevention, Guatemala City, Guatemala

Chronic kidney disease (CKD) of unknown origin (CKDu) is a major public health concern in Central American agricultural workers. While CKD is a risk factor for severe COVID-19 and influenza, it is unknown if populations at risk for CKDu, which are typically younger with fewer comorbidities, are also at risk. During 2020-2022, we annually estimated glomerular filtration rate (eGFR) using serum creatinine among banana farm workers in southwest Guatemala enrolled in a longitudinal cohort (AGRI) study. Influenza-like illness (ILI) was defined as ≥ 1 day of cough, fever, or dyspnea reported on weekly symptom surveys. Workers with ILI completed a questionnaire (flu-iiQ), which produced severity scores for 'systemic' and 'respiratory' symptoms, and impact on 'daily activities,' 'emotions,' and 'other people.' We defined moderate and mild renal impairment as eGFR <60 mL/min/1.73m^2 at one measurement, and 60 to < 90 mL/min/1.73m^2 at two measurements, respectively. We assessed the association between renal impairment and ILI using multivariable regression models adjusted for sex, chronic disease, and job type. During 2020-2022, we screened 2,149 workers (2023 data pending); median age was 28.7 years (interquartile range 23.9 – 35.4) and 82% were male. Overall, 77 (3.6%) had moderate and 234 (10.9%) had mild renal impairment. Of the 352 ILI episodes reported, 17 (4.8%) and 32 (9.1%) were among workers with moderate and mild impairment, respectively. Compared to workers without renal impairment, workers with moderate impairment had marginally higher ILI risk (relative risk = 1.43, 95% CI: 0.94-2.16, p = 0.09), while those with mild impairment had marginally lower ILI risk (RR = 0.76, 95% CI: 0.55-1.04, p = 0.09). The flu-iiQ 'Impact on Others' severity score was higher as renal impairment increased (β= 0.15, p = 0.02); other flu-iiQ scores were similar. These preliminary results from farm workers at high risk for CKDu suggest moderate renal impairment may impact the risk and severity of symptomatic respiratory infections. These findings may help public health authorities to prioritize disproportionately affected populations for vaccination campaigns.

6935

PERFORMANCE OF MALARIA ELIMINATION ACTIVITIES IN SEKE DISTRICT, MASHONALAND EAST PROVINCE, ZIMBABWE, 2023

Julius Shamuyarira

Zimbabwe Assistance Program in Malaria II, Abt Global, Harare, Zimbabwe

Seke district in Zimbabwe became an elimination district in 2022 after achieving an annual parasite incidence <5 cases/1,000 population per year for three consecutive years; a favorable assessment of operational and financial feasibility; and sustainability of the 1-3-7 strategy to report confirmed cases within one day, case investigation within three days, and foci investigation and response within seven days. We conducted a descriptive analysis of malaria surveillance data from Seke District for 2023. Of the 2,409 reported suspected cases passively identified at health facilities, 2,388 (99%) were tested using a malaria rapid diagnostic test or microscopy; of which, 169 (7.1%) tested positive. Through reactive case

detection, 590 household contacts were tested, and 15 (2.5%) tested positive; among whom, 12 (80%) were symptomatic. All 184 confirmed cases (passive and reactive) received appropriate malaria treatment, and 167 (91%) received additional gametocytocidal therapy as single low-dose primaquine. Overall, 172 (94%) cases were uncomplicated, while 11 (6%) were severe cases requiring hospitalization. Among confirmed cases, 60 (33%) were students, 20 (11%) vendors, 14 (8%) farmworkers, and 14 (8%) children <5 years. 88 (48%) of cases sought treatment within 48 hours. Among the 96 cases who sought treatment after 48 hours, 31% were students, 10% vendors, 8% children < 5 years, 8% unemployed, and 41% were other occupations. Overall, 178 (97%) cases were classified as imported; of these, 132 (74%) had a history of travel from malaria high-burden districts, and 11 (6%) from low-burden districts in-country, and 35 (20%) from international locations, mostly from Mozambique (26). All 184 confirmed cases were notified within one day, 156 (85%) of these were investigated within three days, while 12 cases were lost to follow-up, and 16 cases had missing data. No foci investigations were conducted. Case notification and investigation performance was high. Increased capacity for foci investigation and response is needed. Targeted messaging for travelers and students might promote malaria preventive and early care-seeking behaviors.

6936

UTILIZATION OF PREPOSITIONED RESEARCH LABORATORY CAPABILITIES TO SUPPORT SUDAN VIRUS DISEASE RESPONSE IN UGANDA

Willy Kayondo[1], Prossy Naluyima[1], Melissa Gregory[2], Godfrey Pimundu[3], Paul Blair[2], Sharon Atukunda[1], Lydia Tumubeere[1], Brenda Kusiima[1], Paul Ngobi[1], Maurice Kasule Ndawula[1], Michael Luzinda[4], Sarah Namuyanja[4], Stephen Okello[1], Abdullah Wailagala[4], Peter Mutebi[1], Helen Badu[2], Peter Waitt[4], Betty Mwesigwa[1], Vamsi Vasireddy[5], Isaac Ssewanyana[6], Mohammed Lamorde[4], Danielle Clark[2], Susan Nabadda[6], Hannah Kibuuka[1]

[1]Makere University Walter Reed Project, Kampala, Uganda, [2]Austere environments Consortium for Enhanced Sepsis Outcomes, Bethesda, MD, United States, [3]National Health Laboratory & Diagnostics Services, Ministry of Health, Butabika, Uganda, [4]Infectious Diseases Institute, Kampala, Uganda, [5]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [6]National Health Laboratory & Diagnostics Services, Ministry of Health,, Butabika, Uganda

Uganda is prone to outbreaks of high-consequence pathogens including 7 Ebola outbreaks to date. Prepositioning laboratory capability for early detection and effective response is essential for limiting disease spread. The Joint Mobile Emerging Infectious Disease Intervention Clinical Capability (JMEDICC) was established with funding from U.S. Department of Defense and maintained by a partnership across Makerere University Walter Reed Project, the Infectious Diseases Institute and the Austere environments Consortium for Enhanced Sepsis Outcomes. The purpose was to ready a local team to conduct clinical research of medical countermeasures in a filovirus outbreak setting. Laboratory capability development included strategic instrument acquisition allowing for operation inside rapid containment kits, staff competence in Infection Prevention and Control, as well as maintenance of skills through drills/simulation exercises. The Ministry of Health (MoH) leveraged JMEDICC capabilities during the 2022 Sudan virus disease outbreak to offer clinical laboratory testing (biochemistry, hematology and serology) to patients in three Ebola Treatment Units (ETU) for the first time in Uganda. The data generated was crucial for patient care. Prepositioned research capacity and capability enabled safe rapid deployment of mobile clinical laboratories. JMEDICC-MoH collaboration further illustrated the benefits of partnerships to combat global health threats.

6937

A SURVIVOR CASE OF NEONATAL TETANUS: CASE DESCRIPTION AND SURVEILLANCE SYSTEM EVALUATION IN THE URBAN HEALTH DISTRICT OF EBOLOWA, CAMEROON, MARCH 2023

Ngotty Essebe Ruth-Aimée[1], Signe Banjamin[2], Atouba Benjamin[3], Anya Priscilla[4], Mendjime Patricia[5]

[1]Cameroon Field Epidemiology Training Program, Ministry of Public Health, Regional Delagation for the West, Bafoussam, Cameroon, [2]Ministry of Public Health, Regional Delegation for the South, Ebolowa, Cameroon, [3]Ministry of Public Health, Regional Delagation for the South, Ebolowa, Cameroon, [4]Department for the Control of Disease Epidemics and Pandemics; Cameroon Field Epidemiology Training Program, Yaounde, Cameroon, [5]Department for the Control of Disease Epidemics and Pandemics; Cameroon Field Epidemiology Training Program,, Yaounde, Cameroon

Neonatal tetanus (NNT) is a vaccine preventable disease with high lethality rate (80-100%). Cameroon was declared "Maternal and NNT free" in 2012. Elimination strategy of NNT include high vaccination coverage in tetanus toxoid vaccin (≥2 doses) [TT2+] among Women of child bearing age (WCBA) and high-quality surveillance of NNT. On March 9th 2023, the Ebolowa Health District (EHD) was notified of a suspected living NNT case. We aim to investigate to identify exposure factors. A cross-sectional descriptive study was conducted from March 17-26, 2023 in EHD. The case's family was interviewed for case description. Vaccine coverage (VC) and knowledge on NNT evaluation were conducted in the neighbourhood. Health-care workers were interviewed to assess Surveillance system (SS) attributes according to the *2001 CDC guidelines*. Excel (97.2003) software was used for data analysis. Means and proportions were calculated, results presented in tables and figures. The case, female, was born on the floor at home (February 28th, 2023) from a non-vaccinated mother. Umbilical cord was tied with sewing thread and cut using bamboo pestle. The baby presented incessant crying, difficulties breastfeeding, seizures, neck stiffness and spasms 7 days later. Globally 201 neighbours were interviewed. Only 37(18.4%) knew of NNT and 15(7.5%) were aware of its transmission mode. Among the 201 neighbours, WCBA were 85(42%). VC of TT2+ was 21% (18/85) for those WCBA, and 58(68.2%) of them were zero dose for TT2+. A total of 39 health-care workers were interviewed for NNT-SS evaluation, with 16(41%) having at list 3 years' professional experience. The SS was not flexible (51.28%). Completeness (99%), promptness (95%) and usefulness (100%) were satisfactory. Simplicity (70.57%) and acceptability (73.99%) were moderately satisfactory. The EHD recorded the first NNT survivor case in the country. Exposure factors were non aseptic delivery and zero dose mother. VC and knowledge on NNT were very low in the neighbourhood. Utility, completeness and promptness of the NNT-SS were satisfactory. We recommended sensitization, intensive vaccination and training of health-care workers.

6938

THE IMPACT OF COVID-19 POLICY CHANGES ON RT ESTIMATION IN WEST VIRGINIA, JANUARY 22, 2020-DECEMBER 31, 2020

Abigail A. Buesseler[1], Xinyi Hua[1], Dorcas Adom[1], Shobhan Das[1], Wendy Kutten[1], Olawumi O. Olatunde[1], Olivia Sheppard[1], Jhy-Charm Soo[1], Jing Kersey[1], Kin On Kwok[2], Gerardo Chowell[3], **Isaac Chun-Hai Fung**[1]

[1]Georgia Southern University, Statesboro, GA, United States, [2]Chinese University of Hong Kong, Hong Kong, Hong Kong, [3]Georgia State University, Atlanta, GA, United States

Substate-level analysis enables us to better understand geographical variation in COVID-19 transmission and facilitate improvement of prevention efforts with greater granularity. This study analyzes daily cases in West Virginia (data from Johns Hopkins data repository) to estimate the time-varying reproduction number, R_t, in 9 regions across the state. We used the R package EpiEstim to estimate R_t with 7-day-sliding-windows and with non-overlapping-time-windows between 5 policy changes and used

Poisson regression to estimate the incidence rate ratio (IRR) between those 9 regions and West Virginia. Statewide R_t fluctuated throughout the year, with the highest in March 2020 (close to 2) and the lowest R_t (<1) seen in June 2020. The Stay-at-Home Order, Face Mask Mandate, and Virtual Learning Resumes saw 38.7% (95% confidence interval [CI]: 21.9%-57.5%), 10.6% (3.2%-18.9%), and 9.4% (3.2%-15.4%) corresponding decreases in R_t statewide, and varying decreases across the 9 regions. The Eastern region saw no significant R_t changes for all five policy changes. Using the state as the reference group, all regions except Metro-Charleston found significant differences in IRRs. The Northern region had the smallest IRR in 2020 at 0.32 (0.32-0.33), and the Wood-Jackson region had the highest IRR of 1.90 (1.87-1.94). R_t estimates between policy changes showed that policies that isolated people, such as the Stay-at-Home Order and Virtual Learning Resumes, effectively reduced transmission across the state. Geographical variation in case burden is reflected in regions that consistently had IRR >1 or <1 compared to the statewide incidence rate.

6939

ASSESSING IMMUNIZATION COVERAGE AND POLIO VACCINATION STATUS AMONG CHILDREN AGED 12-23 MONTHS. FINDINGS FROM A CROSS-SECTIONAL SURVEY IN HIGH-RISK UNION COUNCILS OF PAKISTAN

Imtiaz Hussain, Muhammad Umer, Ahmad Khan, Sajid B. Soofi
Aga Khan University, Pakistan, Karachi, Pakistan

The current polio epidemiology in Pakistan poses a unique challenge for global eradication as the country is affected by ongoing endemic poliovirus transmission. Across the country, union councils (UCs) that serve as core reservoirs for poliovirus with continuous incidences of polio cases are categorized as super-high-risk union councils (SHRUCs). A cross-sectional survey was conducted in 2023 in 39 SHRUCs over 7 districts using a two-stage stratified cluster sampling technique. 8,011 children aged 12-23 months were covered. A structured questionnaire was used for data collection. Data were analyzed using STATA version 17. Based on both vaccination records and recall, 60% of children were fully-, 34% were partially-, and 6% were non-vaccinated in the SHRUC districts. Among the SHRUC districts, Peshawar in Khyber Pakhtunkhwa (KP) had the highest percentage of fully vaccinated children (83%), followed by SHRUC districts in Sindh (with more than 50%), while the least proportion of fully vaccinated children was found in SHRUC districts of Balochistan. Vaccination cards were available for more than 70% of children in the SHRUC districts of KP and Sindh, and for more than half in the SHRUC districts of Balochistan, except for Killa Abdullah. Results for polio vacancies show that 72.9% of children from the SHRUC districts were vaccinated with at least three doses of OPV and one dose of IPV, while 92.4% were vaccinated with any OPV doses or IPV and 7.6% of children did not receive any polio vaccines. The dropout rate between dose pairs (Penta1 vs Penta3, OPV1 vs OPV3, PCV1 vs PCV3, MCV1 vs MCV2, BCG vs MCV1, and Penta1 vs MCV1) was higher than the WHO-recommended cutoff point of 10% for all vaccine doses in the SHRUC districts except for district Peshawar. To enhance and sustain immunization coverage in the SHRUCs, a multifaceted approach is imperative. This may involve targeted community engagement to dispel misconceptions, enhance vaccine acceptance, and strengthen healthcare systems through training and reliable supply chains.

6940

THE ACCEPTABILITY OF MINIMALLY INVASIVE TISSUE SAMPLING FOR CAUSE OF DEATH DETERMINATION IN RURAL SOUTH AFRICA: A QUALITATIVE ANALYSIS.

Laura-Lynne Brandt, Jessica Price, Zokwane L. Modlane, Gift Mathebula, Sara Jewett, Kathleen Kahn, Ryan G. Wagner
The University of the Witwatersrand, Johannesburg, South Africa

Minimally invasive tissue sampling (MITS) is increasingly being used to strengthen cause of death data in resource-limited settings. However, information on the acceptability of MITS for community deaths across all ages is scarce, as most studies have focused on child and facility deaths. This qualitative study describes factors influencing the acceptability of MITS for community deaths in a rural South African community and reviews the utility of the theoretical framework for acceptability (TFA). We conducted thematic analysis of 20 in-depth interviews with community members from the Agincourt Health and socio-Demographic Surveillance System site who experienced a death in the last 24 months, and 6 focus group discussions with religious leaders, mortuary workers, healthcare workers, traditional healers, and community members. Most community members had positive attitudes towards MITS as they felt knowing cause of death would provide closure, help prevent further deaths and reduce witchcraft accusations. The participants' belief systems did not forbid participation in MITS, but local traditions dictate that infants and traditional healers be buried within one day of death, which might limit participation of these groups. Rumours of organ-trafficking during autopsies made some participants wary of the MITS. However, MITS was considered more acceptable than standard autopsies as it does not involve the removal of organs from the body. Engaging with local traditional leaders and community members, as well as community education about MITS was considered crucial to improving uptake and building trust. Fieldworkers must empathize with grieving families to facilitate consent, minimize the psychological burden of participating in MITS activities and assist with the grieving process. Our findings were largely in line with the TFA; however, the framework failed to account for trust between providers and participants. Given that this trust influenced the acceptability of our intervention, we propose the modification of the TFA to account for this factor.

6941

REACHING THE UNREACHABLE CHILDREN FOR ESSENTIAL VACCINATIONS AN OUTREACH APPROACH THROUGH HEALTH CAMP IMPLEMENTATION

Muhammad Umer, Imtiaz Hussain, Ahmad Khan, Sajid Soofi
The Aga Khan University, Karachi, Pakistan

Despite the robust polio eradication efforts, Pakistan remains a polio-endemic nation. To address the persistent poliovirus transmission, the National Emergency Centre for Polio Eradication has initiated integrated health camps in Polio Super High-Risk Union Councils (SHRUCs) as a part of targeted Supplementary Immunization Activities (SIAs) in collaboration with Aga Khan University, Pakistan. The health camps are meant to deliver basic maternal, child health and essential immunization services. This study presents the coverage of priority children for essential vaccinations from the health camps. High-risk union councils are the primary targets of immunization initiatives during SIAs. To reach out to the underserved children who were either missed or inaccessible during the polio campaigns, health camps are systematically organized on a rotational basis post-campaign. Provincial and District EOCs and the Polio Program offices assist in identifying suitable locations for these health camps. Between July 2021 and September 2023, a total of 2,739 health camps were organized in 41 districts with coverage extending to 201 union councils across all four provinces on a rotational basis. During these camps, 80,780 priority children under the age of five received essential vaccinations. Among them, 28,349 were children who had not received any prior doses, and another 28,349 children were those who had been missed or were unavailable during previous immunization campaigns. Within these health camps, 44,934 children who had consistently been missed by previous immunization campaigns were reached, and 11,396 children who had previously refused vaccination were covered. Additionally, the camps provided essential vaccinations to 273,978 more children. The health camp model, as an outreach strategy, is a highly effective approach for delivering vaccination services to underprivileged populations and enhancing immunization to curb the circulation of the polio virus in the country.

6942

EARLY DETECTION OF CHOLERA OUTBREAKS IN URBAN AND RURAL AREAS OF NAMPULA PROVINCE IN MOZAMBIQUE: PRELIMINARY INTERIM RESULTS OF ENHANCED ACUTE DIARRHEAL DISEASE SURVEILLANCE IN CHOLERA ENDEMIC SETTINGS

Liliana Dengo Baloi[1], José Paulo Langa[1], Cynthia Semá Baltazar[1], Jucunú J. Elias Chitio[1], Imelda Miambo[1], Sofião Manjor[1], Nelmo Manjate[1], Simões Mala[1], Naira Luiz Kanje[1], Aurea Tovele[1], Américo Barata[2], Atija Marcelino[2], Madalena Zacarias[2], Jamilo Chabane[2], Ondari D. Mogeni[3], Saemna Park[3], David Mukasa[3], Geun Hyeog Jang[3], Hyoryoung Lee[3], Young Ae You[3], Deok Ryun Kim[3], Yeonji Jeon[3], Ju Yeon Park[3], Julia Lynch[3], Se Eun Park[3]

[1]National Institute of Health, Maputo, Mozambique, [2]Provincial Delegation, National Institute of Health, Nampula, Mozambique, [3]International Vaccine Institute, Seoul, Korea, Republic of

World Health Organization warned in 2023 that one billion people in 43 countries are at risk of cholera with children under five particularly vulnerable. Mozambique is one of the cholera high-risk countries. Coastal areas of North and Central regions, including Nampula province, are periodically affected by cyclones and floodings. This, coupled with poor water, sanitation, hygiene, and weak healthcare systems, leads to frequent cholera outbreaks. A prospective cholera and diarrheal disease surveillance has been set-up in five sentinel healthcare facilities in Nampula city, Monapo and Meconta Districts of Nampula province. Patients with acute diarrheal symptoms were eligible for enrolment. Clinical data and rectal swab samples were collected for cholera rapid diagnostics test (RDT) and laboratory confirmation. Our preliminary interim analysis shows the following findings while surveillance and data cleaning are ongoing. From September 2022 to January 2024, total 904 eligible patients were enrolled, of which 33.5% (183/547) were RDT positive for cholera. 44.6% (332/745) were culture positive for *V. cholerae* and 55.8% (416/745) positive for non-cholera isolates out of total culture positive isolates. Most cholera cases (counted by either RDT or culture positive) were enrolled at Cholera Treatment Center (64.8%; 289/446) and detected among patients in 15+ years age-group (86.8%; 387/446). Most enrolled patients were from Nampula city (88.3%; 798/904), though outbreaks were detected in both urban and rural areas. Overall crude incidence of cholera was 24.9/100,000 person-years (PY); highest in 15+ years (40.8/100,000 PY). Crude incidence of non-cholera diarrheal disease was 25.6/100,000 PY; highest in 15+ years (44.0/100,000 PY). 83.2% (371/446) of cholera patients were hospitalized for treatment; 75.8% (347/458) of non-cholera diarrheal patients hospitalized. Enhanced and sustained surveillance capacity is critical in early detection of cholera outbreaks and case management. Timely planning and pre-positing of cholera RDT and laboratory diagnostics supplies on sites closer to the cholera high-risk areas are critical.

6943

ANALYSIS AND OPTIMIZATION OF LABORATORY NETWORKS FOR LASSA AND YELLOW FEVER IN NIGERIA: A COMPREHENSIVE APPROACH

Nsonghomanyi Fritz Roland Fonkeng[1], Marie Brunetti[1], Manuela Rehr[1], Onyebuchi Okoro[2], Toluwanimi Adewole[1], Devy Emperador[1], Emmanuel Agogo[1], Heidi Albert[1], Afolabi Akinpelu[3], Babatunde Olajumoke[3]

[1]FIND, Geneva, Switzerland, [2]African Field Epidemiology Network, Abuja, Nigeria, [3]NCDC, Abuja, Nigeria

Nigeria faces significant public health challenges posed by epidemic-prone diseases; the National Centre for Disease Control and Prevention (NCDC) has been actively expanding surveillance and diagnostic networks to enhance outbreak detection and response. However, accessibility to testing remains a key challenge. A descriptive and optimization analysis of the Lassa (LF) and Yellow fever (YF) diagnostic networks and associated sample transport systems were conducted to inform NCDC's policy and future strategic planning. The analysis provided valuable insights into the laboratory network and sample referral systems for both outbreak diseases, focusing on turnaround times for sample transport and laboratory procedures during previous outbreaks. Additionally, the study provided valuable insights for designing an optimized diagnostic network capable of promptly detecting and responding to outbreaks. The DNO analysis revealed that while the average transport time for LF samples met NCDC targets at 0.8 days, YF samples experienced a significantly longer transport time of 10.1 days, primarily due to delays during transportation from sample collection to sample hub. This disparity suggests differing specimen management practices at the local government area or health facility level. Implementing mitigative measures such as allowing cross-border transport or expanding hubs could alleviate long distances between health facilities and hubs, potentially reducing transport time. However, addressing variations in specimen management for YF samples would be crucial for optimizing overall transport efficiency. More studies and research are required to include all priority diseases which requires strengthened data systems and sample collection to provide a comprehensive report. DNO has the potential to offer a systematic and evidence-based approach to enhancing laboratory networks for epidemic-prone diseases.

6944

HEALTH SYSTEM STRENGTHENING THROUGH DATA QUALITY IMPROVEMENTS: A COMPARATIVE ANALYSIS OF HEALTH FACILITY DATA QUALITY PERFORMANCE FROM INITIAL ASSESSMENTS TO SUBSEQUENT VISITS

Aderonke Omokhapue[1], Gloria Sillo[2], Comfort Kingsley-Randa[3], Chinwe Nweze[4], Olayemi Abimbola[1], Justice Adaji[1], IniAbasi Nglass[1], Uchenna Nwokenna[1], Abanyi Liambee [5], Peter Ejim[6], Pam Danjuma[7], Kabiru Bungudu[8], Arja Huestis[9], Rudi Thetard[9], Thomas Hall[9], Grace Nwankwo[10], Erkwagh Dagba[10], Veronica Momoh[10], Jules Mihigo[10], Chukwu Okoronkwo[11], Nnenna Ogbulafor[11], Godwin Ntadom[11]

[1]United States President's Malaria Initiative for States, Management Sciences for Health , Abuja, Nigeria, [2]United States President's Malaria Initiative for States, Management Sciences for Health, Benue, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health , Nasarawa, Nigeria, [4]United States President's Malaria Initiative for States, Management Sciences for Health , Cross River, Nigeria, [5]State Malaria Elimination Program, Ministry of Health, Benue, Nigeria, [6]State Malaria Elimination Program, Ministry of Health, Nasarawa, Nigeria, [7]State Malaria Elimination Program, Ministry of Health, Plateau, Nigeria, [8]State Malaria Elimination Program, Ministry of Health, Zamfara, Nigeria, [9]Management Sciences for Health, Arlington, VA, United States, [10]United States Agency for International Development, United States President's Malaria Initiative, Abuja, Nigeria, [11]National Malaria Elimination Programme, Abuja, Nigeria

Data quality assessments (DQAs) are crucial for ensuring reliable health information and effective healthcare management, aiding stakeholders to understand system strengths and weaknesses. Teams at state and local government levels were trained on malaria DQA processes and conducted routine assessments using the national malaria DQA checklist. The checklist was scripted on KoboCollect, and a PowerBi dashboard was developed to monitor health facility performance. The assessments focused on data availability, consistency, and validity. This study analyzes DQA trends over three years (2021-2023) across four Nigerian states—Benue, Nasarawa, Plateau, and Zamfara. A total of 2,239 HFs were visited, of which 480 (21%) and 70 (3%) received a second and third visit respectively. This aligns with the national DQA guideline that stipulates a minimum of 10% of visited HFs should be revisited. Data availability declined from 84% during the first visit to 82% in health facilities visited for a second time, then increased to 91% among those visited for a third time. The average consistency scores across the first, second, and third visits are 54%, 50%, and 55%, respectively, with a marginal increase observed across the second and the third visit. Consistency scores have been linked to transcription errors from client cards to OPD registers and non-use of client cards due to cost barriers for clients. The validity scores across the first, second, and third visits are 91%, 93%, and 96%, respectively, showing an increasing trend with the highest average score observed in the third visit. Implementation

of improvement plans and maintaining a steady supply of the National Health Management Information System Registers in the HFs are important requirements for data quality. Continuous training to dedicated DQA teams should be adopted to further improve the availability, validity, and particularly the consistency of data to ensure that decision-making, resource allocation, and program adaptation are based on reliable information.

ETIOLOGY OF INFECTIOUS DIARRHEA IN MADAGASCAR: FINDINGS FROM THE COMMUNITY-BASED SURVEILLANCE SYSTEM FROM 2019 TO 2023

Iony Manitra Razanajatovo[1], Laurence Randrianasolo[1], Odile Lalainasoa Rivolala[1], Aina Harimanana[1], Ulrich Raveloson[1], Nirina Nantenaina Ranoelison[1], Léa Randriamampionona[2], Vaoary Razafimbia[2], Antso Hasina Raherinandrasana[3], Dany Bakoly Ranoaritiana Ranoaritiana[4], Manuella Christophère Vololoniaina[5], Soa Fy Andriamandimby[1], Philippe Dussart[1], Rindra Vatosoa Randremanana[1], Tania Crucitti[1], Jean-Michel Heraud[6], Vincent Lacoste[1]

[1]institut Pasteur De Madagascar, Antananarivo, Madagascar, [2]who, Madagascar, Antananarivo, Madagascar, [3]public Health Department Of The Faculty Of Medicine Of Antananarivo, Antananarivo, Madagascar, [4]ministry Of Public Health -Direction De la Veille Sanitaire, De La Surveillance Epidémiologique Et Riposte, Antananarivo, Madagascar, [5]ministry Of Public Health - Direction De la Veille Sanitaire, De La Surveillanceepidémiologique Et Riposte, Antananarivo, Madagascar, [6]who, Geneva, Antananarivo, Madagascar

Diarrhea remains the highest cause of morbidity and mortality among children under five years-old in South Asia and sub-Saharan Africa. Therefore, systematic collection and analysis of data on the etiologies of diarrhea in community settings are needed to prioritize interventions. Our work describes the first laboratory-based surveillance conducted in children under five years, contributing to enrich data on diarrheal etiology in community settings in Madagascar. A pediatric diarrhea surveillance network was carried out from 2019 to 2023 on 21 sentinel surveillance sites of Madagascar. Five children under five-year-old presenting > 3 loose stools in a 24-h period were enrolled weekly. Stool specimens were collected and analyzed by quantitative PCR for a panel of 4 viruses, 4 bacteria and 3 protozoa. Prevalence and seasonal patterns of diarrhea were determined. From 2019 to 2023, the surveillance system captured 1951 diarrhea cases. The median age was 1,3-years old. Of the 1951 stools tested, 1562 (80%) were positive for at least one pathogen. Among positives, 845 (43.3%) were infected with viruses, 1198 (76.7%) with bacteria, 280 (14.3%) with parasites and 947 (60.6%) had co-infections. Enteropathogenic bacteria *Escherichia coli* was detected in 855 (43.8%) stools followed by *Shigella* spp. in 496 (25.4%), *Campylobacter* spp. in 283 (14.7%). Rotavirus was the most prevalent virus detected in 533 (27.7%) stools, adenovirus in 205 (10.5%), astrovirus in 180 (9.2%) and norovirus GII in 101 (5.2%). *Giardia intestinalis* was the most prevalent parasite detected in 202 (10.4%) stools whereas *C. parvum* and *E. histolytica* were infrequent (3.7% and 0.9% respectively). We observed a seasonal pattern where diarrhea occurred during the hot-rainy and the dry-cold seasons. Detection of diarrhea reached its lowest during the inter-season of March and September. This work has, for the first time, described the etiologies of pediatric diarrhea in Madagascar and a sketch of their seasonal circulation. The data highlight the importance of strengthening laboratory capacity for rapid detection and for implementation of diarrhea control and prevention.

6946

IMPACTS OF BAD OBSTETRIC HISTORY ON ANTENATAL CARE UPTAKE IN SUBSEQUENT PREGNANCIES: INSIGHTS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS), BANGLADESH

Maria Rahman Mim[1], Rajib Biswas[1], Shovo Debnath[1], Taukir Tanjim[1], Emily S. Gurley[2], Kazi Munisul Islam[1], Qazi Sadeq-ur Rahman[1], Md. Abdus Salam[1], Md. Atique Iqbal Chowdhury[1], Sanwarul Bari[1], Shams El Arifeen[1], Mohammad Zahid Hossain[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]John Hopkins University, Baltimore, MD, United States

Women who suffer adverse pregnancy outcomes require extra care in subsequent pregnancies to ensure healthy outcomes for mother and baby. To understand whether adverse pregnancy outcomes influence subsequent health-seeking behavior, particularly antenatal care (ANC), we conducted an observational study using the Child Health and Mortality Prevention Surveillance (CHAMPS) data. It includes detailed pregnancy data with ANC histories from all pregnant women in Baliakandi, a rural subdistrict of Bangladesh. We defined a bad obstetric history if a mother had a history of either stillbirth, neonatal death, a child with a congenital anomaly, or ≥2 consecutive miscarriages. Mothers with a bad obstetric history and at least two pregnancy outcomes between January 2018 and January 2024 were included in this analysis. We compared ANC utilization between the pregnancy associated with the bad obstetric outcome and the subsequent pregnancy. A total of 137 mothers were included. In the first pregnancy, 35% received no ANC, increasing to 43% in subsequent pregnancy. However, no difference was found between the first and subsequent pregnancy in the proportion who received the first ANC visit within 12 weeks of pregnancy (31% vs 36%). In spite of an adverse outcome, 43% received ANC from qualified doctors in the first pregnancy, and this decreased to 39% in subsequent pregnancy. Additionally, the proportion completing 4 ANC visits decreased from 17% to 10%. Only 7% mothers in 1st pregnancy and 4% mothers in the 2nd pregnancy took ≥4 ANC from qualified doctors. However, the mean number of ANC visits in the first and subsequent pregnancy remained almost similar (2.4 ± 1.9 vs 2.0 ± 1.3). We have found that mothers with bad obstetric history had less ANC uptake compared to their subsequent pregnancies from qualified health care providers. In addition, few mothers took the recommended 4 ANC visits, which is alarming. Different sociodemographic factors may be responsible for this. However, future research should be directed toward identifying the challenges and developing interventions to encourage mothers to utilize government health facilities to ensure quality ANC.

DENGUE PREPAREDNESS. FRAMEWORK FOR INNOVATIVE TOOLS AND STRATEGIES FOR SURVEILLANCE AND RESPONSE IN OIL AND GAS COMPANY

Joyce Ighedosa, Susan Ngunjiri, Candace McAlester, Patricia Sviech, Yolanda Hill, Gabriel Shi Ze Chia

ExxonMobil Corporation, Spring, TX, United States

The World Health Organization (WHO) in 2023 reported half of the world's population is at risk of dengue, estimating 100-400 million infections each year. *Aedes aegypti*, one of the main vectors for dengue, has an indoor and outdoor day biting pattern. ExxonMobil (EM) has a global workforce with some resident workers and travelers in remote high-risk areas. EM surveillance and evidence-based driven decision led to the development of a global Dengue Control Program, which includes health risk assessments, increased awareness, bite prevention, prompt diagnosis and treatment. Additional strategy includes pre-travel preparation, preventive measures to minimize disease risk, serious illness events, health costs, and business disruption. A retrospective review of case trends and program implementation allows a multidisciplinary approach of a sustainable dengue control program. Regular clinician training on vector-borne diseases such as dengue fever with ongoing review of suitability and availability of dengue vaccines in high-risk areas to ensure current knowledge for appropriate

guidance to travelers. Optimized pre-travel preparation using an innovative tableau travel health dashboard that shows country specific health risks and travel requirements. GeoSentinel Surveillance Network studies in travelers have found dengue as the leading cause of febrile illness among ill travelers returning from Southeast Asia, Latin America, and the Caribbean. Increased emphasis on awareness has shown a steady use of preventive materials. Global business locations are evaluated by required facility specifications, environmental management, and surveillance to ensure program compliance. The Company pretravel preparation ensures 100% identification of risk locations and documentation of risk reviews in the travel health dashboard for clinicians and employees. Dengue disease burden has expanded globally. A robust surveillance and technology embedded in company dengue control program provides guidance and sustainable mitigation tools to reduce serious illness event and support evidence-based priorities in traveler health.

ADVANCING MALARIA CARE THROUGH VARIED INTERVENTIONS: IMPROVING MALARIA RAPID DIAGNOSTIC TEST (RDT) USE IN FOUR NIGERIAN STATES - BENUE, NASARAWA, PLATEAU, AND ZAMFARA

Comfort Kingsley-Randa[1], Attahir Abubakar[2], Olayemi Abimbola[3], Aderonke Omokhapue[3], Methodius Okouzi[1], Arja Huestis[4], Justice Adaji[3], IniAbasi Nglass[3], Uchenna Nwokenna[3], Rudi Thetard[4], Thomas Hall[4], Grace Nwankwo[5], Erkwagh Dagba[5], Veronica Momoh[5], Jules Mihigo[5], Chukwu Okoronkwo[6], Nnenna Ogbulafor[6], Godwin Ntadom[6]

[1]United States President's Malaria Initiative for States, Management Sciences for Health, Nasarawa, Nigeria, [2]United States President's Malaria Initiative for States, Management Sciences for Health, Plateau, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [4]Management Sciences for Health, Arlington, VA, United States, [5]United States Agency for International Development, United States President's Malaria Initiative, Abuja, Nigeria, [6]National Malaria Elimination Programme, Abuja, Nigeria

Inaccurate malaria diagnosis and treatment increase disease burden and drive potential drug resistance. In 2020, 180,394 (18%) fever cases were clinically diagnosed as malaria by assessing symptoms without a confirmatory parasitological test in four States: Benue, Nasarawa, Plateau and Zamfara. WHO recommends Rapid Diagnostic Tests (RDTs) for malaria diagnosis before treatment in areas with limited access to malaria microscopy due to their simplicity and rapid results. The U.S. President's Malaria Initiative for States (PMI-S) aims to improve malaria case management (MCM) by increasing RDT use through various interventions (training, guidelines, RDT availability and supervision). Data from health facilities' (HFs) mentoring visits at baseline (December 2020) and regular follow-up supervisory visits from August 2022 to December 2023 were analyzed. Through collaboration with the supply chain implementing partner, RDT availability increased from 45 to 512 HFs, and RDT use increased from 152 healthcare workers (HCWs) in 73 HFs to 1008 HCWs in 616 HFs. PMI-S increased the availability of MCM job aids, standard operating procedures (SOPs) and revised national guidelines from 30 HFs to 491 HFs. PMI-S advocated for and supported regular supervisory visits by trained government staff to 614 HFs. The increased use of RDTs reflects better adherence to national guidelines, which call for parasitological confirmation of malaria, and reduced clinical diagnoses, which dropped to 2% in December 2023. The availability of jobs aids, the enhanced competence in utilizing RDTs, and the continuous supervisory visits resulted in better diagnosis, and, therefore, appropriate treatment for confirmed cases.

6949

OPTIMIZING THE END OF CYCLE (EOC) REPORTING FOR SEASONAL MALARIA CHEMOPREVENTION (SMC) CAMPAIGN IN ZAMFARA STATE, NIGERIA

Dlakwa Shiwan[1], Abdulmajid Idris Safana[1], Abba Abdullahi Sagagi[1], Yusuf Na Allah Jega[1], Munira Isma'il Mustapha[1], Sherifah Ibrahim[1], Muhammad Murtala[1], Comfort Kingsley-Randa[2], Olayemi Abimbola[3], Aderonke Omokhapue[3], Arja Huestis[4], Justice Adaji[3], IniAbasi Nglass[3], Uchenna Nwokenna[3], Rudi Thetard[4], Thomas Hall[4], Aliyu Sani[5], Kabiru Mohammed Bungudu[5], Rufai Ahmad Anka[5], Grace Nwankwo[6], Erkwagh Dagba[6], Veronica Momoh[6], Jules Mihigo[6], Chukwu Okoronkwo[7], Nnenna Ogbulafor[7], Godwin Ntadom[7]

[1]United States President's Malaria Initiative for States, Management Sciences for Health, Zamfara, Nigeria, [2]United States President's Malaria Initiative for States, Management Sciences for Health, Nasarawa, Nigeria, [3]United States President's Malaria Initiative for States, Management Sciences for Health, Abuja, Nigeria, [4]Management Sciences for Health, Arlington, VA, United States, [5]State Malaria Elimination Program, Ministry of Health, Zamfara, Nigeria, [6]United States Agency for International Development, United States President's Malaria Initiative, Abuja, Nigeria, [7]National Malaria Elimination Programme, Abuja, Nigeria

Zamfara state has been implementing seasonal malaria chemoprevention (SMC) campaigns amidst security challenges which makes reporting and follow ups to facilities with data quality issues difficult, affecting the timeliness of reporting SMC data. The SMC campaign in 2023 included end of cycle (EOC) meetings, occurring 2 days after completion of each cycle of the mass drug administration (MDA). This study aims to assess the effectiveness of introducing a data aggregator system in the EOC meeting to aggregate data across 599 HFs in 14 Local Government Areas (LGAs) of Zamfara State. The Android-based tool enabled LGA data officers to validate SMC MDA data during the EOC meeting, using logical checks. The true figures were confirmed from the primary source document (tally sheet) and corrected. Validated entries were securely transmitted to the central server then exported to the backend view where the data is managed and processed. The system conducted secondary deduplication and data cleaning using unique identifiers. The non-duplicate entries were sorted and displayed on each LGA visualization accessible through a secure web interface. The system generated state and LGA aggregate preliminary reports tables and charts of children reached and treated. Compared to the 2022 cycle 1 baseline of 7% data quality issues requiring retrospective correction, all four 2023 SMC cycles achieved 0% data quality issues upon EOC submission. Reporting timeliness improved from 7 working days (2022) to just 2 days (2023) after each SMC MDA cycle. The EOC meeting approach improved data quality by creating a dedicated time and space close to the end of each SMC cycle, to validate, consolidate, and correct erroneous data discovered during data validation at the EOC meeting. Additionally, the use of an Android tool for the data validation enabled faster correction at the point of validation and reliability of SMC data, reduced security risk and travel to facility costs for correction of data and eliminated human errors typical of paper-based tools. This further exemplifies the potential for automated, real-time EOC reporting and validating tools.

IMPLEMENTATION OF AN APPROACH TO INTEGRATE COMMUNITY HEALTH INTERVENTIONS INTO COORDINATION, MONITORING AND EVALUATION AT THE HEALTH DISTRICT LEVEL IN CÔTE D'IVOIRE

Monné Thérèse Bomin Epse Bleu[1], Melly Aissatou Traore[2], Jean Louis Assa[2], Mamadou Silue[2], Ervé Marius Onané[2], Mea Antoine Tanoh[1], Collette Yah Epse Kokrasset[1], Patricia L. Yepassis-Zembrou[3], Pascal Zinzindohoue[4], Blaise Blaise Kouadio[4]

[1]Côte d'Ivoire National Malaria Control Program, Abidjan, Côte D'Ivoire, [2]Population Services International Côte d'Ivoire, Abidjan, Côte D'Ivoire,

[3]U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Abidjan, Côte d'Ivoire, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Abidjan, Côte D'Ivoire

In Côte d'Ivoire, the coordination and monitoring of community activities is mainly carried out by civil society organizations (CSOs) under contract with international NGOs. The end of these contracts usually leads to partial or total cessation of activities, and access of populations to basic health care. Since 2021, the PMI Stop Djekoidjo project has initiated an approach aimed at increasing local ownership of the coordination, monitoring and evaluation of community health worker (CHW) activities in 29 health districts. The process encompassed 1) development and validation of an operational document, 2) identifying a Community Activities Coordinator (CAC) in each district, 3) training CACs on their job description and entry of data into DHIS2, 4) support for the supervision of CHWs), and 5) organization of coordination meetings with CACs. From January 2021 to December 2023, CHWs recorded data on fever case management for children under five years of age living in communities beyond five km from a health center. Data from all CHWs in the health area were then compiled into a report and forwarded to the health district and entered DHIS2 by the CAC. Data completeness is the percentage of expected CHWs reports submitted in DHIS2.1,600 CHWs were operational during the 2021 to 2023 period. The completeness of data entered DHIS2 increased from 75.3% to 98.6% between 2021 and 2023. The number of fever cases recorded by these CHWs increased by 57.6%, from 76,269 in 2021 to 120,206 in 2023. In addition, the proportion of fever cases tested by rapid diagnostic test increased from 73% in 2021 to 89% in 2023, and positive cases treated with artemisinin-combination therapy increased from 91% in 2021 to 98% in 2023. Despite the withdrawal of CSOs, there has been a gradual increase in the volume of CHW activities between 2021 and 2023. The completeness of data and management of fever cases improved after the introduction of CACs. Thus, the approach appears to be an efficient strategy for consideration in the context of resource scarcity and sustainability of services to the communities.

6951

PROJECTING *IXODES SCAPULARIS* DENSITIES OF INFECTED NYMPHS (DIN), IN EASTERN UNITED STATES, 1997-2022

Madiha Shafquat[1], Julie Davis[2], James H. Stark[1], Patrick H. Kelly[3]

[1]Vaccines and Antivirals Medical Affairs, Pfizer US Commercial Division, Cambridge, MA, United States, [2]Life Sciences, Clarivate Analytics, Chandler, AZ, United States, [3]Vaccines and Antivirals Medical Affairs, Pfizer US Commercial Division, New York, NY, United States

Ixodes scapularis is the primary vector of *Borrelia burgdorferi* sensu lato (*Bbsl*), the causative agent of Lyme disease (LD) in the United States. Risk for LD can be partly quantified by the densities of infected *I. scapularis* nymphs (DIN), a metric of the ecological hazard across areas. We predicted DIN across parts of the Eastern US using meta-analytic models trained on published data. Two systematic literature searches were conducted in PubMed to identify studies published between 1 Jan 2000 and 23 Aug 2023 that measured density of nymphs (DON) and prevalence of *Bbsl* infection in nymphs (NIP) in the 25 states and DC categorized as high-incidence (>10 LD cases/100,000 population) or neighboring high-incidence jurisdictions in 2022 CDC surveillance data. Studies that reported county-level DIN per unit area and NIP were included. Separate multivariate, linear mixed effects models were fit for DON and NIP. Significant ($p<0.05$) model covariates included latitude and longitude, proportion of wild-urban interface, proportion of forested area, white-tailed deer density, presence of *I. scapularis,* LD incidence, and geographic division (US Census). Best fitting models were chosen via Akaike information criterion and used to predict DON and NIP across all counties in the 25 states and DC. Predicted DIN was calculated as the product of predicted DON and predicted NIP. The literature review yielded n = 934 DON observations (26 studies) and n = 845 NIP observations (57 studies). Most observations for both DON and NIP were in the Northeast and reported by two multi-year, multi-county studies. Observations for DON had wider geographic coverage (96% of jurisdictions) than observations for NIP (81% of jurisdictions). DON was predicted to be highest in parts of NY, NJ, PA, and WI and moderately high in the Mid-Atlantic and East North Central. NIP was predicted to be highest in the Northeast and parts of MN, MI, and WI. DIN was thus highest in the Mid-Atlantic. This study demonstrates the utility of existing published data on *I. scapularis* populations that can be used to inform ecological hazard of LD, but also highlights the spatial and temporal limitations of these data.

6952

A SIMPLE AND SENSITIVE COLORIMETRIC NUCLEIC ACID TEST FOR *BABESIA MICROTI* SURVEILLANCE IN WHOLE BLOOD AND TICK VECTORS

Zhiru Li, Katell Kunin, Elodie Sévère, Andy Alhassan, Nathan Tanner, Amit Sinha, Clotilde Carlow

New England Biolabs, Ipswich, MA, United States

Human babesiosis is a disease of increasing public health importance resulting from infection of red blood cells by protozoan parasites of the genus *Babesia*. The parasite is primarily transmitted to humans by *Ixodes* ticks and can also be transmitted through contaminated blood transfusion. We have developed a simple and sensitive RT-LAMP assay with colorimetric readout for the detection of *Babesia microti* targeting the 18S rRNA gene. The assay simultaneously detects both RNA and DNA and shows higher sensitivity than published qPCR assay. The assay showed no cross-amplification with DNAs from *Homo sapiens*, *Ixodes scapularis*, *Borrelia burgdorferi*, *Anaplasma phagocytophilum*, or *Plasmodium falciparum*. The visual colorimetric detection of this isothermal LAMP assay eliminates the need for sophisticated equipment. In addition, its high tolerance to inhibitors enabled us to develop a direct blood protocol without the need for nucleic acid extraction. Using this assay, we also conducted surveillance of 332 *I. scapularis* collected at Ipswich in Massachusetts (USA), and New Hampshire (USA) for *B. microti*, in parallel with LAMP-assays detecting *B. burgdorferi* and *A. phagocytophilum.* We found 18% (27 of 152) of Ipswich and 7% (13 of 180) of New Hampshire ticks positive for *B. microti*. Our results demonstrate that this simple colorimetric nucleic acid test is suitable for *Babesia microti* surveillance in whole blood and tick vectors.

6953

DISENTANGLING THE RELATIONSHIP BETWEEN THE DEER TICK MICROBIOME AND TICK-BORNE PATHOGENS

Sofia Roitman, Zhiru Li, Elodie Sévère, Cécile Hugel, Daniel Bergeron, Clotilde KS Carlow, **Amit Sinha**

New England Biolabs Inc., Ipswich, MA, United States

Tick-borne diseases are a growing threat to public health worldwide, further exacerbated by their range expansions. Aside from known pathogens, ticks also carry a wide variety of other infectious and non-infectious organisms. We aimed to catalog the full spectrum of bacteria present in deer ticks (*Ixodes scapularis*) and the effect of biotic factors such as tick sex, geographic region, and presence of known pathogens on microbiome composition. We sequenced the V4 region of the bacterial 16S rRNA gene from about 300 individual *I. scapularis* ticks from Massachusetts and New Hampshire. A total of 1.63 billion reads were obtained from runs on a Illumina NovaSeq instrument, providing a median depth of 5.6 million reads per sample. Microbiome analysis using the QIIME2 pipeline and Deblur algorithm identified a total of 24,070 bacterial Amplicon Sequence Variants (ASVs) across all samples. A rarefaction curve analysis determined that a minimum sample read count of approximately 125,000 is needed to capture the full spectrum of bacterial diversity in over 90% of our tick samples. Beta diversity analyses and significance testing across all samples indicate that the sex of the tick, geographical region, and *Borrelia burgdorferi* (Lyme disease) infection status are key drivers of tick bacterial microbiome composition. We observed previously unreported correlations between the presence of *Borrelia* and certain microbiome members, including bacteria with pathogenic potential, such as *Mycobacterium* and *Roseomonas*. The microbiome members found to be highly associated with *Borrelia* warrant further study to determine their role in disease.

6954

COINFECTION OF *ANAPLASMA PHAGOCYTOPHILUM* AND *BORRELIA BURGDORFERI* IN NON-HUMAN PRIMATES. IMPACT ON IMMUNE RESPONSE AND DISEASE SEVERITY

Folasade Adekanmbi, Monica Embers

Tulane University National Primate Center, Covington, LA, United States

Anaplasma phagocytophilum (Ap) and *Borrelia burgdorferi* (Bb), the agents of Human Granulocytic Anaplasmosis (HGA) and Lyme disease, respectively, are transmitted by *Ixodes scapularis* ticks. Coinfection has been reported in humans and animals. Ap preferentially infects the neutrophils, which are critical for clearing Bb infection. Severe Combined Immune Deficient (SCID) mice have higher Bb tissue load and pathology and are susceptible to Ap infection, which persists for several months. Nonhuman primates (NHPs) are the most relevant animal models for translational diagnostic and therapeutic intervention due to their susceptibility to both pathogens and reproduction of human disease. Our overarching goal is to study the effect of coinfection in NHPs, but we first investigated concurrent Ap/Bb infections and transmission to uninfected mice. We infected immunocompetent mice with Bb culture and Ap-Infected HL60 (human promyelocytic leukemia) cells via syringe inoculation and confirmed infection of larval ticks. Transmission of both pathogens to uninfected mice through those ticks, post-molt into nymphs, was subsequently demonstrated. We evaluated coinfection using conventional PCR by targeting the *Msp2* gene in Ap, blood smear, immunofluorescence (IFA), and cell culture for Bb. Bb was detected in the ears, heart, skeletal muscle, tibiotarsal joints, spleen, and bladder, while Ap was detected in the blood, liver, and spleen of coinfected and Ap-infected mice. We will propagate Ap in SCID mice and capillary-feed the infected blood to nymphs to generate infected ticks as well. We will use infected ticks to assess coinfection in NHPs by determining pathogen burden in blood and tissues utilizing qPCR, IFA and blood smear. Gross and histopathology, immune responses using flow cytometry, serum cytokine profiles and antibody responses will be assessed. Based on previous studies, we hypothesize that the coinfected NHPs will have a higher bacterial burden, significantly reduced immune response, and more severe tissue pathology than the single-pathogen-infected groups.

6955

HEMOPLASMA AND PIROPLASM SPECIES IN WHITE-EARED OPOSSUMS (*DIDELPHIS ALBIVENTRIS*) FROM ALAGOAS, NORTHEASTERN BRAZIL - PRELIMINARY DATA

Ana CS Silva[1], **Jessica Miller**[2], Epitácio C. Farias Junior[3], Ana CP Azevedo[4], Jonatas C. Almeida[5], Joao L. Garcia[1], Thiago F. Martins[6], Marcelo B. Labruna[6], Thallitha SWJ Vieira[2], Rafael Vieira[2]

[1]Universidade Estadual de Londrina, Londrina, Brazil, [2]The University of North Carolina at Charlotte, Charlotte, NC, United States, [3]Universidade Federal de Alagoas, Viçosa, Brazil, [4]Centro de Triagem de Animais Silvestres, Maceió, Brazil, [5]Universidade Federal de Alagoas, Maceió, Brazil, [6]Universidade de São Paulo, São Paulo, Brazil

The presence of marsupials in domestic environments is relevant for public health purposes, with species of hemotropic *Mycoplasma* (hemoplasmas, HM) and piroplasms known to infect domestic and wild animals, including *Didelphis*. This study aimed to molecularly characterize HM and piroplasm species in white-eared opossums (*Didelphis albiventris*) from transitional areas between the Atlantic Forest and Caatinga biomes in the State of Alagoas, northeastern Brazil. DNA was extracted from EDTA-blood samples from 30 (19 males and 11 females) white-eared opossums using a commercial kit. DNA samples were initially screened by a SYBR Green Universal Real-Time PCR (qPCR) targeting the 16S rRNA gene of HM. Samples were also screened by a nested-PCR (nPCR) assay targeting a fragment of the 18S rRNA gene of piroplasms. Four out of 30 (13.33%, 95% CI 5.31-29.62%) animals tested positive for HM and piroplasms, with one animal was co-infected by both agents. Hemoplasma-positive samples were subjected to conventional PCR assays targeting a fragment of the 16S rRNA (~900 bp) and 23S rRNA (800 bp) genes, followed by Sanger sequencing. Sequencing of both the 16S and 23S rRNA genes revealed that the animals were infected by '*Candidatus* Mycoplasma haemoalbiventris'. Piroplasm 18S rRNA gene sequences showed 100% identity with *Babesia* sp. from *D. albiventris* from Brasília, central-western Brazil (MW290046). Phylogenetic analyses using Bayesian inference revealed the detected *Babesia* sp. formed a polytomy with piroplasm sequences detected in marsupials from Brazil, reinforcing the existence of the piroplasmid clade "South American Marsupialia". Our future steps involve sequencing other gene fragments (*cox-1*, *cox-3*, and *hsp70*) to confirm our preliminary findings. This is the first of *Babesia* sp. in white-eared opossums from Northeastern Brazil.

6956

POTENTIALLY NOVEL *EHRLICHIA* SP. IN WHITE-EARED OPOSSUMS (*DIDELPHIS ALBIVENTRIS*) FROM ALAGOAS, NORTHEASTERN BRAZIL-PRELIMINARY DATA

Ana CS Silva[1], **Jessica Miller**[2], Epitácio C. Farias Junior[3], Ana CP Azevedo[4], Jonatas C. Almeida[3], João L. Garcia[1], Thiago F. Martins[5], Marcelo B. Labruna[5], Thállitha SWJ Vieira[2], Rafael Vieira[2]

[1]Universidade Estadual de Londrina, Londrina, Brazil, [2]The University of North Carolina at Charlotte, Charlotte, NC, United States, [3]Universidade Federal de Alagoas, Viçosa, Brazil, [4]Centro de Triagem de Animais Silvestres, Maceió, Brazil, [5]Universidade de São Paulo, São Paulo, Brazil

The genus *Didelphis*, comprising synanthropic marsupials, is known to host various vector-borne agents, including tick-borne bacteria. Here, we detected a potentially novel *Ehrlichia* spp. in white-eared opossums (*D. albiventris*) in transitional areas of the Atlantic Forest and Caatinga biomes in Alagoas, northeastern Brazil. DNA was extracted using a commercial kit from EDTA-blood samples from 30 (19 males and 11 females) white-eared opossums. DNA samples were initially screened by a nested-PCR (nPCR) assay targeting a fragment of the *dsb* gene of *Ehrlichia* sp. A total of 24/30 (80%; 95% CI: 62.69 - 90.49%) white-eared opossums tested positive for *Ehrlichia* spp. by the *dsb*-nPCR assay. After that, *Ehrlichia*-positive samples were subjected to a PCR targeting a fragment (~844 bp) of the *groEL* gene of *Ehrlichia*, followed by Sanger sequencing. Seven DNA samples were sequenced. *Ehrlichia groEL* gene sequences obtained herein showed 93.77% identity with *Ehrlichia* sp. from *Ornithodoros capensis* of birds from Japan (LC649942). Phylogenetic analyses using Bayesian inference revealed the detected *Ehrlichia* grouped in a single clade, suggesting the white-eared opossums were infected by a putative new *Ehrlichia* sp. species. A total of six/30 white-eared opossums were infested by larvae of *Ornithodoros mimon* ticks at the time of sampling. We report a potentially novel *Ehrlichia* species in white-eared opossums from Alagoas, northeastern Brazil. Our future steps involve sequencing other gene fragments (16S rRNA, *dsb*, *sodB,* and *gltA*) to confirm our preliminary findings.

HUMAN HEALTH DISPARITIES IN MITE-BORNE ILLNESSES

James H. H. Diaz

LSU Health, New Orleans, LA, United States

Mites transmit bacterial infections, such as scrub typhus and rickettsialpox, and cause chronic infestations, such as crusted and nodular scabies. Secondary infections cause impetigo, rheumatic fever, and glomerulonephritis. Mite-borne allergens cause asthma and anaphylaxis. Some populations are disproportionately affected by mite-borne illnesses. Several Internet search engines were queried to identify the most significant population-level risk factors for mite-borne illnesses. There are several human health disparities in mite-borne illnesses characterized by either reduced host immunocompetency or excessive mite exposures. Immunocompetency levels wane with advancing age, viral infections, especially HIV and HTLV-1, cancer and chemotherapy, corticosteroid and transplant antirejection therapy. Excessive mite exposure levels occur in crowded venues including shelters for refugees, evacuees, and the homeless, chronic care institutions, sexually transmitted disease clinics,

animal shelters and veterinary clinics, and food and fruit-processing workplaces. Some populations may be uniquely predisposed to crusted scabies and secondary infections including patients with Down syndrome, other cognitive disabilities, Australian Aborigines, and the indigenous inhabitants of the Fijian, Samoan, and Solomon islands in the South Pacific. Others may be exposed to animal scabies or plant, insect, and foodborne mite infestations in their workplaces. Targeted interventions to control and prevent mite-borne illnesses should be directed at these neglected populations and excessive exposure groups worldwide.

A NEW MULTIPLEX SEROLOGIC ASSAY FOR DETECTION OF *BARTONELLA* SPECIES IN IRAQ DEPLOYED MILITARY WORKING DOGS

Fernanda Fortes de Araujo[1], Jennifer Safko[1], Jessica Bolton[2], Heather Richardson[3], Le Jiang[4], Sarah Jenkins[4], Edward Breitschwerdt[5], Elke BergmannLeitner[2], Naomi Aronson[1]

[1]Uniformed Services University, Bethesda, MD, United States, [2]Walter Reed Army Institute of Research, Silver Spring, MD, United States, [3]DoD Food Analysis and Diagnostic Laboratory, San Antonio, TX, United States, [4]Naval Medical Research Command, Silver Spring, MD, United States, [5]North Carolina State University, Raleigh, NC, United States

Bartonella species seroprevalence was 47.4% in feral dogs in Iraq; blood collected by the U.S. Army Zoonotic Disease Surveillance Program in 2008-9. *Candidatus* Bartonella merieuxii *(C*bm*)* DNA, an uncultured *Bartonella* species, was amplified from 37% of Iraq feral dogs` blood. The objectives of this surveillance study were 1) to define the prevalence of bartonellosis in military working dogs (MWDs) that had deployed to Iraq, 2) to report the species profile. Medical records and paired sera/whole blood samples were obtained from pre and post Iraq deployment for 104 MWDs. Conventional diagnostic testing for *Bartonella* species was performed including Indirect Immunofluorescence Assay (IFA) for *B. bovis, B. henselae, B. koehlerae* and *B. vinsonii berkhoffii* with ≥ 1:64 considered seroreactive. *Bartonella* genus *rpoB* gene qPCR assay was conducted using whole blood DNA, with amplicon sequences compared to GenBank by BLAST analysis. Fifty paired sera were evaluated by Mesoscale/MSD V-PLEX™ platform using a new 10-plex assay with a total of 20 peptides representing B cell linear epitopes predicted by the Bepipred algorithm (Immune Epitope Database iedb.org). The studied population (n=104 MWDs) showed no significant clinical differences in those testing positively for *Bartonella* acquired in Iraq except for a decrease in white blood cells, *p=0.032*. Twelve dogs (12%) were IFA seroreactive for any *Bartonella* spp. including four dogs (4%) IFA seroreactive to the *C*Bm surrogate (*B. bovis)* with titers 1:128 or 1:1024. *Bartonella* genus-specific qPCR assay identified Iraq-related infection of one (1%) MWD with sequencing of *rpoB* gene determined to be *C*Bm with 99.9% sequence homology. In the new Mesoscale assay 15 MWDs (30%) showed statistical differences between pre and post deployment sera (p<0.001), suggesting seroconversion during deployment (luminescence signal post/pre >2). In conclusion, MWDs acquired novel *Bartonella* spp. infections during deployment in Iraq and our newly developed MSD assay can serve as a new diagnostic tool providing an alternative high-throughput assay.

6959

SEVERE TICK-BORNE DISEASE IN NORTH CAROLINA, A TEN-YEAR REVIEW OF HOSPITALIZED CASES

Diana L. Zychowski, Ross Boyce

University of North Carolina, Chapel Hill, NC, United States

Tick-borne diseases such as spotted fever group rickettsiosis (SFGR) and ehrlichiosis are a growing public health concern in the United States. Clinical manifestations are non-specific and include fever, arthralgia, diarrhea, headache, and rash. Delays in treatment are strongly associated with morbidity and death. Yet other demographic and clinical risk factors associated with severe disease remain poorly described. Utilizing a retrospective cross-sectional design, we performed a 10-year review of ehrlichiosis and SFGR cases admitted to the University of North Carolina health system from 2014 to 2024 to identify factors associated with severe disease. A total of 242 admissions from 239 unique individuals with a diagnosis of ehrlichiosis (N=30), SFGR (N=204), or both (N=8) were included in this study. The median age was 55 years (IQR 37-67), with most participants identifying as white (186, 76.9%), non-Hispanic (221, 91.3%), and male (161, 66.5%). Over 88% (N=214) of cases occurred between April and October. Twenty-two percent (N=55) had some form of immunocompromise including asplenia, bone marrow or solid organ transplant, cancer, chronic dialysis, neutropenia, or human immunodeficiency virus. Nearly 15% (N=35) were admitted to the ICU, with 27/35 (77%) having SFGR. Approximately 10% (N=24) required mechanical ventilation. The average number of days from admission to doxycycline administration was 2.2, though the use of doxycycline was not significantly higher among patients requiring ICU care (OR 0.8, 95% CI: 0.3-1.9). Risk factors for ICU admission included underlying pre-existing cardiovascular disease (OR 4.4, 95% CI: 2.1-9.2), diabetes mellitus (OR 2.1, 95% CI: 1.0-4.4), and male sex (OR 2.7, 95% CI: 1.1-6.9). However, older age (e.g. >65 years) and immunocompromised status were not statistically associated with ICU care. Our results show that diabetes and cardiovascular disease may be risk factors for severe
ehrlichiosis or SFGR and there should be a low threshold to administer doxycycline in these high-risk groups when consistent symptoms, laboratory abnormalities and/or exposures are present.

6960

MINIMUM FEEDING TIME REQUIRED FOR *HAEMAPHYSALIS LONGICORNIS* TO TRANSMIT SEVERE FEVER WITH THROMBOCYTOPENIA SYNDROME VIRUS

Bailey J. Hettinger, Eliane Esteves, Clemence Obellianne, Ahmed Garba, Meghan E. Hermance

University of South Alabama Frederick P. Whiddon College of Medicine, Mobile, AL, United States

Severe Fever with Thrombocytopenia Syndrome Virus (SFTSV) is an emerging tick-borne bandavirus that can cause disease in humans with a 6-30% mortality rate. The major tick vector of SFTSV is *Haemaphysalis longicornis*, which is native to eastern Asia but recently emerged in the United States. Emerging viruses and invasive tick species highlight the importance of understanding how a virus such as SFTSV associates with and is transmitted by its tick vector. A notable factor in this tick-pathogen association is the minimum tick attachment time required for the tick to successfully transmit a pathogen during feeding. This transmission time is understood for some bacteria but for many tick-borne viruses, including SFTSV, this tick-to-host transmission time is unknown. The objective of this study is to define the minimum feeding time required for *H. longicornis* nymphs to transmit SFTSV to a vertebrate host. Nymphs were infected with SFTSV by transovarial transmission to generate a population of infected ticks to be used in the tick-to-host transmission time experiments. In a pilot study, mice were each infested with 8 - 10 putatively infected nymphs that were allowed to feed for 5 hours. At the 5 hour post-attachment (h.p.a.) timepoint, nymphs were manually removed from mice and screened via q-RT-PCR for SFTSV RNA. Samples of mouse blood and skin biopsies (proximal and distal to the tick feeding site) were also collected at 5 h.p.a. and screened for viral RNA. SFTSV RNA was detected in the proximal skin biopsies from several mice. These preliminary results suggest that after feeding for 5 hours, SFTSV-infected *H. longicornis* nymphs were able to transmit SFTSV to mice; however, detection of infectious virus in the vertebrate host still needs to be assessed. Follow-up studies will assess tick feeding timepoints less than 5 hours. Methods to pre-screen putatively infected nymphs for SFTSV before they are included in the transmission experiment are also being optimized. In upcoming tick-to-host transmission time experiments, this optimized model system will be used to define the minimum feeding time required for *H. longicornis* nymphs to transmit SFTSV to a host.

6961

INVESTIGATION INTO THE BACTERIOME OF TICKS COLLECTED FROM NINE KENYAN COUNTIES.

Bryson B. Kimemia[1], Lillian Musila[1], Solomon K. Langat[2], Erick Odoyo[1], Stephanie Cinkovich[3], Samoel A. Khamadi[2], Jaree Johnson[4], Elly H. Ojwang[5], Timothy E. Egbo[5], Eric C. Garges[5], Fredrick L. Eyase[1]

[1]Walter Reed Army Institute of Research-Africa (WRAIR-Africa)/Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [2]Centre for Virus Research, Kenya Medical Research Institute (KEMRI), Nairobi, Kenya, [3]United States Armed Forces Health Surveillance Division, Global Emerging Infections Surveillance Branch, Silver Springs, MD, United States, [4]United States Armed Forces Pest Management Board, Silver Springs, MD, United States, [5]Walter Reed Army Institute of Research-Africa (WRAIR-Africa), Kisumu, Kenya

Vector surveillance has become a very important component in public health preparedness. Continuous and rigorous screening of vectors such as ticks allows for up-to-date pathogen situational awareness. This study sought to enhance the knowledge of bacterial pathogens circulating in ticks from Kenya by sampling and screening ticks from nine counties representing major regions in the Country. These are representative of the North-eastern, Coastal, Western, and the Rift Valley region. These were selected to represent a wide variety of climatic and socio-economic zones thus generating a clearer picture of the situation in the country. 16S rRNA metagenomic sequencing on the MinION (Oxford Nanopore Technologies) platform was used to screen the ticks. Bioinformatics analysis involved base-calling, adapter trimming and demultiplexing using Dorado, quality trimming and filtering using Trimmomatic, deduplication, chimaera filtering and OTU clustering using QIIME2-VSearch. Taxonomic classification of the representative sequences was done using a Bayes classifier that was trained on 16S rRNA sequence data from the SILVA 138 database. 1,562 ticks were collected, surface sterilized and pooled into 251 pools with an average of 6 ticks per pool. The ticks collected belonged to 3 genera and 14 species. 237 bacterial species were identified in the ticks and of these, 78 species were identified as pathogens and opportunistic pathogens. The top 5 pathogens with the highest Minimum Infectivity Rate (M.I.R) were *Staphylococcus pseudintermedius* (6.91%), *Staphylococcus aureus* (6.85%), *Rickettsia africae* (3.65%), *Coxiella burnetii* (3.59%) and *Rickettsia japonica* (3.20%). The diverse nature of bacteria identified both pathogens and non-pathogens is proof that ticks are complex arthropod vectors that offer a rich source of emerging and re-emerging infectious diseases. Further investigation needs to be done to determine which of these pathogens are viable and subsequently transmissible. This study greatly contributes to public health awareness within the country.

6962

HOUSEHOLD INSECTICIDE USE AND REAT FLEA RESISTANCE IN MADAGASCAR: IMPLICATIONS FOR PUBLIC HEALTH

Adélaïde Miarinjara[1], Annick Onimalala Raveloson[2], Mireille Harimalala[3], Beza Ramasindrazana[3], Diego Ayala[3], Thomas Gillespie[1]

[1]Emory University, Atlanta, GA, United States, [2]Institut Pasteur de Madagascar. Ecole doctorale Sciences de la Vie et de l'Environnement, Université d'Antananarivo, Antananarivo, Madagascar, [3]Institut Pasteur de Madagascar, Antananarivo, Madagascar

In Madagascar where bubonic plague, a flea-borne disease, is endemic, there is a gap in knowledge regarding household pest control that may impact health and insecticide resistance in vectors. In this study, we investigated 254 households distributed in seven villages within three districts in plague-endemic areas of Madagascar to understand the pattern of insecticide use in homes and to assess rat flea (*Xenopsylla cheopis*) susceptibility to insecticides. Here we present the results from household surveys and insecticide bioassays. We found that insecticide was the most common means for domestic pest control for 91.66 % of respondents, primarily targeting the house flea (80.11%). Most applied liquid formulations (78.41%),and 62.50% used insecticides without dilution. Bedrooms (90.90%) and floors (89.78%) were primarily treated. Only 46.02% of respondents were satisfied with the treatment results. Products were bought from outdoor market vendors (38.64%) or agricultural stores (31.25%). Retailer advice (55.68%) and neighbors' opinions (21.02%) guided insecticide selection. Retailers provided most (84.65%) information on insecticide usage. Yet, 39.54% of respondents could not recall the commercial name of the insecticide used, given that only 26.13% bought labeled products. Laboratory insecticide bioassay revealed widespread resistance to DDT (mortality rate, MR: 0 - 7.50%) and deltamethrin (MR: 0 - 42.50%) among rat fleas from these villages. Flea populations were tolerant (MR: 82.8 - 95.10%) and susceptible (MR: 97.60 -100%) to fenitrothion, with only fleas from one village showing resistance (MR: 45%). The significant reliance on insecticide to control household pests and limited product knowledge pose a risk for health and may contribute to the development of resistance in non-target insects such as the plague vector, *X. cheopis.* Our findings suggest that interventions focused on retailers (i.e., education, incentives) would equip households with accurate pesticide knowledge. Addressing these challenges is imperative for safeguarding public health and mitigating insecticide resistance.

6963

*COXIELLA BURNETII*I N RUMINANTSAND DONKEYS *(EQUUS ASINUS)* FROM SOMALIA

Aamir M. Osman[1], Caroline T. Secato[2], Igor S. Silito[3], Ahmed A. Hassan-Kadle[4], Mohamed A. Shair[4], Abdalla M. Ibrahim[5], Maria CA Serpa[3], Marcos R. André[2], Thallitha SWJ Vieira[6], Marcelo B. Labruna[3], Rosangela Z. Machado[2], **Rafael FC Vieira**[6]

[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Universidade Estadual Paulista, Jaboticabal, Brazil, [3]Universidade de São Paulo, São Paulo, Brazil, [4]Abrar University, Mogadishu, Somalia, [5]Abrar University, Mogadishu, Brazil, [6]The University of North Carolina at Charlotte, Charlotte, NC, United States

Coxiella burnetii, a zoonotic obligate intracellular bacterium that causes Q fever in humans and coxiellosis in ruminants, may pose significant economic losses and health risks. Understanding its epidemiology is paramount for implementing effective control measures. Our study investigated the presence of *C. burnetii* in ruminants and donkeys in Somalia using serological and molecular techniques. Serum samples from 402 animals (190 goats, 133 cattle, 49 sheep, and 30 donkeys) in the Benadir and Lower Shabelle Regions of Somalia underwent testing using the Indirect Fluorescent Antibody Test (IFAT) against *C. burnetii* strain At12. IgG titers for each *C. burnetii* antigen were determined by diluting the samples in two-fold increments with phosphate-buffered saline (PBS), starting at a 1:64 dilution. DNA was extracted from EDTA-blood samples (199 goat, 131 cattle, and 45 sheep) and screened using a qPCR assay based on the repetitive element IS1111 for *C. burnetii.* A total of 53**/**402 (13.2%) animals (endpoint titer: 64 – 8.192) showed antibodies reactive to *C. burnetii.* Donkeys exhibited seroreactivity 6/30 (20%) (endpoint titer: 64 – 512), goats 40/190 (21.1%) (endpoint titer: 64 – 2.048), and sheep 7/49 (14.3%) (endpoint titer: 64 – 8.192), while cattle showed negative results. Two goats tested qPCR-positive for *C. burnetti*. All other animals tested qPCR-negative. This study confirms the presence of anti-*C. burnetii* antibodies in Somali livestock (goats, sheep, and donkeys). Our data highlighting its potential impact on animal and public health through zoonotic transmission. Further investigation into the epidemiology of *C. burnetii* in Somalia and the development of targeted control measures are needed.

6964

SEROPREVALENCE OF *RICKETTSIA* SPP. IN CATTLE, SHEEP, GOATS AND DONKEYS (*EQUUS ASINUS*) FROM SOMALIA

Aamir M. Osman[1], Igor S. Silito[2], Ahmed A. Hassan-Kadle[3], Mohamed A. Shair[3], Abdalla M. Ibrahim[3], Maria CA Serpa[2], Thallitha SWJ Vieira[4], Marcelo B. Labruna[2], **Rafael Vieira**[4]

[1]Universidade Federal do Paraná, Curitiba, Brazil, [2]Universidade de São Paulo, São Paulo, Brazil, [3]Abrar University, Mogadishu, Somalia, [4]The University of North Carolina at Charlotte, Charlotte, NC, United States

Rickettsia spp. are gram-negative obligate intracellular bacteria, with *Rickettsia africae* being transmitted by *Amblyomma* ticks and posing a zoonotic risk, notably causing African tick bite fever (ATBF). Livestock and donkeys (*Equus asinus*) play vital roles in Somalia's economy, facing tick-borne disease risks. Our study investigates rickettsial exposure in livestock and donkeys across two bioclimatic regions in the country. A cross-sectional study collected 402 (190 goats, 133 cattle, 49 sheep, and 30 donkeys) serum samples from Benadir and Lower Shabelle regions of Somalia. Immunofluorescence assays (IFA) were conducted using crude antigens of *R. africae* and *R. rhipicephali*. Sera were diluted in two-fold increments with phosphate-buffered saline (PBS) starting at a 1:64 dilution, and endpoint IgG titers for each *Rickettsia* antigen were determined. A total of 212/402 (52.7%) (endpoint titer: 64–2.048) samples were seropositive for *Rickettsia* spp. *R. africae* was predominant in 20.9% of cases, while *R. rhipicephali* was detected in 9.9%. Co-reactivity was observed in 21.9 percent of the samples. Cattle showed the highest seroreactivity at 90.2%, primarily with *R. africae* (50.4%), followed by goats at 27.4%, primarily with *R. rhipicephali* (18.9%), and sheep at 28.6%, mainly with *R. africae* (18.4%). Donkeys showed 83.3% seroreactivity, mainly to *R. africae* (23.3%). Co-reactivity was prevalent across species. Cattle, donkeys, and sheep were more likely to be seroreactive to *Rickettsia* spp. than goats (OR: 24.5, 13.2, and 1.1, respectively). This study reveals the first serological evidence of *Rickettsia* sp. in Somali ruminants and donkeys, emphasizing the importance of investigating tick-borne diseases within the One Health framework.

6965

ELUCIDATING THE TICK MICROBIAL PROFILE IN DISTINCT ECOLOGICAL REGIONS OF EAST AFRICA

Victor O. Anyango[1], Aool W. Opiyo[1], Lukindu, M[2], Paula Lado[3], Cohnstaedt, L. W[3], Hensley L. E[3], Corey Brelsfoard[1], Maria G. Onyango[1]

[1]Texas Tech University, Lubbock, TX, United States, [2]Uganda Virus Research Institute, Entebbe, Uganda, [3]National Bio and Agro-Defense Facility-USDA, Manhattan, KS, United States

In Africa, where pastoralism is pivotal in the economy, the interaction between ticks and humans may be more significant than initially perceived. Pastoralism contributes to the stability of many African economies, accounting for a significant portion of the Gross Domestic Product (GDP) in countries where it is practiced. These regions are crucial economic hubs and are home to a significant portion of the country's livestock and wildlife. One of the key challenges and threats faced by these pastoralist communities is the increasing risk of animal and zoonotic diseases. This risk poses a significant danger to both the livelihoods of pastoralists as well as their health. To identify habitats with increased transmission of tick pathogens in East Africa, we sampled ticks in six districts of Uganda and four Kenyan counties in high-intense pastoralist farming regions with distinct ecology. We carried out an Illumina sequencing of tick singletons in the 16S V3-V4 hypervariable rRNA region. The microbial abundance and diversity were assessed. Our findings identified diverse microbes of significant public health concern circulating in ticks collected from the East African region. These microbes were not geographically clustered in unique regions but were identified across the different ecological regions. Our findings demonstrate a high incidence of tick-borne pathogens in the East African pastoralist zones. The factors driving tick-borne pathogen transmission in different habitats of East Africa are not well understood. There is a need to better define these factors to prevent tick-borne pathogen epidemics in Africa and global spillover.

6966

EFFICACY OF TWO DOSES OF IVERMECTIN TABLET IN TREATMENT OF SCABIES IN COMPARISON TO ONCE APPLICATION OF 5% PERMETHRIN LOTION- A RANDOMIZED CONTROLLED TRIAL

Priyamadhaba Behera, Debkumar Pal, Chandra Sekhar Sirka, Binod Kumar Patro

All India Institute of Medical Sciences, Bhubaneswar, Bhubaneswar, India

Scabies may cause community outbreaks without early diagnosis and appropriate treatment. Oral ivermectin offsets some challenges associated with topical permethrin 5% application for treating scabies. We aimed to evaluate the efficacy of two doses of oral ivermectin [200 microgram/kg] on day one and day seven compared to 5% [weight/volume] once whole-body application of permethrin lotion in treating scabies. We recruited one hundred participants with mild or moderate scabies and randomized into ivermectin and permethrin arms using computer-generated sequences. Participants and their contacts in the ivermectin arm received two doses of ivermectin [200 micrograms per kg] on days one and seven. The participants and their contacts in the permethrin arm received treatment with 5% [w/v] permethrin application over the whole body. The participants were followed up after four to six weeks of the intervention to determine the cure rate. Institutional ethics approval was obatined from Institutional Ethics Committee of All India Institute of Medical Sciences, Bhubaneswar [IEC reference number: T/IM-NF/CM&FM/21/149]. The trial was registered in ctri.nic.in (CTRI/2022/03/040762) prospectively. We got a similar cure rate (100%) in both arms for the patients after one dose of whole-body application of permethrin or two appropriate doses of ivermectin among mild to moderate cases of scabies. The cost was lower in the ivermectin arm than in the permethrin arm. The cure rate of scabies with one local application of 5% permethrin lotion and two doses of oral ivermectin tablets is similar. Ivermectin has an added advantage regarding lower cost and convenience in its usage.

6967

CORRECT KNOWLEDGE, ATTITUDES, AND CONFIDENCE FOR APPROACHING RICKETTSIOSIS IN A SAMPLE OF MEDICAL STUDENTS IN CLINICAL SCIENCES FROM ENDEMIC AND NON-ENDEMIC REGIONS OF MEXICO

Karla Dzul-Rosado[1], Luis R. Alvarez-Martin[2], Yuliana V Priego Escamilla[2], Kyra Argaez-Ojeda[2], Juan J. Arias-Leon[3], Fernando Puerto-Manzano[4], **Osvaldo Huchim**[5], Baldomero Sanchez-Barragan[6], Luis Emilio Ramon-Garcia[1], Hamid A. Cervantes-Marin[5], Nina Mendez-Dominguez[2]

[1]Centro de Investigaciones Regionales Dr. Hideyo Noguchi. Universidad Autónoma de Yucatan, MERIDA, Mexico, [2]Hospital Regional de Alta Especialidad de la Peninsula de Yucatan, MERIDA, Mexico, [3]Facultad de Medicina. Universidad Autónoma de Yucatan, MERIDA, Mexico, [4]Hospital Regional de Alta Especialidad de la Península de Yucatan IMSS-BIENESTAR, MERIDA, Mexico, [5]Universidad Anahuac, MERIDA, Mexico, [6]Universidad Juarez Autonoma de Tabasco, MERIDA, Mexico

Medical diagnosis is commonly guided by clinical and epidemiological evidence and experience. Anamnesis is fundamental to identifying causes and risks for Rickettsiosis. Ticks, mosquitoes, and other vectors may coexist in undeserved regions, and they may relate to unspecific signs and symptoms. Medical education programs vary across Mexico Objective: We aimed at evaluating differences in knowledge about preventing and diagnosing rickettsiosis, personal experience when assisting patients with probable diagnosis and the confidence they self-identify for accurately establishing a diagnosis of rickettsiosis among medical students from endemic and non-endemic regions. In this cross-sectional study, 144 medical students from seven universities. Were invited to participate by responding a 30-item questionnaire. Sample size was obtained for

two-proportion comparison with 95% confidence, p<0.05, considering a difference of 25% between endemic or non-endemic regions. From 144 participants, 50% male, aged 24.2 years, 46.5 were from non-endemic regions, while 53.4% from endemic regions. Students from endemic regions had more knowledge about the vector, transmission, prevention, and risks for rickettsial infections (64% more); 85% of non-endemic region identified differential diagnoses, compared to 100% residing in endemic regions. In regression analysis, those from endemic regions were more likely to correctly consider rickettsiosis (OR:1.34) in differential diagnosis, to revise specific protocols and guidelines (OR:2.74), were more confident of their diagnostic capacity (OR:1.49), more prone to consider themselves as well trained (20.77) and to indicate appropriately the clinical tests (OR:1.34). Rickettsiosis diagnosis is part of general physicians every day's activities. Knowledge is fundamental for medical students from endemic and non-endemic regions of Mexico, even when experience with rickettsioses may depend on the epidemiology of the region.

6968

EXPLORING TICK VECTOR DYNAMICS IN CRIMEAN-CONGO HEMORRHAGIC FEVER OUTBREAK ZONES OF EAST AFRICA

Winnifred Opio Aool[1], Victor O. Anyango[1], Martin Lukindu[2], Paula Lado[3], Cohnstaedt, W. Lee[4], Lisa Hensley[4], Corey Brelsfoard[1], Maria G. Onyango[1]

[1]Texas Tech University, Lubbock, Tx, United States, [2]Uganda Virus Research Institute, Entebbe, Uganda, [3]National Bio And Agro-Defense Facility-USDA, Manhattan, KS, United States, [4]National Bio and Agro-Defense Facility-USDA, Manhatan, KS, United States

Crimean-Congo hemorrhagic fever virus (CCHFV), a member of the Nairoviridae family and Orthonairovirus genus, is a tick borne, negative-sense RNA virus that causes Crimean-Congo hemorrhagic fever (CCHF). This disease, characterized by a severe course, has a case fatality rate of 30% or more. The primary vector for CCHFV is recognized as *Hyalomma marginatum*, and its presence has been closely linked to outbreaks of human disease. In East Africa, Uganda has faced several CCHF outbreaks since 2013, while Western Kenya documented just one case in October 2000. Interestingly, Central and Western Uganda, where most CCHFV cases occurred previously, show very low environmental suitability for *Hyalomma* species. To deepen our understanding of tick species distribution in CCHF high-risk zones across East Africa and the prevalence of CCHFV infection, we conducted field surveys in six districts in Uganda's high-risk regions and four counties in Kenya's intensive pastoralist farming areas. The findings revealed significant variations in tick species diversity and distribution between and within Kenya and Uganda, with minimal overlap. Surprisingly, no *Hyalomma* species were found in Central Uganda's CCHF high-risk zone, whereas the arid North of Kenya was predominantly (over 60%) populated by this species. In Uganda, *Rhipicephalus appendiculatus* emerged as the most prevalent tick species, constituting 62% of the total collection. We successfully isolated CCHFV from pools of *Rh. appendiculatus* collected from Uganda's CCHF high-risk region. These results suggest that CCHF epidemiology in Uganda may be regionally specific and that *Hyalomma* species might not be the primary vector driving CCHFV transmission in all areas. The absence of the main host species in Uganda's high-risk region may indicate a regional variation in CCHFV's host. These findings provide significant implications for tick and CCHFV control strategies in East Africa.

6969

A DETAILED CHARACTERIZATION OF *RICKETTSIA BELLII* ECOLOGY AND HOST INTERACTIONS

Jaylon Vaughn, Samniqueka Halsey, Deborah Anderson

University of Missouri, Columbia, MO, United States

Vector-borne diseases are a group of ailments transmitted through an arthropod host. One genus of bacteria that falls into this group is *Rickettsia. Rickettsia* are obligate intracellular bacteria that are transmitted to vertebrate hosts through different vectors, specifically ticks, fleas, and human lice. These bacteria present a wide range of phenotypes with some being of medical importance, such as *R. felis,* and others being nonvirulent, such as *R. bellii.* These nonvirulent species often serve as endosymbionts within ticks, bringing on a positive impact on feeding and reproduction. As vector-borne diseases continue to become a growing concern, methods of control are of the utmost urgency. Eliminating vital endosymbiotic species in the tick microbiome has been a discussed method to reduce current tick population size and reproductive capability. *R. bellii* is common throughout the Americas within ticks of multiple genera in their microbiome but its role in tick physiology and immune response to pathogenic *Rickettsia* are not known. The prevalence of other rickettsial agents and the downstream effects of removing them from ticks has been examined yet *R. bellii* has been neglected. Although they share similar genomes, this need of *R. bellii* characterization has not been met. Our long-term goal is to establish the importance of *R. bellii* in influencing the transmission of pathogenic *Rickettsia*. In this study, we examine the presence of *R. bellii* and other endosymbionts within field caught ticks, commenting on their infection rate in ticks. Preliminary data with field-caught *A. amblyomma* ticks in Central Missouri has identified high prevalence of endosymbiont *Rickettisa*, where it appears to dominate the ticks' microbiome. Towards understanding how this may impact the host response, we are characterizing transcriptional and cellular responses to *R. bellii* in vitro. Laboratory studies have highlighted an increase of cytotoxic activity over time, reaching 50% by day 4 post infection. This work will bridge missing gaps in the literature surrounding *R. bellii* while illuminating the role of endosymbiotic bacteria vector-borne diseases control.

Insecticide-based vector control tools have been crucial in reducing malaria. However, the emergence of insecticide resistance (IR) in malaria vectors is seriously hampering their effectiveness. To address this challenge, National Malaria Control Programs (NMCPs) must apply evidence-based resistance management strategies along with the WHO recommendations for routine genetic monitoring of IR. As such, our study investigated how two genes, *Cytochrome 6P4a* and *Cytochrome 6P4b,* contribute to IR in the major malaria vector *Anopheles funestus*. We used population genetics, molecular biology, *in vitro* insecticide depletion assays, and generation of transgenic Drosophila flies exposed to insecticides to establish the impact of mutations and overexpression of the genes on the resistance phenotype. We further designed two field-deployable diagnostic tools to detect and monitor IR. Our population genetics studies unveiled the striking selection of two mutant gene variants in Ghana between 2014 and 2021. These mutants exhibited a 3-fold greater capacity to deplete pyrethroid insecticides compared to the wild types. Also, overexpression of the mutant alleles in the transgenic flies resulted in significantly higher insecticide resistance compared to the wild-type flies (mortality <50% vs. >80%, respectively), confirming the role of *6P4a* and *6P4b* in causing IR. In addition, using our designed diagnostic tools, a strong association was established between carrying the mutant alleles and the inefficacy of bed nets, where mosquitoes

carrying the mutant alleles resisted exposure to insecticide-treated bed nets like OLYSET® and DURANET® than non-mutants, -hence increased mosquito life-span which leads to higher malaria transmission rates. We also confirmed that the mutations are predominantly found in the West African region. Overall, our study established that *CYP6P4a* and *CYP6P4*b confer highly escalated insecticide resistance in the major malaria vector *An. funestus* and provides two field-applicable resistance diagnostic tools with significant implications for NMCP implementation of vector control strategies in Africa.

6971

INSECTICIDE RESISTANCE STATUS AND HIGH *KDR* FREQUENCY IN *AEDES AEGYPTI* IN A DENGUE ENDEMIC CITY OF HONDURAS

Denis Gustavo Escobar[1], Cindy Reyes-Perdomo[1], Luis Galo[1], Oscar Urrutia[2], Lucrecia Vizcaino[3], Audrey Lenhart[3], Gustavo Fontecha[1]

[1]Instituto de Investigaciones en Microbiología-Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, [2]Secretaria de Salud Honduras, Tegucigalpa, Honduras, [3]Entomology Branch, Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Several arboviruses are transmitted to humans through bites from infected *Ae. aegypti*, and insecticide-based interventions are the main strategy for outbreak control. In Honduras, cyclic arbovirus epidemics have led to the intensive use of pyrethroids, leading to the emergence of insecticide resistance. So far, limited data are available about the participation of resistance mechanisms in *Ae. aegypti* in Honduras. Here, we aimed to conduct a phenotypic assessment of insecticide resistance and detect *kdr* alleles in *Ae. aegypti* from the Central District of Honduras. Between May-June 2023, *Ae. aegypti* larvae were collected in 4 localities: Loarque (LO), La Concordia (LC), Rio Abajo (RA) and Altos de Villa Vieja (AV) and reared until F1 as adults for bioassays. Susceptibility bioassays were carried out using the diagnostic doses of deltamethrin, permethrin, malathion and bendiocarb. AS-PCR was employed to detect *kdr* alleles at the 1534 and 1016 positions in mosquitoes randomly selected from each population and phenotype, and allele frequencies were calculated. A total of 1,592 *Ae. aegypti* were bioassayed. Mortality rates for deltamethrin ranged between 86 and 100%, with LC population showing the lowest mortality. For permethrin, the mortality ranged between 1 and 48%, with LC exhibiting the lowest mortality and RA the highest. Similarly, all populations showed malathion resistance, with mortalities between 24 and 74%. All populations were susceptible to bendiocarb. Screening of 275 individuals revealed the presence of *kdr* genotypes at both loci. The allele frequencies for F1534C and V1016I were 1.0 and 0.89, respectively. It is noteworthy that the frequency of the V1016I mutation showed variability between locations. Only the phenotypically resistant mosquitoes to deltamethrin and permethrin, from LC and LO, showed a frequency of 1.0 for the mutant genotype, while the others ranged from 0.48 to 0.97. These findings reveal resistance in *Ae. aegypti* to the pyrethroids used for vector control in Honduras, and resistance to malathion. Additionally, *kdr* alleles were present at high frequencies and were associated with phenotypic resistance.

6972

RELATIONSHIPS BETWEEN BIOLOGICAL AGE, DISTANCE FROM AQUATIC HABITATS, AND PYRETHROID RESISTANCE STATUS OF *ANOPHELES FUNESTUS* MOSQUITOES IN SOUTH-EASTERN TANZANIA

Polius G. Polius

Ifakara Health Institute, Morogoro, Tanzania, United Republic of

Malaria transmission can be highly heterogeneous between and within localities and is influenced by factors such as the survival and biting frequencies of *Anopheles* mosquitoes. This study investigated the relationships between the biological age, distance from aquatic habitats, and pyrethroid resistance status of *Anopheles funestus* mosquitoes, which currently dominate malaria transmission in south-east Tanzania. Female *An. funestus* were collected in houses located 50-100 m, 150-200 m, or over 200 m from the nearest known aquatic habitats. The mosquitoes were exposed to 1×, 5× and 10× the diagnostic doses of pyrethroid (deltamethrin or permethrin), or the synergist, piperonyl butoxide (PBO) followed by the pyrethroids, then monitored for 24 h-mortality. Ovaries of exposed and non-exposed mosquitoes were dissected to assess parity as a proxy for biological age. Adults emerging from larval collections in the same villages were tested against the same insecticides at 3-5, 8-11, or 17-20 days old. Mosquitoes collected nearest to the aquatic habitats (50-100 m) had the lowest mortalities compared to other distances, with a maximum of 51% mortality at 10× permethrin. For the age-synchronized mosquitoes collected as larvae, the insecticide-induced mortality assessed at both the diagnostic and multiplicative doses (1×, 5×, and 10×) increased with mosquito age. The highest mortalities at 1× doses were observed among the oldest mosquitoes (17-20 days). Pre-exposure to PBO increased the potency of both pyrethroids. The proportion of parous females was highest among mosquitoes collected furthest from the habitats. Older An. funestus near the center of the village are more susceptible to pyrethroids than those at the edge of the village. Pyrethroid-based interventions may remain at least moderately effective despite widespread pyrethroid-resistance, by killing the older, less-resistant, and potentially-infective mosquitoes.

6973

HOUSEHOLD RISK FACTORS ASSOCIATED WITH INCREASED MOSQUITO DENSITIES AND INSECTICIDE RESISTANCE PROFILES OF MAIN MALARIA VECTORS IN KWALE COUNTY, COASTAL KENYA

Miguel G. Okoko[1], Caroline W. Kiuru[2], Jonathan M. Karisa[3], Rehema G. Gona[1], Tobias T. Odongo[1], Bruno O. Otieno[1], Festus Y. Yaa[1], Faiz M. Shee[4], Caroline K. Wanjiku[3], Joseph Mwangangi[5], Carlos C. Chaccour[2], Marta F. Maia[6]

[1]Kenya Medical Research Institute- Center for Vector Disease Control, Kwale, Kenya, [2]Barcelona Institute of Global Health Spain, Barcelona, Spain, [3]KEMRI Wellcome- Trust Research Programme Kilifi, Kenya, Kilifi, Kenya, [4]Pwani University, Kilifi, Kenya, [5]Kenya Medical Research Institute-Center for Geographical Medicine Research, Kilifi, Kenya, [6]University of Oxford, Center for Global Health and Tropical Medicine, Oxford, UK, UK, United Kingdom

The spread of insecticide resistance threatens the efficacy of current malaria control programs which rely heavily on insecticide-based vector control interventions. The aim of this study was to determine the insecticide resistance profiles of the main malaria vector species complex in coastal Kenya (Kwale county) and explore household risk factors leading to increased densities of mosquitoes. Adult mosquitoes and larval sampling were performed in the same sites, collected larvae were reared to F1 for susceptibility tests using WHO tube assay kits. A synergist assay with piperonyl butoxide (PBO 4%) was performed to investigate the possible involvement of metabolic resistance mechanisms. GLMM (negative binomial regression models) were used to identify factors influencing the indoor density of different vector species complex.Approximately 8302 mosquitoes were collected, composed of *An. funestus s.l.* (70%), *An. gambiae s.l.* (17%) and other Anophelines (13%). The presence of ITNs in households significantly reduced *An. funestus s.l.* count by 65% (IRR = 0.35, 95% CI 0.13-0.97, P<0.044). Moreover, palm leaves roof type (IRR = 4.46, 95% CI 2.30-8.64, P<0.001) and mud walls (IRR = 6.74, 95% CI 2.81-16.17, P<0.001) significantly increased *An. funestus s.l.* We did not find statistically significant association between indoors densities of *An. gambiae s.l.* and different house characteristics. *An. gambiae s.l.* exhibited resistance to deltamethrin and permethrin, but was susceptible to DDT, pirimiphos-methyl, and bendiocarb. *An. funestus s.l.* also demonstrated resistance to deltamethrin while DDT remained susceptible. The reversal of resistance was observed during the synergistic assay with PBO in both *An. funestus s.l.* and *An. gambiae s.l*. Resistance to pyrethroids is widespread and likely to involve metabolic mechanisms of resistance. Despite resistance, net usage continues to be associated with fewer indoor mosquitoes.

Household structural characteristics strongly influenced indoors densities of malaria vectors, further confirming the association between built environment and potential exposure to malaria.

6974

THE IMPACT OF NEXT-GENERATION DUAL-ACTIVE INGREDIENT LONG-LASTING INSECTICIDAL NET DEPLOYMENT ON INSECTICIDE RESISTANCE IN MALARIA VECTORS: RESULTS OF A THREE-YEAR CLUSTER-RANDOMIZED CONTROLLED TRIAL IN BENIN

[1]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, [2]Department of Epidemiology and Biostatistics, School of Public Health, University of Nevada, Las Vegas, NV, United States, [3]Medical Research Council (MRC) Centre for Global Infectious Disease Analysis, Department of Infectious Disease Epidemiology, Imperial College London, London, United Kingdom, [4]Faculté des Sciences et Techniques, Université d'Abomey-Calavi, Abomey-Calavi, Benin, [5]Faculty of Infectious and Tropical Diseases, Department of Disease Control, London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]MRC International Statistics and Epidemiology Group, London School of Hygiene and Tropical Medicine, London, United Kingdom, [7]Department of Environmental and Occupational Health, School of Public Health, University of Nevada, Las Vegas, NV, United States

To delay the evolution and spread of resistance and alleviate reversals in malaria control gains, long-lasting insecticidal nets (LLINs) incorporating new active ingredients (A.I.s), with distinct modes of action, are urgently needed. Through a three-year, three-arm cluster-randomised controlled trial (cRCT), we assessed the longitudinal impact of dual-A.I. LLINs (chlorfenapyr-PY and pyriproxyfen-PY LLINs) on insecticide resistance, compared to pyrethroid-LLINs (PY-LLINs). Longitudinal phenotypic and genotypic insecticide resistance profiles were measured among 19,292 *An. gambiae* s.l. collected over 39 months (3 months of baseline, followed by three years, post-intervention), using insecticide resistance bioassays and quantitative real-time reverse transcription PCR of metabolic resistance genes, respectively. In all three trial arms, a significant intervention effect was evident, with alpha-cypermethrin resistance intensity decreasing between baseline and twelve months post-LLIN distribution. Over the subsequent two years, alpha-cypermethrin resistance intensity rebounded to comparable or moderately higher levels than at baseline in all three trial arms. In all trial arms, by the third year, the alpha-cypermethrin concentration required to kill 95% of vectors increased to more than fifty times the diagnostic dose. Minimal reductions in chlorfenapyr susceptibility were observed; variable, albeit significant reductions in fertility following pyriproxyfen exposure, with an overall upward trend of increasing susceptibility across trial years was apparent. Several metabolic genes were implicated in resistance selection, including CYP6P4 in the pyriproxyfen-PY arm, and CYP6P3 and CYP9K1 in the chlorfenapyr-PY arm. Study findings indicate that after 24 months of use, chlorfenapyr-PY LLINs no longer mitigated pyrethroid resistance selection in *An. gambiae* s.l., while nets are currently procured every three years. Knowledge about the impact of next-generation LLINs on insecticide resistance selection is crucial for the pragmatic design of prospective resistance management strategies.

THE E205D MUTATION IN THE P450 GENE CYP6P3 DRIVES PYRETHROID RESISTANCE IN THE MAJOR AFRICAN MALARIA VECTOR ANOPHELES GAMBIAE

Jonas A. Kengne-Ouafo[1], Mersimine Kouamo[1], Abdullahi Muhammad[2], Arnaud Tepa[1], Stevia Ntadoun[1], Leon Mugenzi[1], Theofelix Tekoh[1], Jack Hearn[2], Magellan Tchouakui[1], Murielle Wondji[2], Sulaiman S. Ibrahim[2], Charles S. Wondji[2]

[1]Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

To improve the longevity of malaria control tools, this study pinpoints genetic mutations in the major malaria mosquito that cause pyrethroid resistance, paving the way for simple DNA tests to track resistance in the field. The entire genomes of highly resistant and highly susceptible malaria mosquitoes were compared to identify genetic changes linked to resistance (signatures of selective sweeps). The role of a top candidate was then elucidated using functional validation assays. A DNA-based assay was designed to monitor the pyrethroid resistance in the field and its impact on the effectiveness of long-lasting insecticide-treated bednets using standard WHO cone assays. WGS detected a major P450-linked locus on chromosome 2R beside the sodium channel locus to be linked to pyrethroid resistance in Cameroon. We demonstrated that the E205D mutation in a key metabolic resistance P450 *CYP6P3* drives pyrethroid resistance in *Anopheles gambiae. In vitro* metabolism assays with recombinant *CYP6P3* protein revealed that the catalytic efficiency of 205D was 2.5 times higher than E205 with α-cypermethrin. Overexpression of the 205D allele in transgenic flies confers higher pyrethroids and carbamates resistance, compared to controls. A DNA-based assay further supported that the *CYP6P3*-205D variant strongly correlates with pyrethroid resistance in field populations (OR=26.4; P<0.0001) and that it reduces the efficacy of pyrethroid-only LLINs with homozygote RR genotype exhibiting significantly higher survival following PermaNet 3.0 exposure compared to the SS genotype (OR: 6.1, p = 0.0113). Furthermore, the *CYP6P3*-E205D combines with the *kdr* target-site resistance mechanisms to worsen the loss of bednet efficacy. The 205D mutation is widespread in West and Central Africa, but less common or even absent in East and South Africa with signs of introgression with *An. coluzzii* in Ghana. This study emphasizes the importance of P450-based resistance and designs field-applicable tools to easily track the spread of metabolic resistance and assess its impact on control interventions.

6976

ACE-1 DUPLICATION AND COPY NUMBER VARIATION ARE CORRELATED TO RESISTANCE TO ORGANOPHOSPHATES IN *ANOPHELES GAMBIAE* FROM CENTRAL AFRICA

Judith L. Dandi Tchouomene, Jonas A. Kengne-Ouafo, Leon Mugenzi, Magellan Tchouakui, Murielle J. Wondji, Charles Wondji

Centre for Research in Infectious Diseases, Yaoundé, Cameroon

Mosquito resistance to insecticides hinders malaria control. Organophosphates (OPs) and carbamates (CMs) are used in indoor residual spraying (IRS) as a support for pyrethroids, to which many mosquito species are resistant. Unfortunately, West and East Africa see growing resistance to these classes used in IRS, including pirimiphos-methyl (PM), an OP newly recommended by the WHO. Mosquitoes with mutation replacing glycine with serine at position 280 in the acetylcholinesterase enzyme (Ace-1 280S) decrease sensitivity to OPs and CMs. Ace-1 duplications and copy number variation (CNV) enhance resistance, but empirical evidence is scarce in wild *Anopheles* in general, and in Central Africa particularly. We aimed to explore the correlation between specific Ace-1 alleles, the number of duplicated copies, and insecticide resistance levels in *Anopheles gambiae* s.s, *An. coluzzii*, and *An. funestus* s.l, to two organophosphates, PM and malathion (MA) across six Cameroonian localities. Mosquitoes were collected from breeding sites and susceptibility was determined using the WHO assay. Taq-Man and sequencing techniques investigated the Ace-1 gene in dead and surviving

mosquitoes after insecticide exposure. Analysis of 100 clones and qPCR permit to explore gene duplication and relative copy number variations. While *An. funestus* populations exhibited full susceptibility, *An. gambiae* s.l. showed potential or clear resistance to OPs (97%-50% mortality). A significant correlation linked the Ace-1 mutation with resistance in *An. gambiae* s.s. from Nkolondom to the two OPs (PM: OR= 20.33; P=0.04, MA: OR= 98.33; P =0.0019). Analyses revealed for the first time Ace-1 gene duplication and increased CNV correlated with resistant populations to PM and MA in Central Africa. The observed low-frequency (3%) of Ace-1^R mutation in *An. coluzzii* suggests recent selection pressure. These findings highlight the necessity for monitoring susceptibility before effective implementation of IRS in Cameroon. Ace-1 resistance demands long-read sequencing to fully map duplications, ensuring long-term insecticide effectiveness in malaria control.

6977

MALARIA VECTOR ECOLOGICAL DIVERSITY INFLUENCING TRANSMISSION AND RESISTANCE TO INSECTICIDES

Isaac Olayinka Oyewole

Babcock University, Ilisan Remo, Nigeria

Prevalence of malaria could be a function of vector density, transmission dynamics and ability for insecticide resistance and ecological variation could play a vital role. In this study, 1,857 adult *Anopheles* mosquitoes were collected from three ecosystems using standard procedures to establish their diversity, indoor and outdoor feeding and biting habits. The specimens were graded according to their abdominal conditions and preserved dry for morphological, molecular identification and ELISA test. Larvae were collected and reared to adulthood. Susceptibility tests conducted on 2-3-day old emerged female adults using standard WHO procedures. Species collected from the rain forest include; *Anopheles gambiae, An. funestus, An. moucheti, An. Arabiensis, An. nili* those from the savannah mosaic include; *An. gambiae, An. funestus, An. moucheti, An. Arabiensis, An. longipalpis, An. nili, An. maculipalpis, An. coustani, An. rhodesiensis* and *An. ziemani* and those from mangrove ecosystem are; *An. gambiae, An. melas* and *An. nili. Anopheles gambiae* abundance was significantly higher, accounting for 81.3% of all the collections and was found in all the localities. Those established to be vector of malaria include; *Anopheles gambiae, An. funestus, An. moucheti, An. Arabiensis* from the forest, *An. gambiae, An. funestus, An. moucheti, An. Arabiensis, An. longipalpis, An. nili* from the savannah and *An. gambiae, An. melas* from the mangrove. The infection rates ranged from 1.2% in the rain forest to 1.0% in the savannah and 0.9% in the coastal zone, this showed no significant difference (P>0.05). The entomological inoculation rates are 2044, 1716 and 1789 infective bites per person per year for the rain forest, savannah and coastal zones respectively, indicating no significant difference (P>0.05). Species from the coastal zone are more susceptible to doses of insecticides tested followed by those from rain forest while savannah mosaic species showed higher level of resistance. This is a baseline information to guide a community-based strategy for malaria control intervention.

6978

DYNAMICS OF RESISTANCE INTENSITY AND MECHANISMS OF *ANOPHELES GAMBIAE* TO PYRETHROID INSECTICIDES BETWEEN 2021 TO 2023 IN RWANDA

Phocas MAZIMPAKA[1], Dunia Munyakanage[1], Beatus Cyubahiro[1], Alphonse Mutabazi[1], Elias Niyituma[1], Jules NAHIMANA[2], Xavier Misago[1], Jean Claude S. Ngabonziza[1], Kaendi Munguti[3], Naomi W. Lucchi[4], Aimable Mbituyumuremyi[1], Emmanuel Hakizimana[1]

[1]Rwanda Biomedical Centre, Kigali, Rwanda, [2]Abt Associates, Inc., US President's Malaria Initiative, EVOLVE Project, Kigali, Rwanda, Kigali, Rwanda, [3]US President's Malaria Initiative, Kigali, Rwanda, [4]4The Centers for Disease Control and Prevention (CDC), Division of Global Health Protection, Nairobi, Kenya

The prevailing increase of insecticide resistance of *Anopheles gambiae* (s.l) to pyrethroid insecticides represents a crucial threat on the gains achieved from the scaling up of core vector control interventions. This study investigated the dynamics of resistance intensity and mechanisms of *An. gambiae* (s.l) to the pyrethroid insecticides between 2021 and2023 in Rwanda in order to guide the insecticide resistance management strategies. The intensity of resistance was measured at five (5x) and ten (10 x) times to the diagnostic doses for phenotypic resistance tests. The piperonyl butoxide (PBO) as synergist was added to the diagnostic dose to test the detoxification enzymes where the resistance was confirmed per insecticide and surveyed site. Out of the 25 surveyed sites, the high resistance intensity measured at 10 times the concentration of diagnostic dose for *Anopheles gambiae s.l.,* increased from 0% to 12% for Deltamethrin 0.05%, 0% to 7.4% for Permethrin 0.75% and 4% to 44% for Alpha-cypermethrin 0.5%. Therefore, from 2022 to 2023, the usual addition of synergist (PBO) encountered the decrease of susceptibility restoration from 100% (n=18) to 84.6% (n=13) for Deltamethrin 0.05%, 94% (n=20) to 92.6% (n=27) for Permethrin 0.75%, and 92.3% (n=26) to 84% (n=25) for Alphacypermethrin 0.05%. The study demonstrated an incremental increasing of resistance intensity to the pyrethroid insecticides and mainly to alpha cypermethrin. The underlying metabolic resistance mechanism involving detoxification esterase enzymes was detected using PBO and its effect is decreasing overtime. Other potential resistance mechanisms are suspected and require investigations with future projects. The monitoring of insecticide resistance has to be strengthened and integrated into the routine malaria vector surveillance, to guide decision making in deployment and impact evaluation of malaria control interventions in Rwanda.

6979

INSECTICIDE RESISTANCE PROFILE OF *AEDES* MOSQUITOES IN OGUN STATE, NIGERIA

Reham A. Tageldin[1], Hala S. Thabet[1], Matthew Montgomery[1], Ayodele S. Babalola[2], Sulaimon A. Aina[3], Adenike O. Adeniyi[4], Akingbehin P. Olumide[4], Omobolanle G. Akintade[4], Nofisat S. Lawal[4], Adedapo O. Adeogun[2]

[1]U.S. Naval Medical Research Unit EURAFCENT, Cairo, Egypt, Cairo, Egypt, [2]Molecular Entomology and Vector Control Unit, Nigerian Institute of Medical Research, Yaba, Lagos, Nigeria, Lagos, Nigeria, [3]Zoology Department, Olabisi Onabanjo University, Ogun State, Nigeria, Ogun, Nigeria, [4]Pure and Applied Zoology Department, Federal University of Agriculture, Abeokuta, Ogun State, Nigeria, Ogun, Nigeria

Aedes mosquitoes remain important vectors of dengue & yellow fever viruses in Nigeria. We investigated the insecticide resistance patterns of *Aedes* mosquitoes in Ogun State, in southwest Nigeria. Between April & August 2023, larval breeding sites of *Aedes* were identified & immature stages collected from four Local Government Areas, namely Odeda, Abeokuta South, Obafemi-Owode and Sagamu. Emerged females were exposed to four classes of insecticides according to the standard World Health Organization (WHO) protocol: pyrethroids (permethrin 0.75% & deltamethrin 0.05%); organochlorines (DDT 4%); organophosphates (fenitrothion 1.0%) & carbamates (bendiocarb 4%). A total of 2500 female *Aedes* mosquitoes were identified & exposed to insecticides. Of these, 2,297 (91.9%) were *Aedes aegypti,* while 203 (8.1%) were *Aedes vitattus*. *Aedes aegypti* was the sole species collected in Obafemi-Owode & Sagamu, whereas both species were found in Odeda and Abeokuta South. Across all sites, mortality to (DDT) ranged between 82% and 97%, suggesting mild resistance. Mosquitoes from Odeda, Abeokuta South & Obafemi Owode showed full susceptibility to permethrin, while suspected resistance was observed in Sagamu (92%). Mortality to deltamethrin ranged between 91% and 92%, indicating suspected resistance across all sites. Mosquitoes were largely susceptible to bendiocarb, except in Obafemi-Owode, where resistance was suspected (91% mortality). Susceptibility to fenitrothion was recorded in all sites except Sagamu (72% mortality). These findings suggest that resistance to all classes of insecticide is emerging among *Aedes* mosquitoes in southwest Nigeria, highlighting the need for targeted actions to address increased resistance & safeguard public health.

6980

HIGH SURVIVORSHIP OF *ANOPHELES GAMBIAE* LARVAE TO LETHAL CONCENTRATIONS OF CLOTHIANIDIN, ACETAMIPRID OR IMIDACLOPRID IS CONSISTENT WITH CROSS-RESISTANCE TO NEONICOTINOIDS

Marilene M Ambadiang Mae[1], Caroline Fouet[2], Fred Ashu[1], Calmes Bouaka[1], Véronique Penlap-Beng[3], Colince Kamdem[2]

[1]Centre for Research in Infectious Diseases, Yaoundé, Cameroon, [2]Department of Biological Sciences, University of Texas, El Paso, TX, United States, [3]Department of Biochemistry, Faculty of Science, University of Yaoundé 1, Yaoundé, Cameroon

Worldwide, agrochemicals have been effectively repurposed for mosquito control. The effectiveness of this method is challenged by preexisting resistance in larval and adult populations brought about by unintentional pesticide exposure or other cross-resistance mechanisms. Thus, in order to evaluate the effectiveness of repurposed agrochemicals against mosquitoes, understanding of the lethal and sublethal effects of residual pesticide is essential. We reared field-collected mosquito larvae in water that had an agrochemical concentration that, after 24 hours, killed 100% of susceptible mosquitoes (lethal concentration). With the help of this experimental setup, we investigated the effects on mortality rates and life table parameters of third-instar larvae of the two sibling species *Anopheles gambiae* and *Anopheles coluzzii* collected from Yaoundé, Cameroon caused by lethal concentrations of a pyrethroid (deltamethrin), a pyrrole (chlorfenapyr), and three neonicotinoids (acetamiprid, clothianidin, and imidacloprid). We observed that *An. gambiae* and *An. coluzzii* larvae were susceptible to chlorfenapyr and a minimal concentration of 0.10 mg/L killed them in less than 24 hours. In both species, deltamethrin caused low mortality, which is consistent with strong insecticide resistance. In *An. coluzzii* larvae, lethal doses of acetamiprid, imidacloprid, and clothianidin significantly hindered their ability to survive, grow, and emerge. On the other hand, 5 to 60% of *An. gambiae* immature stages were able to grow and emerge in water containing a lethal dose of neonicotinoid, demonstrating cross-resistance to this class of insecticides, depending on the active component and the population examined. These findings corroborate susceptibility profiles observed in adults and suggest that unintentional pesticide exposure or other cross-resistance processes could contribute to the establishment of resistance to neonicotinoids in some *Anopheles* populations.

6981

DIVERGENCES AND SIMILARITIES ON INSECTICIDE RESISTANCE PROFILES IN WILD POPULATIONS OF *ANOPHELES GAMBIAE SL* BREEDING IN VEGETABLE FARMS IN COTONOU, BENIN

Defo Talom Blaise Armand[1], Lontsi-Demano Michel[1], Zeukeng Francis[2], Nakebang Amen Fadel[3], Djouaka Rousseau[1]

[1]International Institute of Tropical Agriculture (IITA), Abomey-Calavi, Benin, [2]University of Buea, Buea, Cameroon, [3]Adam Barka University, Abeche, Chad

Pesticide management by vegetable farmers might play a key role in the selection of insecticide resistance in field populations of mosquito vectors. Here, we investigated the distribution of insecticide resistance profiles recorded with populations of *Anopheles gambiae sl* breeding in vegetable farms in the city of Cotonou in Benin, where no harmonization and no regulation is established, leading to uncontrolled use of pesticides. Two field sites were selected, Houeyiho and Seme. Wild Anopheles gambiae sl larval populations were collected and their susceptibility to lambda-cyhalothrin and permethrin was assessed. Synergist bioassays with PBO were conducted and the kdr target-site mutations were investigated. The genetic diversity of An. gambiae sl was assessed by sequencing the exon-20 element of the voltage-gated sodium channel. Overall, Lambdacyhalothrin constituted the main insecticide used by vegetable farmers. Mortalities to lambdacyhalothrin were 63% and 30% of the mortality rate respectively at Houeyiho and Seme. Susceptibilities to permethrin at Houeyiho and Seme were 14% and 42% of the mortality rate respectively. The PBO synergist assays showed a total recovery of the susceptibility to lambda-cyhalothrin in An. gambiae sl (100% mortality rate) at Seme, while this recovery was partial at Houeyiho (80% mortality rate). As to permethrin, the recovery was partial at houeyiho (73% mortality rate) and total in Seme (100% mortality rate). The kdr 1014F mutation was close to fixation in all the sites. In Hoeuyiho, 6 haplotypes were found, the haplotype diversity was 0.18. In Seme 3 haplotypes were found for a haplotype diversity of 0.09. There was a divergence in *An. gambiae sl*, about the resistance profile to pyrethroid, the involvement of cytochrome P50 in the observed resistance and the genetic diversity from one site to another. However, there was a similarity in Kdr mutation distribution. This study suggests that the implementation of vector control strategies should take into account divergences and similarities in mosquito resistance profiles, even at a small field scale for better management of malaria transmission.

6982

KEY RESISTANCE P450S PROFICIENT PYRETHROID METABOLIZERS, ARE REDUCING NEONICOTINOID EFFICACY IN *ANOPHELES FUNESTUS* WHILE EXACERBATING THE POTENCY OF CHLORFENAPYR

Tatiane Assatse[1], Magellan Tchouakui[1], Mersimine Mangoua[1], Riccardo Thiomela[1], Sonia Ngongang-Yipmo[1], Léon Mugenzi[2], Benjamin Menze[1], Charles Wondji[1]

[1]Centre for Research in Infectious Diseases (CRID), Yaoundé, Cameroon, [2]SYNGENTA, Rosentalstrasse 67, Basel, Basel 4058, Switzerland

Novel insecticides were recently introduced to counter pyrethroid resistance threats in African malaria vectors. To prolong their effectiveness, potential cross-resistance from promiscuous pyrethroids metabolic resistance mechanisms must be elucidated. Previous evidences have established that mutations in *CYP6P9a* and *CYP6P9b* (*CYP6P9a/-b*) are the main drivers of pyrethroid resistance in *Anopheles funestus* in Southern Africa. In this study, we used field strain of *An. funestus* from Malawi to assess the impact of *CYP6P9a/-b*, proficient pyrethroid metabolizers, on the efficacy of two novel insecticides, chlorfenapyr and clothianidin, using CDC bottle assay, coupled with extensive *in vivo* and *in vitro* function validation to directly establish the impact of the major pyrethroid resistance P450s on those insecticides. A strong association between the *CYP6P9a/-b* mutations and the ability to survive clothianidin exposure was noted for mutant versus non-mutant (OR=7.5; P=0.001 for *CYP6P9a* OR=7.08; P=0.002 for *CYP6P9b*). However, mutant had significantly higher mortalities upon chlorfenapyr exposure, compared to non-mutant (OR=0.1; P<0.0001 and OR=0.2; P=0.0003 respectively). Transgenic expression of *CYP6P9a/-b* in Drosophila revealed that flies expressing *CYP6P9a* and *CYP6P9b* were significantly more resistant to clothianidin 12h post-exposure than the control flies, with average mortalities of 45.05% ± 7.03 for *CYP6P9a* (P<0.001) and 30.1% ± 2.9 for *CYP6P9b* (P<0.001) compared to the control flies (73.9% ± 3.3). In contrast, experimental flies over-expressing these two P450s were more susceptible to chlorfenapyr 12h post-exposure compared to control flies, with average mortalities of 62.3% ± 4.1 for *CYP6P9a* (P<0.001) and 61.1% ± 5.9 for *CYP6P9b* (P<0.001) compared to the control (37.6% ± 5.6). This phenotype was also confirmed by RNAi knock-down experiments. This study highlights the risk of cross-resistance between pyrethroid and neonicotinoid and reveals that chlorfenapyr-based control interventions such as Interceptor G2 could remain efficient against some P450-based resistant mosquitoes.

6983

BACTERIA COMMUNITY EXACERBATE PYRETHROID RESISTANCE IN *ANOPHELES FUNESTUS*, MAJOR MALARIA VECTOR IN AFRICA

Fleuriane Metissa Djondji Kamga[1], Leon M. J. Mugenzi[2], Magellan Tchouakui[1], Calmes Urbain Bouaka Tsakeng[1], Bertrand Mbakam[1], Charles S. Wondji[1]

[1]Centre for Research in Infectious Diseases (CRID), Yaounde, Cameroon, [2]SYNGENTA, Rosentalstrasse 67, Basel, Basel 4058, Switzerland

The increasing resistance of *Anopheles* mosquitoes to pyrethroids is subjecting many African countries to a high risk of malaria epidemics. An in-depth understanding of the mechanisms associated with this phenomenon is needed to mitigate this growing threat to malaria vector control. Numerous studies have highlighted the involvement of microbiota in mediating insecticide resistance (IR) in agricultural pests. Based on this, our study sought to investigate the potential role of bacteria in the escalation of insecticide resistance in the major malaria vector *Anopheles funestus* Giles (Diptera : Culicidae). Using the sequencing of the 16S rRNA mitochondrial gene, we comparatively characterized the microbiota of a highly pyrethroid-resistant strain (Fumoz-selected) and a normal-resistant strain (Fumoz unselected). This enabled the identification of bacteria strains associated with the escalation of IR. In addition, to further confirm the involvement of bacteria in the phenotype, we performed an antibiotic treatment (penicillin/streptomycin) of Fumoz unselected mosquitoes, proceeded by exposure to insecticides. As findings, lower bacterial diversity was observed in the selected group, suggesting that, insecticide selection pressure reduces bacterial enrichment. Also, we noticed an overabundance of the *Rhanella* genus in the Fumoz-selected strain (Deseq2: Log2FC-15.776, p=4.23E-11), which could argue its involvement in the escalation of IR phenotype. Concerning the antibiotic treatment, we observed a partial recovery of the susceptibility of treated individuals, to insecticides after exposure to varying WHO diagnostic concentrations of pyrethroids: Permethrin 1X ($\chi2 = 46.936$, $p < 0.0001$), Deltamethrin 5X ($\chi2 = 4.102$, $p = 0.04$) and 10X ($\chi2 = 9.706$, $p = 0.0018$). Overall, our findings confirmed the potential role of bacteria in the escalation of IR in *An. funestus*. This study, therefore, lays the initial groundwork for understanding microbial mechanisms that exacerbate pyrethroid resistance in malaria vectors while jeopardizing vector control efforts.

Aedes aegypti is a major vector of arboviruses worldwide. Understanding major reproductive pathways in males and females is essential for development and success of novel control tools that can reduce human infection risk. Across diverse insect taxa, the behavior and physiology of females dramatically changes after mating – processes largely triggered by the transfer of seminal proteins from their mates. In the vinegar fly *Drosophila melanogaster*, the seminal protein sex peptide (SP) decreases the likelihood of female flies remating and causes additional behavioral and physiological changes that promote fertility including increasing egg production. Although SP is only found in the *Drosophila* genus, its receptor, sex peptide receptor (SPR), is the widely conserved myoinhibitory peptide (MIP) receptor. To test the functional role of SPR in mediating post-mating responses in a non-*Drosophila* dipteran, we generated two independent *Spr*-knockout alleles in the yellow fever mosquito, *Aedes aegypti*. Although SPR is needed for post-mating responses in *Drosophila* and the cotton bollworm *Helicoverpa armigera*, *Spr* mutant *Ae. aegypti* show completely normal post-mating decreases in remating propensity and increases in egg laying. In addition, injection of synthetic SP or accessory gland homogenate from *D. melanogaster* into virgin female mosquitoes did not elicit these post-mating responses. Our results demonstrate that *Spr* is not required for these canonical post-mating responses in *Ae. aegypti*, indicating that other, as yet unknown, signaling pathways are likely responsible for these behavioral switches in this disease vector.

MICRO-SPATIAL PARTITIONING INFLUENCES THE DIVERSIFICATION OF MOSQUITO-ASSOCIATED VIRUS PROFILES AMONG *AEDES AEGYPTI* MOSQUITOES IN PUERTO RICO

Bright Agbodzi[1], Henry J. Barton[2], Nicole Nazario-Maldonado[1], Luis Alonso-Palomares[1], John F. Williams[1], Robert Rodriguez[3], Grayson Brown[4], Rhoel R. Dinglasan[1]

[1]Department of Infectious Diseases & Immunology, College of Veterinary Medicine, University of Florida, Gainesville, FL, United States, [2]Genevia Technologies, Tampere, Finland, [3]Ponce Health Sciences University, Ponce, Puerto Rico, [4]Puerto Rico Vector Control Unit, San Juan, Puerto Rico

Mosquito-borne arboviruses remain a major global health burden. The mosquito's microbiome, particularly, its virome can influence its life ability to transmit arboviruses. However, little is known about the intrinsic diversity of the virome across mosquito populations at smaller spatial scales. *Aedes aegypti* is the primary vector for dengue virus, Zika virus, and Chikungunya virus globally. We hypothesized that micro-spatial factors shape the mosquito core-virome and influence the diversification of mosquito-associated virus (MAV) profiles in *Ae. aegypti.* To test this hypothesis, we used RNA-Seq to characterize the diversity of MAVs among *Ae. aegypti* populations from urban and rural habitats on the main island of Puerto Rico and compared MAV diversity among *Ae. aegypti* collected from 2 urban and 2 rural habitats. Metatranscriptomic analysis identified 15 different viruses in this study that partitioned to rural vs. urban sampling sites. Of these, the most represented families were *Totiviridae* (3 viruses) and *Partitiviridae* (2 viruses). Phasi Charoen-like phasivirus (PCLV), Humaita-Tubiacanga virus (HTV) had the highest viral sequences overall. Of the 15 viruses detected, seven viruses were common to both rural and urban sites; however, six were present in urban *Ae. aegypti* but absent from the rural samples. Also, HTV had the most viral reads (>80%) among rural *Ae. aegypti,* whereas PCLV had very low viral reads (<2%). In contrast, PCLV (>80%) predominated in urban *Ae. aegypti*, while HTV reads were low. Phylogenetic analysis of the PCLV, HTV, and Guadeloupe mosquito virus strains revealed that our strains are quite unique, barely clustering with others from different geographical origins. We further compared MAV prevalence and vector competence for DENV-1 between urban and rural mosquito populations, and discuss how these results not only support our prevailing hypothesis but impact our understanding of arbovirus transmission at local scales. We anticipate that future studies will help assess the generalizability of the observed phenomena in other DENV-endemic regions.

6986

HOST-SPECIFIC DYNAMICS OF MICROBIOTA ASSEMBLY IN *AEDES AEGYPTI* MOSQUITOES AFTER RECIPROCAL TRANSPLANTATION OF CRYOPRESERVED WHOLE GUT-DERIVED MICROBIAL COMMUNITIES

Holly Nichols[1], Vishaal Dhokiya[2], Ananya Hoque[2], Eva Heinz[2], Grant Hughes[2], Kerri Coon[1]

[1]University of Wisconsin-Madison, Madison, WI, United States, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

As in other animals, the mosquito gut is colonized by a diverse consortium of microbes that contributes to host traits including survival, fecundity, insecticide resistance, and vector competence. Accordingly, manipulation of the mosquito microbiome via the introduction of bacteria that reduce

mosquito vector competence and/or fitness is a promising avenue for controlling the transmission of mosquito-borne pathogens. However, many pathogen studies are conducted in laboratory-reared mosquitoes with gut microbial communities that are distinct from field-collected mosquitoes. Here, we describe a new method to isolate, cryopreserve, and transplant whole microbial communities from donor mosquitoes into axenic (germ-free) recipient mosquitoes. A reciprocal swap was conducted between *Aedes aegypti* Liverpool strain mosquitoes reared in isolation for 50 years at the University of Wisconsin-Madison (UW) and Liverpool School of Tropical Medicine (LSTM). Notably, mosquito hosts from each colony reacted differently to microbiome transplantation: UW mosquitoes experienced a shift in community composition after transplantation, but LSTM mosquitoes did not, suggesting host filtering of microbes may differ between geographically isolated mosquito strains. Fidelity of transplanted microbial communities further varied based on initial composition of the donor pool and recipient host genotype, though patterns of assembly were conserved across the mosquito life cycle. Altogether, these results highlight the value of this method for studying mosquito-microbe interactions and lay the foundation for future efforts to identify bacterial candidates for use in mosquito and mosquito-borne disease control. They also provide a critical next step toward the standardization of pathogen infectivity experiments to include laboratory-reared mosquitoes colonized by microbial communities isolated from mosquitoes in disease endemic areas in the field.

INVESTIGATING THE EFFECTS OF TEMPERATURE CHANGE ON OVIPOSITION AND PROGENY VIABILITY OF *AEDES AEGYPTI* AND *CULEX TARSALIS* MOSQUITOES

Olivia M. Martinez, Shelby Cagle, Emma K. Harris, Rebekah C. Kading

Colorado State University, Fort Collins, CO, United States

Temperature is known to affect the transmission efficiency of mosquito-borne viruses, particularly those spread by *Aedes aegypti* and *Culex tarsalis* mosquitoes. Investigating how environmental changes impact *Ae. aegypti* and *Cx. tarsalis* fecundity will inform future action for vector control and subsequent disease mitigation. Our preliminary data has shown impaired egg deposition when Rift Valley fever virus- adult *Ae. aegypti* mosquitoes were exposed to temperatures varying from typical environmental conditions. It is unclear if this behavior is due to infection or altered temperatures. Therefore, we are investigating the relationship between altered temperatures, oviposition rates, and progeny viability within uninfected blood-fed *Ae. aegypti* and *Cx. tarsalis* mosquitoes. We hypothesize that temperature variation will negatively impact egg viability, deposition rates, and offspring development. Blood-fed female mosquitoes (n=50) will be housed individually at lower (18°C), standard (28°C), or higher (32°C) rearing temperatures. Egg production will be assessed by quantifying deposited eggs in comparison to withheld eggs, obtained by ovarian dissection. Deposited egg hatch rates will be recorded to determine offspring viability. Data collection is ongoing. Preliminary trials showed increased developmental rates in *Ae. aegypti* at 32°C when compared to standard temperature. In contrast, *Cx. tarsalis* mosquitoes showed impaired egg-laying behavior and developmental rates at 32°C. Understanding the relationship between mosquito fecundity and temperature is of great importance for anticipating infectious disease dynamics in a complex and shifting global environment.

A SINGLE-CELL ATLAS OF THE *CULEX TARSALIS* MIDGUT DURING WEST NILE VIRUS INFECTION

Emily Anne Fitzmeyer[1], Taru S. Dutt[1], Silvain Pinaud[2], Barbara Graham[1], Corey Campbell[1], Sarah Hélène Merkling[3], Jessica L. Hill[1], Hunter Ogg[1], Emily N. Gallichotte[1], Marcela Henao Tamayo[1], Gregory D. Ebel[1]

[1]Colorado State University, Fort Collins, CO, United States, [2]Research and Development Institute IRD, Monpellier, France, [3]Pasteur Institute, Paris, France

The mosquito midgut functions as a key interface between pathogen and vector. However, studies of midgut physiology and associated virus infection dynamics are scarce, and in *Culex tarsalis* - an extremely efficient vector of West Nile virus (WNV) in the contiguous United States - nonexistent. We performed single-cell RNA sequencing on dissociated *Cx. tarsalis* midguts to define cell types comprising and associated with the midgut, and determine whether specific cell types are more permissive to WNV infection. We identified 15 midgut cell populations comprised of 7 distinct cell types, consistent with existing descriptions of *Drosophila* and *Aedes aegypti* midgut physiology. We found that all midgut cell populations were permissive to WNV infection. However, higher levels of WNV RNA, relative to other cell types, were present in enteroendocrine cells and cells enriched for mitochondrial genes, suggesting enhanced replication in these populations. In contrast, we observed the lowest levels of WNV RNA in proliferating intestinal stem cell (ISC) populations, a finding consistent with previous studies suggesting ISC proliferation in the midgut is involved in viral control. Notably, we did not detect significant upregulation of canonical mosquito antiviral immune genes (e.g., AGO2, R2D2, etc.) associated with WNV infection at the whole-midgut level. Rather, we observed a significant positive correlation between immune gene expression levels and WNV RNA level in individual cells, suggesting that within cells, high levels of WNV RNA may trigger antiviral responses. Our findings describe the cell types that comprise the midgut of *Cx. tarsalis*, and provide insight into the midgut infection dynamics of WNV in this highly efficient WNV vector by characterizing cell-type specific enhancement of, and immune response to, infection at the single-cell level.

6989

THE CONTRIBUTION OF SPECIFIC PROPHENOLOXIDASES TO PLASMODIUM MELANIZATION IN ANOPHELES GAMBIAE MOSQUITOES

Sally Saab, George Dimopolous

Johns Hopkins University, Baltimore, MD, United States

Anopheles gambiae mosquitoes rely on their innate immune responses to fight against *Plasmodium* infection. Among these responses is the melanization immune response, characterized by the deposition of melanin on the parasite's surface preventing it from gaining nutrients and thus triggering its death. Melanization involves a set of biochemical reactions that require the active phenoloxidase (PO), which is secreted into the hemolymph as prophenoloxidase (PPO) zymogen. A cascade of CLIP serine proteases is required for the cleavage and activation of PPO. The classical organization of this cascade in insects starts with the autoactivation of an upstream modular serine protease that integrates the signal from an activated pattern recognition receptor (PRR) into a downstream CLIP serine protease cascade constituted of several members. The most downstream CLIP in this cascade, known as the prophenoloxidase activating proteases, cleaves PPO into active PO which initiates the melanin biosynthesis pathway. Nine different PPOs have been identified in the *Anopheles gambiae* genome. Here, we attempt to identify the PPOs involved in *Plasmodium* melanization. We found that two different prophenoloxidases (PPOs) act together to mediate *Plasmodium* ookinete melanization, and our future aim is to generate transgenic mosquitoes that overexpress both PPOs to be used later in different functional infection assays.

6990

KINETICS OF MAYARO VIRUS INFECTIONS OF NEW WORLD AND OLD WORD *ANOPHELES* VECTORS

Luis Antonio Alonso Palomares, Jeremiah Miller, Ava Sheppard, Jhon Williams, John Lednicky, Rhoel R. Dinglasan
University of Florida, Gainesville, FL, United States

The Mayaro virus (MAYV) is an *Alphavirus in the family Togaviridae*. The virus has been classified into three genotypes (D, L, and N); genotype D has the greatest geographical distribution in the Americas. The primary vector for MAYV in the sylvatic transmission cycle are *Haemagogus* mosquitoes. However, the virus can also be transmitted in urban cycles by *Aedes aegypti*. MAYV infections can cause long-term debilitations in afflicted countries. It has been shown that mosquitoes of the genus *Anopheles* can transmit the MAYV. To understand the potential expansion of the virus eastward to Africa, we tested if MAYV (genotype D) infection kinetics differs between Old World (*Anopheles gambiae*) and New World (*Anopheles albimanus*) anophelines, as compared to infections in *Aedes aegypti* (Orlando) mosquitoes from Florida. We observed that MAYV disseminated infection of *An. albimanus* was rapid, wherein *virus was found in saliva* after only 2 days post infection (dpi), at a 26.6% infection prevalence. This translated to a higher prevalence of infection, increasing to 80% after 7 dpi as compared to *Ae. aegypti. Importantly, we also* detected the virus in ovaries, wherein ovary infection rates increased from 80% (2 dpi) to 100% (7 dpi), indicating a high potential for vertical transmission and persistence in the environment. At 2, 7, and 14 dpi, *An. gambiae* had a 100% midgut infection. Although the virus was not detected in saliva at 2 dpi, infection prevalence in saliva increased from 20% (7 dpi) to 60% (14 dpi); suggesting transmission in the Old World is possible. We also observed that *An. albimanus* infection with MAYV impacts lifespan and have profiled the mosquito host response to infection at 7 dpi to gain insight into the mechanisms affected by MAYV. Since the virus can already be transmitted as early as 2 dpi, *An. albimanus* are indeed competent in transmitting MAYV within a shorter extrinsic incubation period and should be considered as potential targets for vector control during local outbreaks.

6991

OPTIMIZATION OF ANTIMALARIAL DRUGS DELIVERY AND EVALUATING THEIR EFFECTS ON THE SURVIVAL AND FECUNDITY OF LABORATORY REARED ANOPHELES GAMBIAE MOSQUITOES

Moline Achieng Okal[1], Cyrus Ayieko[2], Hoseah Akala[1], John Waitumbi[1]
[1]Walter Reed Army Institute of Research, Kisumu, Kenya, [2]Maseno University, Kisumu, Kenya

WHO global technical strategy for malaria control targets to reduce malaria cases by 90% by the year 2030. While the up scaling of control strategies in the initial years led to significant reduction in global malaria cases, malaria burden has plateaued in the last five years. Recent studies have demonstrated the potential of using standard antimalarials to block the development and transmission of pre-erythrocytic stages within the vector. This study aimed to determine the maximal tolerable doses and the efficacy of the antimalarial drugs (artemether, lumefantrine, primaquine and tafenoquine) on the fecundity of the reared *An. gambiae s.s* mosquitoes. *An. gambiae s.s* Kisumu strain were reared in the insectary by maintaining standard insectary conditions. Fifty, 3–5 days old, blood naive and starved mosquitoes were introduced into ten labelled paper cups. Eight doses consisting of serial dilutions of each antimalarials drug in 10% glucose solution. Mosquitoes were allowed to feed on cotton wool soaked in different concentrations of antimalarials and mortality monitored for ten days. To monitor fecundity, a fresh batch of mosquitoes were fed with human blood and subjected to the highest tolerable drug doses. The number of eggs laid was monitored over 8 days period. Controls were fed 10% glucose without drugs. Kaplan–Meier survival analysis was performed to estimate the tolerable drug doses while Chi- square method was used to assess the fecundity of *Anopheles* mosquitoes. The highest tolerable doses were 700 ng/ml for artemether and lumefantrine and 5000 ng/ml for tafenoquine and primaquine. The number of eggs did not differ between the mosquitoes exposed to the different drugs and control groups. The mosquitos tolerated doses of artemether and lumefantrine, tafenoquine and primaquine that were equivalent to doses recommended for use in human host. These doses do not seem to have an effect on mortality or on mosquitos' fecundity hence can be recommended for future use as potential transmission blocking compounds.

6992

ENTEROBACTER CLOACAE AND *SERRATIA MARCESCENS* METABOLITES MINIMIZE *PLASMODIUM* GAMETOCYTE DEVELOPMENT *IN VITRO.*

Esinam Abla Akorli, Grace Odoom, Emmanuel Osei-Frempong, Jeffrey Kankam Boateng, Stephanie N.A Addo, Jewelna Akorli
Noguchi Memorial Institute for Medical Research, Legon, Ghana

Bacteria belonging to the family Enterobacteriaceae proliferate in the *Anopheles* mosquito midgut following a blood meal, and two members; *Enterobacter cloacae* and *Serratia marcescens* limit *Plasmodium* infection within the vector. As candidates for transmission-blocking strategies, it remains uncertain which will be more effective in targeting parasites: the increase in bacterial cell numbers in the vector and/or introduction of the vector to bacterial metabolites. We have already shown that metabolites from a 4hr spent media from *E. cloacae* and *S. marcescens* has varied effects on oocyst numbers in *Anopheles* mosquitoes. This current study aims to determine the concentration-dependent effect of bacterial metabolites on *Plasmodium*. Spent media following 6 different time-points culturing of two isolates each of *E. cloacae* (*EspG1*, *EspG3*) and *S. marcescens* (*SmG5*, *SmG6*) were lyophilized and reconstituted at 3mg/mL. *P. falciparum* 3D7 and Dd2 gametocyte stages IV-V were obtained with sorbitol synchronization, and incubated with bacterial metabolites for 72 hours. We have also begun to investigate the properties of the metabolites by applying heat (56ºC) and proteinase K treatments. Viable parasites were assessed with SYBR Green I and absorbances were read using a fluorescence plate reader. The overall treatment effect of the metabolites across all time-points differed between *SmG6* and *EspG1* (P= 0.003). There was evidence of interaction between the metabolites and parasite strains suggesting that the killing effect was stronger in some metabolite-parasite combinations than others. *Plasmodium* intensity reduced across all time-points with the highest effect at 4 and 6hrs for 3D7 and, 1hr for Dd2. Heating reduced the efficacy of *E. cloacae*-derived metabolites only (P=0.02) while proteinase K treatment had no effect. Our data provides preliminary results on studies that aim to understand the mechanisms, potential applications and feasibility of mosquito midgut symbiont-based approaches for mosquito/disease control.

6993

ELIZABETHKINGIA ANOPHELIS MSU001 ISOLATED FROM *ANOPHELES STEPHENSI*: MOLECULAR CHARACTERIZATION AND COMPARATIVE GENOME ANALYSIS

Shicheng Chen[1], Nicolas Terrapon[2], Jochen Blom[3], **Edward D. Walker**[4]
[1]Northern Illinois University, DeKalb, IL, United States, [2]Marseille Université, Marseille, France, [3]Justus-Liebig University, Giessen, Germany, [4]Michigan State University, East Lansing, MI, United States

Elizabethkingia anophelis is an aerobic, non-fermenting, non-motile, non-spore-forming gram-negative rod that readily colonizes the mosquito gut, forms part of the gut microbiome, and offers potential for control of mosquito-borne pathogens via paratransgenesis. However, it also is an opportunistic pathogen of humans. This study involved characterization of a new strain, E. anophelis MSU001, isolated from *Anopheles stephensi* (JHU strain) in the laboratory, and characterized by matrix-assisted laser desorption/ionization time of flight mass spectrometry (MALDI-ToF/MS), biochemical testing, and genome sequencing. The strain was isolated by

dissecting a gut of An. stephensi and plating contents onto Luria-Bertani agar medium with erythromycin. Average nucleotide identity analysis revealed 99% identity of MSU001 with the type species E. anophelis R26. Phylogenetic placement revealed a clade with mosquito-associated strains separate from a clade of clinical isolates. Comparative genome analysis showed that it shared at least 98.6% of genes with mosquito-associated isolates (except E. anophelis As1), while it shared at most 88.8% of common genes with clinical isolates, suggesting divergence between strains adapted to the mosquito gut and clinically-significant strains. Metabolites from MSU001 inhibited growth of E. coli but not mosquito gut symbionts Serratia marcescens and Asaia sp. strain W12. Mosquito-associated E. anophelis strains carried glycoside hydrolase- and auxiliary activities-encoding genes distinct from those of clinical isolates, indicating their potential role in reshaping chitin structure and other components involved in larval development or formation of the peritrophic matrix. Like other Elizabethkingia, MSU001 also carried genes encoding two-component system proteins, transcription factor proteins, DNA-binding proteins, and a diverse repertoire of antibiotic resistance genes and several virulence factors. Its potential for opportunistic infections in humans should be further evaluated prior to implementation as a paratransgenesis agent.

6994

REPRODUCTIVE STRATEGIES ASSIST THE BIOLOGICAL INVASION PROCESS OF *AEDES ALBOPICTUS*

Ayda Khorramnejad, Claudia Alfaro, Stefano Quaranta, Alejandro Nabor Lozada-Chavez, Laila Gasmi, Hugo Perdomo, Laurent Chiarelli, Mariangela Bonizzoni

University of Pavia, Pavia, Italy

The success of biological invasions depends on a species ability to survive and reproduce in a new environment, traits which mediate the effective establishment and persistence in new habitats. The arboviral vector *Aedes albopictus* is a successful invasive mosquito, which conquered tropical and temperate areas of the world in less than 100 years. The rapid spread of *Ae. albopictus* has been ascribed to its ecological plasticity, its ability to overwinter through photoperiodic diapause and produce desiccation resistance eggs. Whether *Ae. albopictus* reproductive capacity has contributed to its invasive success has not thoroughly investigated yet. Here, we compared the phenotypic variations and reproduction potentials of several *Ae. albopictus* populations. We observed extensive phenotypic variations between invasive and native populations with invasive mosquitoes being statistically bigger in size and having a higher reproductive output. To investigate the biological underpinnings of these differences, we visualized ovaries during their development and analyzed their physiology and protein profile in a comparative manner including mosquitoes of an invasive population with respect to those of the laboratory Foshan reference strain. We observed that females of the invasive population better allocate the energy reserves acquired during the larval stage and that from a blood meal resulting in higher production of fertile eggs than Foshan mosquitoes. Proteomic analyses and ovarian micrographs showed a delay in oogenesis in invasive mosquitoes which correlated with a higher fecundity and fertility. We further performed reciprocal crosses between mosquitoes of Foshan and the invasive population which highlighted a potential contribution of males on the reproductive success of invasive mosquitoes. Overall, our findings show reproductive strategies assisted the biological invasion process of *Ae. albopictus*.

6995

CHARACTERIZING RESIDUAL MALARIA TRANSMISSION IN THREE SELECTED HIGH BURDEN DISTRICTS OF WESTERN PROVINCE, ZAMBIA

Benjamin Chanda[1], Tresford Kaniki[1], Patricia Mambo[1], Rayford Muyabe[1], Mwansa Mwenya[1], Chama Chisyha[1], Busiku Hamainza[2], Thomas Burkot[3], Ruth Ashton[4], Erica Oranga[5], Megan Littrell[6], Keith J. Mbata[7], Joseph Wagman[6]

[1]PATH, Kaoma, Zambia, [2]National Malaria Elimination Centre, Lusaka, Zambia, [3]Australian Institute of Tropical Health and Medicine, Cairns, Australia, [4]Tulane Univsity, New Orleans, LA, United States, [5]PATH, Seattle, WA, United States, [6]PATH, Washington, DC, United States, [7]University of Zambia, Lusaka, Zambia

Zambia remains a highly malaria-endemic country, with infection risk highest in rural regions such as Western Province. The primary vectors responsible for transmission vary by region and include *Anopheles funestus s.s.*, *An. gambiae s.s.*, and *An. arabiensis*. Since 2002, implementation of standard vector control interventions, namely insecticide treated nets and indoor residual spraying, has contributed substantially to reducing the malaria burden in Zambia: between 2002 and 2018 national-level malaria prevalence in children under 5 dropped from 22% to 9%, while inpatient malaria cases and deaths each declined by approximately two-thirds. However, in Western Province malaria burden remains high, with 2021 estimates of under 5 prevalence near 50% and all-ages case incidence at 785/1000 person-years at risk. This consistently high burden despite quality implementation of effective malaria control programming shows that residual transmission persists, and underscores the need to better understand key entomological drivers of residual transmission to guide targeted scale up of complimentary interventions and to inform development of new tools and approaches. This study aimed to characterize, for the first time, the full breadth of *An. funestus* biting behaviors in four high burden communities of Western Zambia. Longitudinal vector surveillance was conducted from January to April 2024 using human landing catches (HLC) conducted over 24 hours, indoors and outdoors, at households and at schools and markets. Results indicate biting occurs both indoors and outdoors with a peak in the early morning from 01:00 - 6:00, but substantial potential for malaria transmission also exists in the later morning hours - particularly indoors at schools, where more than 1 bite per person was recorded between 6:00 and 11:00 each collection day. Future work should expand 24-hour vector surveillance activities year-round, explore sporozoite positivity by time and location of human biting, and overlay vector and human behaviors to map a fuller understanding of community-wide malaria transmission risk and identify gaps in current vector control approaches.

FOREST EDGE LANDSCAPE CONTEXT AFFECTS MOSQUITO COMMUNITY COMPOSITION AND RISK OF PATHOGEN EMERGENCE

Adam Hendy[1], Nelson F. Fe[2], Igor Pedrosa[2], André Girão[2], Taly N.F. dos Santos[2], Claudia R. Mendonça[2], José T. Andes Júnior[2], Flamarion P. Assunção[2], Edson R. Costa[3], Vincent Sluydts[4], Marcelo Gordo[3], Vera M. Scarpassa[5], Michaela Buenemann[6], Marcus M.V.G. Lacerda[2], Maria Paula G. Mourão[2], Nikos Vasilakis[1], Kathryn A. Hanley[7]

[1]University of Texas Medical Branch, Galveston, TX, United States, [2]Fundação de Medicina Tropical Doutor Heitor Vieira Dourado (FMT-HVD), Manaus, Brazil, [3]Universidade Federal do Amazonas, Manaus, Brazil, [4]University of Antwerp, Wilrijk, Belgium, [5]Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil, [6]New Mexico State University, Las cruces, NM, United States, [7]New Mexico State University, Las Cruces, NM, United States

Forest edges, where humans, mosquitoes, and wildlife interact, may serve as a nexus for zoonotic arbovirus exchange. Although often treated as uniform interfaces, the landscape context of edge habitats can greatly impact ecological interactions. Here, we investigated how the landscape context of forest edges shapes mosquito community structure in an Amazon rainforest reserve near the city of Manaus, Brazil. Between July 2021 and June 2022, we sampled diurnally active mosquitoes using hand-nets at ground level and on 5 m platforms at three distinct forest edge types bordering urban land cover, rural land cover, and natural treefall gaps, while sites in continuous forest served as controls. Mosquito communities differed considerably between forest edges and continuous forest. Urban edges had the most distinct communities, dominated by ground dwelling *Aedes albopictus* and *Limatus durhamii*, followed by rural edges, and treefall gaps where *Haemagogus*, *Psorophora*, and *Sabethes* species were common. Rural edges supported the highest species diversity, providing suitable habitat for both urban and forest specialists, including key arbovirus

vectors. *Haemagogus janthinomys* was notably abundant at ground level at treefall gaps, where there is a high risk for interaction between this species and ground dwelling wildlife and humans. Our findings emphasize the importance of landscape context in assessing pathogen emergence risk at forest edges.

6997

MOLECULAR XENOMONITORING FOR POST-VALIDATION SURVEILLANCE OF LYMPHATIC FILARIASIS IN BANGLADESH: EVIDENCE TO SUPPORT LYMPHATIC FILARIASIS (LF) ELIMINATION AS A PUBLIC HEALTH PROBLEM

Prakash Ghosh[1], Nishad Tasnim Mithila[1], Debashis Ghosh[1], Md. Arko Ayon Chowdhury[1], Shomik Maruf[1], Md Rasel Uddin[1], Soumik Kha Sagar[1], Md Utba Rashid[1], Mohammad Sohel Shomik[1], M.M. Aktaruzzaman[2], A. S. M. Sultan Mahmood[2], Ahmed Abd El Wahed[3], Mohammad Shafiul Alam[1], Mary Cameron[4], Nils Pilotte[5], Emily A. Dodd[6], Tara A. Brant[6], Kimberly Y. Won[6], Dinesh Mondal[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Communicable Disease Control (CDC), Directorate General of Health Services (DGHS), Mohakhali, Dhaka, Bangladesh, [3]Institute of Animal Hygiene and Veterinary Public Health, Leipzig University, Leipzig, Germany, [4]Department of Disease Control, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Department of Biological Sciences, Quinnipiac University, Hamden, CT, United States, [6]Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Bangladesh achieved validation of elimination of lymphatic filariasis (LF) in 2023. To cement this achievement and sustain elimination, the program must continue emphasis on post validation surveillance and response measures to prevent recrudescence of infection. Tailoring a sensitive surveillance strategy by combining host- and vector-directed surveillance tools is imperative to track the transmission of LF at this phase. Since molecular xenomonitoring (MX) is a non-invasive and sensitive means for surveillance, we used this technique to detect any *Wuchereria bancrofti* (Wb) DNA. We included 62 villages under Gangachara Upazila, spanning in two evaluation units (EU) in Rangpur district, in the cross-sectional survey. We applied an index-based approach to collect mosquitoes from residences of LF clinical patients (n=83) and their neighboring households (n=315) within a≈50 m radius. Mosquitoes were collected Jun 2022-Nov 2023 using CDC gravid traps placed in each household for three consecutive nights. Mosquitoes were identified morphologically using a standard taxonomic key and placed into pools of up to 25 mosquitoes. Female Culex quinquefasciatus (fed and gravid) were tested for Wb DNA using previously described real time PCR pool screening method. We collected 47,611 *Cxulex quinquefasciatus* mosquitoes including 44,785 females; 1.6% were fed and 72.9% were gravid. In total, 1,225 mosquito pools (15-25 mosquitoes per pool), comprising either blood-fed or gravid females, were tested. We detected Wb DNA in four pools corresponding to estimated prevalence rates of 0.03% (95% Confidence Interval (CI): 0.01-0.07%) or 0.03% (95% CI: 0.01-0.07%) using maximum likelihood estimation and Bayesian estimation, respectively. These data indicate the persistence of low levels of Wb infection in the EUs below the provisional threshold (<0.25%) set by WHO and are consistent with results of previous transmission assessment surveys. Our findings support the adoption of MX by the national LF elimination program to monitor transmission of infection in combination with host surveillance data, which could help prevent the recrudescence of LF.

6998

DETECTION OF *AEDES ALBOPICTUS* IN DISTRICT 3 OF MANAGUA, NICARAGUA

Jacqueline Mojica[1], Jose G. Juarez[1], Harold Suazo[1], Maria M. Lopez[1], Angel Balmaseda[1], Eva Harris[2], Josefina Coloma[2]

[1]Sustainable Science Institute, Managua, Nicaragua, [2]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

The Asian tiger mosquito, *Aedes albopictus* (Skuse), is an invasive mosquito species that has established itself in all continents of the globe, except for Antarctica. It is the vector of over 30 arboviruses, serving also as a bridge vector for diseases such as West Nile virus and Eastern equine encephalitis virus. Entomological larvae, pupae and adult surveys were conducted during the rainy and dry seasons of 2022 and 2023 in a rural (Nejapa) and urban (Camilo Ortega) sector of District 3 of Managua, Nicaragua. We randomly selected 500 households from a parent arboviral clinical and serological cohort study as well as 65 key sites, all in the catchment areas of our study health posts. All mosquito life stages were transported to our main facilities in Managua for classification and separation by stage (unfed and bloodfed), sex and species. We found only 2 larvae of *Ae. albopictus* in each survey of the dry season of 2022 (Camilo Ortega) and 2023 (Nejapa), with no *Ae. albopictus* found in the rainy season of 2022. However, in the 2023 rainy season, we collected 557 *Ae. albopictus* larvae-pupae and 223 adults in both communities. A total of 415 immature aquatic forms and 76 adult mosquitoes (65 females) were collected in households. In key sites, we collected 142 larvae/pupae and 137 adults (79 females). We observed that in >60% of households and >40% of keys sites, the preferred habitat for immature forms was "other container" (*i.e.,* boot, toy, plastic bottle, etc). Our results reveal the introduction of *Ae. albopictus* into communities of District 3 of Managua over the past two years. Further surveillance is required to determine if *Ae. albopictus* will displace *Ae. aegypti* in the area or if co-habitation will occur. Additionally, this ecological displacement is critical to determine in the context of novel vector control activities targeting *Ae. aegypti* in Managua.

6999

GLOBAL ANALYSIS OF *ANOPHELES STEPHENSI* BIONOMICS AND CONTROL APPROACHES THROUGH A SYSTEMATIC LITERATURE REVIEW

Tabeth Mwema[1], Sarah Zohdy[2], Mekala Sundaram[3], Christopher A. Lepzcyk[1], Lana Narine[1], Janna R. Willoughby[1]

[1]College of Forestry, Wildlife, and Environment, Auburn University, Auburn, AL, United States, [2]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, Georgia, United States of America, Atlanta, GA, United States, [3]Department of Infectious Disease, University of Georgia, Athens, GA, United States

Anopheles stephensi is a mosquito endemic to South Asia and the Arabian Peninsula that has recently expanded its range into Africa, posing a significant threat to global malaria control efforts. This study investigates the efficacy of trapping methods and larvicides and larvivorous fish in controlling *An. stephensi* mosquitoes through an analysis of global literature, identified by searching all relevant databases (PubMed, Web of Science, and Google Scholar) for studies focused on *An. stephensi*'s behavior and biology. Data from 83 articles revealed that host-seeking human-baited traps improve collection efficiency significantly when compared to mechanical baited traps, with no difference observed between human-baited and animal-baited traps. However, mechanical unbaited traps outperform mechanical baited traps. *Anopheles stephensi*'s indoor and outdoor biting and resting behaviors exhibit no significant difference, and its breeding habitats include discarded household utensils and vegetative areas. *Bacillus thuringiensis israelensis, Beauveria bassiana* and temephos are the most effective larvicides among those considered. Comprehensive surveillance programs covering both larval and adult populations are crucial for assessing intervention impacts and quantifying resistance levels. Increased use of biolarvicide control tools is recommended to control *An. stephensi*, since

resistance to traditional chemical insecticides is confirmed in adults. Understanding historical surveillance and control approaches is essential to the advancement of invasive *An. stephensi* mitigation efforts in Africa and the reduction of impacts on malaria morbidity and mortality.

7000

ASSESSMENT OF TWENTY-FOUR HOURS BITING PATTERNS AND HUMAN EXPOSURE RISK TO BITES OF *ANOPHELES* MOSQUITOES IN SOUTH-EASTERN TANZANIA

Constantine Mukisa Muwonge, Fredros O. Okumu, Halfan S. Ngowo

Ifakara Health Institute, PO Box 53, Ifakara, Tanzania., Morogoro, Tanzania, United Republic of

Over the past two decades, Tanzania has made remarkable progress in reducing the malaria burden, instilling hope for its elimination by 2030. This success is attributed to the large-scale implementation of core vector control interventions such as LLINs and IRS. However, persistent transmissions from 24 hour exposure to infective mosquito bites remain a challenge to current elimination efforts. This study aimed to assess the 24-hour biting patterns and human exposure risk to bites of *Anopheles* mosquitoes in Ulanga district South-eastern Tanzania to inform strategies for addressing persistent transmissions. Hostseeking mosquitoes were collected hourly using a miniaturized double net trap over 24 hours both indoors and outdoors. Pooled hourly collections were morphologically and stored as dried samples for subsequent laboratory analyses Data analysis was done using R statistical software and all tables charts and graphs were generated using grammar for graphics R package. *An. arabiensis* and *An. funestus* were found to be the major vectors in the study area, accounting for 94% and 4% of the entire collections respectively. Interestingly, both species exhibited a shift towards day-biting behavior and their aggressiveness was not just limited to morning and evening hours but widely distributed across the entire daytime period. There was no difference between indoor and outdoor biting rates of the two species except only during daytime for the case of *An. arabiensis*. More than half of the mosquitoes collected during the daytime were unfed, a probable indicator of daytime host-seeking behavior. More than 65 percent of the dissected mosquitoes were parous potentially indicative of an older population with high malaria transmission potential. The suddenness of the day-biting behavior of malaria vectors may potentially increase the risk of malaria transmission This highlights the need for novel tools to supplement the existing interventions and intensive community engagement to increase awareness regarding day-biting mosquitoes and their associated malaria transmission risk.

7001

CHARACTERIZATION OF THE SPECIFIC COMPOSITION, TROPHIC AND RESTING PREFERENCES AS WELL AS THE LEVEL OF INFECTION OF MALARIA VECTORS IN THE CITY OF OUAGADOUGO, BURKINO FASO

Nicolas Zanre[1], Aboubacar Sombié[2], Awa Gnémé[1], Hyacinthe K. Toé[1], Antoine Sanon[1], Athanase Badolo[1]

[1]University of Joseph KI-ZERBO, Ouagadougou, Burkina Faso, [2]University of Kaya, Kaya, Burkina Faso

Malaria in urban areas is a scourge whose importance is increasing with the increase in immigration to urban areas. Urban malaria remains a public health problem whose fight relies on better knowledge of vector biology. The objective of this research was characterize the specific composition, trophic and resting preferences as well as the level of infection of malaria vectors in the city of Ouagadougo. Adult mosquitoes were collected during the rainy season from July to October 2023 in the city of Ouagadougou. A total of 31 neighborhoods across three health districts (Baskuy, Bogodogo and Nongremassom) were visited. The choice of neighbourhoods in the three districts was 10 neighborhoods per district and was done randomly. Mosquitoes were collected outside and inside houses. The distance between the houses is 100 meters. Collections were made using electric vacuum cleaners. Collections were carried out in the morning between 6 a.m. and 9 a.m. and in the evening between 4 p.m. and 5 p.m. to increase the chances of collecting resting mosquitoes. PCR was used to identify the members of Anopheles gambiae complex, as well as the origin of the blood meals. The ELISA method was used to determine the infection of mosquitoes by *P. falciparum*. Approximately thirty-nine thousand seven hundred and twenty-seven (39,727) mosquitoes including 1,304 *Anopheles gambiae* s.l females were collected. After molecular identification, 1261 (96.7%) was *Anopheles arabiensis* and 43 (0.03%) from *Anopheles coluzzii*. Five hosts were identified as the source of blood meals, 108 (43.37%) human blood meals, 93 (37.65%) blood meals in cattle, 24 (9.71%) in pigs, 18 (7. 28%) on dogs and 04 (1.61%) on goats. The majority, 66.41% of *Anopheles gambiae* s.l were collected outside homes. A total of 10 mosquitoes infected with *P. falciparum* sporozites were identified, representing an infection rate of 0.7%. Anopheles represent 5.6% of the number of mosquitoes collected in the different areas. Despite this relatively low infection rate, the exophilic behavior of these mosquitoes, associated with rapid urbanization, deserves specific attention in the fight against malaria.

DEVELOPMENT OF ENVIRONMENTAL DNA (EDNA) SAMPLING FOR ARBOVIRUS VECTOR SURVEILLANCE IN SOUTHERN NEVADA

Katharine B. Major[1], Vivek Raman[2], Karen L. Figueroa Chilito[1], David Greer[2], Christian De Haan[2], John Cataline[2], Joseph Franceschini[2], Daniel Goldstein[2], Christopher Begay[2], Chad L. Cross[1], **Louisa Alexandra Messenger**[1]

[1]University of Nevada, Las Vegas, Las Vegas, NV, United States, [2]Southern Nevada Health District, Las Vegas, NV, United States

Accurate, rapid, and cost-effective surveillance of arbovirus mosquito vectors is critical for monitoring species distribution and infection prevalence and ultimately mitigating transmission risk. Vector surveys conducted by the Southern Nevada Health District (SNHD) are limited to a few productive sentinel sites, with considerable infrastructure and logistical requirements. New vector surveillance methods that are simple and unbiased at the sampling stage are needed. One potential method to increase efficient vector sampling capacity may be to exploit detection of environmental DNA (eDNA), shed by vectors breeding in aquatic environments. In this study, we first designed and optimized a novel multiplex TaqMan qPCR assay, based on SNPs in COXI, for simultaneous detection of the three major regionally important arbovirus vector species: *Culex* (*Cx.*) *quinquefasciatus*, *Cx. tarsalis,* and *Aedes* (*Ae.*) *aegypti*. 50ml water samples were collected from across Clark County using sterile plastic syringes and 0.22µm filters. Collection sites included water bodies that were adjacent to overnight gravid traps and BG sentinel traps, set by the SNHD, to compare vector species composition between sampling methods and additional aquatic environments in local public parks, golf courses, and drainage ditches. eDNA was extracted from filter membranes and screened for vector species presence using our qPCR assay. eDNA deposited by co-occupying *Cx. quinquefasciatus* and *Ae. aegypti* was detected in water samples, without observable larvae breeding, from multiple drainage ditches. *Cx. tarsalis* was identified in water samples from stormwater runoff and drainage channels in a public park. eDNA surveillance has the potential to be implemented as a field-friendly, arbovirus vector surveillance tool for expanded entomological monitoring capacity in southern Nevada, to detect changes in dispersal patterns of arbovirus vector species as well as the spread of new invasive vector species. eDNA amplicon-seq is ongoing to characterise vector population dynamics and insecticide resistance mechanisms to inform potential regional control initiatives.

UNDERSTUDIED MALARIA VECTORS MAY DRIVE RESIDUAL MALARIA TRANSMISSION IN CHOMA DISTRICT, AN AREA OF LOW MALARIA TRANSMISSION

Kochelani Saili[1], Limonty Simubali[1], Mary E. Gebhardt[2], Twig Mudenda[1], Japhet Matoba[1], Gift Mwaanga[1], Mukuma Lubinda[1], Lewis Chuula[1], Reginald Nawa[1], Ben Katowa[1], Edgar Simulundu[1], William J. Moss[2], Douglas E. Norris[2], Int'l Centres for Excellence in Malaria Research --[3]

[1]Macha Research Trust, Choma, Zambia, [2]Department of Molecular Microbiology and Immunology, Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]

Choma District in southern Zambia continues to measure low rates of malaria transmission despite very low counts of f what have been recognized as the primary vectors, *Anopheles funestus* and *An. arabiensis.* This altered vector landscape may create opportunities for understudied secondary vectors to subsequently act as sources of residual malaria as demonstrated by the recent presence of *Plasmodium falciparum* sporozoites in *An. squamosus, An. coustani* and *An. rufipes*. This study investigated understudied malaria vectors; species composition, relative abundance, and sporozoite infectivity as measures of potential malaria transmission. The study was conducted in three catchment areas of Choma district; Macha, Simaubi and Mapanza, which together recorded a parasite prevalence of less than 1% from October 2022 to February 2024. Forty-eight sentinel households in historical malaria hotspots were recruited. Monthly, Center for Disease Control and Prevention Light Traps were set indoors (sleeping area), the peri domestic area (outdoor kitchens) and near animal shelters (goat pens and/or cattle kraal). In 1,991 trap night-traps, 11,114 *Anopheles* mosquitoes were collected. *Anopheles squamous* was the dominant species (*n*=5,190; 58.6%). Other species were *An. gambiae* s.l., *An. coustani* s.l., *An. rufipes*, *An. pretoriensis*, *An. funestus* group, *An. Pharoensis* and most mosquitoes were collected from goat pens (n=8,112; 73.0%). There was a statistically significant higher mean count of anopheline mosquitoes outdoors in the peri domestic area (mean=1.44, 95% CI 1.22-1.65) and outdoors near goat pens (mean=23.8, CI 22.7-24.9) than indoors (mean= 0.78, CI 0.68-0.89) (t-test, $t_{(1483)} = 8.38$, $P > 0.001$ and $t_{(1483)} = 4.88$, $P > 0.001$ respectively). Sporozoite infectivity rates in *An. coustani, An. squamosus* and *An. rufipes* were 0.52%, 0.58% and 0.10% respectively. High outdoor counts of understudied malaria vectors present a potential risk to sustaining residual malaria transmission.

7004

THE ESCALATING BIOLOGICAL THREAT: OBSERVATIONS FROM TEN YEARS OF MAPPING INSECTICIDE RESISTANCE IN MALARIA VECTORS.

Stephen O. Okeyo[1], Duncan K. Athinya[1], Seline A. Omondi[2], Eric O. Ochomo[2], Melinda P. Hadi[3]

[1]Vestergaard Frandsen EA Ltd, Nairobi, Kenya, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Vestergaard Sarl, Lausanne, Switzerland

Insecticide resistance remains a key biological threat recognized by World Health Organization (WHO) as a key biological threat to the stagnating gains in malaria control and elimination. Insecticide Resistance Management (IRM) is important to identify areas where resistance has been reported and understand the associated resistance mechanisms. IR Mapper has offered insecticide resistance mapping support since 2012. IR Mapper collates insecticide resistance information reported in peer reviewed, published literature, with monthly updates. These are loaded onto a cloud database, then visualized on the mapping platform developed using ArcGIS API. Partnerships and collaborations have been focal in the IR Mapper process. Growing from a platform that maps phenotypic resistance and resistance mechanisms, to addition of malaria endemicity layers and modelled surfaces that predict the probability of resistance to cover scarcity of resistance data due to monitoring constrains. This analysis gives a view of pyrethroid resistance trends between the years 2000-2015, when pyrethroid LLINs offered the greatest impact against malaria, and 2016-2023 when gains stagnated, focusing on sub-Saharan Africa which holds more than 90% of global malaria cases and deaths. By the main vector species, pyrethroid resistance in *Anopheles gambiae* s.l., increased 1.3-fold, from a median mortality of 59 (IQR: 30-78) between 2000-2015 to a median mortality of 45 (IQR: 16-72) between 2016-2023. In *An. funestus*, pyrethroid resistance has grown from a median mortality of 54 (IQR:23-74) in 2000-2015 to a median mortality of 60 (IQR: 40) in 2016-2023. The most reported resistance mechanism are knock-down resistance gene mutations and over expression of mixed function monooxygenases. Regions with the highest malaria burden also show high levels of pyrethroid resistance. IR Mapper continues to be a valuable tool in aiding vector control decisions by being a point of reference for up-to-date insecticide resistance data. With ever changing needs, IR Mapper is getting an update to encompass additional molecular resistance mechanisms such as the P450 gene family data.

7005

QUANTIFYING FEW, FIXED, AND FINDABLE: A DIGITAL, STRATIFIED SURVEILLANCE APPROACH TO ASSESS LARVAL SOURCE MANAGEMENT FEASIBILITY IN MOZAMBIQUE'S CAPITAL CITIES

Samira Sibindy[1], Alexandra Wharton-Smith[2], Dulcisaria Marrenjo[1], Abdul Sumail[2], Paul Hollwedel[2], Arnon Houri Yafin[2], Baltazar Candrinho[1]

[1]NMCP, Ministry of Health, Maputo, Mozambique, [2]ZzappMalaria, Tel Aviv, Israel

Malaria remains a major health challenge in Mozambique. Insecticide-treated nets and indoor residual spraying face issues such as rising insecticide resistance and outdoor biting, and depend on community compliance. Larval source management (LSM) offers a supplementary method, especially in urban and semi-urban areas. To evaluate the feasibility of Larval Source Management (LSM) and its alignment with the "few, fixed, and findable" criteria set by the WHO, we assessed the density, types, positivity, and permanency of water bodies in the 11 provincial capital cities of Mozambique. To ensure unbiased sampling, we combined stratified and random sampling methods, enhancing the representativeness of our data. All areas of the cities were stratified based on factors such as population density, topography, and proximity to rivers. Sectors were randomly selected for surveillance from each strata. Field officers were assigned to walk through the selected sectors and report water bodies using the Zzapp mobile app. Water bodies were reported, categorized (e.g., swamp, agricultural), and sampled for larvae. In all cities, the density of water bodies was below 200 per square kilometers, making LSM feasible. With over 50 houses per water body, the cost per person for LSM is projected to be low ("Few"). Most water bodies were classified as permanent or semi-permanent ("Fixed"). Field workers thoroughly mapped the area, and we report related quantitative measures for area coverage and community acceptance ("findable"). In total, an area of 34.3 sq km was scanned, revealing 3,168 water bodies. Among all sampled water bodies across 11 cities, positivity rates for Anopheles and non-Anopheles larvae were 3% and 11%, respectively, with regional variations for Anopheles between 2-5%. Water bodies hosting Anopheles larvae included ponds (8%), swamps (4%), and other sites like puddles, agricultural, and construction sites (~2%), while pools and tires were not conducive to Anopheles larvae. The study provides a quantitative evaluation of the "few, fixed, and findable" criteria and suggests that all cities included in the study meet the WHO standards for LSM.

7006

HOW DOES BEDNET USE AFFECT FEMALE *ANOPHELES* EXPOSURE IN COTE D'IVOIRE: ASSESSING VECTOR-HUMAN INTERACTION USING ENTOMOLOGICAL SURVEILLANCE AND ACCELEROMETER-BASED BEDNET MONITORING

Soro Dramane[1], **Paul Krezanoski**[2], Laurence Yao[1], Benjamin Koudou[1]

[1]Centre Suisse de Recherches Scientifiques in Côte d'Ivoire, Abidjan, Côte d'Ivoire, [2]University of California, San Francisco, San Francisco, CA, United States

The timing of bednet use may not correspond with the timing of vector exposure in malaria-prone households leading to continued transmission of malaria despite wide-scale distribution of long-lasting insecticide treated bednets. Surveys about bednet use provide only a snapshot of bednet use the previous night, whereas remote monitors can provide objective measurements of whether a bednet is in use over longer time periods. This observational study deployed accelerometer-based bednet monitors in Cote d'Ivoire to assess how exposure to female *Anopheles* mosquitoes overlapped with patterns in bednet use. Bednet use monitors were attached to the side of one bednet in each of 50 households from 3 regions representing different malaria transmission settings: urban Yamoussoukro (20 households), peri-urban Tiassalé (20) and rural Korhogo (10). Accelerometer data was classified using a previously trained random-forest machine learning algorithm (Koudou et al. 2022). Entomological surveillance was performed using window traps. Mixed-effects regression models were employed to account for multiple measures per household. Negative binomial regressions were used to assess the biting rate, defined as the number of fed *Anopheles* mosquitoes retrieved from the window traps per night. Fifty households were followed for a mean of 115 nights each (5,749 total nights), and mean bednet use was 10.3 hours per night (95% CI: 9.8 - 10.9). Each additional hour of bednet use per night was associated with a 4.0% decrease in the nightly biting rate (95% CI: 0.0% to 7.5%; p=0.03), which is equivalent to 29.4% decreased rate of mosquito biting for each hour of additional bednet use averaged over a month. There were differences between regions, with peri-urban Tiassalé (+83%; p=0.05) and urban Zatta (+94%; p=0.07) having higher rates of fed mosquitoes compared to Korhogo. These findings suggest that bednets provide variable protection between regions based on differences in vector and human behaviors. Further work characterizing these differences by vector species and the timing of biting could shed light on better ways to prevent malaria in the future.

7007

ADVANCES IN ARTIFICIAL INTELLIGENCE FOR VECTOR IDENTIFICATION AND MONITORING

Tristan Ford, Jewell Brey, Sameerah Talafha, Thomas Jenkins, Sanket Padmanabhan, Roy Faiman, Autumn Goodwin

Vectech, Baltimore, MD, United States

Recent advances in artificial intelligence and machine learning, such as the use of convolutional neural networks (CNNs) for image recognition, have emerged as a promising modality with the capability to visually differentiate between mosquito species. Here we present the first performance metrics of IDX, Vectech's system for AI mosquito identification, as part of Maryland's mosquito control program in the USA. Specimens were collected over 14 weeks in 2023 from 12 CDC gravid trap collection sites in Anne Arundel county, identified morphologically by an entomologist, and imaged using the IDX system. By comparing entomologist identification to the algorithm output by IDX, we are able to calculate the accuracy of the system across species. Over the study period, 2,591 specimens were collected and imaged representing 14 species, 10 of which were available in the identification algorithm on the device during the study period. The micro average accuracy was 94.9%. Of these 10 species, seven consisted of fewer than 30 samples. The macro average accuracy when including these species was 79%, while the macro average when excluding these species was 93%. In the next iteration of this technology, Vectech is optimizing the vector identification capabilities of IDX to handle high-accuracy identification of both primary and secondary malaria vectors including *Anopheles gambiae s.l., An. funestus, An. stephensi, An. coustani, An. pharoensis* and others that will allow public health organizations in malaria endemic countries to increase entomological surveillance capability. These advances demonstrate the utility of artificial intelligence in contemporary entomological practice and its potential to support current vector surveillance and control programs around the world.

7008

DOES DOMESTIC USE OF INSECTICIDAL SPRAYS UNDERMINE PUBLIC HEALTH CONTROL STRATEGIES?

Walter Fabricio Silva Martins[1], Lee Haines[2], Martin J. Donnelly[1], David Weetman[1]

[1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]University of Notre Dame, Indiana, IN, United States

Despite the ongoing threat of evolving insecticide resistance to anti-mosquito campaigns worldwide, insecticide-based intervention remains the primary strategy for preventing vector-borne disease (VBD) transmission. Untangling the drivers of mosquitoes' evolving resistance to insecticides is critical for resistance management and interventions' effectiveness. Meanwhile, public health and agriculture-related insecticide use have been suggested as primary drivers of increased mosquito resistance, although the role of household insecticide use for self-protection remains an unappreciated contributing factor. Herein, we aimed to assess the level of household insecticide usage in VBD-endemic countries through a literature review and determine mosquito resistance to pyrethroid-based domestic insecticides. Our findings indicate that using household insecticides for self-protection has been commonplace over the past decade in all 19 studied countries across the Americas, Africa and Asia, with ≈60% of homeowners surveyed using insecticide-based products. Our results also suggest that the widespread use of domestic insecticides may impose heterogeneous insecticidal selection pressure, driven by a vast spectrum of pyrethroid blends identified worldwide within 67 distinct insecticidal aerosol products. Aerosolized household formulations may vary in effectiveness - our susceptibility results for 10 *Aedes aegypti* populations from three Brazilian Northeastern states (PB, PE, RN) revealed mortality rates from 30% to 100%, which aligns with susceptibility profiling against public health pyrethroid insecticides. Furthermore, genotypic-phenotypic inferences indicate that ≈100% of surviving *Ae. aegypti* mosquitoes exposed to two aerosolized insecticides were triple-resistant homozygotes (*Kdr* - 410Leu/016Ile/1534Cys), which are also known to impact public health insecticides efficacy. Together, this evidence highlights the need to re-scrutinise the impact of private use of domestic insecticides on public health programmes to ensure the sustainability of current and novel vector control interventions.

APPLICATION OF PREDICTIVE MODELLING OF DENGUE CASE NUMBERS USING METEOROLOGICAL DATA IN PERU

Samuel Cutler, Allegra Wilson, Najeevan Soor, Jacqueline Buchanan

Airfinity LLC, London, United Kingdom

Climate change is anticipated to increase the frequency and magnitude of extreme weather events during the El Niño Southern Oscillation (ENSO), intensifying meteorological determinants that compound mosquito-borne diseases. In 2023, Peru experienced its highest-ever dengue burden after surpassing 270,000 cases, and the situation is expected to worsen with ENSO continuing from June 2023 into 2024. The objective of this study is to assess the accuracy and applicability of a meteorological predictive model for dengue cases in Peru amidst varying scenarios during ENSO, with potential adaptability to other ENSO-affected countries. Weekly dengue cases for Peru and meteorological data from January 2014 to July 2023 were aggregated monthly. Using a linear model with a five-month lag

applied to meteorological variables, we forecasted dengue cases from July 2023 to July 2024. Forecast accuracy was assessed by the percentage error between forecasted and actual case counts. ENSO projection scenarios of an increase in the ten-year monthly precipitation average of 10%, 20%, and 50% were evaluated. Monthly dengue cases correlated with precipitation, but not temperature. Forecasting projected 292,337 cases (CI: 213,256-400,742) by the end of 2023 and 188,455 (CI: 135,815-261,497) dengue cases for the first half of 2024. Forecasts were accurate to +/- 7% difference for the last half of 2023 and February 2024, while a difference of -52.7% was observed for January 2024, likely exaggerated by small numbers due to reporting year recalibration. ENSO projections for increases in the ten-year monthly precipitation average for the first half of 2024 ranged from 223,530 (CI: 160,164-311,967) to 442,437 (CI: 308,735-634,039). The forecasting success demonstrates the potential of this methodology as an early warning system for dengue-endemic countries increasingly affected by weather events brought on by climate change. Projection scenarios can be used to better target existing vector control interventions as dengue vaccination capacity is further developed.

7010

SEMI-FIELD EVALUATION OF AQUATIC PREDATORS FOR THE CONTROL OF *ANOPHELES FUNESTUS* IN RURAL SOUTHEASTERN TANZANIA

Herieth H. Mahenge, Letus L. Muyaga, Joel D. Nkya, Andrew D. Kafwenji, Yohana A. Mwalugelo, Najat F. Kahamba, Halfan S. Ngowo, Emmanuel E. Kaindoa
Ifakara Health Institute, Morogoro, Tanzania, United Republic of

Biological control is a promising alternative or complementary approach for controlling vector populations in response to the spread of insecticide resistance in malaria vectors. This study evaluated the efficacy of three selected potential predators on the density and fitness parameters of *Anopheles funestus* larvae in rural Tanzania. Common predator families (Aeshnidae, Coenagriondae, and Notonectidae) and *An. funestus* group larvae were collected from natural aquatic habitats in rural south-eastern Tanzania. Predators were starved for 12hours while *An. funestus* larvae were given fish food before starting the experiment. *Anopheles funestus* larvae were placed into artificial habitats containing predators, exposing them to potential predation. The number of surviving *An. funestus* larvae was counted every 24hours. An emergence trap was placed at the top of artificial habitats to capture emerging mosquitoes. Emerged mosquitoes were monitored until they died. Female wings were measured and used as a proxy for body size. Generalized linear mixed models (GLMM) with binomial variates at 95% CI and Cox proportional hazard models were used to assess the proportion of dead mosquitoes and the daily survival determined. There were significant differences in the number of emerged mosquitoes between the treatment and control groups ($p<0.001$). Thus, all predator species played a significant role in reducing the density of *An. funestus* mosquitoes ($P<0.001$). Furthermore, these predators had notable effects on the fitness parameters and survival of emerged mosquitoes ($P<0.001$). Among the three predators studied, Coenagrionidae were most efficient followed by Notonectidae, with Aeshnidae being the least efficient. Selected aquatic predators have the potential to reduce the survival and density of *Anopheles funestus* larvae. They might eventually be included within an integrated malaria vector control strategy, ultimately leading to a reduction in malaria transmission.

7011

NAVIGATING THE EVALUATION OF NOVEL IRS PRODUCTS: LESSONS LEARNED FROM ASSESSING RESIDUAL EFFICACY WITHOUT SUSCEPTIBLE MOSQUITO COLONIES

Oscar Urrutia[1], Patricia Benitez[1], Lucía Fernández Montoya[2], Seneyda Castañeda[1], Adelman Cortés[3], Juan Carlos Fajardo[3], Lenin Barahona[3], Juan Miguel Flores[4], Lorenzo Ubaldo Pavon Rodriguez[1], **Nicole Álvarez-Fernández**[5]
[1]Ministry of Health Honduras, Tegucigalpa, Honduras, [2]Clinton Health Access Initiative, Panama City, Panama, [3]Ministry of Health Honduras, Comayagua, Honduras, [4]Solintsa, Tegucigalpa, Honduras, [5]Clinton Health Access Initiative, Tegucigalpa, Honduras

Novel, longer-lasting insecticidal products are now on the market that can help countries extend IRS protection and combat resistant mosquitoes. However, residual efficacy varies widely from setting to setting. While the need to measure the residual efficacy of such products prior to their implementation is paramount to appropriately targeting them, justifying their higher price point, and sometimes even for registering the product, many countries lack the susceptible mosquito colonies required to do so. One such example, Honduras, was in search for a longer-lasting product capable of addressing resistant vector populations, yet did not have a susceptible colony to measure its local residual efficacy. With support from CHAI and Envu, the country embarked on a study to evaluate the residual efficacy of Fludora® Fusion on local surfaces using local wild mosquitoes. This session presents the findings of the study conducted in Honduras, highlighting the challenges encountered in the absence of a susceptible mosquito colony and because of the specific post-exposure holding times required for assessing this innovative product. The lessons learned will support other countries that, like Honduras, are interested in introducing novel IRS products and need practical solutions to overcome a lack of susceptible mosquito colonies to measure their residual efficacy.

7012

DEVELOPMENT AND EVALUATION OF A NOVEL, MULTI-ACTIVE INGREDIENT ATTRACTIVE TOXIC SUGAR BAIT FOR MOSQUITO CONTROL

Alexandra Bauer, Daniel W. Pérez-Ramos, Abdullah A. Alomar, Raquel Lima de Souza, Maria EB Resck, Yesenia L. Sanchez, Ana Romero-Weaver, Eva A. Buckner, **Eric P. Caragata**, Barry W. Alto
University of Florida, Vero Beach, FL, United States

The continuingly high burden of disease caused by mosquito-borne pathogens highlights the need to develop novel tools to suppress mosquito populations. Attractive toxic sugar baits seek to exploit mosquito nectar-feeding behavior through a lure-and-kill approach, coaxing mosquitoes to feed on baits containing a lethal products. To be viable, these products must retain their efficacy for weeks or even months after their initial deployment. Declines in activity over time could potentially mediate resistance amongst exposed mosquitoes. To address this issue, we have developed a novel attractive toxic sugar bait that contains several different chemical and microbial active ingredients. Each active ingredient mediates adult mosquito mortality through a distinct mechanism, potentially mitigating issues of insecticide resistance. Our data demonstrate high efficacy of this bait as an attractant. We observed rapid, and significant mortality amongst pyrethroid-susceptible and -resistant, adult *Aedes aegypti* and *Culex quinquefasciatus* mosquitoes after feeding on the bait under laboratory conditions. We also demonstrate synergistic mortality effects accrued when the different active ingredients were tested in combination. Semi-field trials highlight that the bait retains high mosquitocidal activity under environmental heterogeneity. Further testing of the bait is ongoing, but these initial findings highlight a promising new tool for mosquito control.

7013

HOW FREQUENTLY DO WE NEED TO TREAT BREEDING SITES WITH *BACILLUS THURINGIENSIS ISRAELENSIS* (*BTI*)? EVIDENCE FROM LARGE-SCALE LARVAL SOURCE MANAGEMENT ON BIOKO ISLAND

Jeremias Nzamio Mba Eyono[1], Nestor Rivas Bela[1], Restituto Mba Nguema Avue[1], Lucas Ondo Nze[1], Santiago Eneme Mbang[1], Salvador Akue Obiang[1], David S. Galick[1], Wonder P. Phiri[1], David L. Smith[2], Guillermo A. García[3], Carlos A. Guerra[3]

[1]MCD Global Health, Malabo, Equatorial Guinea, [2]University of Washington, Institute of Health Metrics and Evaluation, Seattle, WA, United States, [3]MCD Global Health, Silver Spring, MD, United States

Larval source management (LSM) is one of the few vector control interventions available to target indoor and outdoor biting mosquitoes. In 2023, due to increasing evidence of residual biting both indoors and outdoors, the Bioko Island Malaria Elimination Project (BIMEP) expanded LSM in urban Malabo as a complement to indoor household interventions. The larvicide *Bacillus thuringiensis israelensis* (*Bti*) in granular form was used due to it being available, affordable and easy to apply. A critical aspect of the product is the required frequency of treatment of breeding sites to maximize impact. The manufacturer recommends a 7-to-14-day frequency of application, however there is limited field evidence about the effect size of different frequencies. Here, we investigate the effect of treatment frequency over four months (85 field days) in urban Malabo. At varied frequency bins, daily data on prospective breeding sites detected, verified positive sites, and sites treated were utilized to estimate positivity rate (sites positive/sites found/day). The median frequency of field teams visiting target areas was 10 days. Initial findings reveal a 7-day revisit frequency considerably lowers positivity rates than longer intervals. Visit frequency bins of 8-10, 11-14, and 15-20 days had similar effects on positivity, while frequencies longer than 20 days did not significantly reduce positivity relative to baseline. These findings may be context specific, and suggest that on Bioko, shorter than longer intervals did maximize the impact of LSM. This represents an operational challenge as shorter revisit intervals demand more resources. Moreover, the fact that medium intervals (between 8-20 days) appear to provide similar results in positivity that remain significantly below baseline levels gives some implementation flexibility. As part of the BIMEP's approach to adaptive malaria control, this information will prove useful to inform LSM targeting strategies whereby places with higher larval densities could be revisited at the highest operationally feasible frequency while others can be visited at the longer intervals resulting in impact.

7014

ASSESSING THE SUSCEPTIBILITY AND EFFICACY OF TRADITIONAL NEUROTOXIC (PYRETHROID) AND NEW GENERATION INSECTICIDES (CHLORFENAPYR, CLOTHIANIDIN, AND PYRIPROXYFEN), ON WILD PYRETHROID RESISTANT POPULATIONS OF *ANOPHELES GAMBIAE* FROM SOUTHERN BENIN

Germain Gil Padonou[1], David Mahouton Zoungbédji[1], Alphonse Keller Konkon[1], Albert Sourou Salako[1], Virgile Gnanguènon[2], Raoul Oloukoi[2], Daniel Impoinvil[3], Lamine Baba-Moussa[4], Martin C. Akogbéto[1]

[1]Ministère de la Santé, Cotonou, Benin, [2]US Agency for International Development, Cotonou, Benin, [3]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Université d'Abomey Calavi, Abomey Calavi, Benin

This study aimed to determine the susceptibility of wild *Anopheles gambiae* sensu lato (s.l.), the main malaria vector in southern Benin, to chlorfenapyr (CFP), pyriproxyfen (PPF), clothianidin (CTD), and three pyrethroids insecticides (alpha cypermethrin, deltamethrin, and permethrin). Additionally, the efficacy of ITNs containing CFP, PPF and alpha-cypermethrin (ACM) was assessed with wild *An. gambiae* s.l. reared to adults from larvae and the susceptible laboratory strain, *An. gambiae* sensu stricto (Kisumu). Wild *An. gambiae* from the communes of Allada, Ifangni, Akpro Missérété, and Porto-Novo were tested for susceptibility to CFP and PPF using the WHO bottle test and to the pyrethroids and CTD using the WHO tube test. WHO ITN efficacy tests using standard plastic cones were used to evaluate the efficacy of ACM only, (CFP, ACM), and (PPF, ACM) nets. The ovaries of blood fed *An. gambiae* from Ifangni and the susceptible laboratory strain, *An. gambiae* (Kisumu) exposed to a PPF treated net were dissected, and egg development status was examined using Christopher's stages to determine the fertility status. Using a standardized protocol, the oviposition rate and oviposition inhibition rate were calculated from live blood fed *An. gambiae* placed in oviposition chambers after exposure to PPF. In resistance bioassays, the mosquito populations from the four communities, pyrethroid mortality ranged from 5% to 80%, while CFP and CTD mortality ranged from 98% to 100%. At Ifangni, all mosquitoes exposed to nets with (PPF, ACM) were infertile while most (74.9%) of mosquitoes exposed to nets with ACM only had fully developed their eggs to Christopher's stage five. The oviposition inhibition rate after exposure of the mosquitoes to the PPF was 99% for the wild population of *An. gambiae* s.l. and *An. gambiae* (Kisumu). Pyrethroid-resistant *An. gambiae* from the selected communes in southern Benin were susceptible to CFP, CTD, and PPF. Furthermore, nets with (PPF, ACM) and (CTD, ACM) insecticides were effective against pyrethroid resistant mosquitoes from Ifangni. Continued monitoring for insecticide resistant *An. gambiae* is needed in Benin.

7015

SPECIES-SPECIFIC SALIVARY ANTIGEN ELISAS AS BIOMARKERS OF EXPOSURE TO LA CROSSE VIRUS VECTORS IN NORTH CAROLINA

Hannah Alexander[1], Berlin Londoño-Renteria[2], Ross Boyce[3], Brian Byrd[1]

[1]Western Carolina University, Cullowhee, NC, United States, [2]Tulane University, New Orleans, LA, United States, [3]UNC-Chapel Hill, Chapel Hill, NC, United States

La Crosse virus (LACV) is the leading cause of pediatric arboviral neuroinvasive disease in the United States. Three mosquito species are likely responsible for the majority of LACV transmission – *Aedes triseriatus*, the primary, endemic vector and two invasive, secondary vector species: *Ae. albopictus* and *Ae. japonicus*. The risk of LACV disease is geographically persistent in North Carolina; however, current estimates of disease risk do not accurately reflect exposure risk or the genuine burden of disease. Furthermore, low incidence and poor detection rates grossly limit the evaluation of potential public health interventions. We seek to use mosquito salivary gland ELISAs to measure LACV vector exposure as a proxy for exposure/disease risk. Here we share the development of salivary gland (crude extract) IgG ELISAs for *Ae. triseriatus*, *Ae. albopictus* and *Ae. japonicus*. Using convenience human sera (n=41 individuals) from North Carolina, we compared optical density (OD) values for all three species. Pairwise comparisons (ANOVA, Tukey's HSD comparisons) detected higher mean OD values for *Ae. albopictus* as compared to *Ae. triseriatus* ($P = 0.013$). This is consistent with prior knowledge that *Ae. albopictus* is the more common peridomestic container *Aedes* in the areas where the human samples were obtained (Piedmont NC). Field and colony OD values of *Ae. triseriatus* were highly correlated ($r=0.88$) suggesting homologous immunogenic proteins are present in divergent species strains. The results of ongoing western blot and peptide sequence analyses will be shared. The application of these novel methods will be further demonstrated using field collected human sera from ongoing epidemiological studies in western NC (Summer 2024).

7016

IMPACT OF INDOOR RESIDUAL SPRAYING WITH SUMISHIELD® 50WG ON ENTOMOLOGICAL DRIVERS OF TRANSMISSION IN KIGOMA REGION NORTHWEST TANZANIA

Alphaxard Manjurano[1], Karen Nelwin[1], Eric Lyimo[1], Coleman Kishamawe[1], Jacklin Mosha[1], Ziada Kiwanuka[1], Doris Mangalu[1], Charles Dismas Mwalimu[2], Gaudence Rutta[3], Naomi Serbantez[4], Lulu Msangi[4], Kristen George[5], Lilia Gerberg[5], Bradford Lucas[5], Mubita Lwifwatila[3], Sheila Ogoma Barasa[3]

[1]National Institute for Medical Research, Mwanza, Tanzania, United Republic of, [2]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [3]Vector Link- Abt Associates, Mwanza, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, USAID, Dar es Salaam, Tanzania, United Republic of, [5]U.S. President's Malaria Initiative, USAID, Washington DC, WA, United States

Despite the deployment of insecticide-treated nets (ITNs), indoor residual spraying (IRS), and artemisinin-based combination therapy (ACT), the population in Tanzania's Lake Zone remains at high risk of malaria transmission. PMI VectorLink Tanzania has supported IRS implementation in the region since 2015. The impact of IRS on transmission drivers was assessed through routine entomological surveillance. The IRS campaign with SumiShield® 50WG took place from October 5th to November 4th, 2022, in Kasulu and Kibondo districts. Monthly entomological surveillance, using various methods, was conducted before and after spraying in three sentinel sites: Kagerankanda and Minyinya (sprayed) and Murufiti (unsprayed). *Anopheles* species collected included *An. gambiae* (25.1%), *An. funestus* (29.8%), *An. arabiensis* (44.9%), and *An. parensis* (0.2%) in sprayed sites, with *An. funestus* predominating (75.1%) in unsprayed sites. Indoor resting densities were generally higher in Minyinya and Murufiti than in Kagerankanda. IRS led to reduced human biting rates in sprayed sites compared to unsprayed ones. Annual Entomological Inoculation Rates (EIR) varied, with the lowest in Kagerankanda (0 i/b/p) and the highest in Minyinya (39 i/b/p) and Murufiti (19.5 i/b/p). IRS with SumiShield® 50WG reduced human biting rates in sprayed areas, suggesting its effectiveness. However, varied impacts on indoor resting densities and EIR were observed, with reduced transmission noted in one sprayed site.

7017

COMPARISON OF UNTREATED AND TREATED INSECTICIDE-TREATED NETS TO DETERMINE THE VALIDITY OF WHO TUNNEL ASSAYS

Kenio Mawa Benson

Kilimajaro Christian Medical University Collage, Moshi, Tanzania, United Republic of

The WHO has established guidelines that provide specific, standardized procedures for testing Insecticide-Treated Nets (ITNs) for personal protection and malaria vector control. In these guidelines, the tunnel test is recommended for the evaluation of bio-efficacy of Insecticide treated nets against malaria transmitting mosquitoes. The laboratory bioassays results are an indicator of the bioavailability of the active ingredient of the tested product samples. In standard tunnel test a restrained bait (guinea pig or rabbit) is exposed to 50-100 mosquitoes for 12-15h overnight. According to animal welfare regulations, restraining laboratory animals for prolonged periods should be avoided unless it is not possible to achieve research objectives by other means. Here, three tunnel assays: 3-hours daytime, 6-hours daytime with sedated guinea pigs and 15h overnight with un-sedated bait were conducted. Firstly, untreated net was used to determine the feeding success. Then treated net material (unwashed Olyset) was evaluated and the main outcome measure was mortality and blood feeding success (BFS) which are determinants of a WHO tunnel assay validity. Both pyrethroid resistant and susceptible mosquito strains were used in the assay. The control experiments all replicate of both Kisumu and Muleba KisKis strains passed the WHO criteria of blood feeding success > 50%. In the treatment arm using susceptible Kisumu strain the % mean mortality at 24 hours was 90%, 84% and 98% for 3h day, 6h day and 15h overnight respectively while blood feeding inhibition was 87%, 73%, 92% for 3h day, 6h day and 15h overnight respectively. For the resistant strain Muleba Kis the %mean mortality at 24 hours was 8%, 35% and 23% for 3h day, 6h day and 15h overnight respectively, the blood feeding inhibition was 51%,30% and 27% for 3h day, 6h day and 15h overnight respectively. The results suggest that it is possible to avoid restraining laboratory animals for prolonged period of time by replacing the traditional method with the modified tunnel and achieve the recommended WHO research objectives.

7018

LATE MORNING BITING BEHAVIOUR OF *ANOPHELES FUNESTUS* IS A RISK FACTOR FOR MALARIA TRANSMISSION IN SCHOOLS IN SIAYA, WESTERN KENYA

Seline Omondi[1], Jackline Kosgei[1], George Musula[1], Margaret Muchoki[1], Bernard Abong'o[1], Silas Agumba[1], Caroline Ogwang[1], Daniel P. McDermott[2], Martin J. Donnelly[2], Sarah G. Staedke[2], Jonathan Schultz[3], Julie R. Gutman[3], John E. Gimnig[3], Eric Ochomo[1]

[1]Entomology section, Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States

Children in Kenya spend a substantial amount of time at school, including at dawn and dusk when mosquitoes are often active. With changing vector behaviour towards early morning biting, it is important to determine whether there is an additional risk of transmission in schools. This study sought to understand whether late morning biting by *Anopheles funestus* previously documented in households in western Kenya was replicated in schools. From the 4th to the 6th of August 2023, human landing collections were conducted hourly in four schools in Alego Usonga Sub-County, Siaya County. The collections were conducted inside and outside five classrooms in each school and ran for 17 hours, starting at 18:00 until 11:00 hours the next morning. *Anopheles funestus* was the predominant species collected, accounting for 93.2% of the 980 mosquitoes collected, with peak landing between 06:00 and 07:00 hours and continuing until 11:00 hours. All *An. funestus* were identified as *An. funestus* sensu stricto by PCR. More than half of the collected *An. funestus* were either fed or gravid, potentially indicative of multiple bloodmeals within each gonotrophic cycle, and had a sporozoite rate of 2.05%. Other species collected included *An. gambiae* sensu lato (n=49; 6.3%), *An. coustani* (n=2, 0.26%), and *An. ziemanni* (n=2, 0.26%). Of the 49 *An. gambiae* s.l., 48 were identified by PCR as *An. arabiensis*. None of the *An. gambiae* s.l. tested positive for sporozoite infection. School children spend up to 10 hours per day at school, reporting between 06:00 and 07:00 hours and often staying in school until 17:00 hours, meaning that they are potentially exposed to infectious mosquito bites while at school. Targeting vector control approaches to schools and other peridomestic spaces in the morning hours when *An. funestus* is active may help control malaria in school-aged children.

7019

KNOCKING OUT TO KNOCK IN: IMPACT OF LOSS OF END JOINING FACTORS ON HOMOLOGY DIRECTED REPAIR INCIDENCE IN THE DISEASE VECTOR MOSQUITO, *AEDES AEGYPTI*.

Daniel B. Whitefield, Keun Chae, Zach N. Adelman

Texas A&M University, College Station, TX, United States

Aedes aegypti mosquitoes are vectors for a number of viruses of public health concern. Homing-based gene drives offer an intriguing tool to combat these disease vectors. Many homing-based gene drives leverage the Double Strand Break (DSB) repair pathway, Homology Directed Repair (HDR), to convert wild type genes to the engineered drive gene. However, another DSB repair pathway, Non-Homologous End Joining (NHEJ), is antagonistic to HDR and can even result in resistance alleles that prevent further super-Mendelian inheritance from the gene drive. Here, we utilize

previously generated *Aedes aegypti* strains with key NHEJ factors knocked out to evaluate the impact of loss of NHEJ efficiency on the incidence of HDR. The key NHEJ factors and associated knockout strains are *Ku80* (Ku80$^{-/-}$ strain), *DNA-PKcs* (DNA-PKcs$^{-/-}$ strain), and *Ligase IV* (Lig4$^{-/-}$ strain). We initiated site-specific DSBs utilizing CRISPR/Cas9 and guide RNA targeting a locus in the *kmo* gene (which is involved in eye pigmentation to allow for facile phenotype screening of results). Our data suggest that a loss of NHEJ efficiency in the germline cells of *Aedes aegypti* is compensated for by an increase in the incidence of HDR. Knockout of *DNA-PKcs* and *Ligase IV*, but not *Ku80* elevates the rate of HDR over that observed in the NHEJ wild type strain. Therefore, gene drive approaches that rely on HDR could potentially be made more efficient by incorporating some method of NHEJ down-regulation into the overall strategy. Such approaches could prove useful in vector control.

ANTIBODIES TO *AEDES AEGYPTI* D7L SALIVARY PROTEINS AS A NEW SEROLOGICAL TOOL TO ESTIMATE HUMAN EXPOSURE TO *AEDES* MOSQUITOES

Sophana Chea[1], Laura Willen[2], Sreynik Nhek[1], Piseth Ly[1], Kristina Tang[2], James Oristian[2], Roberto Salas-Carrillo[2], Aiyana Ponce[2], Paola Carolina Valenzuela Leon[2], Dara Kong[1], Sokna Ly[3], Ratanak Sath[3], Chanthap Lon[3], Rithea Leang[4], Rekol Huy[4], Christina Yek[2], Jesus G. Valenzuela[2], Eric Calvo[2], Jessica E. Manning[2], **Fabiano Oliveira**[2]

[1]International Center of Excellence in Research - Cambodia, Phnom Penh, Cambodia, [2]Laboratory of Malaria and Vector Research - NIAID, Rockville, MD, United States, [3]International Center of Excellence in Research – Cambodia, Phnom Penh, Cambodia, [4]National Center for Parasitology, Entomology, and Malaria Control, Ministry of Health, Phnom Penh, Cambodia

Aedes spp. are the most prolific mosquito vectors in the world. Found on every continent, they can effectively transmit various arboviruses, including the dengue virus which continues to cause outbreaks worldwide and is spreading into previously non-endemic areas. The lack of widely available dengue vaccines accentuates the importance of targeted vector control strategies to reduce the dengue burden. High-throughput tools to estimate human-mosquito contact and evaluate vector control interventions are lacking. We propose a novel serological tool that allows rapid screening of human cohorts for exposure to potentially infectious mosquitoes. We tested 563 serum samples from a longitudinal pediatric cohort study previously conducted in Cambodia. Children enrolled in the study were dengue-naive at baseline and were followed biannually for dengue incidence for two years. We used Western blotting and enzyme-linked immunosorbent assays to identify immunogenic *Aedes aegypti* salivary proteins and measure total anti-*Ae. aegypti* IgG. We found a correlation (r_s=0.86) between IgG responses against AeD7L1 and AeD7L2 recombinant proteins and those to whole salivary gland homogenate. We observed seasonal fluctuations of AeD7L1+2 IgG responses and no cross-reactivity with *Culex quinquefasciatus* and *Anopheles dirus* mosquitoes. The baseline median AeD7L1+2 IgG responses for young children were higher in those who developed asymptomatic versus symptomatic dengue. The IgG response against AeD7L1+2 recombinant proteins is a highly sensitive and *Aedes* specific marker of human exposure to *Aedes* bites that can facilitate standardization of future serosurveys and epidemiological studies by its ability to provide a robust estimation of human-mosquito contact in a high-throughput fashion.

7021

THREE YEARS OF ENTOMOLOGICAL SURVEILLANCE IN HOUSES RECEIVING TARGETED INDOOR RESIDUAL SPRAYING (TIRS) AGAINST *AEDES AEGYPTI* IN MEXICO

Azael Che-Mendoza[1], Wilbert Bibiano-Marin[1], Natalie Dean[2], Elizabeth Halloran[3], Ira Longini[4], Matthew H Collins[2], Lance A Waller[2], Hector Gomez-Dantes[5], Audrey Lehart[6], Thomas Hladish[4], Anuar Medina-Barreiro[1], Gloria Barrera-Fuentes[1], Gabriela Gonzalez-Olvera[1], Norma Pavia-Ruz[1], Guadalupe Ayora-Talavera[1], Oscar David Kirstein[2], Pablo Manrique-Saide[1], Gonzalo Vazquez-Prokopec[2]

[1]Universidad Autonoma de Yucatan, Merida, Mexico, [2]Emory University, Atlanta, GA, United States, [3]University of Washington, Seattle, WA, United States, [4]University of Florida, Gainesville, FL, United States, [5]Instituto Nacional de Salud publica, Cuernavaca, Mexico, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States

Targeted indoor residual spraying (TIRS) is a novel approach for *Aedes aegypti* control that uses adult female mosquito resting behavior to target insecticide applications and has the advantage of being deployed preventively (before the peak transmission season). We report the preliminary entomological findings of the TIRS trial, a two-arm, parallel, cluster randomized controlled trial conducted in Merida, Mexico. The protocol involves one preventive application of TIRS during each of three consecutive years (May-June 2021-2023) on a total ~27,900 houses. Indoor adult *Ae. aegypti* collections using Prokopack aspirators on a sub-sample of 1,500 houses were monitored monthly for a period of 6 months post-TIRS application, covering the peak arbovirus transmission season. Before TIRS, house infestation rates and female mosquito abundance were similar for both study arms. After TIRS, the strongest impact was observed during the first three months for both infestation (OR=0.18-0.41, P<0.05) and mosquito abundance (IRR=0.08-0.37, P<0.05). Significant reductions were maintained throughout the 6 months post-intervention in Year 1. Average treatment coverage increased from 60.2% in 2021 to 74.9% of target households per cluster in 2023. Intervention clusters (central and external blocks) were categorized according to TIRS coverage: 1= >75% of coverage in both central and external blocks; 2= <75% central/external blocks (n=10); 3= >75% central/<75% external blocks; 4= <75% central/>75% external blocks. Significant reduction in *Ae. aegypti* abundance was observed between houses in clusters with higher than 75% versus below 75% TIRS coverage (IRR=0.55, P<0.005); we observed significant increases in density (IRR=3.14 and 2.11, P<0.005) and positivity (OR=2.4 and 2.6, P<0.005) in the central vs external blocks when external blocks had <75% TIRS coverage. These promising results on entomological impact emphasize the importance of maintaining broad coverage to ensure better effectiveness of TIRS in the real world setting.

TESTING A COMBINED IIT-SIT APPROACH TO CONTROL *AEDES AEGYPTI* AND URBAN ARBOVIRUS TRANSMISSION IN YUCATAN, MEXICO

Abdiel Martín-Park[1], Azael Che-Mendoza[2], Yamili Contreras-Perera[2], Wilbert Bibiano-Marín[2], Anuar Medina-Barreiro[2], Emilio Trujillo-Peña[2], Norma Pavía-Ruz[3], Henry Puerta-Guardo[3], Guadalupe Ayora-Talavera[3], Jorge Palacio-Vargas[4], Fabián Correa-Morales[5], Gonzalo Vazquez-Prokopec[6], Zhiyong Xi[7], Pablo Manrique-Saide[2]

[1]Universidad Autonoma de Yucatan - CONAHCYT, Merida, Mexico, [2]Universidad Autonoma de Yucatan, Merida, Mexico, [3]Centro de Investigaciones Regionales "Dr. Hideyo Noguchi", Universidad Autónoma de Yucatan, Merida, Yucatan, Mexico., Merida, Mexico, [4]Servicios de Salud de Yucatan, Merida, Mexico., Merida, Mexico, [5]Centro Nacional de Programas Preventivos y Control de Enfermedades, Ciudad de Mexico, Mexico., Ciudad de Mexico, Mexico, [6]University of Emory, Atlanta, GA, United States, [7]Michigan State University, East Lansing, MI, United States

Due to the successful implementation of the sterile insect technique (SIT) in area-wide control of several insect pests of agricultural and

veterinary importance, significant efforts have been made to develop analogous techniques for mosquito control. One of them is Incompatible Insect Technique (IIT), in which males carrying the maternally inherited endosymbiotic bacteria *Wolbachia* are released to induce incompatible mating with target females who either do not carry *Wolbachia* or carry different *Wolbachia* strains. We present baseline and preliminary results from a two-arm cluster randomized controlled trial to evaluate the entomological and epidemiological impact of *Aedes aegypti* population suppression via IIT-SIT on arbovirus transmission in urban neighborhoods of the city of Mérida, Mexico. The intervention includes integrated control activities structured in two phases: 1) an Attack phase (~1-2 months prior to the transmission season) with area-wide ULV adulticide spraying to control Aedes adults in four weekly applications followed by 2) Male *Aedes aegypti* releases (2,000 male mosquitoes per hectare twice a week). We present information of the overall study design, baseline epidemiological and entomological data, and preliminary results of entomological impact. Findings from this study will allow establishing a link between epidemiologic, entomo-virological, and entomological indicators to determine the effectiveness of IIT-SIT in real world conditions. Built on the successful field trial and existing mosquito mass rearing capacity established in Merida, scaling-up this innovation is not only logical but also feasible. Successful findings from this study will pave the way for future expansions of the technology to the entire city and nationwide using a rolling-carpet strategy, which has been successfully demonstrated for area-wide control of screwworm and medfly in Latin America.

NON-HOUSEHOLD ENVIRONMENTS PROMOTE DENGUE TRANSMISSION: IMPLICATIONS FOR VECTOR CONTROL

Víctor H. Peña-García[1], A. Desiree LaBeaud[1], Bryson A. Ndenga[2], Francis M. Mutuku[3], Donal Bisanzio[4], Jason R. Andrews[1], Erin A. Mordecai[1]

[1]Stanford University, Stanford, CA, United States, [2]Kenya Medical Research Institute, Kisumu, Kenya, [3]Technical University of Mombasa, Mombasa, Kenya, [4]RTI International, Washington, DC, United States

Aedes-borne pathogens have been increasing in incidence despite vector control activities implemented in endemic settings. Vector control for *Aedes*-transmitted arboviruses typically focuses on households because vectors breed in household containers and bite indoors. Yet, our recent work shows a high abundance of *Aedes* vectors in public spaces. We used field-collected data on the distribution of vectors in different urban environments in Kenyan cities of Kisumu and Ukunda along with movement data to create an agent-based model. The model quantified the number of infections happening in both household (HH) and non-household (NH) environments. We additionally modeled the outcome of vector control activities implemented in different environments in preventive (before an outbreak) and reactive (after an outbreak commences) scenarios. We estimated that more than half of infections take place in NH environments, where the main spaces for transmission are workplaces and markets. Accordingly, a greater reduction of cases was estimated when control activities targeted only NH as opposed to when targeting only HH. As expected, greater control effectiveness is achieved when activities are implemented earlier and at higher levels of coverage. Additionally, we included spatial variables to study how the movement of individuals affects the dengue burden of both environments under three different urban conformations of NH: randomly distributed, centered, or clustered. According to the model, the number of cases is slightly higher when NH are randomly distributed, suggesting a role as spreaders of disease toward nearby HHs. Also, we discovered that the number of people visiting NH is an important factor determining dengue burden. At very low movement of people, transmission decreases and the number of infections in both environments becomes roughly even. Together, these results lead us to rethink the way urban transmission is understood, which is often placing HH as the main transmission environment. Accordingly, new control guidelines and risk factors estimation methods should be developed to render control and prevention truly effective.

VERTICAL AND HORIZONTAL TRANSMISSION OF *MICROSPORIDIA MB*: A *PLASMODIUM* INHIBITING NATURAL SYMBIONT OF *ANOPHELES*

Syeda Tullu Bukhari

International Center of Insect Physiology and Ecology, Mbita, Kenya

Microsporidia MB, a naturally occurring symbiont in *Anopheles arabiensis* inhibits *Plasmodium* development and is avirulent. *Microsporidia MB* is transmitted vertically, from mother to offspring, and horizontally through mating. Transmission is expected to promote its spread through mosquito populations, enhancing the potential of *Microsporidia MB* as a candidate for the development of a symbiont-mediated malaria transmission-blocking strategy. In-depth understanding of *Microsporidia MB* transmission patterns is required for mass production of mosquitoes, a pre-requisite for mosquito release, and robust estimates from theoretical models on *Microsporidia MB* spread in the natural populations following release. Iso-female lines originating from field-collected *Microsporidia MB*-infected and uninfected females were compared for various life history traits from the egg to adult stage. Bioassays were conducted on first filial-generation mosquitoes to determine effect of diet type and quantity on *Microsporidia MB* prevalence and density. *Microsporidia MB* -infected and uninfected males were compared individually and in groups for mating competitiveness. Larval development time of *Microsporidia MB* -infected *An. arabiensis* is shorter compared to uninfected mosquitoes. Diet type and quantity influence density of *Microsporidia MB*. *Microsporidia MB* -infected adults have a higher mating rate compared to uninfected mosquitoes. In general, *Microsporidia MB* -infection has a positive effect on the development of *An. arabiensis* mosquitoes. *Microsporidia MB*-infection is influenced by diet type and quantity, therefore, diet can be manipulated to rear highly infected mosquitoes. *Microsporidia MB* is inherently able to spread in mosquito populations due to higher mating rate making it a promising candidate for malaria transmission-blocking strategy.

DATA-DRIVEN TARGETING OF MALARIA AT-RISK POPULATIONS FOR DISTRIBUTION OF TOPICAL REPELLENTS IN ZIMBABWE

Brighton Gambinga

Zimbabwe Assistance Program in Malaria II, Abt Global, Harare, Zimbabwe

Reported annual malaria incidence in Zimbabwe ranged from 9 to 32 cases per 1,000 population over the past five years, with 14 cases per 1,000 population reported nationally in 2023. Over 75% of malaria cases nationally are reported from three of the country's ten provinces. Despite consistently reporting indoor residual spraying (IRS) coverage of >85% of the population, prevention gaps remain, particularly among farmers whose livelihoods require outdoor nighttime activities and time away from home-based vector control strategies. To address residual transmission resulting from protection gaps among these farmers, we explored criteria for topical repellents as a supplementary protective intervention. Wards (administrative unit 3) considered eligible for a topical repellent-based intervention included those with a reported annual parasite incidence >100 cases per 1,000 population, an IRS population coverage >85%, and a large population of agricultural workers engaged in outdoor nighttime activities during peak malaria season. Of the country's 396 wards, we identified seven (1.8%) meeting these criteria using descriptive and spatial analyses of routine surveillance, and malaria programmatic, socioeconomic, and 2022 census data. A bottom-up approach through stakeholder engagement was used to target communities and healthcare authorities at the sub-national and national-levels to gather insights on priority populations to be covered by topical repellents. A ward with approximately 6,000 people will be prioritized for distribution and monitoring of topical repellents commencing in July 2024. This data-driven approach with key informant input was essential to tailor malaria interventions at the subnational level and address these unique drivers of malaria transmission.

TWO MOSQUITO SALIVARY ANTIGENS DEMONSTRATE PROMISE AS BIOMARKERS OF RECENT EXPOSURE TO *PLASMODIUM FALCIPARUM* INFECTED MOSQUITO BITES

Sarah Lapidus[1], Morgan M. Goheen[1], Mouhamad Sy[2], Awa B. Deme[2], Ibrahima M. Ndiaye[2], Younous Diedhiou[2], Amadou M. Mbaye[2], Kelly Hagadorn[1], Seynabou D. Sene[3], Mariama N. Pouye[4], Laty G. Thiam[4], Aboubacar Ba[4], Noemi Guerra[1], Alassane Mbengue[4], Inés Vigan-Womas[4], Sunil Parikh[1], Albert I. Ko[1], Daouda Ndiaye[2], Erol Fikrig[5], Yu-Min Chuang[5], Amy K. Bei[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Laboratory of Parasitology and Mycology, Cheikh Anta Diop University, Aristide le Dantec Hospital, Dakar, Senegal, [3]Malaria Experimental Genetic Approaches & Vaccines, Pôle Immunophysiopathologie et Maladies Infectieuses, Institut Pasteur de Dakar, Dakar, Senegal, [4]G4 – Malaria Experimental Genetic Approaches & Vaccines, Pôle Immunophysiopathologie et Maladies Infectieuses, Institut Pasteur de Dakar, Dakar, Senegal, [5]Yale School of Medicine, New Haven, CT, United States

Measuring malaria transmission intensity using the traditional entomological inoculation rate is difficult. Antibody responses to mosquito salivary proteins such as SG6 have previously been used as biomarkers of exposure to *Anopheles* mosquito bites. Here, we investigate four mosquito salivary proteins as potential biomarkers of human exposure to mosquitoes infected with *P. falciparum*: mosGILT, SAMPSP1, AgSAP, and AgTRIO. AgSAP and AgTRIO are transcriptionally upregulated in *P. falciparum*-infected mosquitoes, and all four proteins have either a prior reported association with sporozoites or could be secreted into *An.* saliva. We tested population-level human immune responses to these proteins in longitudinal and cross-sectional plasma samples from individuals with known *P. falciparum* infection from low and moderate transmission areas in Senegal using a multiplexed magnetic bead-based assay. AgSAP and AgTRIO were the most closely associated with recent exposure to infected mosquitoes. Antibody responses to AgSAP, in a moderate endemic area, and to AgTRIO, in both low and moderate endemic areas, were significantly higher than responses in a healthy non-endemic control cohort ($p = 0.0245$, 0.0064, and <0.0001 respectively). Antibody responses did not significantly differ between the low and moderate transmission area for any of the four proteins, or between equivalent groups during and outside the malaria transmission seasons. For AgSAP and AgTRIO, reactivity peaked 2-4 weeks after clinical *P. falciparum* infection and declined 3 months after infection. Since reactivity to both AgSAP and AgTRIO peaked after infection and did not differ seasonally, nor between areas of low and moderate transmission, the data suggest reactivity is likely reflective of exposure to infectious mosquitos or recent biting rather than to general mosquito exposure. Kinetics suggest reactivity is relatively short-lived. AgSAP and AgTRIO are promising candidates to incorporate into multiplexed assays for serosurveillance of population-level changes in *P. falciparum*-infected mosquito exposure.

DEPLOYMENT OF ATTRACTIVE TARGETED SUGAR BAITS IN WESTERN ZAMBIA: INSTALLATION, MONITORING, REMOVAL, AND DISPOSAL PROCEDURES DURING A PHASE III CLUSTER RANDOMIZED CONTROL TRIAL

Erica Orange[1], Irene Kyomuhangi[2], Mundia H. Masuzyo[3], Mwansa Mwenya[3], Patricia Mambo[3], Kochelani Saili[4], Chama Chishya[3], Javan Chanda[3], Ruth A. Ashton[5], Thomas P. Eisele[5], Joshua Yukich[5], John Miller[3], Kafula Silumbe[3], Busiku Hamainza[6], Joseph Wagman[7], Annie Arnzen[7], Angela F. Harris[8], Julian Entwistle[8], Laurence Slutsker[9], Thomas R. Burkot[10], Megan Littrell[7]

[1]PATH, Seattle, WA, United States, [2]Centre for Health Informatics Computing and Statistics, Lancaster University, Lancaster, United Kingdom, [3]PATH, Lusaka, Zambia, [4]Macha Research Trust, Choma, Zambia, [5]Centre for Applied Malaria Research and Evaluation, Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, [6]National Malaria Elimination Centre, Lusaka, Zambia, [7]PATH, Washington, DC, United States, [8]Innovative Vector Control Consortium, Liverpool, United Kingdom, [9]Independent Consultant, Atlanta, Georgia, [10]Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia

Attractive Targeted Sugar Baits (ATSBs) offer a complementary vector control strategy to interventions targeting blood feeding or larval control by attacking the sugar feeding behavior of adult mosquitoes. Western Zambia was the first location to receive and deploy ATSB Sarabi v1.2 stations, in a Phase III cluster randomized control trial (cRCT). The cRCT was implemented in 70 study clusters (35 intervention and 35 control) across three districts, representing a population of 23,466 households at baseline. The trial measured epidemiological and entomological outcomes during a two-year seasonal deployment of ATSB stations (November 2021-June 2022; November 2022-June 2023). Two ATSB stations were installed on eligible structures in intervention clusters through planned installation campaigns. During deployment, ATSB monitoring was conducted to maintain high coverage of ATSBs and to assess their condition. Damaged ATSBs required replacement per pre-defined criteria for holes, leaks, mold, depletion, and dirt. Annual cross-sectional household surveys measured ATSB coverage. ATSBs were removed from all structures at the end of each transmission season and transported to Lusaka for incineration. A total of 67,945 ATSBs were installed in Year 1 (41,695 initially + 26,250 during monitoring) and 69,494 ATSBs were installed in Year 2 (41,982 initially + 27,512 during monitoring). The primary reasons for ATSB replacement were holes and mold. Cross-sectional surveys documented high coverage of ATSB stations across both years with 93.1% of eligible structures having ≥2 ATSB stations in any condition; however, only 71.5% of eligible structures had ≥2 ATSB stations not meeting the replacement criteria, demonstrating the high volume of ATSB damage. Additional research is needed to better understand the impact of damage on ATSB effectiveness, including the thresholds below which holes and mold are associated with reduced product efficacy. This presentation will describe the Zambia trial ATSB station installation, monitoring, removal, and disposal methods, quantify ATSB station coverage, and report reasons for ATSB station replacement.

MATRIX-ASSISTED LASER DESORPTION/IONIZATION TIME-OF-FLIGHT (MALDI-TOF) MASS SPECTROMETRY AS A RELIABLE APPROACH FOR THE SURVEILLANCE OF CHIKUNGUNYA VIRUS IN MOSQUITO VECTORS

Amber Holley, Megan Burch, Maureen Laroche

University of Texas Medical Branch, Galveston, TX, United States

Since its first outbreak in Africa, Chikungunya virus has spread to South Asia, the Indian Ocean islands, and the Americas, affecting over 100 countries. Quick identification of vector species and determination of infection status is critical for accurate vector-borne disease surveillance. Mosquito identification is often performed through morphological criteria and/or molecular methods, which can be time-consuming and expensive. Here, we use MALDI-TOF (Matrix-Assisted Laser Desorption/Ionization Time-Of-Flight) mass spectrometry to simultaneously identify mosquito species and infection status with CHIKV, which is more accessible, quicker, and cheaper than the current methods. Experimentally infected and non-infected *Aedes aegypti* and *Aedes albopictus* were dissected to obtain either legs or combined head and thoraxes for spectra generation. Spectra were grouped according to body part, species, and infection status. Spectra were assessed for quality using FlexAnalysis software and for reproducibility and specificity using pseudo-gel and PCA analyses with ClinProTools software. Leg spectra from infected and non-infected mosquitoes clustered separately in PCA analyses, while significant overlap was observed with cephalothorax spectra, indicating leg data were more suitable for differentiation. A database was created with high-quality reference spectra for each species. Samples were queried against this database, and all were correctly identified to the species level. Additionally, all non-infected mosquitoes were recognized as such while 97% of infected mosquitoes were correctly detected as infected. MALDI-TOF MS has been a critical development in the clinical and surveillance field for rapid and sensitive testing of microbial and arthropod samples. The present study

demonstrates the use of MALDI-TOF MS in the concurrent identification of mosquito species and infection status with CHIKV. The continual addition of quality spectra to the database and modifications to the current protocol will aid in the quick and accurate identification necessary for the surveillance of this spreading arboviral disease.

7029

LANDSCAPE PREDICTORS OF *AEDES AEGYPTI* ABUNDANCE IN A DENGUE-ENDEMIC LOCALITY IN MANAGUA, NICARAGUA

Sophia E. Kruger[1], Dimitris Gounaridis[2], José G. Juárez[3], Harold Suazo[3], Jacqueline Mojica[3], Eva Harris[4], Josefina Coloma[4], Joseph N.S. Eisenberg[1]

[1]University of Michigan School of Public Health, Ann Arbor, MI, United States, [2]University of Michigan School for Environment and Sustainability, Ann Arbor, MI, United States, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]University of California School of Public Health, Berkeley, CA, United States

Dengue has been traditionally recognized as an urban disease where urban centers are thought to provide ample habitat for *Aedes aegypti* reproduction and susceptible human hosts to drive dengue virus (DENV) transmission. Increasing evidence of DENV infections in rural populations challenges this narrative. DENV transmission is driven by various spatial, environmental, and anthropogenic factors, often summarized by a dichotomous urban-rural variable. However, this urban-rural dichotomy overlooks underlying drivers of spatial spread, many of which can be captured by landscape features. As such, this study proposes to quantify the landscape structure and composition of two characteristically urban and peri-urban neighborhoods in Managua, Nicaragua, a dengue endemic locality. Elucidating differences in landscape composition between peri-urban and urban sites will facilitate a more nuanced analysis of DENV epidemiology among heterogeneous spatial patches. We approached this analysis using remote sensing and landscape structure characterization techniques and household level *Ae. aegypti* abundance data that were systematically collected within 500 households across both neighborhoods using manual aspiration and container inspection. We employed high resolution multispectral WorldView 3 imagery and a machine learning Random Forests model to classify land types of the two study sites. Using FRAGSTATS software, we computed landscape metrics to spatially assess patch connectivity, geometry, and aggregation for each land type across the two study sites. To assess the relationship between landscape metrics and *Ae. aegypti* abundance we will also integrate ancillary environmental and climatic data and generate DENV transmission risk estimates using spatial regression and spatial clustering techniques. This landscape scale analytic framework provides a more mechanistic understanding of spatial risk patterns and moves beyond the urban-rural dichotomy concept for risk mapping and will allow us to delineate specific urban features and typologies that sustain dengue transmission within urban- or rural-like landscapes.

7030

THE POTENTIAL USE OF DIGITAL TOOLS FOR LARVAL SURVEYS IN VECTOR CONTROL: EXPERIENCE FROM ANAMBRA AND ONDO STATES OF NIGERIA

Azuka Iwegbu[1], Chukwuebuka Ezihe[1], Saliu Ogunmola[1], Abiola Oluwagbemiga[1], Tarekegn A. Abeku[2]

[1]Malaria Consortium, Abuja, Nigeria, [2]Malaria Consortium, London, United Kingdom

Malaria Consortium is conducting studies to assess the entomological and epidemiological impacts of insecticide-treated net (ITN) campaigns in 2021 and 2022 in Ondo and Anambra states respectively. These studies involved the use of a digital questionnaire completed alongside the collection of mosquito larvae for resistance tests. We report observations from using the digital tool, and explore its potential use for mapping larval habitats to inform the targeting of vector control interventions. The digital tool was developed using SurveyCTO, a customisable application, and deployed on mobile devices. The tool facilitated the collection of data on breeding sites capturing various attributes of the habitats. *Anopheles* larvae were collected alongside images of the sites and their geocoordinates, type and characteristics, and the timestamps of collection. Data were submitted in real time which allowed research staff to monitor field activities in progress and immediately map survey sites. Although the primary use of the digital data was to locate the sources of mosquitoes used in resistance tests, the findings indicated the potential use of the tool to link species- after rearing and identification of adult mosquitoes - with the collection sites to deploy larval source management (LSM) and other measures. Digitization of larval surveys for resistance monitoring or other entomological studies could allow mapping of important breeding sites for vector control, beyond the primary purposes of the sample collections. Insecticide resistance monitoring activities in several African countries are based on larval collection and rearing. If during such activities information is gathered on larval habitats employing similar digital tools, this could allow real-time monitoring of transmission foci by integrating into the surveillance system. A similar approach could also be used at community levels for mapping of breeding sites for wider geographic coverage of LSM measures.

7031

STRATEGIES FOR ALTERING THE FREQUENCY AND COVERAGE OF INSECTICIDE-TREATED NET MASS CAMPAIGNS WITH DIFFERENT NET TYPES TO MAXIMIZE CASES AVERTED UNDER FIXED BUDGETS

Andrew C. Glover[1], Hannah Koenker[2], Kate Kolaczinski[3], Thomas S. Churcher[1]

[1]Imperial College London, London, United Kingdom, [2]PMI REACH Malaria, PATH, Baltimore, MD, United States, [3]The Global Fund, Geneva, Switzerland

Mass campaigns of insecticide-treated nets (ITNs) are recommended every three years to control malaria. However, evidence indicates most nets do not last this long, and those that do may have impaired effectiveness in areas of pyrethroid resistance. The availability of pyrethroid-only, pyrethroid-PBO and dual-active ingredient (AI) ITNs with differing costs and durability means it is unclear whether biennial distribution of a cheaper net may be more cost-effective than triennial distribution of other more costly but more effective ITNs. It is also unclear whether distributing fewer but better pyrethroid-PBO and dual-AI nets through mass campaigns will be more cost-effective than larger quantities of pyrethroid-only nets under fixed budget constraints. Here we fit retention curves to Demographic and Health Survey data to estimate sub-national mean net retention times in Burkina Faso, Ghana, Malawi, Mali, Mozambique and Senegal. Central estimates of mean retention times were less than 2 years for 68.8% of regions investigated. Models indicate considerable sub-national heterogeneity, with mean retention ranging from 0.95 years (95% CrI: 0.92-0.97) in urban Maputo, Mozambique, to 3.04 years (95% CrI: 2.84-3.23) in urban Est, Burkina Faso. By accounting for sub-national heterogeneity in net retention, in addition to transmission intensity and pyrethroid resistance, we generate projections of cases averted for biennial vs triennial mass campaigns for pyrethroid-only, pyrethroid-PBO and dual-AI nets under different costed strategies using a transmission-dynamics model. Results highlight distribution strategies for administrative-one level regions investigated where biennial distribution with pyrethroid-pyrrole nets could be more cost-effective than triennial pyrethroid-only campaigns under fixed budget constraints. As policymakers look to move towards distributing pyrethroid-pyrrole nets in the face of increasing pyrethroid resistance, our findings highlight increased distribution frequencies could also be considered concurrently in some regions for optimal cost-effectiveness.

7032

MODELLING THE POTENTIAL OF GENE DRIVE MOSQUITOES FOR MALARIA CONTROL IN SETTINGS WITH MULTIPLE VECTOR SPECIES IN MAINLAND TANZANIA

Ismail Nambunga

Ifakara Health Institute, Morogoro, Tanzania, United Republic of

Malaria persists as a significant global health challenge especially in regions such as mainland Tanzania where multiple vector species mediate transmission dynamics. This study aims at evaluating the potential of gene drive (GD) modified mosquitoes to combat malaria with such complex eco-epidemiological settings. Focusing on the Kilombero Valley – a well-documented site for malaria endemicity with predominant *Anopheles funestus* and *Anopheles arabiensis* mosquito populations, we propose a multifaceted approach to understanding the impact of deploying GD mosquitoes as part of an integrated vector management (IVM) strategy. Through mathematical modelling and scenario analysis, we will simulate the release of GD mosquitoes into local vector population and assess the efficacy of replacement drive strategies in diminishing the rate of malaria transmission. The study will determine the necessary scale of GD mosquito releases required for substantial reduction, factoring in the variation in epidemiological conditions specific to Kilombero Valley. We will also investigate the integration of GD mosquitoes with current control measures, such as insecticide treated nets (ITNs) to discern potential synergistic or antagonistic outcomes on malaria control. A critical component of our research includes the identification of thresholds for escaped GD mosquitoes that could present ecological or health concerns. In here, we aim to develop a comprehensive monitoring plan to address the risks associated with escape and unintended establishment, contemplating both full-drive (super-mendelian inheritance) and effector-only (mendelian inheritance) constructs to enable robust risk management strategies. The study's results will provide strategic insights into the operational feasibility of incorporating GD mosquitoes within broader malaria elimination initiatives, paving the way for novel, sustainable approach to vector control in settings challenged by the presence of multiple vector species.

7033

VALIDATION USING ATTRACTIVE SUGAR BAITS (ASBS) CONTAINING A FLUORESCENT DYE IN SIAYA, WESTERN KENYA: AN EVALUATION OF ANOPHELES FEEDING RATES

Jackline Jeruto Kosgei[1], Seline Omondi[1], Daniel McDermott[2], Vincent Moshi[1], Martin Donnelly[2], Collins Ouma[3], Julian Entwistle[4], Angela F F. Harris[4], John E. Gimnig[5], Feiko O. Ter Kuile[6], Bernard Abongo[1], Eric Ochomo[1]

[1]Kenya Medical Research Institute (KEMRI), Kisian station, Kisumu city, Kenya, Kisumu, Kenya, [2]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Department of Biomedical Sciences, School of Public Health and Community Development, Maseno University, Maseno, Kenya, [4]Consultant to Innovative Vector Control Consortium, Liverpool, United Kingdom, [5]Division of Parasitic Diseases and Malaria, Centre for Disease Control and Prevention, Altlanta, GA, United States, [6]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpol, United Kingdom

Vector control is an essential component of malaria prevention. Additional mosquito control tools like Attractive targeted sugar baits (ATSBs) are urgently needed to further suppress malaria transmission worldwide. Prior to epidemiological trials on ATSBs, validation studies were conducted to assess the levels of mosquito feeding on attractive sugar baits (ASBs) with uranine fluorescent dye and to evaluate whether the deployment of two versus three bait stations per building structure led to a significantly different daily feeding rate in local malaria vectors as a proxy for ATSBs. The study followed a cross-over design in twelve clusters of Siaya western Kenya. Either two or three ASBs were deployed to all structures and switched over at two months' time point so that clusters which initially received two ASBs were given three and vice versa. ASB monitoring was done for four months from initial deployment then an additional four months for extended monitoring of ASBs. Mosquitoes were collected using UV light traps and Prokopack aspiration indoors and outdoors then screened for morphological characteristics and fluorescence due to the uranine dye. Samples of mosquitoes collected were processed by PCR and sporozoite infectivity. Data analysis was performed using R statistical software. *An. funestus* s.s. was the dominant malaria vector with overall dye feeding of 11.2% followed by *An. gambiae* s.l. at 3.5%, translating to daily feeding rates of 4.8% in *An. funestus* and 1.2% in *An. Gambiae*. No significant difference was detected between two or three ASB stations. *An. funestus* s.l. comprised 82% *An. funestus* s.s. and 6.3% *An. leesoni* while *An. gambiae* s.l. constituted 68% *An. arabiensis* and 21% *An. gambiae* s.s. Sporozoite positivity rate was 2.28% and1.00%. in *An. funestus* s.l. and *An. gambiae* s.l. respectively. *Anopheles funestus* s.s. demonstrated higher rates of feeding on ASBs compared to *An. gambiae* s.l. No significant difference was detected between deploying two or three bait stations per structure. The study provided important information utilized in the subsequent deployment of ATSBs in epidemiological trials.

7034

COMPARISON OF SEASONAL MOSQUITO POPULATIONS ACROSS A DIVERSIFYING SEMI-PASTORAL LANDSCAPE IN LOITOKITOK SUB-COUNTY, KENYA

Keli N. Gerken[1], Richard R. Olubewa[2], Max Korir[3], Tatenda Chiuya[4], Eric M. Fèvre[1], Andrew P. Stringer[5], Andrew Morse[6], Matthew Baylis[6]

[1]International Livestock Research Institute, Nairobi, Kenya and Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, United Kingdom, [2]International Livestock Research Institute, Nairobi, Kenya, [3]International Livestock Research Institute One Health Centre in Africa, Nairobi, Kenya, [4]Centre for Development Research (ZEF), University of Bonn, Bonn, Germany, [5]Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, United Kingdom, Liverpool, United Kingdom, [6]Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, United Kingdom

Ecological variables have a profound impact on mosquito populations and micro-environments suitable for proliferation of certain species can result in disease transmission hotspots. Rift Valley fever virus (RVFV), a priority zoonotic arbovirus, is transmitted by a wide range of mosquito species, and endemic transmission is poorly understood. A subset of randomly sampled households in different ecozones and land use types (cropland, grassland, and shrubland) were used to capture outdoor mosquitos associated with livestock using Biosentinel (BG) traps baited with CO_2 set for 48-96 hours. We trapped in three seasons, the August 2023 dry period, the rains at the end of November into December 2023, and in February 2024 after the El Niño phenomenon prolonged the short rains. Total mosquitos were adjusted for trapping time and transformed for analysis. We caught 323 mosquitos over 30 trapping events, lasting on average 54.5 hours. The majority, 94%, of mosquitos were *Culex spp.* We caught *Anopheles spp*. at one trapping event in a cropland household at 1,497 meters elevation, and eight of the ten total *Aedes spp.* were captured in shrubland. We had similar mosquito totals in shrubland and grassland landcover (β=1.01, SE=0.06, *p=0.89*) and caught more mosquitos in cropland households (β=1.10, SE=0.05 *p=0.10*) but did not identify a significant association with the elevation or ecozone. The greatest impact was seasonality, with significantly fewer mosquitos in the August dry period (β=*0.84,* SE=0.06, p=0.005), and catches were only slightly higher in February (β=1.04, SE= 1.04, *p=0.41*) compared to December. Furthermore, in December, we repeated trapping at three households and caught significantly more mosquitos six weeks after our weather station recorded the first major rainfall event compared to three weeks after (β =1.12, SE=0.03, *p=0.01*). We captured very few mosquitos during the dry season and demonstrated that following the first major rainfall event after a dry period, mosquito abundance continues to increase significantly. We also caught more in cropland and, as this land use type continues to expand, could increase total mosquito abundance.

7035

THE USE OF INSECTICIDE TREATED EAVE RIBBONS AS A PROTECTION TOOL AGAINST POPULATIONS OF MOSQUITOES THAT TRANSMIT MALARIA AND DENGUE

Ruth Shirima[1], Emmanuel Hape[1], Arnold Mmbando[1], Betwel Msugupakulya[1], Emmanuel Kaindoa[1], Godfrey Katusi[1], Nomi Urio[1], Polius Pinda[1], Letus Muyaga[1], Yohana Mwalugelo[1], Halfan Ngowo[1], Fredros Okumu[1], Lizette Koekemoer[2]

[1]Ifakara Health Insitute, Morogoro, Tanzania, United Republic of, [2]Wits Research Institute for Malaria, Johannesburg, South Africa

Mosquito-borne diseases such as malaria and dengue continue to pose a significant public health challenge in disease-endemic communities worldwide. While insecticide-treated nets and indoor residual spraying have been successful in preventing these diseases, they face challenges such as insecticide resistance, high costs, logistical difficulties, and limited durability. Therefore, there is a need for simpler and affordable interventions that can be used on a large scale in endemic communities to supplement current approaches. This study evaluated the efficacy of insecticide-treated eave ribbons as a potential tool for complementing the current vector control methods. Eave ribbons are pieces of hessian fabric placed around the eave spaces of houses to kill or repel mosquitoes. Laboratory cone bioassays were conducted to assess the efficacy of eave ribbons treated with the organophosphate, pirimiphos-methyl, for killing the malaria vectors, *Anopheles funestus* and *Anopheles arabiensis*, and the dengue vector, *Aedes aegypti*, under varying exposure durations and insecticide doses. A semi-field experiment was done to assess the efficacy of eave ribbons treated with pirimiphos-methyl against the malaria vectors. The findings revealed that treated eave ribbons resulted in higher mosquito mortality than the untreated ribbons, but the impact increased with increased exposure duration or dose. The semi-field study indicated moderate levels of bite prevention and mortality of the mosquitoes. At the doses of 1g a.i./m^2 and 2g a.i./m^2 pirimiphos-methyl, there was no significant protection against *An. arabiensis*, but at the dose of 4g a.i./m^2 pirimiphos-methyl, there was a significant protection in outdoor biting *An. arabiensis* (RR = 0.80, 95% CI: 0.71-0.91, $p < 0.001$), but not *An. funestus*. In conclusion, while insecticide-treated eave ribbons may have potential for controlling malaria and dengue vectors, further research is needed to validate their efficacy in field settings and to identify suitable insecticides or insecticide combinations that are highly effective, particularly against pyrethroid-resistant vectors.

MALARIA TRANSMISSION RISK IN THE CITY OF ACCRA, GHANA

Abdul Rahim Mohammed Sabtiu, Isaac Kwame Sraku, Yaw Akuamoah-Boateng, Judith Azumah, Anisa Abdulai, Simon K. Attah, Fred Aboagye-Antwi, Yaw Asare Afrane

University of Ghana, Accra, Ghana

Unplanned urbanization in sub-Saharan Africa is altering urban malaria transmission dynamics, challenging existing control methods such as indoor residual spraying (IRS) and long-lasting insecticide-treated nets (LLINs). Therefore, understanding these dynamics is crucial for tailored control strategies. This study investigated the vector densities, bloodmeal sources and infectivity rate of malaria vectors in Accra, Ghana. Biting and resting mosquitoes were collected in ten sites within the city of Accra, Ghana using human landing catches (HLC) and Prokopack aspirators (PPA) during the dry and rainy seasons in 2023. Sites were selected and categorized into five sectors (two sites per sector): Irrigated Urban Farming (IUF), Lower (LS), Middle (MS) and High (HS) socioeconomic status, and Peri-urban (PU) sites. Vector speciation, sporozoite infection and blood meal analysis were determined using PCR. Overall, a total of 42,331 mosquitoes were collected over the entire sampling period; Culicine = 17,820 [HLC = 16,742, PPA = 1,078], Anopheline = 21,520 [HLC = 20,931, PPA =589], Aedine = 1,708[HLC = 1491, PPA = 217]. Significantly high biting activity was observed in the late evening (LE) for both seasons [Dry (69.93%, 2,925/4,183); Rainy (70.44%, 8,367/11,878)] [F (2, 27) = 6.03, $P = 0.019$, 95% CL 135.2691 - 1388.731]. High biting activity (HBR = 352.9) and entomological inoculation rate (EIR) 0.409 (ib/m/n) were observed in IUF site categories compared to other sectors. Vectors preferred to feed on humans (HBI = 86.30%, 359/416). Higher sporozoite infection rate (Tuba = 77.27%) was found in indoor resting mosquitoes. The L1014F mutations were detected at higher frequencies (0.98 - 1) in all sites, followed by G119S (0.86 – 0.89). L1014S was detected at very low frequencies (0.15 – 0.5). The study highlights the importance of adopting novel approaches to complement existing strategies in controlling urban malaria vectors.

UNDERSTANDING THE ECO-EPIDEMIOLOGY OF MOSQUITOES IN HOUSTON, TEXAS: INFORMING PUBLIC HEALTH STRATEGIES

Morgan Jibowu[1], Melissa Nolan[2], Maximea Vigilant[3], Eric L. Brown[4], Ryan Ramphul[4], Heather T. Essigmann[4], Sarah M. Gunter[1]

[1]Baylor College of Medicine, Houston, TX, United States, [2]University of South Carolina, Columbia, SC, United States, [3]Harris County Public Health Mosquito and Vector Control Division, Houston, TX, United States, [4]The University of Texas School of Public Health, Houston, TX, United States

Mosquito-borne diseases present a significant challenge to public health, particularly in regions like Harris County, Texas, characterized by a humid subtropical climate and dense population. Effective disease surveillance and control strategies necessitate a comprehensive understanding of mosquito community dynamics, including species composition, abundance, and distribution. To address this need, we extensively analyzed routine mosquito surveillance data collected from 2018 to 2022, comprising nearly 4 million female mosquitoes collected over 55,000 trap nights using three trap types. Our analysis revealed *Culex quinquefasciatus* (the primary vector for West Nile virus in the southern United States) as the predominant species (88%), alongside *Aedes albopictus, Culex salinarius, Aedes taeniorhynchus,* and *Aedes aegypti.* Biodiversity analysis indicated variations in species richness and diversity among trap types and years, with BG-sentinel traps capturing the highest diversity in 2018. To investigate variation in female *Culex quinquefasciatus* abundance, global and local spatial autocorrelation analyses were performed to identify high-abundance neighborhoods surrounded by similar high-abundance neighborhoods (hotspots) for 2020 to 2022. Interestingly, we observed the highest abundance of female *Culex quinquefasciatus* in some of the oldest communities in Harris County, characterized by a higher median home age. Our findings underscore the importance of understanding population dynamics and species composition for targeted disease surveillance and control efforts. Furthermore, these results emphasize the interconnectedness of humans, mosquitoes, and the built environment in a large metropolitan region. Continued monitoring and research efforts are essential for effectively implementing public health interventions, safeguarding both human and animal populations against vector-borne illnesses.

URBAN VECTORIAL TRANSMISSION OF MALARIA IN KOULIKORO DISTRICT, MALI

Moussa Keita[1], Alassane Dit Assitoun[1], Mahamoudou Touré[2], Daouda Ouologuem[1], Ibrahim Sissoko[1], Daouda Sanogo[2], Fousseyni Kane[1], Soumba Keita[2], Sory Ibrahim Diawara[1], Mahamadou Diakite[1], Seydou Doumbia[1], Nafomon Sogoba[1]

[1]Malaria Research and Training Center / International Center of Excellence for Malaria in Research / University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali., Bamako, Mali, [2]University Clinical Research Center /. International Center of Excellence for Malaria in Research / University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali., Bamako, Mali

The rapid but unplanned urbanization occurring in several African countries and the global warming could lead to an increase in malaria burden through the proliferation of mosquitoes breeding sites in specific areas of the cities. The study aimed to determine the species composition of malaria vector population during the transmission season from August to November

2021 in an urban area of Mali, Koulikoro. Mosquitoes were collected each month in 60 randomly selected rooms using Pyrethrum spray catches. Specification of vectors was done using molecular techniques while other entomological indicators such as blood meal sources and infection rates were determined by ELISA techniques. A total of 2106 Culicidae specimens were collected and among which 30.1% were *Anopheles gambiae s.l.* and 69.9% were Culex sp. Three species composed of the *Anopheles gambiae s.l.* population: *Anopheles coluzzii* (84.2%), *Anopheles arabiensis* (11.6%), and *An. gambiae sensu stricto* (4.2 %). The mean density of *An. gambiae s.l.* was 2.7 individuals per room. The mean human blood index was 98.1% and the infection rate was 0.50%, with 0.1 infected bites per person per month. This study not only reported the presence of the three main vector species in the Koulikoro urban area but also a significant human and vector contact enough to sustain malaria transmission. The observed adaptation of the main malaria vectors to the urban environment calls for more attention in terms of vector control specific to this environment. **Keywords :** Malaria, Anopheles; Urban, Mali.

THE IMPACT OF CLIMATE CHANGE ON MOSQUITO ENTOMOLOGY AND SPATIOTEMPORAL DENGUE TRANSMISSION

Daniel J. Laydon, Sally Jahn, Wes R. Hinsley, Ilaria Dorigatti, Neil M. Ferguson

Imperial College London, London, United Kingdom

Dengue disease is caused by four serotypes (DENV- 1-4). Infection confers lifelong immunity to a homologous serotype, but only temporary immunity against a heterologous serotype. Secondary infection drastically increases the likelihood of disease. Dengue's primary vectors, *Aedes aegypti* mosquitoes, display high sensitivity to climate. Therefore, climate change has the potential to markedly affect the spatiotemporal dynamics and disease burden of dengue, by increasing disease incidence (and the frequency of secondary infections) in traditionally low transmission settings. Here we infer the relationship between temperature and rainfall and dengue transmission intensity. We then use these inferred relationships to investigate the impact of projected climate change-driven shifts in temperature and rainfall on dengue transmission. We developed an age-structured, stochastic transmission model that captures human infection history. Where possible, the model further represents mosquito entomology parameters (e.g. fecundity, carrying capacity, extrinsic incubation period, mortality and biting rate) mechanistically as functions of temperature and rainfall. UNWPP population data is used to model non-stationary demography. Previously estimated laboratory-derived relationships between temperature and mosquito parameters are used as model prior distributions. Using approximate Bayesian computation, we calibrate our model against multiple epidemiological data streams, including large, historical and spatiotemporally resolved incidence, prevalence and seroprevalence datasets. We reproduce climate-driven seasonal and inter-annual dengue disease incidence, and our analysis shows that the majority of inter-annual variation in dengue incidence is climate-driven. Together with the World Climate Research Programme (WCRP) Coupled Model Intercomparison Project Phase 6 (CMIP6) high resolution climate projections, we project potential changes in dengue transmission. Our work will inform ongoing dengue vaccination and control policies.

TRENDS IN ORGANOPHOSPHATE RESISTANCE AMONG *AEDES AEGYPTI* IN TAPACHULA: IMPLICATIONS FOR VECTOR CONTROL FROM 2018 TO 2021

Karla Saavedra-Rodriguez[1], Alma Lopez-Solis[2], Francisco Solis-Santoyo[2], Farah Vera-Maloof[2], Patricia Penilla-Navarro[2]

[1]Colorado State University, Fort Collins, CO, United States, [2]Centro Regional de Investigacion en Salud Publica, Tapachula, Mexico

In Tapachula, Mexico, the exclusive deployment of pyrethroids (PYRs) for 15 years in *Aedes aegypti* control programs resulted in substantial PYR resistance and subsequent failures in dengue prevention. In response, PYRs were phased out in 2013 in favor of organophosphates (OPs), which have a different mechanism of action. However, the extensive application of OPs since then has raised the risk of developing resistance mechanisms in field populations of *Ae. aegypti*. Therefore, ongoing surveillance of mosquito susceptibility to OPs is crucial to mitigate resistance development. This study used the bottle bioassay to track changes in susceptibility from 2018 to 2021, determining the lethal concentration 50 (LC_{50}) for two OPs—malathion and chlorpyrifos—at 24 collection sites throughout Tapachula. The results showed a slight but significant increase in resistance to both insecticides over time. Mosquito populations showed moderate to high resistance to chlorpyrifos and low resistance to malathion. Given that OPs and PYRs constitute two of the three insecticide classes used in public health, it is essential to develop more sensitive bioassays and molecular markers to detect early signs of OP resistance.

7041

INNOVATIONS RESULTING FROM THE USE OF CULTURED *ANOPHELES* CELL LINES

Jessica Jagelski, Michael Larsen, Niklas Klauss, **Michael B. Wells**

Idaho College of Osteopathic Medicine, Meridian, ID, United States

Research involving *Anopheles* cell culture systems represents an accessible, cost-effective, versatile approach to support *in vivo* experiments. Molecular biology approaches that can both inform, or themselves constitute, novel interventions to block pathogen transmission can be first elucidated in cell culture. Our particular focus is cellular secretion mechanisms. We first provide a summary of available *Anopheles* cultured cell lines, then describe past successes resulting from work in these lines. Cellular secretory pathways may hold key information about the contributions of mosquito secretions to pathogen infectivity in human hosts immediately following a transmission event, as was shown previously for ticks. We then offer a comprehensive approach to molecular characterization of *Anopheles* cellular secretion, including an efficient cDNA-based method for determining the sex of an Anopheles cell line, and provide preliminary data. In summary, we hope to leverage cellular secretion to develop new methods of preventing the spread of mosquito-borne diseases. This work highlights the importance of molecular processes, including cellular secretion, in the transmission of mosquito-borne diseases.

7042

HYBRIDIZATION BETWEEN *AEDES AEGYPTI* AND *AE. MASCARENSIS* MOSQUITOES LEADS TO DISRUPTION OF MALE SEX DETERMINATION

Jiangtao Liang[1], Lin Kang[2], Pawel Michalak[2], Igor Sharakhov[1]

[1]Virginia Tech, Blacksburg, VA, United States, [2]Edward Via College of Osteopathic Medicine, Monroe, LA, United States

Understanding the sex determination pathway and its disruptions in mosquitoes is critical for the effective control of disease vectors through genetic manipulations based on sex separation. When male hybrids of *Aedes aegypti* females and *Ae. mascarensis* males are backcrossed to *Ae. aegypti* females, a portion of the backcross progeny manifests as males with abnormal sexual differentiation. We discovered a significant correlation between the abnormality of pupae and the feminization of subsequent adults exemplified by the relative abundance of ovarian and testicular tissues. All intersex individuals were genetic males as they expressed a male determining factor, *Nix*. Further, our analysis of the sex-specific splicing of *doublesex* and *fruitless* transcripts demonstrated the presence of both male and female splice variants indicating that sex determination is disrupted. A comparative transcriptomic analysis revealed similar expression levels of the majority of female-associated genes in reproductive organs and carcasses between intersexual males and normal females. Moreover, intersexes had largely normal gene expression in testes but significant gene downregulation in male accessory glands when compared with normal males. We conclude that evolving hybrid incompatibilities between *Ae.*

aegypti and *Ae. mascarensis* is due to the disruption of sex determination and is accompanied by changes in gene expression associated with sexual differentiation.

7043

CHROMATIN ARCHITECTURE OF THE MALARIA VECTOR, *ANOPHELES COLUZZII*

Kathryn Taquet[1], Cameron Anderson[1], Christian Mitri[2], Kenneth Vernick[2], Michelle Riehle[1]

[1]Medical College of Wisconsin, Milwaukee, WI, United States, [2]Institut Pasteur, Paris, France

Transcriptional enhancers are non-coding regulatory elements that are responsible for most gene expression above basal levels in eukaryotes. Through their regulation of gene expression, enhancers likely play a role in natural *Anopheles* vector susceptibility phenotypes such as behavior, ecological adaptation, insecticide resistance, and an intrinsic resistance to *Plasmodium falciparum* infection. To better characterize the chromatin architecture of a major African malaria vector, Micro-C approaches were used on an *An. coluzzii* hemocyte cell line to comprehensively identify enhancer-promoter physical interactions. Downstream analyses were performed on the high-resolution enhancer-promoter contact matrices to identify open/closed chromatin domains (A/B compartments), topologically associating domain (TAD) boundaries, and chromatin loop interactions. Results will be presented on chromatin architecture data coupled with gene expression data focused on the previously characterized *Plasmodium* resistance island (PRI) and well characterized immune genes, such as LRIMs, TEPs, and APLs. A molecular understanding of endogenous gene regulation is crucial for a functional understanding of mosquito immune biology and for use in the generation of genetically modified mosquitoes.

HEAD-SPECIFIC TRANSCRIPTOMIC STUDY REVEALS KEY REGULATORY PATHWAYS FOR WINTER DIAPAUSE IN MOSQUITO *CULEX PIPIENS*

Prabin Dhungana, Xueyan Wei, Cheolho Sim

Baylor University, Waco, TX, United States

The primary vector of West Nile virus, *Culex pipiens*, undergoes reproductive dormancy during the adverse winter season. Although there is much documentation on the correlation between phenotypic shifts and global transcriptome modifications, there is still a lack of information concerning tissue-specific transcriptomic changes. This knowledge gap is a major challenge in interpreting the regulatory mechanisms at the tissue level. To examine the transcriptome dynamics particular to different tissues that contribute to the diapause phenotype, the present work used RNA-seq technology to analyze the regulatory mechanisms of head-specific genes. RNA samples were obtained from the heads of diapausing and nondiapausing female mosquitoes at two specific time intervals, namely ZT0 and ZT16, and then subjected to sequencing. The findings revealed significant variations in the number of differentially expressed genes between ZT0 and ZT16 under diapause (912) and non-diapause (767) conditions. Additionally, there were differences in the number of differentially expressed genes between diapause and non-diapause at ZT0 (499) and ZT16 (1106) periods, indicating the presence of circadian and seasonal variations in gene expression. In addition, eleven genes associated with the diapause phenotype were chosen, and the abundance of transcripts at six different periods for 24 hours was determined. qRT-PCR analysis showed similar up- and down-regulation of transcripts between the diapause and nondiapause phenotype thus validating the results of RNA-seq. In summary, our findings reveal crucial genes and their corresponding regulatory pathways that play a vital role in the diapause phenotype and are regulated by the circadian clock. The newly presented information here will significantly enhance our comprehension of insect diapause and may provide novel opportunities for vector control strategies

7045

SUPPRESSION OF H3K27ME2 DEMETHYLASE DISRUPTED DIAPAUSE FORMATION IN MOSQUITO *CULEX PIPIENS*

Xueyan Wei, Prabin Dhungana, Cheolho Sim

Baylor University, Waco, TX, United States

The northern house mosquito, *Culex pipiens*, undergoes diapause to endure the harsh winter environment. Diapause triggers a cascade of transcriptional and physiological changes, enhancing stress resistance, promoting fat storage, arresting ovarian development, and prolonging lifespan. Understanding of the basis of diapause can help in uncovering potential targets for genetic or biological control methods. Epigenetic regulation, known to influence developmental and behavioral traits in some mosquito species, has attracted attention to researchers. Our previous study revealed a significant reduction in H3K27me2 levels in the fat body of diapausing female *Cx. pipiens* upon diapause onset, suggesting a link between histone methylation and diapause initiation. However, the exact mechanism of the regulatory pathways remains elusive. Here, we inhibited histone demethylases responsible for H3K27 methylations using the histone demethylase inhibitor GSK-J4. Mosquitoes injected with GSK-J4 exhibited elevated H3K27me2 levels, accompanied by reduced lipid conservation and shortened lifespan, ultimately disrupting diapause. Our findings highlight the involvement of H3K27me2 in diapause formation, suggesting potential for targeting histone methylation in novel mosquito control strategies.

7046

MOLECULAR DIVERSITY OF *ANOPHELES* SPECIES OVER THREE YEARS OF INSECTICIDE-TREATED DURABILITY MONITORING IN KAYES, WESTERN MALI.

Ibrahim Traore[1], Moussa BM CISSE[1], Lazeni Konate[1], Yacouba Dansoko[1], Tidiani Sinayoko[1], Alice Dembele[1], Jean Marie Sanou[1], Ibrahim Keita[1], Mamadou Sow[1], Abdourhamane Dicko[2], Vincent Robert[3], Neil F. Lobo[4], Ousmane A. Koita[1]

[1]Laboratoire de Biologie Moleculaire Appliquee, Bamako, Mali, [2]National Malaria Control Program, Bamako, Mali, [3]Institut de Recherche pour le Developpement, Montpellier, France, [4]Notre Dame University, Indiana, IN, United States

Local Anopheles species' composition and bionomic characteristics are drivers of insecticide-treated nets (ITN) effectiveness. This study aims to investigate the diversity of Anopheles mosquitoes during understudied low-density periods towards evaluating species-specific drivers of residual transmission after universal coverage of ITNs. From 2018 to 2020, adult Anopheles were collected in Western Mali using indoor and outdoor CDC light traps, outdoor BG-Pro traps, and indoor Prokopak aspirator collection methods. Morphological identification was performed using taxonomic keys. Molecular identification was performed using specific PCR protocols, and the phylogenetic analysis of rDNA-ITS2 was conducted to identify specimens that could not be identified. Circumsporozoite enzyme-linked immunosorbent assay was used to estimate mosquitoes' *Plasmodium falciparum* infection rate. Of 308 adult female Anopheles sampled, five species were identified morphologically, including *An. gambiae* s.l. (53.6%), *An. rufipes* (15.2%), *An. funestus* s.l. (3.9%), and non-identified specimens (22%). With molecular identification, eight species were identified *An. gambiae* ss (45.8%), *An. coluzzii* (15.6%), *An. arabiensis* (1.3%), *An. funestus*, *An. rufipes* (16.9%), *An. pretoriensis* (2.9%), *An. ziemannii* (4.2%), *An. pharoensis* (1%) and non-identified specimens (6.8%). *An. gambiae* sl was the predominant species with endophilic behavior. Only *An. gambiae* ss was infected with *P. falciparum* sporozoites (0.7%; n = 141). Consensus ITS2 sequences were aligned to construct a phylogenetic tree. The sequence of the novel species clustered within Series Myzomyia. This study highlights the complexity of Anopheles mosquitoes. Detecting a novel and unidentified species suggests potential underreported Anopheles diversity and a potential vector of malaria transmission during the low transmission season. This points to the importance of continuous surveillance and

advanced molecular identification techniques to understand the drivers of malaria towards reducing residual malaria transmission effectively on the road to malaria eradication.

7047

MOLECULAR SURVEILLANCE OF ANOPHELINE VECTORS TO SUPPORT MALARIA ELIMINATION IN BRAZIL

Pablo Secato Fontoura[1], Caio Cesar Moreira[1], Marcia Caldas Castro[2], Marcelo Urbano Ferreira[3], Maria Anice Mureb Sallum[1]

[1]School of Public Health, University of São Paulo, Sao Paulo, Brazil, [2]TH Chan School of Public Health, Boston, MA, United States, [3]Biomedical Science Institute, University of São Paulo, Sao Paulo, Brazil

In 2022, the Brazilian Ministry of Health launched a Malaria Elimination Plan for Brazil. To support malaria elimination, rapid and cost-effective monitoring of the country's main malaria vectors is fundamental for understanding mosquito dynamics and planning timely vector control actions. The primary objective of this project is to establish a practical protocol for molecular analysis of *Anopheles* mosquitoes. This protocol will be used to develop a large-scale implementation strategy for entomological surveillance, specifically for identifying *Anopheles* species in various water collections. In this study, we will analyze the changes in mosquitoes, both spatially and temporally, before and after the application of the VectoMax biolarvicide in fish farming ponds in a malaria-endemic area in Juruá Valley, Acre State, Amazon region, Brazil. Our approach involves the use of metabarcoding of the D2 rDNA marker. Sampling and molecular pipelines were used to verify the species that were using the fishponds as habitats using mass identification of *Anopheles* species. Preliminary results showed that in the pre-intervention period, 2,016 monthly collections of *Anopheles* immature forms were carried out in 170 fishponds, with the presence of approximately 32,210 different larval stages (L1 to L4). The average density of larvae before the fishpond intervention was 0.467 (95% CI, 0.444 to 0.490) anopheline larvae per dip. There was a decrease in the density of larvae to an average of 0.046 (95% CI, 0.041 to 0.051) larvae per dip after implementing larvicide. For analyses and sequence processing, we used MOTHUR v.1.36.1 to analyze the sequence data obtained from the Illumina MiSeq platform. Metabarcoding of immature stages could confirm the temporal and spatial distribution of *Anopheles* species in different water collections in a malaria endemic area. It is expected to translate scientific evidence into a practical metabarcoding protocol to apply at state and municipal level to support entomological surveillance of Anopheline vectors.

7048

POPULATION STRUCTURE OF THE *AEDES ALBOPICTUS* VIROME IN SUFFOLK COUNTY, LONG ISLAND, NY

Brandon D. Hollingsworth[1], Nathan Grubaugh[2], Brian Lazzaro[1], Christopher Romano[3], Scott Campbell[3], Courtney C. Murdock[1]

[1]Cornell University, Ithaca, NY, United States, [2]Yale School of Public Health, New Haven, CT, United States, [3]Suffolk County Arthropod-borne Disease Lab, Hauppauge, NY, United States

Aedes albopictus is an invasive mosquito species known to vector several arboviruses worldwide and was recently detected in Suffolk County, Long Island, NY. Advances in next-generation sequencing have fundamentally shifted our understanding of viruses worldwide and revealed a variety of symbiotic viruses with no known pathogenicity that infect a range of hosts, including *Ae. albopictus*. However, little is known about the distribution of these viruses, their ecology, and how they interact with each other and their hosts. Additionally, given that many of these viruses are likely species-specific, viral phylogenetic structure likely reflects their host's population dynamics and structure. Using georeferenced individual *Aedes albopictus* sampled across Suffolk County, between May 2022 and October 2023, we describe how virome composition varies between individuals and how diversity shifts across seasons and environments. We additionally use phylogeographic models based on whole genomes of select viruses to estimate *Ae. albopictus* population structure in the region. By comparing these results to those predicted by models, we test for the relative impact of active (flight) and passive (human-mediated) dispersal on *Ae. albopictus* population structure. This work will not only help inform future vector control in the area by identifying possible source and sink populations and routes of invasion, but also serve as a proof-of-concept that can be applied to other vector species.

7049

RADIATION EXPOSURE INDUCES GENOME-WIDE ALTERNATIVE SPLICING EVENTS IN *AEDES AEGYPTI* MOSQUITOES

Immo A. Hansen, Harley Bendzus-Mendoza, Amanda Rodriguez, Donovan Bailey, Hailey Luker

NMSU, Las Cruces, NM, United States

The sterile insect technique (SIT) is a radiation-based method to control arthropod pest populations. Ionizing radiation, used to sterilize the pests, affects gene transcription patterns, including alternative splicing events in irradiated cells. In this study, we investigated the effect of radiation on alternative splicing in male *Aedes aegypti* mosquitoes. *Ae. agypti* is a major vector of dengue, Zika, and other arboviral diseases. Analyzing RNA sequencing data, we found that radiation altered the splicing of genes involved in a variety of biological processes, including signal transduction, phosphorylation, and metabolism. Specifically, we observed changes in the expression of splicing factors and alternative splicing events in transcript-coding genes. Our results suggest that radiation damage produced by ionizing radiation can alter the splicing of genes involved in important biological functions in male *Ae. aegypti* mosquitoes. Understanding the impact of radiation on alternative splicing may prove critical for improving mosquito Sterile-Insect-Technique and to prevent the transmission of mosquito-borne diseases.

HYBRID ASSEMBLY AND ANNOTATION OF TWO GEOGRAPHICALLY DISTINCT STRAINS OF THE MALARIA VECTOR *ANOPHELES ALBIMANUS* REVEALS LOW INTRA-SPECIFIC DIVERGENCE

Dieunel Derilus[1], Gareth Weedall[2], Michael W. Vandewege[3], Batra Dhwani[4], Mili Sheth[4], Lorie A. Rowe[5], Ananias A. Escalante[6], Audrey Lenhart[1], Lucy M. Impoinvil[1]

[1]Entomology Branch, Division of Parasitic Diseases and Malaria, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]School of Biological and Environmental Sciences, Liverpool John Moores University, Liverpool, United Kingdom, [3]College of Veterinary Medicine, North Carolina State University, Raleigh, NC, United States, [4]Biotechnology Core Facility Branch, Division of Scientific Resources, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [5]Tulane National Primate Research Center, Department of Microbiology, Viral Characterization, Isolation, Production and Sequencing Core, Tulane University, Covington, LA, United States, [6]Department of Biology/Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA, United States

Anopheles albimanus is one of the principal malaria vectors in the Americas and exhibits phenotypic variation across its geographic distribution. High-quality reference genomes from geographically distant populations are essential to deepen our understanding of the biology, evolution and genetic variation of this important malaria vector. In this study, we applied long-read PacBio and short-read Illumina sequencing technologies to assemble the complete genomes of two reference strains of *An. albimanus*, Stecla (originating from El Salvador), and Cartagena (originating from Colombia); and investigated the structural features of these genomes, including gene content, transposable elements (TE) genetic variations, and structural rearrangements. Our hybrid assembly approach generated reference-quality genomes for each strain and recovered ~96% of the expected genome size. The genome assemblies of Stecla and Cartagena consisted of 109 and 149 scaffolds, respectively, with estimated genome sizes of 167.5 Mbp (N_{50}=88 Mbp) and 167.1 Mbp (N_{50}=87 Mbp), respectively. They exhibited a high level of completeness and contained a smaller number of gaps and

ambiguous bases than either of the two previously published reference genomes for this species, suggesting a considerable improvement in the quality and completeness of the assemblies. A total of 12,082 and 12,120 protein-coding genes were predicted in Stecla and Cartagena, respectively. TE analyses indicated more repetitive content was captured in the long-read assemblies. The assembled genomes shared 98.12% pairwise identity and synteny analyses suggested that gene position was primarily conserved between both strains. These genome assemblies will serve as an important resource for future research in comparative genomics, proteomics, epigenetics, transcriptomics, and functional analysis of this important malaria vector

7051

PHOSPHOPROTEOMICS ANALYSES OF *AEDES AEGYPTI* FAT BODY REVEAL BLOOD MEAL-INDUCED SIGNALING AND METABOLIC PATHWAYS

April Daniela Lopez, Mathew J. Pinch, Immo A. Hansen
New Mexico State University, Las Cruces, NM, United States

The mosquito fat body is the principal source of yolk protein precursors (YPP) during mosquito egg development in female *Aedes aegypti*. To better understand the metabolic and signaling pathways involved in mosquito reproduction, we investigated changes in the mosquito fat body phosphoproteome at multiple time points after a blood meal. Using LC/MS, we identified 3,570 phosphorylated proteins containing 14,551 individual phosphorylation sites. We observed protein phosphorylation changes in cellular pathways required for vitellogenesis, as well as proteins involved in primary cellular functions. Specifically, after a blood meal, proteins involved in ribosome synthesis, transcription, translation, and autophagy showed dynamic changes in their phosphorylation patterns. Our results provide new insight into blood meal-induced fat body dynamics and reveal potential proteins that can be targeted for interference with mosquito reproduction. Considering the devastating impact of mosquitoes on human health, worldwide, new approaches to control mosquitoes are urgently needed.

7052

PREVALENCE OF MALARIA AND LONG-COVID AMONG INDIVIDUALS PREVIOUSLY INFECTED WITH THE SARS-COV-2 VIRUS IN ETHIOPIA AND UGANDA: A CASE CONTROL STUDY

Jane E. Achan[1], Asadu Sserwanga[1], Yonas Teshome[2], Tedila Habte[2], Humphrey Wanzira[1], Simon Kigozi[1], Anthony Nuwa[1], Godfrey Magumba[1], Agonafer Tekalegne[2], Jimmy Opigo[3], Fredrick Nakwagala[3], James Tibenderana[1]
[1]Malaria Consortium, Kampala, Uganda, [2]Malaria Consortium, Addis Ababa, Ethiopia, [3]Ministry of Health, Kampala, Uganda

By 15th April 2024, more than 12 million patients had recovered from SARS-CoV-2 infection across Africa. Although most patients fully recover after acute infection, a proportion experience long-term complications and symptoms referred to as long COVID. The potential interplay between any such post-COVID syndromes and the risk of other infectious diseases like malaria is largely unknown. We determined the prevalence of malaria and long COVID among individuals with previous SARS-CoV-2 infection in a case-control study in Uganda and Ethiopia. Detailed clinical evaluation was conducted using a standardized clinical tool and malaria was diagnosed using rapid diagnostic tests, microcopy and molecular methods. Previous *Plasmodium falciparum* exposure was assessed using serologic responses to a panel of *P. falciparum* antigens using a multiplex bead assay. Additional evaluations including radiological investigations were carried out as needed. Of 3,251 individuals enrolled between 15th September 2022 and 30th March 2024, 1700 (52%) were female and median age (SD) was 35 (15.3) years. Preliminary findings show an overall prevalence of malaria infection was 9.5% (197/2076, 95% CI 8.3 to 10.8), with a higher prevalence among controls (16.7%, 150/898) compared to cases (4.0%, 47/1178), 95% CI 10.1% to 14.5%, p<0.0001. Overall, the prevalence of long COVID was 62.2% (1119/1800, 95% CI 59.9 to 64.4). The commonest manifestations of long COVID included mental health issues, headache, memory loss, brain fog, muscle/joint/bone pains, chest pain/dyspnea and suicidality. Some symptoms persisted up to 24 months post-acute illness. No clear healthcare pathways for the management of these long-term complications were reported. Additional findings will be presented. The burden of long COVID in these settings is significant and defining treatment strategies and recommendations for African patients with long COVID is critical.

Crimean-Congo hemorrhagic fever (CCHF), the most widespread tick-borne viral human infection, poses a threat to global health. In this study, clinical samples collected through national surveillance systems were screened for acute CCHF virus (CCHFV) infection using RT-PCR and for exposure using ELISA. For any CCHF-positive sample, livestock and tick samples were also collected in the neighborhood of the confirmed case and tested using ELISA and RT-PCR, respectively. Genome sequencing and phylogenetic analyses were also performed on samples with positive RT-PCR results. In Eastern Senegal, two human cases and one *Hyalomma* tick positive for CCHF were identified and a seroprevalence in livestock ranging from 9.33% to 45.26% was detected. Phylogenetic analyses revealed that the human strain belonged to genotype I based on the available L segment. However, the tick strain showed a reassortant profile, with the L and M segments belonging to genotype I and the S segment belonging to genotype III. Our data also showed that our strains clustered with strains isolated in different countries, including Mauritania. Therefore, our findings confirmed the high genetic variability inside the CCHF genotypes and their introduction to Senegal from other countries. They also indicate an increasing CCHF threat in Senegal and emphasize the need to reinforce surveillance using a one-health approach.

INVESTIGATING THE EMERGING BURDEN OF DENGUE IN THE KATHMANDU VALLEY, NEPAL THROUGH A LONGITUDINAL POPULATION-BASED SEROSURVEY

Aastha Shrestha[1], Melina Thapa[1], Sudichhya Tamrakar[1], Urursha Ranjitkar[1], Nishan Katuwal[1], Sabin B. Shahi[1], Shiva Ram Naga[1], Rajeev Shrestha[1], Jason R. Andrews[2], Kristen Aiemjoy[3], Dipesh Tamrakar[1]
[1]Dhulikhel Hospital Kathmandu University Hospital, Dhulikhel, Nepal, [2]Stanford University School of Medicine, Standford, CA, United States, [3]University of California Davis School of Medicine, Davis, CA, United States

Dengue, an arthropod-borne infection by *Aedes aegypti* and *Ae. albopictus*, is intensifying globally due to climate change. In Nepal, dengue was previously limited to lower elevations, but recent clinical reports indicate transmission is now occurring at higher altitudes. This study aimed to characterize the population-level risk of dengue in the Kathmandu Valley, Nepal's densely populated region. We enrolled a geographically representative, stratified random sample of individuals between the ages of 1 and 25 residing in Kathmandu and Kavrepalanchok districts. We collected dried blood spot (DBS) samples from participants between 2019-2021 and collected a follow-up sample in 2023. We tested samples for IgG responses against dengue-derived recombinant antigens using commercial ELISA kits. We determined seropositivity cut-offs using Gaussian mixture models, then calculated seroincidence as the number of individuals who seroconverted

from negative to positive divided by their person-time. We enrolled 843 participants (352 in Kathmandu and 491 in Kavre) and analyzed 2091 blood samples. The median age at baseline was 11 years (IQR: 6-17); 47% (396/843) were female. Dengue seropositivity rose from 1.9% (15/792) in 2019 to 12.4% (44/354) in 2023 and was highest in Kathmandu, where it rose from 4.1% (11/271) to 34.0% (36/106). Seroincidence was highest in Kathmandu (99.2 per 1000 person-years, 95% CI: 69.8-136.7). In Kavre, seroincidence ranged from 0 in Panauti to 31.0 (95% CI: 8.5-79.5) in Panchkal. Across all regions, seroincidence increased with age, peaking among 15-25-year-olds at 47.7 infections per 1000 person-years (95%CI: 31.2-70.0). In conclusion, this study reveals a significant rise in dengue incidence in Kathmandu Valley between 2019 and 2023, which may be linked to warming temperatures. The findings indicate an urgent need for interventions to mitigate dengue's rise in Nepal's higher altitudes and contribute to the broader understanding of climate change on vector-borne diseases worldwide.

DETECTION OF ANTIBODIES TO POSSIBLE FILOVIRUS-LIKE PATHOGENS IN RURAL COMMUNITIES IN SARAWAK, MALAYSIA

Charles Kevin Dee Tiu[1], Ivan Yap[2], Mong How Ooi[3], Kiing Aik Wong[4], Anand Mohan[5], Samuel Leong Kheng Wong[6], Lin-Fa Wang[1], David Perera[4]

[1]Duke-NUS Medical School, Singapore, Singapore, [2]Sarawak Infectious Disease Centre, Sarawak, Malaysia, [3]Sarawak General Hospital, Kuching, Sarawak, Malaysia, [4]Institute of Health and Community Medicine, Universiti Malaysia Sarawak, Kota Samarahan, Sarawak, Malaysia, [5]Department of Pediatrics, Bintulu Hospital, Bintulu, Sarawak, Malaysia, [6]Petrajaya Community Clinic, Kuching, Sarawak, Malaysia

Ebolaviruses (EBOV) are zoonotic pathogens that have the potential to cause severe morbidity and mortality. They are deemed to be viruses with high pandemic potential. During our analysis of samples from rural communities in Sarawak, Malaysia, we note the presence of antibody signatures against EBOV in the high throughput serological platform, Phage Immunoprecipitation Sequencing VirScan. We followed up these results using commercially available ELISA for verification. Here, we present preliminary data that shows detection of EBOV glycoprotein (GP) antibodies in several communities in the rural forests of Sarawak, Malaysia.Samples from the rural communities and urban controls were ran on commercially available ELISA with a variety of EBOV GP (Bundibugyo, Tai Forest, Reston, Sudan and Zaire GP) as antigens. Manufacturer recommended cutoff determination was used to interpret the results and the individuals' ELISA results to different EBOV GP was then assessed. Antibody responses were primarily detected against Bundibugyo, Reston, Sudan and Zaire EBOV GP, with a cross-reactive pattern noted in individuals with positive results. Of the EBOVs studied, Sudan and Reston responses are predominant. We observed that individuals residing in the rural community yielded higher ELISA ZEBOV results compared to their urban counterparts.
While known to be lethal and highly pathogenic in most cases, there are certain EBOV (e.g., Reston) that causes asymptotic infections in humans. Given that there were no reports of unidentified illness and there have been no known Filoviruses circulating in the locale, it is possible that a novel zoonotic Filovirus-like pathogen may be the cause of these antibody signatures. Further work - such as neutralization tests - are required and are being conducted to verify our results.

7056

RE-EMERGENCE OF RIFT VALLEY FEVER VIRUS LINEAGE H IN SENEGAL IN 2022: *IN VITRO* CHARACTERIZATION AND IMPACT ON ITS GLOBAL EMERGENCE IN WEST AFRICA

Marie Henriette Dior Ndione[1], Ousseynou Sene[1], Samba Niang Sagne[1], Ndeye Sakha Bob[1], Moundhir Mahmadi[1], Idrissa Dieng[1], Aboubacry Gaye[1], Haoua Ba[1], Moussa Dia[1], Elisabeth Thérèse Faye[1], Sokhna Maimouna Diop[1], Yoro Sall[2], Boly Diop[2], Mamadou Ndiaye[2], Cheikh Loucoubar[1], Etienne Simon-Loriere[3], Anavaj Sakuntabhai[3], Ousmane Faye[1], Amadou Alpha Sall[1], Diawo Diallo[1], Ndongo Dia[1], Oumar Faye[1], Moussa Moïse Diagne[1], Malick Fall[4], Mamadou Aliou Barry[1], Gamou Fall[1]

[1]Institut Pasteur de Dakar, Dakar, Senegal, [2]Ministry of Health, Dakar, Senegal, [3]Institut Pasteur, Paris, France, [4]Cheikh Anta Diop University, Dakar, Senegal

Rift Valley Fever (RVF) is an re-emerging vector-borne zoonosis causing major epidemics and huge losses in livestock production. In West African countries, the lineages A, C and N were previously detected but since 2020, mainly the lineage H from South Africa were detected in Senegal. In this study, clinical samples collected through national surveillance system were screened for RVF virus (RVFV) acute infection by RT-PCR and exposure by ELISA. Molecular and *in vitro* phenotypic characterization were also performed on RT-PCR positive samples. Four human cases were detected RVFV positive by RT-PCR (2) and ELISA (2) in four regions in Senegal. Phylogenetic analyses revealed that these strains belonged to lineage H and clustered with West African strains, specifically found in Senegal and Mauritania in 2020. The *in vitro* characterization showed that the lineage H had significant higher replication than lineage C. Our findings showed a re-emergence of the lineage H in Senegal in 2022 and showed its higher replication compared to previous lineage C identified in West Africa. This study gives new insights on the biological properties of the lineage H and will be useful for the implementation of control strategies of RVF in Senegal and neighboring countries.

7057

MPOX VIRUS SEROPREVALENCE AMONG INDIVIDUALS VULNERABLE TO INFECTION IN EAST AFRICA

Brennan Cebula[1], Michelle Imbach[2], Kara Lombardi[2], Fengming Hu[2], Natalie Collins[3], Camila Macedo Cincotta[2], Kristina Peachman[4], Leigh Anne Eller[2], Neha Shah[1], Sheila Peel[4], Hannah Kibuuka[5], John Owouth[6], Jonah Maswai[1], Valentine Sing'oei[6], Emmanuel Bahemana[7], Julie Ake[1], Michael T. Thigpen[1]

[1]U.S. Military HIV Research Program, CIDR, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, [3]Emerging Infectious Diseases Branch, CIDR, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [4]Diagnostics and Countermeasures Branch, CIDR, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [5]Makerere University Walter Reed Project, Kampala, Uganda, [6]HJF Medical Research International, Kisumu, Kenya, [7]HJF Medical Research International, Mbeya, Tanzania, United Republic of

Endemic in Central and West Africa as a zoonotic infection, mpox has recently been associated with human-human transmission in many non-endemic countries. No mpox cases have been reported in East Africa, but asymptomatic or mild cases in conjunction with limited mpox testing capacity could underestimate disease spread. Results from a mpox seroprevalence study among individuals in East Africa vulnerable to infection during the 2022-23 global outbreak are presented. The African Cohort Study (AFRICOS) is a prospective cohort of adults and adolescents living with, or vulnerable to HIV in four African countries. Cohort participants in Kenya, Tanzania, and Uganda were identified as vulnerable to mpox by meeting one of the following criteria per their study enrollment questionnaire: men or transgender women who have sex with men, HIV pre-exposure prophylaxis use, alcohol/recreational drug use during sex, four or more sex partners in the past six months, sexually-transmitted infection in the past month, or transactional sex. A participant's most recently collected plasma/

serum was tested for anti-clade IIb mpox antibodies using the Meso-Scale Discovery (MSD) Orthopoxvirus panel 1 MULTI-SPOT kit. Mpox seropositive participants' most recent demographic and social behavior data were described. Of the 618 participants identified as vulnerable to mpox, 50 (8.1%) were seropositive. Median age was 53 (interquartile range: 44-63) and 13 (26%) were female. Ten reported recent behaviors associated with mpox vulnerability (eight men who have sex with men and two reporting transactional sex). The high seroprevalence observed in these participants with relatively low mpox vulnerability per their recent behavior data suggests prior infection with other orthopoxviruses or cross-reacting immune responses to Vaccinia virus vaccination may be contributing. However, these results may also indicate previously unrecognized human mpox in East Africa and highlight the need for expanded seroprevalence studies and prospective surveillance to address the persistent knowledge gap in mpox epidemiology in Africa.

7058

FOLLOWING A 50-YEAR HIATUS TAMANA BAT VIRUS (TABV) IS DETECTED AGAIN IN IQUITOS, PERU

Alejandra Garcia-Glaessner[1], Breno Muñoz-Saavedra[1], Diana Juarez[1], Patricia Barrera[1], Gabriela Salmon-Mulanovich[1], Tatiana Quevedo[2], Carlos Calvo-Mac[2], Marcela Uhart[3], Nicole R. Gardner[4], Christine K. Johnson[4], Amy C. Morrison[4], **Mariana Leguia**[1]

[1]Pontificia Universidad Catolica del Peru, Lima, Peru, [2]EpiCenter for Emerging Infectious Disease Intelligence, Lima, Peru, [3]University of California, Davis, Lima, CA, United States, [4]University of California, Davis, Davis, CA, United States

Tamana Bat Virus (TABV) is a putative flavivirus first identified and isolated in 1973, from the salivary glands, saliva and spleen of *Pteronotus parnellii*, an insectivorous bat collected in the Tamana bat caves of Trinidad, in South America. At the time, the authors showed serological evidence of TABV infection in bats (72/850, 8.5%) of several species (15), as well as in humans (21/172, 12%), suggesting this novel flavivirus could potentially be a pathogen of concern. The complete TABV genome of the original isolate was sequenced 30 years later, in 2002, but in the 50 years since its original discovery in Trinidad there have been no further reports of TABV anywhere, until now. As part of ongoing metagenomic investigations of the virome of various bat species residing at the human-animal interphase in the Amazonian Region of Peru, we used unbiassed NGS to identify partial genomic sequences matching TABV in a feces sample from a pale spear-nosed bat (*Phyllostomus discolor*) collected within the city of Iquitos. Given that the genomic sequences initially identified covered only ~46% (4,587 of 10,053 total bp) of the complete TABV genome, we used this information in combination with the previously published TABV whole genome to design TABV-specific primers for tiling amplification, and we further supplemented 5'- and 3'-UTR sequences using 5'- and 3'-RACE. With this approach we have generated a complete TABV genome from Peru, which in turn has enabled other downstream analyses, including a basic phylogeny. Here, we report complete genomic characterization of TABV from a sample collected from a city-dwelling omnivorous bat known to feed on insects, fruit, pollen, nectar and flowers. Further, we report on ongoing efforts to test additional samples for this relatively novel flavivirus to further characterize its little-known epidemiology.

METABOLOMIC BIOMARKERS IN DENGUE VIRUS INFECTION FOR PREDICTING SEVERE DISEASE

Jaime A. Cardona-Ospina[1], Paul S. Soma[2], Rebekah C. Gullberg[2], Barbara Graham[2], M. Nurul Islam[2], Carol D. Blair[2], Barry J. Beaty[2], John T. Belisle[2], Angel Balmaseda[3], Eva Harris[1], Rushika Perera[2]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Department of Microbiology, Immunology, and Pathology, Colorado State University, Fort Collins, CO, United States, [3]Sustainable Sciences Institute, Managua, Nicaragua

Dengue virus (DENV) infection results in a range of clinical outcomes, spanning from self-limited febrile disease known as dengue fever (DF) to severe disease characterized by hemorrhage and vascular leakage called dengue hemorrhagic fever/dengue shock syndrome (DHF/DSS). While diagnostic tools aid in identifying infections, the triage of those at risk of progression to DHF/DSS relies on clinical and hematological parameters. Here, we aimed to identify prognostic biomarkers by analyzing the metabolome of DENV-infected children early after infection (≤3 days post-symptom onset). Using liquid chromatography/mass spectrometry, we analyzed the serum metabolome of children from the prospective Pediatric Dengue Hospital-based Study and the Pediatric Dengue Cohort Study in Nicaragua. To control for potential confounders, children who progressed to DHF/DSS (n=14) were matched with DF cases (n=81) using propensity score full matching. We used a multivariate regression with regularization to identify discriminant features between both clinical groups. The dataset (n=95) was split into training/testing subsets (50:50) for parameter estimation of the model via cross-validation (n=10). The median age was 10.6 years (interquartile range 7.9-12.6, female 52.6%). From a total of 3850 metabolomic features that were extracted, filtered, and normalized, only 56 were discriminant between children who developed DHF/DSS vs. DF during follow-up. Fifty-four were enriched in DF, while only two were enriched in DHF/DSS. Interestingly, a molecular feature with mass to charge 780.5538 was associated with DHF/DSS in primary and secondary infections (OR 3.66, 95%CI 1.39 to 14.42 and OR 3.59, 95%CI 1.38 to 13.89, respectively), while a molecular feature with mass to charge 777.695 was associated with DF in both primary and secondary infections (OR 0.07, 95%CI 0.01 to 0.42). Further analysis will identify metabolites associated with DF vs DHF and will explore metabolic pathways during the acute, critical and recovery phases of disease. Our results suggest that specific metabolomic markers may serve as early prognostic indicators during DENV infection.

7060

PREVALENCE AND PREDICTORS OF PERSISTENT SYMPTOMS POST-ACUTE COVID-19 INFECTION AMONG A COHORT OF FRONTLINE HEALTHCARE WORKERS IN BANGLADESH

Md Zakiul Hassan[1], Ahamed Khairul Basher[1], Md Abdullah Al Jubayer Biswas[1], Aninda Rahman[2], Mahmudur Rahman[3], Fahmida Chowdhury[1], Kaydos-Daniels Neely[4]

[1]icddr,b, Dhaka, Bangladesh, [2]Communicable Disease Control, the Director General of Health Services, the Ministry of Healthand Family Welfare Government of Bangladesh, Dhaka, Bangladesh, [3]Global Health Development/EMEMPHNET, Dhaka, Bangladesh, [4]US Centers for Disease Control and Prevention, Atlanta, GA, USA, Atlanta, GA, United States

Despite evidence of a wide range of persistent symptoms among COVID-19 survivors, commonly known as long COVID, their frequency, clinical spectrum and risk factors are not well characterized. We assessed the prevalence and predictors of long COVID among healthcare workers (HCWs) in Bangladesh. Between July 2021-December 2023, we enrolled a cohort of HCWs from purposively selected 10 hospitals across Bangladesh to prospectively record COVID-19 illness. At enrolment, we captured data on HCWs' demographics, co-morbid conditions and COVID-19 illness. The study physician followed the participants biweekly to record any new and persistent symptoms following acute illness. We used the WHO case definition for long COVID (symptoms occurring 3 months from the acute COVID-19 infection and persisting for at least2 months). We performed a multivariable logistic regression to identify the predictors of long COVID. The analysis included 875 HCWs with lab-confirmed SARS-CoV-2 infection: 30% (261) doctors, 53% (468) nurses, and 17% (146) support staff. Themedian age of the HCWs was 35 (IQR, 29-44), and 69% (601) were female. Of the 875 HCWs, 462 (53%) reported persistent symptoms, with fatigue being the most common (83%), followed by brain fog (14%), cough (5%), breathing difficulties (4%),and joint pain (4%). HCWs with co-

morbidities (aOR 3.39, 95% CI 2.32-4.95; p=0.0001), breathing difficulty during the acute phase (aOR 2.84, 95% CI 1.77-4.55; p=0.0001), and those who required hospitalization during acute infection (aOR 2.25, 95% CI 1.53-3.04; p=0.0001) were more likely to develop persistent symptoms than HCWs without a history of co-morbidities, respiratory symptoms, or hospitalization. Nurses (aOR 1.36, 95% CI 1.01-1.85; p=0.04) were more likely to develop persistent symptoms than doctors. More than half of the HCWs in our cohort experienced long-term symptoms of COVID-19, with a greater risk observed among nurses and those with the co-morbid condition. These findings underscore the pressing need for long-term care and rehabilitation strategies with a standardized guideline to enhance the post-acute recovery of COVID-19 patients.

7061

VIRAL CLEARANCE IN COVID-19 PATIENTS WITH AND WITHOUT COMORBIDITIES IN BAMAKO, MALI.

Fatimata Amath Diallo[1], Fah Gaoussou Traore[1], Abdoulaye Dao[2], Ibrahim Sanogo[1], Mamadou Coulibaly[1], Mariam Sow[1], Antieme Combo Georges Togo[1], Yaya Sadio Sarro[1], Gagni Coulibaly[1], Mohamed Abdou Diallo[3], Mama Sy Konake[4], Yacouba Toloba[2], Seydou Doumbia[1], Bassirou Diarra[1], Mahamadou Diakite[1]

[1]University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, [2]University Teaching Hospital Point G, Bamako, Mali, [3]Department of Laboratory and Biomedical Research, National Institute of Public Health (INSP), Hippodrome, Bamako, Mali, [4]Bamako Regional Direction of Health, Ministry of Health and Social Development, Bamako, Mali

Coronavirus Disease 2019 (COVID-19) rapidly spreading to the rest of the world afteridentification. Comorbidities have increased morbidity and mortality rates and have been linkedto more hospitalization and intensive care unit (ICU) admissions. Thus, the aim of our study wasto determine the duration of the positivity of SARS-CoV-2 in COVID-19 patients with and withoutcomorbidities at the University Teaching Hospital (UTH) of Point-G, Bamako, Mali. A Crosssectional study was conducted between March 2020 and December 2022 enrolling SARS-CoV-2 RT-PCR positive patients in IRB approved protocol after written consent. Treatment was donein accordance with the national protocol combining Chloroquine, azithromycin, and vitamin C for7 days. Clearance was defined as anyone with two consecutive negative RT-PCR results within24 hours on nasopharyngeal swabs. One hundred and twenty-eight patients were included, andthe sex ratio was 1.6. While most patients had no symptoms, some had a wide range of symptomsfrom mild complaints to hospitalization at ICU. Among the 128 patients, 91 had comorbidities ofwhich 13.3% had critical symptoms. The average duration of viral clearance was 11.76days±4.48. The difference between age groups (years) was not statistically different, 14 days±0for [8-17], 11.5±3.54 for [18-60], and 12.6 ±6.39 for those aged greater than 60 years respectively(p= 0.24). In addition, we didn't find a difference on gender based with 12.3±5.31 for women and11.4±3.85 for men respectively (p=0.43). On the other hand, the average time to clearance ofpatients without comorbidities was higher than those with comorbidities, 13 days±3 vs. 11.30days±3.85 respectively (p = 0.007). The most common comorbidities identified were high bloodpressure (N=61), diabetes (N=36), sickle cell disease (N=8) and HIV (N=5). Viral RNA frompatients without comorbidities persists for a somewhat long period than those on patients withcomorbidities. A complete monitoring of these patients including the check for long COVID-19together with some immunological factors will determine the impact of COVID-19 on Human hostfactors.

7062

CLINICAL AND RISK FACTOR PROFILE OF OROPOUCHE VIRUS DISEASE DURING AN ONGOING OUTBREAK IN THE PERUVIAN AMAZON: FINDINGS FROM THE RIVERA ACUTE FEBRILE ILLNESS SURVEILLANCE STUDY.

Josh Michael Colston[1], Pablo Peñataro Yori[1], Francesca Schiaffino[2], Maribel Paredes Olórtegui[3], Tackeshy Pinedo Vasquez[3], Paul F. Garcia Bardales[3], Valentino Shapiama Lopez[3], Loyda Fiorella Zegarra Paredes[3], Karin Perez[3], Greisi Curico[3], Margaret N. Kosek[1]

[1]University of Virginia School of Medicine, Charlottesville, VA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Asociación Benefica PRISMA, Iquitos, Peru

Oropouche fever is an emerging arthropod-borne zoonotic disease caused by the Oropouche virus (OROV) and leads to undifferentiated acute febrile illness (AFI) symptoms. OROV transmission is endemic among wild animal hosts in the forests and jungles of Central and South America, with occasional spillover to humans in the bites of midges and mosquitoes resulting in sporadic outbreaks. Incidence is increasing with over 500,000 cases and >30 outbreaks reported in the Americas, likely underestimated due to surveillance limitations. An outbreak of OROV is currently underway in Amazonian Brazil and Peru. RIVERA is an ongoing surveillance study of AFI etiology with a case-control design. AFI patients and matched controls are enrolled at urban and rural health facilities in and around Iquitos, in the Peruvian Amazon. Blood samples are tested for 32 locally relevant endemic and emerging pathogens using multiplex PCR. Using a nested case-control approach, OROV-positive AFI patients from the parent study were identified, and symptomatic AFI cases negative for all pathogens (unattributed AFI) were treated as controls. Relevant risk factors, signs and symptoms were compared, and logistic regression models fitted to the OROV positive/unattributed AFI binary outcome. From 8/25/2021, through 3/31/2024, 24 cases of OROV attributable AFI were identified, with 18 (75%) occurring in 2024. 1,012 unattributed AFI controls were recruited in the same period. The odds ratio for joint pain in the prior two weeks in cases compared to controls was a statistically significant 12.4 (2.89, 53.33). 16.7% (4) of OROV cases reported having traveled in the preceding 15 days compared with 7.2% of controls, giving a statistically significant odds ratio of 3.11 (1.12, 8.60). As the outbreak plays out, we will prospectively add new cases of OROV attributable AFI to the analysis, eventually giving large enough numbers for confounder matching and adjustment. OROV disease is characterized by muscle and joint pain, malaise, and headache in this study population in the Peruvian Amazon. Those contemplating travel within Amazonia, should take precautions against OROV insect vectors.

7063

THE GLOBAL HEALTH BURDEN OF CHIKUNGUNYA FROM 2011 TO 2020: A MODEL-DRIVEN ANALYSIS ON THE IMPACT OF AN EMERGING VECTOR-BORNE DISEASE

Adrianne M. de Roo[1], Gerard T. Vondeling[1], Kristy Murray[2], Maarten J. Postma[3]

[1]Valneva Austria GmbH, Vienna, Austria, [2]Emory University, Atlanta, GA, United States, [3]University of Groningen, Groningen, Netherlands

Chikungunya is a mosquito-borne arboviral disease posing an emerging global public health threat. Understanding the global burden of chikungunya is critical for designing effective prevention and control strategies. However, current health estimates caused by chikungunya remain limited and are potentially underestimated. Considering the increasing risk of large-scale outbreaks driven by climate change and globalization, it is crucial to have a thorough understanding of the health burden of chikungunya. Therefore, we aimed to estimate the global and regional burden of chikungunya from 2011 to 2020 based on a data-driven simulation model. Based on worldwide case numbers from several publicly available sources, we estimated the disability-adjusted life years (DALYs) for the acute and chronic phase of chikungunya per country, super-region, and globally over a ten-year time period. Because the true burden of chikungunya is likely underreported due to misdiagnosis amongst others, we included an underreporting

factor for the reported case numbers. DALYs were calculated using the GBD methodology and represent the sum of the years of life lost due to premature mortality (YLLs) and years lived with disability (YLDs). Our model revealed 17.5 million chikungunya cases in 110 countries between 2011 and 2020, causing 1.8 million DALYs lost in this ten-year timeframe. The majority was driven by long-term chronic illness, accounting for 1.4 million DALYs lost. YLDs take up most of the total DALYs, with 77%. YLLs in the acute phase were 426,000. In 2014, the highest DALY burden was recorded, with 640,000 DALYs. This aligns with the significant case numbers reported in the Latin American and Caribbean super-region that year. These results show that the burden of chikungunya should not be neglected. The disease's unpredictable nature in combination with the emerging spread due to climate change poses a significant threat to public health and can cause a substantial health burden for individuals affected.

RAPID ALTERNATIVE DETECTION ASSAY OF SARS-COV2 RNA USING A ONE-STEP RT-FAST-MULTIPLEX PCR AND LATERAL FLOW IMMUNOASSAY

Insaf Bel Hadj Ali[1], Hejer Souguir[1], Mouna Melliti[1], Mohamed Vall Taleb Mohamed[1], Monia Ardhaoui[2], Yusr Saadi[3], Kaouther Ayouni[4], Henda Triki[4], Sondes Haddad-Boubaker[4], Ikram Guizani[1]

[1]Laboratory of Molecular Epidemiology and Experimental Pathology (LR16IPT04), Institut Pasteur de Tunis, University of Tunis El Manar, Tunis, Tunisia, [2]Laboratory of Molecular Epidemiology and Experimental Pathology (LR16IPT04),Institut Pasteur de Tunis, University of Tunis El Manar, Tunis, Tunisia, [3]Laboratory of Molecular Epidemiology and Experimental Pathology (LR16IPT04), Institut Pasteur de Tunis, University of Tunis El Manar, Tunis, Tunisia, [4]Laboratory of Clinical Virology, WHO Regional Reference Laboratory for Poliomyelitis and Measles for the EMR/Laboratory of Virus, Host and Vectors (LR20IPT02), Institut Pasteur de Tunis, University of Tunis El Manar, Tunis, Tunisia

COVID-19 pandemic has put emphasis on diagnosis and surveillance, and the subsequent shortage of diagnostics reagents and kits. It is strategic for the countries to be able to access, expand diagnosis, and acquire capacity to deploy alternative rapid accurate nucleic acid tests that are at lower costs. Here, we propose a visual SARS-CoV-2 detection using a one-step RT-fast-multiplex PCR amplification coupled to lateral flow immunoassay detection on a generic PCRD dipstick. Simplex fast-PCRs were developed by screening 17 primer pairs. They include 12 designed primer pairs targeting genes encoding the S protein (N=6 pairs), the N protein (N=2 pairs), the E protein (N=2 pairs), and the Open Reading Frame ORF1ab (N=2 pairs), and 5 other primer pairs selected from the published and validated WHO quantitative (q) RT-PCR protocols. For PCRD detection, labelled primers with Fam/Biotin or Dig/Biotin were used in fast RT-PCR protocols using RNA isolated from patients' nasopharyngeal swabs. Two primer pairs were selected based on their specificity, sensitivity, stability and absence of background to noise in the PCRD, and were used to set up a multiplex assay targeting two different viral genomic regions, N and E genes. The selected assay was then evaluated on 98 samples including 46 SARS-CoV+ with Ct values varying from 15 to 38, and 48 SARS-CoV-, comparing the performances to those of the RT-qPCR used to diagnose the patients by the virology lab of IPT. Our one step RT-fast-multiplex PCR coupled to PCRD showed a sensitivity of 86,96% (40/46) and a specificity of 97,75% (47/48). All patients presenting Ct values lower than 33 were positive with our assay. Patients with Ct values higher than 33 showed negative results. Our results brought proof of principle on the usefulness of the one step RT-fast-multiplex PCR assay coupled to PCRD for specific, sensitive, and rapid detection of SARS-COV-2 without requiring costly laboratory equipment, and thus at reduced costs and prone to be deployed when resources are limited. This new method of SARS- CoV2 detection appears as a good alternative for Covid19 diagnosis or screening at points of need.

FIELD EVALUATION OF VALIDITY AND FEASIBILITY OF PAN LASSA RAPID DIAGNOSTIC TESTS FOR LASSA FEVER IN ABAKALIKI, NIGERIA: A PROSPECTIVE DIAGNOSTIC ACCURACY STUDY

Temmy Sunyoto[1], Jelte Elsinga[1], Letizia di Stefano[1], Pier Francesco Giorgetti[2], Htet Aung Kyi[3], Chiara Burzio[4], Ximena Campos Moreno[4], Chiedozie K. Ojide[5], Nnennaya Ajayi[6], Richard Ewah[7], Emeka Onwe[7], Chioma Dan-Nwafor[8], Anthony Ahumibe[8], Chinwe Lucia Ochu[8], Adebola Olayinka[8], Sylvie Jonckheere[4], Pascale Chaillet[4], Michel van Herp[4]

[1]MSF, Luxembourg, Luxembourg, [2]MSF, Abakaliki, Nigeria, [3]MSF, Abuja, Nigeria, [4]MSF, Brussels, Belgium, [5]Alex Ekwueme Federal Teaching Hospital, Abakaliki, Nigeria, [6]Alew Ekwueme Federal Teaching Hospital, Abakaliki, Nigeria, [7]AEFUTHA, Abakaliki, Nigeria, [8]NCDC, Abuja, Nigeria

Background Lassa fever is a viral haemorrhagic fever with few options for diagnosis and treatment. A point-of-care bedside test diagnosing Lassa fever,adhering to REASSURED criteria, is not currently available but is urgently needed in west African regions with high Lassa fever burden. We aimed to assess the validity and feasibility of a rapid diagnostic test (RDT) to confirmLassa fever in people in Nigeria.Methods We estimated the diagnostic performance of the ReLASV Pan-Lassa RDT (Zalgen Labs, Frederick, MD, USA) as a research-use-only test, compared to RT-PCR as a reference standard, in 217 participants at a federal tertiary hospital in Abakaliki, Nigeria. We recruited participants between 2022 and 2023. The RDT was performed using capillary blood at the patient bedside and using plasma at the laboratory. The performance of the test, based on REASSURED criteria, was assessed for user friendliness, rapidity and robustness, sensitivity, and specificity.ResultsParticipants were aged between 0 and 85 years, with a median age of 33 years (IQR 22·0-44·3), and 24 participants were younger than 18 years. 107 (50%) participants were women and 109 (50%) were men. Although the specificity of the Pan-Lassa RDT washigh (>90%), sensitivity at bedside using capillary blood was estimated as 4% (95% CI 1-14) at 15 min and 10% (3-22) at 25 min, far below the target of 90%. The laboratory-based RDT using plasma showed better sensitivity (46% [32-61] at 15 min and 50% [36-64] at 25 min) but did not reach the target sensitivity. Among the PCR-positive participants with Lassa fever, positive RDT results were associated with lower cycle threshold values. Personnel conducting the bedside test procedure reported being hindered by the inconvenient use of full personal protective equipment and long waiting procedures before a result could be read.ConclusionThe Pan-Lassa RDT is not currently recommended as a diagnostic or screening tool for suspected Lassa fever cases. Marked improvement in sensitivity and user friendliness is needed for the RDT to be adopted clinically. There remains an urgent need for better Lassa fever diagnostics in low-resource settings.

7066

COMPARATIVE ANALYSIS OF NS1/IGM RAPID DIAGNOSTIC TESTS WITH NS1 AND IGM ELISA FOR DENGUE CASES AND ITS POSSIBLE CORRELATION WITH UNDER-REPORTING OF DENGUE CASES IN INDIA.

Vishwa Deepak Tiwari[1], Sundaram Pandey[1], Mayank Gangwar[2], Surendra Pratap Mishra[3], Gopal Nath[2], Jaya Chakravarty[1]

[1]Department of Medicine,Institute of Medical Sciences, Banras Hindu University, Varanasi, India, [2]Department of Microbiology,Institute of Medical Sciences, Banras Hindu University, Varanasi, India, [3]Department of Clinical Biochemistry,Institute of Medical Sciences, Banras Hindu University, Varanasi, India

According to the guideline of National Center for Vector Borne Diseases Control (NCVBDC), Government of India, IgM Antibody Capture ELISA kit (MAC ELISA) is provided for definitive diagnosis of dengue infection in the network of sentinel surveillance laboratories, established across the country. Therefore, a negative IgM ELISA result concludes to a dengue negative result. However, most patients with dengue infection get tested by Rapid Diagnostic Kit (RDT) during the first 4 days of the febrile illness

when IgM are not usually formed. This could be a possible factor behind under-reporting of Dengue cases in India. Our study aims to compare the results of the rapid test for dengue with NS1 and IgM ELISA and find the possible correlation that IgM negative NS-1 Antigen (NS1Ag) positive cases have with under-reporting of Dengue cases and to formulat an efficient combination of serological tests which could bring the "missed-out" Dengue cases in the fold of reported cases. Blood samples (n=264) from patients diagnosed with dengue with RDT in CCI Lab, SSL Hospital, BHU were used in our study from September 2023 to November 2023. We performed NS-1 ELISA and IgM ELISA by DENV NS-1 ELISA kit and IgM Antibody Capture MAC ELISA kit, respectively in all the samples. RDT of 264 samples, showed NS1 Ag positive in 251 sample out of which 239 were NS-1 positive and 12 were NS-1/IgM co-positive while 13 were IgM positive. Out of the 239 samples solely positive for NS-1Ag by RDT, we detected 237 sample to be positive through NS-1 ELISA and from the co-positive samples, we found 10 to be positive from NS-1 ELISA. Similarly, IgM positive samples via RDT were 25 in which 13 were solely positive for IgM out of which 12 were found positive by IgM ELISA while all 12 positive for both NS-1/IgM by RDT was positive by IgM ELISA. Overall, out of 264 samples, 257 (97.34%) were found positive for NS-1Ag via NS-1 ELISA and only 54 (20.45%) were positive for IgM via IgM ELISA. This shows almost 80% of the cases will be missed if only IgM ELISA is used for definitive diagnosis of Dengue. Our study suggests revision of guidelines, recommending NS1-ELISA alongside IgM for accurate dengue case reporting in India.

DETECTION OF ANTI-MARBURG VIRUS IGG ANTIBODIES IN WATSA, DEMOCRATIC REPUBLIC OF THE CONGO: 25 YEARS AFTER OUTBREAK

Sydney Merritt[1], Nicole A. Hoff[1], Skylar A. Martin[1], Olivia A. Smith[2], Jean Paul Kompany[3], Merly Tambu[3], Angelica L. Barrall[1], Megan Halbrook[1], Kamy Musene[1], Michael Beia[3], Teri Ann Wong[2], Jean Jacques Muyembe-Tamfum[3], Didine Kaba[4], Axel T. Lehrer[2], Anne W. Rimoin[1], Placide Mbala-Kingebeni[3]

[1]Fielding School of Public Health, University of California, Los Angeles, Los Angeles, CA, United States, [2]University of Hawaii at Manoa, Department of Tropical Medicine, Medical Microbiology and Pharmacology, Honolulu, HI, United States, [3]Insitut National de Recherche Biomedicale (INRB), Kinshasa, Congo, Democratic Republic of the, [4]Kinshasa School of Public Health, University of Kinshasa, Kinshasa, Congo, Democratic Republic of the

Marburg virus (MARV) is a rare, but potentially fatal, zoonotic pathogen responsible for Marburg virus disease (MVD) among humans and non-human primates. As a member of the *filoviridae* family of viruses, and close relative of *Ebolavirus*, historic outbreaks of MARV have almost been exclusively in Sub-Saharan Africa, with six alone reported between Uganda and the Democratic Republic of the Congo (DRC). The most recent MARV outbreak in DRC was reported in the Watsa/Durba region of Haut Uele province from 1998-2000-near recent reported MARV outbreaks in Uganda in 2022. With limited outbreaks of MARV and no available clinically approved MARV vaccines, this study sought to elucidate the prevalence of anti-MARV antibodies (Ab) among a mixed cohort of Watsa/Durba residents enrolled in 2023. This cohort (n = 370) included known MVD survivors of the 1998 outbreak (n = 6), close contacts (n = 29) and healthcare workers (n=318). Among this group, 6.8% of respondents reported recent travel to Uganda, and 9.5% were under 24 years of age - thus, born after the 1998 outbreak. Additionally, a small sample of the cohort (n = 3) indicated that their primary occupation was gold-panning - an activity shown to be a significant risk factor for MARV exposure. Using a multiplex bead-based immunoassay, the seroreactivity to MARV antigens was compared among the Watsa/Durba cohort with the cut-off for seroreactivity calculated at 6711 Median Fluorescence Intensity (MFI) for MARV glycoprotein (GP) and 11491 MFI for viral matrix protein 40 (VP40). In this comparison, the seroreactivity to MARV GP was 3.5% and 1.2% to MARV VP40. Interestingly, none of the seroreactive individuals were known survivors of the 1998 outbreaks. There were no associations between travel to Uganda and seroreactivity, nor employment as a goldminer. When using a less stringent cut-off to determine seroreactivity, all known survivors were classified as reactive for both MARV GP and VP40 - with 42.9% and 39.4% seroreactivity among the entire Watsa cohort. This high seroprevalence may indicate exposure to MARV or MARV-like antigens despite no active outbreak declared in the area.

7068

DETECTION AND PARTIAL GENOMIC CHARACTERIZATION OF ROTAVIRUS A STRAINS CIRCULATING IN DIARRHEAL OUTBREAKS IN LLAMA AND ALPACA FLOCKS FROM BOLIVIA

Belén C. Choque-Pardo, Alejandra Torrez, Sonia Jimenez-Pacohuanca, Volga Iñíguez, Sergio Gutiérrez-Cortez, Carla Calderon Toledo, Julia Barreta

Instituto de Biología Molecular y Biotecnología, La Paz, Bolivia, Plurinational State of

In marginal agricultural areas of the Bolivian highlands, South American camelids (SAC) often constitute the indigenous farmer's only resource for food, clothing, and extra income. Acute diarrheal diseases affecting llama and alpaca newborns constitute major annual financial losses for farmers due to high levels of mortality. The objective of this study was to report the preliminary genomic analysis of two RVA strains affecting llama and alpaca flocks with diarrhea during March–June 2018 using an NGS-based approach. For this purpose, seven fecal samples were selected out of twenty five from animals with diarrhea in two highland regions. Following viral RNA extraction, cDNA library construction, and sequencing on an Iseq100 platform (Illumina), the genotype of each RVA gene was determined using the RotaC v2.0 tool. Sequences were compared to those of RVA strains obtained from GenBank. For each gene, multiple alignments were carried out using MAFFT 7.0, and phylogenetic trees were constructed using neighbor-joining in MEGA-X. Two samples isolated from alpaca and llama revealed the presence of two different genotypes: G8-P[14] and G3-P[14] that were partially classified as: G8-P [14]-I2-Rx-C2-M2-A11-N2-Tx-E3-H3 and G3-P [14]-I2-R2-C2-M2-A17-N2-T6-E3-H3, respectively. The isolated segment genotypes G8, P[14], I2, C2, M2, A17, E3, and T6 were closely associated with RVA strains isolated from vicuñas, guanacos, and alpacas, while R2, N2, and H3 were related to bovine-RVA strains, and G3 and A11 to strains identified in humans. This data suggests complex reassortment events among rotaviruses from diverse host species, which may have contributed to the genetic constellation of llama and alpaca RVA strains, highlighting the need for monitoring the potential emergence of novel rotavirus strains in the region.

7069

COMORBIDITIES AND HOSPITALIZATION RISK FROM DENGUE, CHIKUNGUNYA, AND ZIKA, PUERTO RICO, 2012-2023

Zachary J. Madewell, Parker K. Acevedo, Dania M. Rodriguez, Liliana Sánchez-González, Joshua M. Wong, Vanessa Rivera-Amill, Gabriela Paz-Bailey, Laura E. Adams

CDC, San Juan, PR, United States

Previous research has established links between comorbidities and severe arbovirus infections, but there is limited research on how specific comorbidities impact hospitalization risk for each arbovirus. We analyzed data from 2012–2023 from the ongoing Sentinel Enhanced Dengue Surveillance System in Puerto Rico, focusing on adults aged ≥18 years diagnosed with dengue, chikungunya, or Zika virus infection via RT-PCR or serology. Mixed-effects logistic regression was used to evaluate associations between each comorbidity and arbovirus, adjusting for age group, sex, days post onset, previous dengue infection, respiratory viral coinfection, pregnancy, other comorbidities, and hospital site. To account for potential confounding by disease management practices, including admission for dengue warning signs, we additionally adjusted the dengue analyses for severe dengue status. Of 18,941 adults with acute febrile

illnesses, median age was 40 years [IQR: 26-57] and 52.6% were female. From these, 1,359 (7.2%) had Zika, 1,250 (6.6%) had chikungunya, and 594 (3.1%) had dengue. The most frequent comorbidities were obesity (Zika: 39.5%, chikungunya: 20.0%, dengue: 22.7%) and hypertension (Zika: 26.6%, chikungunya: 29.4%, dengue: 22.1%). Logistic regression showed increased odds of hospitalization among adults with hypertension and Zika (OR: 2.28, 95% CI: 1.21–4.28), diabetes and chikungunya (OR: 2.11, 95% CI: 1.28–3.48), and cancer and chikungunya (OR: 2.97, 95% CI: 1.27–6.95) compared with patients without those comorbidities. No associations were found between any comorbidity and hospitalization for dengue. No associations were found between asthma, congenital heart disease, high cholesterol, obesity, thyroid disease, or hospitalization for any arbovirus. While null findings for dengue may reflect the lower case count compared with Zika and chikungunya, future analyses leveraging the ongoing PR dengue epidemic could strengthen this investigation. These findings underscore the importance of understanding comorbidities for arbovirus management.

TRANSMISSION DYNAMICS OF RIFT VALLEY FEVER AND CRIMEAN-CONGO HEMORRHAGIC FEVER VIRUSES IN THREE DIFFERENT ECOLOGICAL REGIONS IN SENEGAL

Elisabeth Thérèse Faye[1], Déthié Ngom[1], Samba Niang Sagne[1], Ousseynou Sene[1], Aliou Khoulé[1], Sokhna Maimouna Diop[1], Boly Diop[1], Yoro Sall[1], Etienne Simon-Lorière[2], Oumar faye[1], Mawlouth Diallo[1], Anavaj SAKUNTABHAI[2], Cheikh Talla[1], Cheikh Loucoubar[1], Mamadou Aliou Barry[1], Diawo diallo[1], **Gamou Fall**[1]

[1]Institut Pasteur de Dakar, Dakar, Senegal, [2]Institut Pasteur de Paris, Paris, France

Rift Valley Fever (RVF) and Crimean Congo Hemorrhagic Fever (CCHF) are 2 emerging diseases with great economic, medical and veterinary impact. Humans can be infected through arthropod bites or contact with fluids or tissues from infected animals. As a result, livestock workers are at high risk of contracting these diseases. In the absence of specific treatment and licenced vaccines for humans, their epidemiology needs to be better understand for the implementation of preventive measures. Here we sampled humans, animals and arthropods in Kedougou (South) Barkedji (Center), and Podor (North) to analyze the circulation dynamics of RVF and CCHF. Indeed, at-risk and low risk healthy humans as well as cattles, sheep and goats from transhumant and sentinel herds were sampled. Ticks were collected by extirpation while mosquitoes were collected using different traps. Animal and human samples were tested by IgM and IgG ELISA while arthopod samples were tested by RT-PCR and virus isolation. In humans as in animals, the seroprevalence rates varied by virus, sex, locality, age and exposure level to animals for humans. RVF and CCHF were not detected in arthropods but a North-South gradient of relative abundance of their main vectors has been found. The data showed different transmission modes for these two viruses according to the area. Indeed, in the North and Center, RVF is circulating in at-risk and low risk populations, while CCHF is mainly detected in at-risk populations. However, in the South, a different transmission pattern has been observed with RVF circulating only in at-risk populations while CCHFV is circulating in both at-risk and low risk populations. These data suggest the enzootic and regular circulation of these viruses in Senegal with different transmission modes. This emphasize the need to reinforce surveillance and to consolidate data to identify risk factors in order to better prevent and control the spread of these viral infections.

7071

UNRAVELING THE TRANSMISSION DYNAMICS OF RIFT VALLEY FEVER : INSIGHTS FROM EAST AND CENTRAL AFRICA

[1]Institute of Tropical Medicine ITM, Antwerp, Belgium, [2]Uganda Virus Research Institute, Entebbe, Uganda, [3]Washington State University - Global Health Program, Nairobi, Kenya, [4]National Institute for Biomedical Research INRB, Kinshasa, Congo, Democratic Republic of the, [5]African Population and Health Research Center APHRC, Nairobi, Kenya, [6]Laboratoire Rodolphe Mérieux INRB-Goma, Goma, Congo, Democratic Republic of the, [7]University of Nairobi, Nairobi, Kenya, [8]Washington State University, Pullman, WA, United States, [9]Kenya Medical Research Institute, Nairobi, Kenya, [10]Virunga General Reference Hospital, Goma, Congo, Democratic Republic of the, [11]Uganda Ministry of Health, Kampala, Uganda, [12]Laboratoire Vétérinaire de Goma, Labovet, Goma, Congo, Democratic Republic of the, [13]International Livestock Research Institute, Nairobi, Kenya, [14]Ministry of Agriculture, Animal Industry and Fisheries, Entebbe, Uganda, [15]Emory University, Atlanta, GA, United States

In East Africa, outbreaks of Rift Valley Fever (RVF), a vector-borne viral zoonosis, follow a 5-10-year cycle, with periods of quiescence in between. Although RVF outbreaks in animals are known to precede human cases, some human outbreaks may go unnoticed and are difficult to predict. A multi-country initiative of the Center for Research on Emerging Infectious Diseases-Eastern and Central Africa (CREID-ECA), undertook surveillance of acute febrile illness (AFI) and community human-animal linked seroprevalence studies to unravel the dynamics of cryptic RVF transmission. In Kenya, the Democratic Republic of the Congo (DRC) and Uganda, a 2-year longitudinal health facility-based study enrolled AFI cases while the human-animal serosurveys is assessing RVF burden in communities in direct contact with animals. Human and animal sera are analyzed for anti-RVF virus antibodies (ELISA) and viral RNA (PCR). Demographic, behavioral and environmental factors and RVF knowledge were assessed by questionnaires. In the health facility-based study, 4,755 subjects (median age 31 years, IQR 22-44, female 57.4%) were enrolled. In Uganda, 77 (4%) participants tested positive for IgM/PCR, documenting unusual sustained cases, in contrast to Kenya and DRC where no acute cases were detected. A total of 232 (4.9%) participants tested positive for total RVF antibodies: DRC 1.5%, Kenya 2.0%, and Uganda 9.5% ($p< 0.001$). At multivariable analysis, male participants (OR: 1.73; 95% CI 1.29, 2.32), age ≥50 years (OR: 1.64; 95% CI 1.16, 2.27), low schooling (OR: 1.49; 95% CI 1.05, 2.16) and sheep contact (OR: 1.6; 95% CI 1.00, 2.52) were significantly associated with RVF seropositivity. No significant association was found between RVF knowledge and previous RVF exposure. The community serosurvey in Kenya detected 1.8% (5/282) RVF IgG in humans and 4.4% (31/706) in livestock with goats significantly less affected than cattle (OR = 0.29 CI 0.12, 0.65). A substantial exposure to RVF was identified in the three countries with significant differences among them. Complete findings from this study will provide important insights for understanding the epidemiology of RVF in ECA.

7072

DENGUE VIREMIA AMONG FEBRILE PERSONS IN GRENADA, WEST INDIES

Melanie Kiener[1], Markeda Fletcher[2], Elsa Chitan[2], Trevor P. Noel[2], Benjamin A. Pinsky[1], Calum Macpherson[2], A. Desiree LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Windward Islands Research & Education Foundation, True Blue, Grenada

Dengue virus (DENV) is endemic in Grenada, a small island developing state in the Caribbean, and circulates at low levels causing sporadic outbreaks during rainy seasons. However, the incidence of DENV is likely underestimated, as the gold-standard diagnostic test, reverse transcription polymerase chain reaction (RT-PCR), is not routinely available on the island. To more accurately determine the incidence of DENV infection in Granada, we performed febrile illness surveillance among adults and children in Grenada using serum RT-PCR for DENV, Zika virus (ZIKV) and chikungunya virus (CHIKV). Participants also provided demographic, symptom and mosquito behavioral data to evaluate factors associated with infection. Enrollment is ongoing, but to date 214 participants have been enrolled and tested from June 2023 through February 2024. Most participants are female (66%), with median age of 32 years (IQR 24-44) and were enrolled from private clinics throughout the country (66%). To date we have identified 27 positive DENV cases, an incidence of 12.6%, and one case of CHIKV, an incidence of 0.5%. No cases of ZIKV have been identified. The peak DENV incidence rate occurred in July 2023 (21.7% of samples tested positive). In interim univariate analysis comparing DENV positive and negative persons, those with DENV were less likely to live in a house (56 vs 85%, $p<0.01$), more likely to report use of window screens (63 vs 36%, $p=0.02$), and more likely to endorse controlling mosquito breeding sites around the home (100 vs 81%, $p=0.03$). We do not currently observe statistically significant differences between age, sex, education, income, subjective reporting of mosquitoes or reported symptoms. Our results show a relatively high incidence of DENV among febrile persons in Grenada. Possible epidemiologic risk factors are observed, but analyses will be ongoing as we continue to enroll additional participants.

7073

SURVEILLANCE OF CORONAVIRUS IN WILD MAMMALS SEIZED AND RESCUED BY THE NATIONAL FOREST AND WILDLIFE SERVICE OF LIMA, PERU

Carol A. Sanchez Chicana[1], Lisseth M. Leiva Herrera[2], M. Teresa Lopez-Urbina[2], Victor L. Izaguirre Pasquel[3], Walter Silva[4], Luis A. Gomez-Puerta[2], Armando E. Gonzalez[2], Juan A. Jimenez Chunga[1]

[1]School of Biological Sciences, Universidad Nacional Mayor de San Marcos, Lima, Peru, [2]Department of Animal and Public Health, School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]School of Pharmacy and Biochemistry, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]Servicio Nacional Forestal y de Fauna Silvestre – SERFOR, Lima, Peru

Coronaviruses are pathogens that cause respiratory or enteric diseases in humans and animals. They exhibit high genome plasticity and replication errors, allowing them to change host range. The illegal trafficking of wildlife is a key factor in the emergence of infectious diseases, as it can lead to long-distance circulation and outbreaks of viruses in areas other than their usual environment. The aim of this study was to detect coronaviruses in mammals seized and rescued by the National Forestry and Wildlife Service from tracheal and rectal swabs using a pancoronavirus PCR assay that amplifies the RNA-dependent RNA polymerase (RdRp) gene. Ninety mammals were collected, of which 11.11% (10/90) tested positive by molecular analysis of the collected tracheal swabs. The species that tested positive were *Aotus* sp. (n=1), *Sapajus apella* (n=3), *Saimiri sciureus* (n=2), *Procyon cancrivorus* (n=1), and *Otaria flavescens* (n=3). Sequencing analysis of the ten positive PCR products indicated that nine of them shared 98% similarity with porcine epidemic diarrhea virus (PEDV) from GenBank. In addition, all of them were 100% identical to each other. The remaining sample showed a 95.52% similarity to feline coronavirus (FCoV). Both belonged to the genus Alphacoronavirus. We constructed a phylogenetic tree using sequences from this study and a large set available from GenBank. The maximum likelihood phylogenetic tree supports the hypothesis that PEDV sequences form a monophyletic clade, and FCoV sequence was found to be closely related to other FCoV from different countries. Notably, we only detected the viral RNA in the respiratory tract, despite the enteric nature of these viruses. This discovery confirms airborne transmission, a recently proposed alternative pathway. This study represents the first report of PEDV and FCoV in animals other than their natural hosts, highlighting the importance of epidemiologic surveillance.

7074

ASSESSING CORRELATIONS IN SEROLOGICAL STATUS TO MULTIPLE VACCINE-PREVENTABLE DISEASES: A CASE-CONTROL STUDY IN ZAMBIA, 2016

Alyssa Sbarra[1], Simon Mutembo[2], Andrea Carcelen[2], Evans Betha[3], Innocent Bwalya[3], Elizabeth Kabeta[3], Lombe Kampamba[3], Christine Prosperi[2], Gershom Chongwe[3], Amy Wesolowski[1], Saki Takahashi[1]

[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Department of International Health, International Vaccine Access Center, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]Tropical Diseases Research Centre, Ndola, Zambia

Novel methods for assessing immunization system performance could provide additional insights on opportunities for improvements to reach unvaccinated children. One method to examine gaps in vaccination programs or assess the likelihood of recent infection history is to conduct serologic analyses measuring antibody responses to multiple vaccine-preventable diseases (VPDs), such as measles, diphtheria and tetanus. This study aimed to assess correlations in serological status across VPDs by testing whether individuals who are measles seronegative were more likely to have also missed diphtheria and tetanus vaccination. Nationally-representative samples stored in a biorepository collected during the 2016 ZAMPHIA study were previously tested for measles and rubella IgG serostatus. Paired measles seronegative and seropositive samples from this biorepository among children aged 2-to-10-years-old were identified by exact matching on gender, age, province (i.e., first-administrative unit) and HIV status and proximity matching for district (i.e., second-administrative unit), such that samples from districts closer together were more likely to be matched. Additional paired samples were identified by exact matching on gender, province and HIV status with proximity matching for age, such that samples with similar ages were more likely to be matched. For all selected samples (n = 1298), plasma sera were tested for diphtheria and tetanus IgG antibodies using enzyme-linked immunosorbent assays. Antibody concentrations were standardized using a four-point logistic regression and seropositivity was determined using internationally recognized thresholds. Serologic results for diphtheria and tetanus were analyzed based on underlying measles serostatus using conditional logistic regressions controlling for age and province. Results suggest differential titers over age and varying associations across measles serostatus. More broadly, this study illustrates a key use case of serological data on VPDs to identify the geographic and demographic reach of vaccination programs.

A SYSTEMATIC LITERATURE REVIEW OF COMMUNITY ACUTE RESPIRATORY INFECTIONS (ARI) AND ACUTE GASTROENTERITIS (AGE) INCIDENCE RATES: A SYSTEMATIC LITERATURE REVIEW OF COMMUNITY-BASED OBSERVATIONAL STUDIES

Sumona Datta[1], **Adva Gadoth**[2], Morgan A. Marks[2], Katherine B. Carlson[2], Emma Viscidi[2], Marilú Chiang[3], Robert H. Gilman[4], Carlton A. Evans[5]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Moderna, Inc., Cambridge, MA, United States, [3]Asociación Benefica PRISMA, Lima, Peru, [4]Johns Hopkins University, Baltimore, MD, United States, [5]IFHAD, Imperial College London, London, United Kingdom

Acute respiratory infections (ARI) and acute gastroenteritis (AGE) are major causes of global morbidity and mortality. Most estimates of ARI and AGE incidence emphasize medically attended disease. Such data can severely underestimate true disease burden, especially in low- and middle-income countries (LMIC) where access to healthcare is limited. A systematic literature review of community-based observational studies was conducted to estimate community incidence rates of ARI and AGE. A PubMed search conducted in January 2024 identified 205 studies published between 1965-2017. Studies were included if sampling was performed at the community level with prospective monitoring for ARI or AGE. Studies of single pathogens, and those with follow-up of <12 months or insufficient data to calculate incidence were excluded. Weighted averages of incidence (cases per 1000 person-years (PY)) were calculated by age group from studies using similar case definitions. Meta-regression methods were conducted to identify differences in ARI/AGE incidence by study design characteristics. Eighteen studies of ARI incidence including 26,504 participants were identified, with 13 conducted in LMIC. Eleven studies of AGE incidence among 8,812 participants were identified, all from LMIC. The average all-age incidence rate was 1701 per 1000 PY (95% CI 1680-1723) for ARI and 320 per 1000 PY (95% CI 312-328) for AGE. Children under 5 had the highest incidence of both ARI (3188 per 1000 PY; 95% CI 3150-3227) and AGE (1349 per 1000 PY; 95% CI 1302-1398). ARI incidence was also elevated among adults ≥60 years (2405 per 1000 PY; 95% CI 2359-2453). ARI incidence rates were lower when symptom screening was performed virtually versus through in-person interviews (aIRR=0.30, 95% CI=0.13-0.68). In summary, this systematic literature review of community-based observational studies estimated a high incidence of ARI and AGE, particularly among young children and older adults. Accurate measurement of these conditions is vital to understand their burden and impact, and to help inform proper design, evaluation and implementation of related interventions.

MARBURG VIRUS DISEASE OUTBREAK PREPAREDNESS AND RESPONSE IN THE SOUTH REGION OF CAMEROON, FEBRUARY - APRIL 2023

Ngongla Ngongla Firmin Néhémie[1], Mfonkou Toumansie Jacques Delors[1], Abanda Laurent Fabrice[1], Kameni Charmelle[1], Ze Ondoua[1], Anya Amvella Priscilla[2], Esso Endale Linda[3], Bidjang Robert Mathurin[1], Etoundi Mballa Georges Alain[4]

[1]South Regional Delegation of Public Health, Ministry of Public Health, Cameroon, Ebolowa, Cameroon, [2]Cameroon Field Epidemiology Training Program, Ministry of Public Health Cameroon, Yaoundé, Cameroon, [3]Department for the control of Disease, Epidemics and Pandemics, Ministry of Public Health Cameroon, Yaoundé, Cameroon, [4]Public Health Emergency Operations Coordination Center, Ministry of Public Health Cameroon, Yaoundé, Cameroon

Since the declaration of the first Marburg Virus Disease (MVD) outbreak in Equatorial Guinea on February 13, 2023, several neighboring countries have been implementing preparedness efforts to prevent MVD cross-border transmission and respond in case of confirmation. We described the experience of the South region, Cameroon, bordering Equatorial Guinea, in MVD preparedness activities. We conducted a descriptive study of preparedness from February to April 2023. We collected data from activity reports and from the regional staff involved in MVD preparedness. Preparedness activities were organized into 7 key pillars: coordination, epidemiological surveillance, specimen transportation and biologic diagnostic, case management and infection prevention and control, risk communication, emergency supply, continuity of essential care and services. The regional Incident Management System (IMS) was activated on February 13, 2023 with the Regional Delegate of Public Health as incident manager. Case definitions were developed and disseminated in the community and health facilities. We defined a suspected case as any resident or visitor in the region with sudden fever (T°≥38°c) or anyone with unexplained bleeding or any unexplained death since January 18, 2023. A total of 120 community health workers were recruited to strengthen rapid detection. At the 6 points of entry, 4272 passengers were screened to detect suspected MVD cases. A total of 159 alerts were investigated with 7 validated as suspected case and samples, collected and transported to Centre Pasteur Cameroon; all came negative. About 62283 persons were sensitized on MVD and prevention methods through radio spots and communications in gathering places. Three isolation and treatment units were established in the districts and protective equipment, disinfection and decontamination provided. A total of 14 biweekly meetings were organized and 11 situation reports developed. No MVD case was confirmed while the Region activated its IMS. The aim was to strengthen MVD preparedness activities. It is important to sustain preparedness efforts, not only for MVD but also for other epidemics.

7077

INVESTIGATING THE EPIDEMIOLOGY AND RISK FACTORS FOR DENGUE VIRUS AND CHIKUNGUNYA VIRUS INFECTIONS IN KARACHI, PAKISTAN

Aslam Khan[1], Momin Kazi[2], Junaid Iqbal[2], Raheel Allana[2], Talyha Khalid[2], Caroline Ichura[1], Desiree LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Aga Khan University, Karachi, Pakistan

Dengue virus (DENV) and chikungunya virus (CHIKV) are spread by *Aedes* species mosquitos that can thrive in pooled fresh water and have recently caused outbreaks across south Asia. Pakistan has endured recent outbreaks of DENV in addition to CHIKV, which can present similarly. Concurrently, Pakistan has also suffered repeated periods of severe flooding with some of the worst floods in history occurring in 2022, when approximately one-third of the country was under water. Given the ongoing climate crisis, this trend is likely to continue and worsen. With this reported re-emergence of infection we hypothesize there is a substantial burden of DENV and CHIKV in Karachi that can be linked to the built environment, human behavior, and other elements like surrounding litter. With shifting of vector proliferation to newer communities it is critical to better understand the epidemiology and transmission of these arboviruses in the region and the links to climate, especially in densely populated cities like Karachi. Through this cross-sectional pilot study of children we evaluated risk factors for dengue and chikungunya infection in the peri-urban setting in Karachi, in relation to the environmental impact, behavior, and demographics associated with infection. We recruited 500 children from two demographic and health survey program sites Karachi, Pakistan. In a single visit, participants are undergoing phlebotomy and survey administration to identify risk factors for exposure to these pathogens. All serum samples will be tested for DENV IgG and CHIKV IgG by enzyme-linked immunosorbent assay (ELISA) to determine seroprevalence. Within the cohort, 100 children had prior serum collected two years prior and will be evaluated for interval DENV/CHIKV seroconversions. This study is ongoing with active data collection and will be completed by mid-2024. Initial preliminary data suggests a high burden of DENV compared to CHIKV with majority of participants testing positive for DENV. With active data collection ongoing, we anticipate to continue to delineate the burden of DENV exposure in this cohort and will link to potential risk factors for the community.

7078

CLINICAL CHARACTERISTICS ASSOCIATED WITH DENGUE SEROTYPES IN AMAZONAS, PERU

Milagros L. Garcia-Cordova[1], Fátima Burgos[1], Rafael Tapia-Limonchi[1], Lizandro Gonzales[2], Carmen Gutierrez[3], Stella M. Chenet[1]

[1]Instituto de Investigación de Enfermedades Tropicales, Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas (UNTRM), Chachapoyas, Peru, [2]Dirección Regional de Salud (DIRESA), Chachapoyas, Peru, [3]Facultad de Medicina (FAMED), Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas (UNTRM), Chachapoyas, Peru

Dengue represents a major public health challenge worldwide. In Peru, a significant rise in dengue cases has particularly impacted the region of Amazonas, reporting a total of 24 981 cases and 28 deaths until the epidemiological week 7th of 2024, almost double the amount reported in 2023. In this study, we analyzed the clinical and epidemiological characteristics associated with the circulating serotypes in Amazonas by using 591 serum samples from dengue-confirmed patients collected in five provinces between 2021 and 2024. Serotype detection was conducted with a multiplex reverse transcription polymerase chain reaction (RT-PCR) assay. Statistical analysis was performed using R software v.4.3.1. Results revealed that 250 patients were infected by DENV-1 and 341 by DENV-2. According to our results, these serotypes have co-circulated across all affected provinces. For instance, DENV-1 caused the majority of infections in Bagua (13.6%) and Bongará (24.8%), while DENV-2, in Chachapoyas (9.4%), Condorcanqui (18.5%) and Utcubamba (59.8%) ($p < 0.001$). Additionally, dengue infections with warning signs were more frequent in patients with DENV-2 compared to DENV-1 ($p = 0.005$), and severe cases were exclusively reported in DENV-2 infections, highlighting its association with the severe form of the disease. Fever (DENV-1: 93.20% and DENV-2: 91.50%) and headache (DENV-1: 88.80% and DENV-2: 87.68%) were the most prevalent symptoms. Nausea (prevalence rate: 1.28, 95% CI: 1.02-1.62), conjunctivitis (prevalence rate: 1.78, 95% CI: 1.04-3.03), and abdominal pain (prevalence rate: 2.71, 95% CI: 1.35-5.45) showed a significant association with DENV-2. Its enhanced pathogenicity could be due to its faster replication, resulting in a higher viral load that could lead to severe cases. In conclusion, this study emphasizes the widespread circulation of DENV-1 and DENV-2 in Amazonas, highlighting the necessity to understand its transmission dynamics. Furthermore, it underscores the importance of real-time molecular surveillance that could provide an early prognosis of the disease severity.

7079

SEROPREVALENCE OF CHIKUNGUNYA VIRUS INFECTION IN SURAT THANI PROVINCE, THAILAND

Pathraporn Wichaidit[1], Thanita Somton[1], Krida Uakridathikarn[1], Arunee Tipwong[1], Sopon Iamsirithaworn[2], Taweewun Hunsawong[3], Aaron Farmer[3], Darunee Buddhari[3]

[1]Ministry of Public Health, Surat Thani, Thailand, [2]Ministry of Public Health, Nonthaburi, Thailand, [3]Department of Virology, WRAIR-AFRIMS, Bangkok, Thailand

Chikungunya virus (CHIKV) infection is characterized by an abrupt onset of high fever, profound joint pain, and although low mortality, often lasting morbidity due to joint pain. Although globally distributed, there are multiple gaps in our understanding of CHIKV epidemiology, which pose challenges for the evaluation of CHIKV vaccines and countermeasures. CHIKV epidemics are frequently explosive, emerging unpredictably and waning to low levels after high levels of population immunity achieved. In 2008-2009 a large-scale outbreak of CHIKV occurred in 47 of 76 provinces in Thailand including Surat Thani province in southern Thailand. Despite a second outbreak in 2018-2019, little is known about the distribution of disease in the area. This study examined the seroprevalence and patterns of CHIKV transmission and persistence in communities within Surat Thani stratified by age. Investigators enrolled 1,700 participants aged 2 years and older to collect the blood for CHIKV serological testing in 10 rural, semi-urban and urban communities of Surat Thani province. Seropositivity was determined by CHIKV IgM/IgG (positive ≥40 EIA units) and CHIKV PRNT80 (NT80). The median age of enrollees was 25.0 years (IQR 9.3-39.9) with 62.5% of female gender. The primary occupation was student (49.6%). Overall, the seropositive rate for CHIKV IgM and IgG was 0.12% and 16.06%, respectively. Female had significantly higher levels of CHIKV IgM ($p=0.034$) and IgG ($p=0.007$) than male participants. Seropositive data by age group indicated that subjects between 18-50 years old had significantly higher IgM ($p=0.053$) and IgG ($p<0.0001$) levels than other groups. CHIKV IgG seropositive rate increased in an age dependent manner (from 4.6 years to 88 years old). The CHIKV NT 80 showed good correlation with all positive CHIKV IgG. The 2 urban community sites showed significantly higher seropositivity by CHIKV IgG than rural and semi urban sites ($p=0.048$ and 0.006 respectively) but was not significant based on CHIKV NT80 level. This data identifies CHIKV seroprevalence in the study area and will be crucial for future vaccine and countermeasure studies.

7080

FACTORS ASSOCIATED WITH DEATH IN PATIENTS ADMITTED WITH EBOLA VIRUS DISEASE TO EBOLA TREATMENT UNITS IN GUINEA, SIERRA LEONE, AND LIBERIA DECEMBER 2013 TO MARCH 2016

Ibrahima KABA[1], Trokon Omarley Yeabah[2], Gomathi Ramaswamy[3], Prabin Dahal[4], Alexandre Delamou[1], Benjamin T. Vonhm[2], Ralph W. Jetoh[2], Laura Menson[5], Adam C. Levine[6], Pryanka Relan[7], Anthony D. Harries[8], Ajay MV Kumar[8]

[1]African Center of Excellence for the Prevention and Control of Transmissible Diseases, Conakry, Guinea, [2]National Public Health Institute, Monrovia, Liberia, [3]All India Institute of Medical Sciences, Bibinagar, India, [4]Infectious Diseases Data Observatory, Centre for Tropical Medicine & Global Health, Oxford, United Kingdom, [5]ISARIC Pandemic Sciences Institute, Oxford, United Kingdom, [6]Warren Alpert Medical School of Brown University, Rhode Island, RI, United States, [7]WHO Health Emergencies Programme, World Health Organization, Geneva, Switzerland, [8]International Union Against Tuberculosis and Lung Disease (The Union), Paris, France

The 2013-2016 West African Ebola Virus Disease (EVD) outbreak resulted in 28,600 cases and 11,300 deaths officially reported to the World Health Organization. Previous studies investigating factors associated with death had conflicting findings, interventions showing promising outcomes had small sample sizes, studies were often single- or dual-country based and most focused on laboratory-confirmed EVD and not on clinically-suspected EVD. We used the Ebola data platform of the Infectious Disease Data Observatory (IDDO) to review individual patient records to assess factors associated with death, and particularly whether there were differences between laboratory-confirmed and clinically-suspected cases. This was a cohort study involving analysis of secondary data in the IDDO database. The study population included all patients classified as having either clinically-suspected or laboratory-confirmed EVD, admitted to 22 Ebola Treatment Units (ETU) in Guinea, Liberia and Sierra Leone between December 2013 and March 2016. Baseline characteristics and treatments were documented along with ETU exit outcomes. Factors associated with death were investigated by multivariable modified Poisson regression. There were 14,163 patients, of whom 6,208 (43.8%) were laboratory-confirmed and 7,955 (56.2%) were clinically-suspected. Outcomes were not recorded in 2,889 (20.4%) patients. Of the 11,274 patients with known outcomes, 4,090 (36.3%) died: 2,956 (43.6%) with laboratory-confirmed EVD and 1,134 (18.8%) with clinically-suspected EVD. The strongest risk factor for death was confirmed disease status. Patients with laboratory-confirmed disease had 2.9 times higher risk of death compared to clinically-suspected patients. Other factors significantly associated with death included a higher risk for patients aged ≥60 years and a lower risk for patients in Sierra Leone. Although laboratory-confirmed patients admitted to ETUs fared worse than clinically-suspected patients, the latter still had a substantial risk of death and more attention needs to be paid to this group in future EVD outbreaks.

MODELING DENGUE FORCE OF INFECTION AMONG EXPATRIATES LIVING IN THAILAND

Erica Rapheal[1], Amornphat Kitro[2], Hisham Ahmed Imad[3], Marco Hamins-Puertolas[4], Aaron Farmer[5], Taweewun Hunsawong[5], Jutarmas Olanwijitwong[6], Lapakorn Chatapat[6], Watcharapong Piyaphanee[7], Kathryn B. Anderson[8]

[1]University of Minnesota School of Public Health, Minneapolis, MN, United States, [2]Chiang Mai University Department of Community Medicine, Chiang Mai, Thailand, [3]Mahidol University Vivax Research Unit, Bangkok, Thailand, [4]University of California, San Francisco Department of Medicine, San Francisco, CA, United States, [5]Armed Forces Research Institute of Medical Sciences Department of Virology, Bangkok, Thailand, [6]Mahidol University Hospital for Tropical Diseases, Bangkok, Thailand, [7]Mahidol University Hopsital for Tropical Diseases, Bangkok, Thailand, [8]SUNY Upstate Institute for Global Health and Translational Science Department of Medicine, Syracuse, NY, United States

Dengue fever virus (DENV) is a mosquito-borne illness that causes as many as 96 million cases of dengue fever annually. Two dengue vaccines are now licensed for use in several countries, but a vaccine that confers sustained tetravalent protection in DENV-naive individuals remains aspirational. Travelers from non-endemic regions have unique viral exposure histories and associated immunological profiles. The WHO recommends Takeda's Qdenga® vaccine for populations with at least 60% DENV seroprevalence but does not make specific recommendations for travelers. Models of dengue force of infection in children suggest that most people born in dengue endemic areas (DEA) will be DENV seropositive by age 6; whether non-locals share this exposure profile is a critical epidemiological question in the recommendation of novel dengue vaccines for travelers. In this analysis, we use catalytic models of force of infection (FOI) to estimate time to 60% DENV seropositivity for a cross-section of expatriates in Thailand. Demographic and risk history data was collected using a short survey. Blood specimens were tested for neutralizing antibody titers against all four DENV serotypes, Japanese encephalitis, and Zika, using plaque reduction neutralization tests. Our full model adjusted for average daily time outside, years not exposed to DENV, gender, living setting, and four mosquito prevention strategies: repellent, nets, long sleeves, and air conditioning. We estimated an adjusted average FOI of 0.016 (95% CI: 0.004-0.069) per year spent in DEA (approx. 55.7 years to 60% seropositivity). Urban living setting was significantly associated with DENV seropositivity (OR = 2.66; 95% CI: 1.18-6.00) in the adjusted model. These findings suggest that expatriates have a dengue exposure profile unique from locals, which is characterized by a lower force of infection. With the current need to deprioritize vaccination of dengue-naive individuals, this suggests that even long-term travelers will require separate vaccine recommendations.

7082

TRENDS IN MORTALITY CAUSED BY VIRAL HEPATITIS IN THE UNITED STATES POPULATION: A RETROSPECTIVE CROSS-SECTIONAL STUDY USING THE CDC WONDER DATABASE.

Muhammad Sohaib Asghar[1], **Abuoma C. Ekpendu**[1], Mohammed Akram[2], Rumael Jawed[3], Pankajkumar Patel[1], Chad K. Brands[1]

[1]Advent Health, Sebring, FL, United States, [2]HCA Aventura, Aventura, FL, United States, [3]Nazareth Hospital, Philadelphia, PA, United States

In this retrospective cross-sectional study, spanning from 1999 to 2023, we examined mortality trends using national mortality datasets among individuals infected with hepatitis virus. Our aim was to analyze these trends in mortality among US residents by demographic characteristics including age, gender, race/ethnicity, and geographic characteristics like urbanization and census region. The national mortality data from the multiple causes of death files in the CDC WONDER Database were queried by applying the ICD-10 codes as B15-B19 for viral hepatitis to identify deaths among the US population from 1999 to 2023. Trends in age-adjusted mortality rate (AAMR) were assessed for age groups, gender, race/ethnicity, urbanization, and census region using state-level data. Results were expressed as annual percentage changes (APC), average annual percentage changes (AAPC), and 95% confidence intervals (CI). The data was analyzed on statistical software i.e., the Joinpoint regression by National Institutes of Health (NIH version 5.0.2). The county-level data was analyzed according to the National Center for Health Statistics [NCHS] urbanization classification scheme 2013. The crude mortality rate for viral hepatitis from 1999-2023 was found to be 4.4 per 100,000 US population and AAMR was 3.4 per 100,000 US population. Mortality rates for viral hepatitis were found to be highest for the male gender, age group 55-74 years, American Indians or Alaskan Natives, Census Region West, and metropolitan suburban areas (although rural areas showed the highest upgoing trends with AAPC: +2.64). Geographically, states in the top 90th percentile for viral hepatitis-associated mortality included the District of Columbia, Oklahoma, Oregon, California, New Mexico, and Washington. These findings provide valuable insights into age-adjusted mortality patterns among the United States population with these diseases. Mortality rates among the US population with viral hepatitis were noted to slightly decrease overall from 1999 to 2023 (AAPC -0.61, p=0.002), and certain subgroups with specific demographic and geographic characteristics had high AAMR.

7083

DENGUE SEROPREVALENCE AND FORCE OF INFECTION IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Antoine Nkuba Ndaye[1], Vicco Anna[2], Benoit Mputu-Ngoyi[1], Paul Tshiminyi-Munkamba[1], Lionel Baketana-Kinzonzi[1], Elysé Matungulu-Biyala[1], Frida Nkawa[1], Shubham Shrivastava[3], Belen Pedrique[4], Martine Guillerm[4], Isabela Ribeiro[4], Sheila Makiala-Mandanada[1], Steve Ahuka-Mundeke[1], Ilaria Dorigatti[2]

[1]Institut National de Recherche Biomédicale, Kinshasa, Congo, Democratic Republic of the, [2]School of Public Health, Imperial College London, London, United Kingdom, [3]Interactive Research School for Health Affairs (IRSHA), Bharati Vidyapeeth (Deemed to be University), Pune, India, [4]Drug for Neglected Diseases initiative, Geneva, Switzerland

Introduction: There is limited knowledge on dengue transmission in the Democratic Republic of Congo (DRC). However, recent publications highlight an increasing dengue prevalence among individuals presenting with febrile symptoms in Kinshasa, the capital of DRC. The extent of dengue circulation in the country is unknown, which poses questions around the burden of dengue infection and the potential impact of new interventions. The objective of our analysis was to assess the age-stratified dengue seroprevalence and estimate the force of infection (FOI, per-capita risk of dengue infection for a susceptible subject) in Kinshasa and Matadi. Methods: By leveraging samples collected from individuals aged 0 to 94 years in a SARS-CoV-2 serosurvey, we assessed the age-stratified dengue seroprevalence using a combination of two Enzyme-Linked Immunosorbent Assay (ELISA) IgG antibody tests, respectively a purified dengue particles test (ELISA-1) and a recombinant non-structural protein 1 (NS1) (ELISA-2) assay and a serotype-specific Plaque Reduction Neutralization Test (PRNT) for all 4 dengue serotypes. We employed a Bayesian framework to estimate the FOI for each location and reconstruct the results obtained across each testResults: Overall, 3580 plasma samples were tested by IgG ELISA-1 and a subset of 202 samples was also tested by IgG ELISA-2 of which 70 were also tested by PRNT. Our findings reveal endemic dengue circulation in DRC, with an average FOI of 2.9% (95% CrI: 2.2-3.9) in Kinshasa and 1.4% (95% CrI: 0.9-2.0) in Matadi and an overall population seroprevalence of 41% (95% CrI: 34-48) in Kinshasa and 23% (95% CrI: 17, 32) in Matadi respectively. Conclusion: These results confirm endemic dengue transmission in different regions of DRC and highlight the dengue transmission differences between the two cities. These findings underscore the importance of establishing dengue surveillance in the country, to monitor prevalence and changes in transmission in a changing climate.

A MULTICENTER STUDY TO ASSESS THE EFFECTIVENESS OF AN INACTIVATED COVID-19 VACCINE AGAINST HOSPITALIZED COVID-19 IN THE PHILIPPINES

Kristal An Agrupis[1], Maria Vinna Crisostomo[1], Jedas Veronica Daag[1], March Helena Jane Lopez[1], Kiarah Louise Florendo[1], Jude Raphael Lo[1], Yang-Yang Qi[2], Gianne Lariz Magsakay[1], Gretchen Velasco-Ranada[3], Mitzi Marie Chua[4], Mitzie Lou Osabel[5], Lorenz von Seidlein[6], Xuan-Yi Wang[2], Michelle Ylade[1], Jacqueline Deen[1]

[1]Institute of Child Health and Human Development, University of the Philippines - National Institutes of Health, Manila, Philippines, [2]Key Laboratory of Medical Molecular Virology of MoE & MoH, and Institutes of Biomedical Sciences, Shanghai Medical College, Fudan University, Shanghai, China, [3]Mariano Marcos Memorial Hospital & Medical Center, Batac City, Ilocos Norte, Philippines, [4]Vicente Sotto Memorial Medical Center, Cebu City, Philippines, [5]Davao Regional Medical Center, Tagum City, Davao del Norte, Philippines, [6]MahidolOxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

There is limited information on the protection conferred by Coronavac (Sinovac, China), an inactivated COVID-19. We conducted a multi-center, hospital-based test-negative case control study to determine the vaccine effectiveness of a complete CoronaVac regimen with or without a homologous or heterelogous booster dose against hospitalized and critical COVID-19.

Between 9 November 2022 and November 2023, we enrolled adult patients experiencing acute respiratory illness (ARI) admitted to three government referral hospitals. We collected clinical and socio-demographic data, vaccination histories, and oro/nasopharyngeal swabs for SARS-CoV-2 RT-PCR testing from eligible patients who consented to participate. Patients testing positive in at least one SARS-CoV-2 RT-PCR test were classified as cases while those testing negative served as controls. Critical COVID-19 was defined as having either respiratory failure, acute respiratory distress syndrome, sepsis/shock or multi-organ failure. We enrolled 2,365 participants, and 165 (7.0%) were SARS-CoV-2 positive. More than a year after the last vaccine dose, unmatched analysis showed that full vaccination of CoronaVac did not protect against hospitalized and critical COVID-19 (VE:0.69%,CI: -23.7%-20.3%, p=0.9511 and VE:5.4%, CI:17.8%-24.0%, p=0.6201 respectively), but conferred 31.3% (CI: 9.5 - 47.9, p=0.0077) protection against death. The protection against death increased to 45.8%(CI:18.6%-63.8%, p=0.0031) with a booster dose. Cases were significantly older than the controls (mean age±SD: 58.12±20.15 vs. 53.41±17.60, p=0.001). An age-matched analysis showed that a full regimen of CoronaVac provided 61.3% (CI:5.3% - 84.2%,p=0.0376) protection against critical COVID-19, and 27.1% (CI:-25.3%-57.6%, p=0.2528) against death, which increased significantly to 91.2% (CI: 30.7% - 98.9%, p=0.0210) and 60.1% (CI:16.4%-81.0%, p=0.0150) with a booster dose, respectively. Our findings show that a primary series of inactivated COVID-19 vaccination provided protection against critical outcomes over time, which was enhanced by booster vaccination.

7085

MOLECULAR EPIDEMIOLOGY IMMUNOLOGICAL RESPONSES TO SARS-COV-2 OTHER RESPIRATORY VIRUSES IN SELECTED URBAN RURAL AREAS OF GHANA

George Agyei[1], Michael Owusu[1], Philip El-Duah[2], Yaw Adu-Sarkodie[1]

[1]kwame Nkrumah University Of Science and Technology, Ghana, Ghana, [2]institute Of Virology, Charite, Germany

Ghana implemented non-pharmaceutical interventions and vaccination campaigns to mitigate the impact of COVID-19. However, the effectiveness of these interventions has not been fully evaluated. Understanding the prevailing levels of exposure and immunity in different sociodemographic settings offers an important overview of the epidemiology of respiratory viruses in these populations. This study seeks to determine the prevalence of SARS-CoV-2 and other respiratory viruses (RVs) in selected areas in Ghana, using Kumasi Metropolis as a case study. Nasopharyngeal swabs and blood (serum) samples of 109 participants above 10 years in Kumasi were collected with consent. Their socio-demographic data, clinical symptoms, and vaccination status were taken with structured questionnaires. Viral RNA was extracted and tested with multiplex real-time RT-PCR detecting respiratory viruses including SARS-CoV-2, Influenza A, Human Rhinovirus (HRV), Adenovirus, Picornaviruses, and common cold coronaviruses. Samples with Ct ≤ 30 will be sequenced and analysed. Results from 109 participants from Kumasi who were aged 10-55 years, mostly females (62.4%) showed an RNA positivity rate of 1.0% for both SARS-CoV-2 (n =1) and HRV (n = 1). Both positive cases were females aged 35 and 37 with headache and fever as common symptoms, traders, not living alone, married and both cases were detected in the Manhyia study site. None of these characteristics was found to have a statistically significant association to respiratory virus positivity as determined by a Fisher's exact test (P < 0.05). We observed a low circulation of RVs in Kumasi. The collected serum samples will be tested for SARS-CoV-2 antibodies, their longevity and new seroconversions by ELISA. Further sampling will be done in urban and rural areas represented by Tamale, Buoyem, Forikrom, and Obuasi to estimate the prevalence of SARS-CoV-2 and other respiratory viruses circulating in Ghana. The mean IgG levels will be analyzed using R to determine the difference in seroprevalence for rural and urban areas. Individuals with a positive ELISA result will be sampled again after one year.

7086

BEYOND RAINFALL: ENVIRONMENTAL DRIVERS OF HISTORIC RIFT VALLEY FEVER OUTBREAKS IN KENYA

Gina E C Charnley*[1], Keli Gerken* (joint 1st author)[2], Juliane Heck[3], Bernard Bett[4], Eric M. Fèvre[2]

[1]School of Public Health, Imperial College London, and Institute for Global Health, University College London, London, United Kingdom, [2]International Livestock Research Institute, Nairobi, Kenya and Institute of Infection, Veterinary and Ecological Sciences, University of Liverpool, Liverpool, United Kingdom, [3]Deanery School of Biomedical Sciences, University of Edinburgh, Edinburgh, United Kingdom, [4]International Livestock Research Institute, Nairobi, Kenya

Rift Valley fever (RVF) is a viral vector-borne zoonosis of the *Phlebovirus* genus, causing widespread abortion in livestock with potential to cause severe disease in humans. RVF was first identified in Kenya in 1931 and has since led to numerous outbreaks that have resulted in loss of life and livelihoods. Several environmental variables have been linked to cases in some areas, but these efforts have not considered ecologically relevant spatial heterogeneity on a national scale. Here, we collated a database of historic cases in Kenya by expanding methods described in previous systematic reviews. To account for underreporting, we transformed RVF as a binary outcome variable for a specific year and geographic regions divided according to existing Agro-Ecological Zones (AEZ) in all models. We selected scaled temperature, precipitation, potential evapotranspiration, Palmers Drought Severity Index (PDSI) and soil moisture as environmental predictors. Linear relationships were tested using Linear Mixed Models (LMM), with AEZ and species as random effects. Non-linear relationships were tested using General Additive Models (GAM), fit to datasets subset by AEZ. The best fit LMM included precipitation and PDSI which showed precipitation to have a strong positive effect and PDSI a slightly negative effect on RVF occurrence in Kenya, with AEZ significant as a random effect. Including AEZ as a random effect produced the top 17 LMM models and the non-linear relationships (in the GAMs) varied in magnitude and shape depending on AEZ, suggesting the relationships between the environment and RVF are distinct among regions. These findings support the hypothesis that heavy rainfall after drought, which decreases soil permeability, is an environmental risk factor for RVF transmission, and this effect is more significant in some AEZs potentially due to varying soil types. The results of this study will contribute to ongoing national efforts to map the risk of RVF in Kenya. We conclude the drivers of historic RVF outbreaks extend beyond solely rainfall and further climate extremes, such as drought and flooding, may lead to more frequent outbreaks.

CAN'T START A FIRE WITHOUT A SPARK: HIGHLY VARIABLE VIRUS IMPORTATION RATES UNDERLIE THE UNPREDICTABLE TIMING OF CHIKUNGUNYA OUTBREAKS

Alexander Dolnick Meyer[1], Sandra Mendoza Guerrero[2], Steven T. Stoddard[2], T. Alex Perkins[1]

[1]University of Notre Dame, Notre Dame, IN, United States, [2]Bavarian Nordic Inc, San Diego, CA, United States

The epidemiology of chikungunya virus (CHIKV) is notoriously sporadic. Outbreaks of this mosquito-borne pathogen are often intense and short-lived and, in many populations, are not repeated for years, or even decades. This unpredictability presents a major challenge to public health preparedness and intervention trial planning. Epidemiological theory suggests three primary drivers of the frequency of outbreaks of a pathogen such as CHIKV. Two of those drivers, the basic reproduction number (R_0) and population immunity, are commonly estimated. The third—the importation rate of the pathogen itself—remains elusive and poorly quantified, although for CHIKV this importation is believed to occur mainly through the movement of infected humans. To address this gap, we performed a model-based analysis of age-stratified serological data that yielded joint estimates of R_0, population immunity, and the importation rate of CHIKV infections for each of 35 populations affected by CHIKV between 1950 and 2020. Our approach leverages the fact that some imported infections may not have resulted in chikungunya outbreaks due to population immunity or stochastic fade-out. Estimated annual CHIKV importation rates spanned orders of magnitude across the populations considered, with posterior means ranging from one imported infection per 4.5 to 80 million residents. Combining these values with R_0, immunity, and growth rate estimates for each population results in highly variable expected inter-epidemic periods for chikungunya, ranging from as few as eight years between outbreaks or as many as 100. This variability highlights the significance of the CHIKV importation rate as a driver of chikungunya's sporadic epidemiology. More broadly, these results demonstrate the value of better understanding pathogen importation rates for enhancing public health preparedness.

RISK FACTORS FOR LASSA FEVER VIRUS INFECTION IN A POPULATION-BASED COHORT STUDY IN SIERRA LEONE

Donald Grant[1], **Matt A. Price**[2], Nell Bond[3], Celia R. Glezer[4], Emily J. Engel[4], Robert F. Garry[4], Robert Samuels[1], Crystal Y. Zheng[4], Mambu Momoh[1], Lansansa Kanneh[1], John S. Schieffelin[4], Jeffrey G. Shaffer[4], Suzanna C. Francis[2], Marija Zaric[2], Patricia E. Fast[2], Swati Gupta[2]

[1]Kenema Government Hospital, Kenema, Sierra Leone, [2]IAVI, New york, NY, United States, [3]Tulane University, New orleans, LA, United States, [4]Tulane University, New Orleans, LA, United States

An improved understanding of Lassa fever virus (LASV) epidemiology is needed to inform efficacy trials for LF vaccines. Investigators at Kenema Government Hospital (KGH) in Sierra Leone, Tulane University, and IAVI implemented a prospective study (X100) to characterize risk factors for incident LASV exposure. Participant data and blood was collected using finger sticks and dried blood spots (DBS) at two time points (baseline and 18-24 months later). DBS were tested by pan-LASV-NP IgG ELISA (Zalgen Labs, MD, USA). Re-exposures were defined as seropositive at baseline, with a ≥4x antibody titre at follow up. Independent predictors of incident exposure were characterized with a mixed effects model to control for cases clustering within households. Between April 2021 and May 2022, 8,237 residents aged ≥2 years were enrolled; baseline and follow-up data were available for analysis for 6,447 (78.3%) participants, our analysis set for this abstract. Of the 6,447 participants, 655 (10.2%) had evidence of incident exposure to LASV. While controlling for other covariates, we found that residing in Kenema district, a traditionally "higher risk" geographic area, was associated with incidence (incidence rate ratio IRR 1.73, 95% CI: 1.41-2.11) as was being seronegative at baseline (IRR 2.26, 95% CI: 1.82-2.78). Children ages 2-10 were less likely to become LASV positive compared to other ages (IRR 0.72, 95% CI: 0.59-0.88). Efforts to store food securely from rodents, perhaps as a proxy for known rodent infestations, was associated with incidence (IRR 1.74, 95% CI: 1.26-2.39) as was having cleared all bush within 5 meters of the dwelling, suggesting rodents moved into the house rather than into foliage that was >5 meters from a home (IRR: 1.55, 95% CI: 1.27-1.89). We observed multiple individual and household characteristics associated with high rates of LASV seroincidence in this rural, population-based cohort of Sierra Leonians at risk of LASV infection. These data improve our understanding of LASV epidemiology and will inform clinical trial design, recruitment, and conduct.

7089

MOLECULAR DIAGNOSIS AND CLINICAL CHARACTERISTICS OF CHIKUNGUNYA VIRUS INFECTIONS IN THE PERUVIAN JUNGLE, 2020-2023

Miguel A. Aguilar-Luis[1], Hugh Watson[2], Ronald Aquino-Ortega[1], Yordi Tarazona-Castro[1], Wilmer Silva-Caso[1], SeungHwan Lee[3], Sang Chun Ji[3], Felipe Cabellos-Altamirano[4], Juana del Valle-Mendoza[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Evotec ID, Lyon, France, [3]Seoul National University College of Medicine and Hospital, Seoul, Korea, Republic of, [4]Dirección Subregional de Salud de Jaén, Jaen, Peru

Chikungunya virus (CHIKV) infections cause acute febrile illness associated with unspecific symptoms that can progress to joint pain and arthritis over time. In 2015, Peru reported its first autochthonous case, followed by an outbreak nationwide. Peruvian Andean and jungle regions report prevalence rates ranging between 2.4% and 9.4%, sometimes surpassing dengue as the primary cause of AFI. In high-risk areas, it is important to differentiate CHIKV infection from other arboviruses due to its concurrent circulation. To evaluate the prevalence and clinical manifestations of CHIKV in Peruvian patients, we conducted a study in the Peruvian jungle. AFI patients were enrolled if they had a 38°C axillary temperature and a source of infection that was unknown. Infection signs and symptoms were recorded using a standardized format after they were evaluated. Blood samples were collected for the detection of CHIKV infection by qRT-PCR and/or IgM detection using ELISA assays. During the study period (2020 through 2023), a total of 4413 patients with AFI were enrolled. 256 (5.80%) CHIKV cases were identified by qRT-PCR, and 472 (10.69%) were identified by IgM detection. Most infected patients were adults aged between 18-39 years (52.73% for qRT-PCR positive and 49.15% for IgM positive), with females being the predominant affected gender (54.69% for qRT-PCR positive and 62.92% for IgM positive). The most common clinical symptoms in CHIKV qRT-PCR and IgM positive patients were headaches (87.85% and 90.16%), myalgias (77.33% and 74.14%), and arthralgias (74.90% and 78.95%). The highest number of positive cases occurred in July 2021 (10.45%). In conclusion, our study underscores the substantial burden of Chikungunya virus (CHIKV) in the Peruvian jungle, revealing notable prevalence rates among patients with acute febrile illness. In regions where CHIKV co-circulates with other arboviruses, robust surveillance and diagnostic efforts are particularly important. It is crucial to understand the epidemiology and clinical presentation of CHIKV infection in order to develop effective disease management and control strategies.

7090

UNVEILING THE PATH TO POLIO ERADICATION: INSIGHTS FROM CONSECUTIVE SEROPREVALENCE SURVEYS AMONG PAKISTANI CHILDREN

Sajid Bashir Soofi[1], Muhammad Umer[1], Imtiaz Hussain[1], shabina ariff[1], Jeff Partridge[2], imran ahmed[1], Ahmad Khan[1]

[1]Aga Khan University, Karachi, Pakistan, [2]Bill & Melinda Gates Foundation, Seattle, WA, United States

After the cessation of the trivalent oral poliovirus vaccine (tOPV), Pakistan has maintained immunity to type 2 poliovirus by administering inactivated polio vaccine (IPV) in routine immunization alongside monovalent OPV

type 2 (mOPV2) and IPV in supplementary immunization activities (SIAs). This study assesses the poliovirus type 2 immunity change after tOPV cessation and due to SIAs with mOPV2 and IPV among children aged 6-11 months. Three cross-sectional sequential serological surveys were conducted in 12 polio high-risk areas of Pakistan. Twenty-five clusters from each geographical stratum were selected using probability proportional to size. Seroprevalence of type 2 poliovirus was 49%, with significant variation observed among surveyed areas; <30% in Pishin, >80% in Killa Abdullah, Mardan & Swabi, and Rawalpindi. SIAs with IPV improved immunity from 38% to 57% in Karachi and 60% to 88% in Khyber. SIAs with IPV following mOPV2 improved immunity from 62% to 65% in Killa Abdullah, and combined mOPV2 and IPV SIAs in Pishin improved immunity from 28% to 89%. Results also reflected that immunity rates for serotypes 1 and 3 were consistently above 90% during all three phases and across all geographical areas. The study findings highlight the importance of implementing effective vaccination strategies to prevent the re-emergence of poliovirus. Moreover, the results provide crucial information for policymakers working towards achieving global polio eradication.

7091

ADDRESSING CHALLENGES IN WASTEWATER EPIDEMIOLOGICAL SURVEILLANCE IN TROPICAL REGIONS: COSTA RICAN EXPERIENCE

Luz Chacon Jimenez[1], Luis Rivera-Montero[1], Jose Montiel-Mora[1], Ernesto Alfaro-Arrieta[2], Pablo Rivera-Navarro[3], Kenia Barrantes-Jiménez[1]

[1]Universidad de Costa Rica, Montes de Oca, Costa Rica, [2]Laboratorio Nacional del Aguas, Instituto Costarricense de Acuaductos y Alcantarillados (National Water Laboratory, Costa Rican Institute of Aqueducts and Sewerage (Instituto Costarricense de Acueductos y Alcantarillados), La Unión, Costa Rica, [3]Laboratorio Nacional del Aguas, Instituto Costarricense de Acuaductos y Alcantarillados (National Water Laboratory, Costa Rican Institute of Aqueducts and Sewerage (Instituto Costarricense de Acueductos y Alcantarillados), La Union, Costa Rica

The increasing recognition of wastewater-based epidemiology (WBE) as an invaluable tool for public health surveillance has prompted the initiation of a comprehensive program in Costa Rica. This study focuses on a pivotal wastewater treatment plant (WWTP) in the Great Metropolitan Area, serving approximately 10% of the Costa Rican population. Commencing in June 2023 and concluding a year later, the program systematically monitors the presence of various viral pathogens, including hepatitis A, enterovirus, rotavirus A, norovirus G1 and G2, Influenza A, Monkeypox, and SARS-CoV-2. This monitoring involves a concentration step followed by RNA extraction, one-step reverse transcription, and quantitative polymerase chain reaction (RT-qPCR) amplification with TaqMan probes. Despite observing an increasing viral pathogen load in wastewater and reported cases, particularly during the rainiest months of October and November, we noticed a reduction in the pathogen viral load. This reduction was confirmed by values obtained for our internal controls: PMMoV and somatic coliphages, suggesting external factors such as rainfall that can affect detection efficiency. Nevertheless, the program successfully identified the presence of hepatitis A in wastewater, coinciding with a significant outbreak of Hepatitis A in the Great Metropolitan Area. Additionally, Influenza and SARS-CoV-2 were concurrently detected with a noticeable increase in reported cases of respiratory diseases. This approach enhances our understanding of the dynamics of infectious diseases and strengthens the overall public health surveillance system in Costa Rica.

7092

HIGH CIRCULATION OF AVIAN INFLUENZA H9N2 SUBTYPE IN LIVE BIRD MARKETS: A NEW EMERGING THREAT IN SENEGAL

Mamadou Malado Jallow[1], Moussa Moise Diagne[1], Ndiende Koba Ndiaye[1], Marie Pedepa Mendy[1], Seynabou Mbaye Ba Souna Diop[1], Sara Sy[1], Davy Kiory[1], Deborah Goudiaby[1], Malick Fall[2], Ndongo Dia[1]

[1]Institut Pasteur de Dakar, Dakar, Senegal, [2]Département de Biologie Animale, Faculté des Sciences et Techniques, Université Cheikh Anta DIOP, Dakar, Senegal

Avian influenza virus (AIV) of the H9N2 subtype has gained increasing attention in recent years due to its widespread circulation in poultry populations and sporadic zoonotic transmission to humans. In Senegal, only one human case of H9N2 infection has been reported so far, despite ongoing influenza surveillance since 1996. However, until now, this surveillance was only focused on humans and the country has never experienced documented H9N2 infection in poultry even though unusual poultry outbreaks associated with mortalities are occasionally reported. So here, we present results of an active influenza surveillance effort focusing on live-bird markets (LBM). The Senegalese National Influenza Center initiated in December 2023 an active influenza surveillance in two LBM in Dakar. Each week, fresh feces, water troughs, carcass washing water and cloacal swabs from birds are collected in each market. Samples are examined by RT-PCR for the presence of, among others, AIV H9, H7 and H5 subtypes, which are then characterized further by next-generation sequencing. In total, 205 samples have been collected so far. Overall, AIVs were detected in 100 of the 205 poultry samples analyzed (48.8%). AIVs were most frequently detected in birds drinking water (32%), carcass washing water (28%), fecal samples (28%), and less frequently in cloacal swabs (12%). All influenza A-positive isolates were H9N2 subtypes. Genome sequences were obtained for 22 isolates and the phylogenetic analysis revealed that Senegalese H9N2 viruses belong to the G1-like lineage and are closely related to H9N2 viruses identified in Burkina Faso, Niger and Tunisia. Furthermore, H9N2 viruses from Senegalese poultry clustered with the H9N2 human case detected through the national influenza surveillance, and possessed multiple molecular markers associated with an increased potential for zoonotic transmission and virulence. Results of this study contribute to our understanding of the epidemiology and genetic characteristics of H9N2 in Senegal and highlight the need to strengthen surveillance and control of AIV in live poultry markets to mitigate public health threats.

THE PHAGE FACTOR IN ANTIBIOTIC RESISTANCE SPREAD IN THE HOSPITAL AND URBAN SEWAGE SYSTEMS IN GREATER ACCRA REGION, GHANA

Emelia Adjekai Pobee, Joseph H.K Bonney

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Phages, which are recognized for their endurance and resistance, play an important role in spreading antibiotic resistance genes (ARGs) throughout the environment. This study aimed to assess the prevalence of ARGs in viral fractions of hospital wastewater and urban wastewater sampled from various sites in Greater Accra, Ghana. Whole genome sequencing was performed on DNA isolated from the samples, which was then assembled using the MetaViral SPADES platform. Subsequently, ABRicate was utilized to identify ARGs from the viral contigs. The findings revealed a wide array of ARG classes such as cephalosporin, macrolide, Carbapenem, aminoglycoside, and tetracycline antibiotics prevalence across hospitals, with notable prevalence of the *bla* genes, *mcr-1* genes, and *mecA* genes. Remarkably, ARGs detected in hospital wastewater were concomitantly detected in raw urban wastewater, indicating potential contributions from multiple sources. The study emphasizes the significance of exploring the carriage of ARG genes in the viral fraction and the role of hospital

wastewater in ARG dissemination. These findings offer valuable insights into the dynamics of antibiotic resistance in wastewater systems, thereby guiding strategies to mitigate its spread and impact on public health.

COMET: A DATABASE TO UNTANGLE VIRAL, MOSQUITO, AND ABIOTIC DRIVERS OF VECTOR COMPETENCE

Emily N. Gallichotte[1], Cole Brookson[2], Gregory D. Ebel[1], Colin Carlson[2]

[1]Colorado State University, Fort Collins, CO, United States, [2]Georgetown University, Washington DC, DC, United States

Many recent emerging pathogens are arthropod-borne (arbo-) viruses, with over one-third of the world's population at risk for infection. Responding to "the next Zika" and forecasting future risks of vector-borne disease requires laboratory-based studies of mosquito infection. These experiments are often the best way to measure vector competence, and are critical to understanding outbreak risk. While hundreds of these studies have been conducted in the last few decades, their data is rarely shared or readily available. Further, there are numerous challenges to interpreting and comparing different studies. These include inconsistent terminology, insufficient experimental/methodological detail, and differences in reported outcomes. In collaboration with arbovirology labs at several institutions, we therefore compiled, cleaned, and standardized data on the infection, dissemination and transmission of mosquito-borne viruses, from published experimental studies into a database called COMET (vector competence experimental testing). We have thus far compiled over 100,000 measurements of mosquito vector competence for human-infective viruses from over 100 published studies. Using these data we will perform meta-analyses and modeling to decompose and predict extrinsic (temperature, humidity, other unaccounted-for experimental variability) and intrinsic (mosquito-omics, viral-omics) drivers of vector competence. In addition to its role in supporting research on vector-virus interactions and arboviral evolution, we anticipate that COMET will be an invaluable resource for public health agencies interested in contextualizing risk from local vectors during future disease outbreaks.

7095

CO-OCCURRENCE OF VIRAL PATHOGENS IN CHILDREN: INVESTIGATING RESPIRATORY AND GASTROINTESTINAL SYMPTOMS IN SÃO PAULO, BRAZIL, 2021

Adriana Luchs[1], Natanael S. Adiwardana[2], Ellen Viana[1], Lais S. Azevedo[1], Raquel Guiducci[1], Yasmin França[1], Simone Guadagnucci[1], Adriana Parise[1], Vanessa M. Silva[1], Mauricio L. Nogueira[3]

[1]Adolfo Lutz Institute, Sao Paulo, Brazil, [2]Pediatric Emergency Care at Barueri Central Emergency Center, Sao Paulo, Brazil, [3]São José do Rio Preto School of Medicine, Sao Jose do Rio Preto, Brazil

Pneumonia and diarrhea are leading causes of death in children under 5 worldwide. This study investigates viral agents causing respiratory illness in ≤ 3 years old patients with diarrhea in São Paulo, Brazil, during spring 2021. Twenty paired samples (oropharyngeal swab and feces) were screened for viruses including HBoV, HAdV, RVA, EV, PeV-A, NoV, SARS-CoV-2, Influenza A/B, RSV and HAstV. Positive samples for HAdV, HBoV, EV, NoV and PeV-A underwent sequencing and phylogenetic analysis. HBoV and NoV were detected in 75% (15/20) of cases, with co-infections in 65% (13/20), suggesting their involvement in respiratory illness with gastrointestinal symptoms in children. HAdV, EV, PeV-A and RSV were each found in two cases (10%; 2/20), with Flu A identified in one case (5%; 1/20). A substantial number of co-infections involving respiratory and enteric viruses were observed (75%; 15/20), notably HBoV+NoV (40%; 8/20) and NoV+PeV-A (5%; 1/20). Triple infections occurred in 7 cases: HBoV+NoV+RSV (10%; 2/20), HBoV+NoV+HAdV (10%; 2/20), HBoV+NoV+EV (5%; 1/20), and NoV+EV+PeV-A (5%; 1/20). All samples tested negative for RVA, HAstV and SARS-CoV-2. Among the NoV samples, GII.4 Sydney[P16] predominated (69.2%; 9/13), followed by GII.2[P16] (27.1%; 3/13) and one GII.4 Sydney[P31] strain (7.7%; 1/13). HBoV was identified as HBoV-1, EV as Coxsackievirus A6 (CVA6), HAdV as type 6 (HAdV-C6) and PeV-A as PeV-A1. Phylogenetic analysis revealed no evidence of a community outbreak, with HBoV-1 strains forming distinct clusters and NoV strains showing diverse genotypes, indicating independent origins. Similarly, molecular analysis of HAdV-C6, CVA6 and PeV-A1 strains suggested distinct genetic sources. Our findings underscore the co-occurrence of respiratory and enteric diseases, an often-neglected epidemiological scenario, and despite the small sample size, highlight local viral diversity and significant exposure to enteric viruses. These results underscore the complexity of conducting differential diagnoses when symptoms overlap and emphasize the crucial role of syndromic surveillance.

7096

CO-CIRCULATION OF TWO LINEAGES OF OROPOUCHE VIRUS IN THE AMAZON BASIN, COLOMBIA, 2024

Daniel Limonta[1], Jaime Usuga[2], Laura S. Perez-Restrepo[2], Karl A. Ciuoderis[3], Isabel Moreno[2], Angela Arevalo[2], Vanessa Vargas[2], Michael G. Berg[4], Gavin A. Cloherty[4], Juan P. Hernandez-Ortiz[2], Jorge E. Osorio[3]

[1]University of Wisconsin, Madison, WI, United States, [2]One Health Colombia, National University of Colombia, Medellin, Colombia, [3]Global Health Institute, University of Wisconsin, Madison, WI, United States, [4]Infectious Diseases Research, Abbott Diagnostics and Abbott Pandemic Defense Coalition, Abbott Park, IL, United States

Oropouche virus (OROV) is a reemerging vector-borne orthobunyavirus with a three-segmented genome that causes acute fever and has spread silently across Latin America since its identification in 1955 in Trinidad and Tobago. In February 2024, the PAHO/WHO began to issue epidemiological alerts because of the dramatic increase in OROV cases in the Amazonian states of Brazil that have more recently extended to bordering Peru and Bolivia. A pre-publication showed that the OROV strain causing the large-scale outbreak in Brazil is a new viral lineage with reassorted genome segments (OROV BR-2009-2018). We have previously established surveillance programs for acute fever illness in several clinics across Colombia and collect blood samples to screen for arboviruses and other pathogens at our One Health Center located in Medellin, Colombia. This center is a consortium established between the Global Health Institute at the University of Wisconsin-Madison and the National University of Colombia-Medellin and is also a member of the Abbott Pandemic Defense Coalition (APDC). Our newly designed OROV RT-qPCR assay and NGS sequencing enabled the confirmation of OROV infection in 22 febrile individuals from the Leticia municipality, Colombian Amazonas department, from January to March 2024. Nine of these individuals were infected with the new reassortant, BR-2009-2018 OROV, while 13 cases were infected with PE-CO-EC/2008-2021 OROV identified previously by our group in Colombia (Ciuoderis et al, Emerg Microbes Infect. 2022). No medical complications or hospitalizations have been reported in the OROV-infected patients during this outbreak. The co-circulation of different OROV strains in this Colombian arboviral hotspot raises concerns about new reassortments and the emergence of new lineages with more severe clinical phenotypes and enhanced vector competence. This ongoing investigation highlights the complex arbovirus dynamics in South America and is a demonstration of the challenges of preventing and controlling the reemergence of arboviruses in the Americas.

7097

SEROPREVALENCE OF DENGUE VIRUS IN THE TAMPA BAY REGION OF FLORIDA AMONG HOSPITALIZED PATIENTS WITH RESPIRATORY SYMPTOMS IN 2020 AND 2021

Emma C. Underwood[1], Iset Vera[1], Dylan Allen[1], Joshua Alvior[1], Marci O'Driscoll[2], Suzane Silbert[2], Kami Kim[1], Kelli L. Barr[1]

[1]University of South Florida, Tampa, FL, United States, [2]Tampa General Hospital, Tampa, FL, United States

Dengue Virus (DENV) is a flavivirus vectored by Aedes mosquitoes that is suspected to cause over 400 million human infections and 40,000

estimated deaths annually. Since 2010, the United States has seen over 45,000 reported cases, 34,000 of which were locally acquired. Florida has the highest number of DENV cases in the nation with 3,182 reported infections as of 2023. The state has seen multiple DENV outbreaks due to imported cases from the Caribbean and being home to two major competent vectors, *Aedes aegypti* and *Aedes albopictus.* All four serotypes of DENV have been found within the state, although serotype 4 has only been found in mosquitoes pools. The Tampa Bay region is particularly at risk due to having a large tourism industry and immigrant population. Hillsborough county, where Tampa Bay resides, does not have passive surveillance measures for DENV and the main form of mosquito management is through nontargeted air and ground adulticide spraying. To test prevalence of DENV in the Tampa Bay region of Florida, our study utilized enzyme linked immunosorbent assays (ELISAs) for IgG antibodies to test 334 serum and plasma samples collected at Tampa General Hospital during 2020 and 2021. As we tested for IgG antibodies to indicate a previous exposure, current respiratory status of patients would not impact DENV status. We found that over forty percent of samples were positive for serotypes 1/3 and over sixty percent of samples were positive for serotypes 2/4 by ELISA. DENV serotypes were separated into two groups, 1/3 and 2/4, for ELISAs as they are serologically similar to one another. Plaque reduction neutralization tests (PRNTs) were performed to confirm positive results with each serotype being tested individually. While we cannot determine if the cases in this study are locally or travel acquired, we can say that seroprevalence of DENV is higher than reportable cases suggest.

7098

EFFECT OF PRIOR DENGUE INFECTION AND SINGLE-DOSE DENGUE VACCINATION ON THE RISK OF SUBSEQUENT VIROLOGICALLY CONFIRMED DENGUE: A FIVE-YEAR PROSPECTIVE COHORT STUDY IN CEBU, PHILIPPINES

Michelle Ylade[1], Ma. Vinna Crisostomo[1], Jedas Veronica Daag[1], Kristal An Agrupis[1], Anna Maureen Cuachin[1], Ava Kristy Sy[2], Deok Ryun Kim[3], Hyeon Seon Ahn[3], Ana Coello Escoto[4], Leah Katzelnick[4], Cameron Adams[5], Laura White[5], Aravinda de Silva[5], Jacqueline Deen[1], Anna Lena Lopez[1]

[1]University of the Philippines Manila, Manila, Philippines, [2]Research Institute for Tropical Medicine, Muntinlupa, Philippines, [3]International Vaccine Institute, Seoul, Korea, Republic of, [4]National Institutes of Health, Bethesda, MD, United States, [5]University of North Carolina School of Medicine, Chapel Hill, NC, United States

In 2015, a three-dose dengue vaccine (CYD-TDV,Dengvaxia) was licensed for those 9 years and older in dengue-endemic areas. The World Health Organization (WHO) recommended that CYD-TDV would be used in settings with at least 70% seroprevalence. The Philippines Department of Health (DOH) implemented a three-dose dengue vaccination program in high dengue burden regions targeting children aged 9 to 14 years old. In June 2017, the program was expanded to Cebu province. A follow-up analysis of the CYD-TDV Phase 3 trials showed that vaccination conferred protection among dengue-seropositive but increased risk for severe dengue among dengue-seronegative participants, the dengue vaccination program was halted with children in Cebu offered only one dose. We conducted a prospective community-based cohort study in Cebu to evaluate the effect of baseline dengue serostatus and a single dose of CYD-TDV on the subsequent risk of virologically-confirmed dengue (VCD). We enrolled 2,996 healthy children 9 to 14 years of age in May 2017. Baseline sera were collected and batch tested by indirect IgG ELISA and focus reduction neutralization test (FRNT). Out of 2,996 sera, 320 (10.7%) was dengue naïve, 292 (9.7%) had one previous dengue infection (monotypic profile) and 2,384 (79.6%) had >2 previous dengue infections (multitypic profile). From June to August 2017, 1,790/2,996 (59.7%) children received a single dose of CYD-TDV. Active surveillance for an acute febrile illness (AFI) was conducted from November 2017 to October 2023. Those who developed AFI were identified, data were collected, and blood drawn for confirmation of dengue by RT-PCR. Cumulative incidence for VCD was 1.02 cases per 100 person-years and the incidence varied by baseline DENV serostatus. Crude and adjusted analyses showed that a single dose of CYD-TDV did not confer protection against VCD in children who were dengue naïve or had a monotypic profile at baseline. One dose conferred significant protection against hospitalized VCD among participants who had a multitypic profile at baseline: at first 3 years, 70% (95% CI 20-88; p=0.017), 5-year follow-up period, 67% (95% CI 19-87; p=0.016).

7099

MORPHOLOGICAL AND MOLECULAR IDENTIFICATION OF *AEDES* MOSQUITO POTENTIAL VECTOR OF ARBOVIRUS IN KATI FALADIE, MALI

Fatalmoudou Tandina, Antoine Dara, Laurent Dembele, Kadia Doumbia, Sekou Sissoko, Adam Garango, Mohamed Touré, Fatoumata Ballo, Siaka Goita, Abdoulaye Djimdé

USTTB, Bamako, Mali

In Mali *Aedes* vectors and arbovirus coexist, several patients have been seropositive for these five arboviruses. However, given the *Aedes* vector species diversity across various ecoclimatic settings, which *Aedes* species is specific vector for which arbovirus remains to be determined. Precise identification of Aedes mosquitoes will help to differentiate between vectors and non-vectors. In addition, understanding the repertoire of *Aedes* mosquito species that are responsible for sustaining any specific arbovirus transmission at any specific ecoclimatic setting would target vectors fighting. We hypothesize that the new distribution of *Aedes* mosquitoes could contribute to the emergence of arboviruses in Mali. This project aims to identify the *Aedes* mosquito potential vector of arbovirus in Kati-Faladie rural aera from Mali using molecular tool. This study carried out in Faladie, a rural village in Kati, 80 kilometers from Bamako in Mali. Mosquitoes were captured by aspiration and biogents sentinel in Faladie. Collected specimens were identified using morphological dichotomies keys of Culicidae, PCR and sequencing. Circulating arbovirus was characterized from captured mosquitoes by RT-PCR for non-structural protein 5 NS5 gene and sequencing. 287 *Aedes* mosquitoes collected were morphologically identified as: *Aedes aegypti* 82,22% (N=287), *Aedes aedimorphus* 1,74% (N=287), *Aedes mucidus* 0,35% (N=287), *Aedes Aedimorphus hirsutus* 0,35% (N=287) and *Aedes* spp. 15,33% (N=287). With sequencing *Aedes* mosquitoes were identified as: *Aedes aegypti 73,87% (*N=287*), Aedes Aedimorphus hirsutus* 0,35% *(*N=287*), Aedes furcifer* 0,70% *(*N=287*), Aedes albopictus* 0,70% *(*N=287*), Aedes vitattus* 0,70% *(*N=287*) and Aedes spp 23,70% (*N=287*).* 56.44% (n=162) of our samples tested by RT-PCR were positive for arbovirus and 43.55% (n=125) negative. Sequencing of the positive arbovirus samples (n=162) and *Aedes spp* (68). This study will shed light on the *Aedes* species that transmits arboviruses in Mali.

PRELIMINARY EVIDENCE OF SILENT CIRCULATION OF *ORTHOFLAVIVIRUS NILENSE* IN EQUIDAE POPULATION IN PIAUI STATE, NORTHEAST BRAZIL

André A. Dos Santos[1], Jéssica C. De Almeida Dias[2], Marcio J. L. Siconelli[2], Milene S. Ferreira[3], Livia C. Martins[3], **Benedito Antonio Lopes Da Fonseca**[2], Lilian S. Catenacci[4]

[1]Instituto de Medicina Veterinária - Universidade Federal do Pará, Belém, Brazil, [2]School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil, [3]Evandro Chagas Institute, Belém, Brazil, [4]Centro de Ciências Agrárias - Universidade Federal do Piaui, Teresina, Brazil

The West Nile virus (WNV; *Orthoflavivirus nilense*) is an arbovirus that belongs to the *Flaviviridae* family, *Orthoflavivirus* genus. Considered an emerging pathogen in South America, WNV can cause encephalitis in animals and humans. Until recently, Piaui state was the only Brazilian state reporting West Nile fever in humans and one of the few states reporting WNV infections in animals that could be used as sentinel animals. Aiming at detection of WNV circulation in animals of the Equidae family from Piaui state, a cross-sectional epidemiological study was conducted from 2019 to 2021, in eight municipalities with confirmed cases of West Nile fever in humans. Three-hundred seventy-seven whole blood samples collected

in the field were centrifuged and frozen in liquid nitrogen until tested. Epidemiological data collection was obtained by interviewing animal owners using a personalized questionnaire. Antibodies to several arboviruses were detected by the Hemagglutination Inhibition test in 75.86% (286/377) of the samples and 63.92% (241/377) were specific for the *Orthoflavivirus* genus. Until now, Plaque Reduction Neutralization Test (PRNT) was performed in 30 samples and, in a preliminary analysis, the presence of neutralizing antibodies to WNV ($PRNT_{50}$) was detected in 66.66% (20/30) of the samples. These preliminary results indicate that, in this northeastern Brazilian state, WNV has infected animals of the Equidae family even though there have been no reports of epizootic events by the public health officials of this state, despite the need for a compulsory reporting of any epizootic event to the Ministry of Health. To our knowledge, this is the first report of detection of neutralizing antibodies to WNV in the Equidae population in Brazil, and these results evidenced a high seroprevalence of neutralizing antibodies to WNV in animals that could serve as sentinel animals to an early detection of a WNV outbreak. Although only a small fraction of the samples was tested, these preliminary results detected the silent circulation of WNV leading to an underestimated prevalence and underreporting of a virus with zoonotic and encephalitogenic potential.

7101

CHARACTERIZATION OF KOUTANGO VIRUS FROM PHLEBOTOMINE SANDFLIES COLLECTED IN ISIOLO AND BARINGO COUNTIES OF KENYA.

Jane Wambui Thiiru[1], Solomon K. Langat[2], Francis Mulwa[2], Stephanie Cinkovich[3], Hellen Koka[2], Santos Yalwala[1], Samoel Khamadi[2], Justus Onguso[4], Nicholas Odemba[1], Francis Ngere[1], Jaree Johnson[5], Elly Ojwang[6], Timothy Egbo[6], Eric Garges[6], Fredrick Eyase[1]

[1]Walter Reed Army Institute of Research-Africa (WRAIR-Africa)/Kenya Medical Research Institute, Nairobi, Kenya., Nairobi, Kenya, [2]Centre for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya, [3]Global Emerging Infections Surveillance Branch, United States Armed Forces Health Surveillance Division., Maryland, MD, United States, [4]Institute for Biotechnology Research, Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya, [5]United States Armed Forces Pest Management Board, Maryland, MD, United States, [6]Walter Reed Army Institute of Research - Africa, Kisumu, Kenya

Koutango virus (KOUTV), a lineage of West Nile Virus, is highly neuroinvasive in animal models and has been associated with human disease. Recent studies in parts of Africa, including Kenya, have identified KOUTV among phlebotomine sandfly populations. However, our understanding of this virus remains limited. The present study aimed to characterize KOUTV from Kenyan phlebotomine sandflies. Sandflies were sampled from selected sites in different geographical regions of Kenya between 2021 and 2023 using CDC light traps. Female sandflies were taxonomically identified and pooled based on genus. Virus isolation was performed in Vero cells. The viral genome was determined using next-generation sequencing on illumina Iseq 100. Phylogenetic and molecular clock analyses were done to decipher the virus's evolutionary relationships. Comparative analyses of amino acid sequences were performed to determine variations. Protein modeling in Pymol was conducted to elucidate variations in key protein regions. Evolutionary pressure analysis was used to investigate both point and episodic selection pressure. In vitro cell growth experiments were used for virus growth kinetics in vero-E6 and C6/36 cells. We report two KOUTV isolates one each from Baringo and Isiolo counties in Kenya. The current KOUTV isolates clustered in a single clade with previously identified KOUTV from Kenya. Comparative analysis revealed alanine amino acid at NS5 653. Diversifying pressure was acting on NS3 267 of the KOUTV lineage. There was no significant difference in the growth rates of KOUTV in Vero-E6 and C636 cells when compared to West Nile virus Lineage 1a. The isolation of KOUTV in two disparate sites in sandflies suggest circulation of the virus amongst sandfly population. The growth of the virus in Vero-E6 may point to the ability of the virus to infect primates. Similarly, growth in C6/36 cells points to amenability of the virus to mosquitoes, hence potential vectors. The close genetic relationship of KOUTV strains between East and West Africa may be enabled by the bird migratory route between the two regions.

DISSECTING ANTIGEN-SPECIFIC T CELL RESPONSES TO MPOX IN VACCINATION AND INFECTION BY GENOME-WIDE ANTIGEN SCREENING

A-Reum Kim, Alessandro Sette, Alba Grifoni

La Jolla Institute for Immunology, La Jolla, CA, United States

The mpox epidemic in July 2022 caused by Monkeypox virus (MPXV) prompted a public health emergency. Even after the epidemic peak, cases of mpox are still being reported both within and outside traditional endemic areas. The smallpox vaccine, Dryvax®, which successfully eradicated smallpox, comprises a live replicating vaccinia virus (VACV) and provides robust protection against MPXV, but poses safety concerns for immunocompromised individuals. In response, a non-replicating modified vaccinia Ankara (MVA) vaccine, JYNNEOS, was developed for smallpox and mpox, which is associated with the deletion of numerous open reading frames (ORFs). Recent data obtained during the 2022 mpox epidemic indicate that JYNNEOS may induce less immunogenicity and protection than Dryvax®. T cells play a pivotal role in controlling and terminating pox-virus infections, yet there is limited information on the antigen targets recognized by T cells following VACV vaccinations (Dryvax® and JYNNEOS) and/or MPXV infection. To fill this gap of knowledge, our study focuses on identifying the antigens and epitopes recognized by T cells in donors who have been vaccinated and/or infected. First, we classified the ORFs present in the two VACV vaccine strains and MPXV by their ortholog determination. We then measured T cell responses induced after JYNNEOS vaccination with pools of predicted peptides spanning the entire MVA proteome. Employing our deconvolution strategy, 113 CD4 and 83 CD8 MVA-derived epitopes were identified, exhibiting an unbiased recognition between structural and non-structural proteins. Among the recognized antigens, we identified the top 10 immunodominant antigens for CD4+ and CD8+ T cells with five antigens recognized by both populations of T cells. This comprehensive antigen identification provides a valuable understanding of T cell responses following JYNNEOS vaccination during the mpox epidemics, enabling comparison with responses post-Dryvax® vaccination and MPXV infection. Ultimately, these insights into potential protective antigen targets contribute to the development of next-generation pox vaccines with enhanced efficacy.

7103

PRIOR ZIKA VIRUS INFECTION RESTRICTS DIVERSITY OF SUBSEQUENT ACUTE-PHASE PLASMABLAST RESPONSE TO DENGUE VIRUS SEROTYPE 2 AND PREFERENTIALLY SELECTS A SINGLE CLONE

Tulika Singh[1], Sandra Bos[1], Tiffany Kim[2], Gerald Vásquez Alemán[3], Miriam Walter[2], Nharae Lee[1], Elias Duarte[1], Aaron Graber[1], Amir Balakhmet[1], Jose Victor Zambrana[3], Jorge Ruiz[3], Angel Balmaseda[4], Eun-Young Kim[2], Steven Wolinsky[2], Eva Harris[1]

[1]Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, [2]Feinberg School of Medicine, Northwestern University, Chicago, IL, United States, [3]Sustainable Sciences Institute, Managua, Nicaragua, [4]Laboratorio Nacional de Virología, Centro Nacional de Diagnóstico y Referencia, Ministerio de Salud, Managua, Nicaragua

Zika virus (ZIKV) and dengue virus serotypes 1-4 (DENV 1-4) co-circulate in the tropics, such that people are exposed to multiple viruses. DENV causes febrile illness ranging from mild to severe disease with vascular leak. We have shown that prior ZIKV infection is associated with increased the risk of subsequent severe DENV2 infection. Plasmablasts rapidly peak in the acute response to DENV infection and secrete antibodies. We hypothesized that prior ZIKV vs DENV1 infection selects for different antibody specificities in the acute immune response to subsequent DENV2 infection. Using single-cell transcriptomics and antibody variable heavy (VH) and light (VL) chain gene annotation, we compared the acute plasmablast (PB) response to DENV2 infection in peripheral blood mononuclear cells (PBMCs) from children with primary DENV2 (n=1), secondary DENV1-DENV2 (n=2), or

secondary ZIKV-DENV2 (n=3). A mean of 1,383 B cells were analyzed per child. The acute ZIKV-DENV2 PB clonal diversity (Shannon Diversity Index, H=5.6) was lower than that of DENV1-DENV2 (H=6.63), suggesting more selection pressure in ZIKV-DENV2 PBs. Surprisingly, a single clonotype of VH3-23_VK1-39, with a 17- or 18-amino acid VH hypervariable region, predominated (33-50%) in ZIKV-DENV2 PBs of all 3 children. We did not find this clone in acute DENV2 or DENV1-DENV2 PBs. In contrast, the most frequent clone in the DENV1-DENV2 group was only present in 1.7-6% of PBs. Monoclonal antibodies (mAbs) representing the VH3-23_VK1-39 clone potently neutralized ZIKV (Neutralizing titer; NT_{50}=0.012µg/mL) but not DENV1-4 (NT_{50}>10 µg/mL). In contrast, most mAbs (6-7) of a set of 8 representative clones from the DENV2 and DENV1-DENV2 PBs neutralized DENV1-4 (NT_{50} in µg/mL: DENV1=0.4-40, DENV2=0.4-20, DENV3=0.6-7, DENV4=0.3-20) but not ZIKV (NT_{50}>10 µg/mL). Thus, the acute PB response to ZIKV-DENV2 demonstrates less diversity and a preference for a single clone that does not neutralize DENV2. This supports that prior ZIKV immunity may not elicit effective immunity in the acute phase of a subsequent DENV2 infection and may partly explain increased risk associated with this infection history.

7104

BLOOD BIOMARKERS THAT PROSPECTIVELY PREDICT HIV-1 INFECTION IN HIGH RISK ADULTS.

Kioko Mwikali, Abdirahman Abdi, Eunice Nduati
KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

High heterogeneity in HIV-1 transmission is observed with individuals in sub-Saharan Africa exhibiting a nearly 4-fold elevated risk of male-to-female HIV-1 transmission per sexual contact compared to higher income countries. It is possible that environmental exposures may predestine one to becoming more susceptible to HIV-1 acquisition, for example by affecting host constitutive defence mechanism. We recently explored potential blood biomarkers predictive of HIV-1 acquisition using a retrospective case-control study nested in an HIV-1 high-risk longitudinal cohort. Plasma samples taken 3 months prior to HIV-1 infection were used for transcriptional analysis of the RNA encapsulated in small extracellular vesicles (sEVs) circulating in plasma. Preliminary data of the host and pathogen transcripts revealed distinct gene expression patterns 3 months prior to HIV acquisition, in individuals who 3 months later acquire HIV (cases) compared to those who remain HIV negative (controls). Notably, dampening of immunological pathways important for inducing antiviral immunity were associated with HIV-1 acquisition. Interestingly, significantly higher Pegivirus C RNA was observed in those who became HIV-1 positive compared to those who remained negative. Although this was contrary to the protective role of Pegivirus C in slowing HIV-1 disease progression to AIDS, our results suggest that Pegivirus C infection might dampen the immune system and predispose high risk adults to HIV-1 acquistion.

7105

SURVEILLANCE OF ACUTE FEBRILE ILLNESSES IN THE COUNTRY OF GEORGIA: INSIGHTS FROM A HOSPITAL-BASED STUDY

Magda Metreveli[1], Nora Kokaia[2], Manana Makharadze[2], Tamar Jajanidze[1], Shorena Mazmaniani[1], Damon Ellison[3], Thomas Musich[1], Nino Trapaidze[1]
[1]Walter Reed Army Institute of Research-Europe and the Middle East, Tbilisi, Georgia, [2]Research Institute of Medical Parasitology and Tropical Medicine, Tbilisi, Georgia, [3]Walter Reed Army Institute of Research-Europe and Middle East, Silver Spring, MD, United States

Understanding the pathogens causing acute febrile illness (AFI) is crucial to address global and militarily health challenges. AFI-related morbidity and mortality remain significant concerns in Georgia. The service members operating in the country are at high risk of exposure to AFI agents. We initiated a hospital-based surveillance study in Georgia to determine infectious causes of undifferentiated febrile illnesses. The study enrolled patients aged 4 years and older who exhibited persistent fever (≥38°C for ≥48 hours) without definitive diagnoses and collected samples for testing. We utilized an enzyme-linked immunosorbent assay (ELISA), serum agglutination test and immunoblotting to detect antibodies against regionally relevant pathogens, including *Leishmania* spp., *Leptospira* spp., Crimean-Congo Hemorrhagic Fever Virus, *F. tularensis*, West Nile Virus, *R. typhi*, Spotted Fever, *Brucella* spp., *C. burnetii*, Tick-borne Encephalitis virus, *Borrelia* spp., and Hantavirus. From February 2023 to March 2024, we enrolled 196 outpatient subjects with a mean age of 46 years (range 13-81 years) of which 60% were female and 40% were male. Testing results indicated *R. typhi* as the predominant pathogen, with IgM positives in 60% of the samples followed by *Leptospira* spp. (29%), *F. tularensis* (15%), *Brucella spp*. (14%), *Borrelia spp.* (11%) and Spotted Fever (9%). In addition, 43% of the samples demonstrated the presence of IgM antibodies against 2 or more pathogens. In attempt to identify the agent causing the illness, samples were also subjected to polymerase chain reaction-based assay using the BioFire Global Fiver Panel. However, no positive AFI pathogens were obtained. The results of our study indicate presence of various AFI agents in the country and highlights the need of continued surveillance and research to develop region-specific diagnostic methods and analyses. The latter is essential to control and mitigate the spread of these infectious agents in the region.

7106

HUMAN *IN VITRO* MODELING CHARACTERIZES MECHANISM OF ACTION OF ADJUVANTATION SYSTEMS DEFINING SCALABLE AND AFFORDABLE PRECISION VACCINE FORMULATIONS FOR EARLY CHILDHOOD

Sanya Thomas, Caitlin Syphurs, Kevin Ryff, Simon Doss-Gollin, Kayla Lesch, Ofer Levy, Joann Arce, Simon van Haren
Boston Children's Hospital, Boston, MA, United States

Children demonstrate distinct immunity in early life including diminished Th1-polarizing cytokine production contributing to high susceptibility to infections caused by intracellular pathogens such as respiratory viruses. This challenge also pertains to pediatric vaccine discovery and development, and could be overcome by developing precision adjuvantation systems with well characterized mechanisms of action (MOA) tailored to enhance age-specific immunogenicity. To this end, we employed novel age-specific human *in vitro* assays to characterize cellular and molecular activities of a selection of adjuvants in children aged between 2-4 years in soluble, oil-in-water and liposomal formulations, including several developed for global open access. In a whole blood assay, which predicts the reactogenicity potential of adjuvants, formulations containing the TLR4 agonist, monophosphoryl lipid A (MPLA), potently induced an innate immune response with primary activation of monocytes, and liposomal formulations were more selective in inducing cytokine production compared to soluble and oil-in-water formulations in children as well as adults. In a monocyte-derived dendritic cell (MoDC) assay, which dissects the mechanism by which adjuvants activate differentiation of T helper (Th) cell subsets, liposomal formulations activated MoDCs to produce Th1-polarizing cytokine response, which is important for anti-viral host defense, with more robust TNF induction observed in children than adults. In a DC-T cell interface assay that demonstrates antigen processing and presentation, activation of influenza-specific $CD4^+$ T cells was driven by MPLA-containing formulations and that of $CD8^+$ T cells was induced by the adjuvant QS-21 with greater variability observed in children than in adults. Insight into the MOA of adjuvanted vaccine formulations via age-specific human *in vitro* modeling may advance global health by accelerating and de-risking development of affordable and scalable precision-adjuvanted vaccines.

SEROLOGICAL PROFILING OF RESPONSES TO VACCINATION AND/OR INFECTIONS CRITICAL TO UNLOCK IMMUNE CORRELATES OF PROTECTION

Jessica S. Bolton[1], Rupsa Boelig[2], Elke S. Bergmann-Leitner[1]

[1]Biologics Research & Development Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, [2]Department of Obstetrics and Gynecology, Division of Maternal Fetal Medicine, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, United States

Pathogen-specific antibodies are commonly used to assess immunity to various pathogens. Serological readouts often rely on measuring antibodies to a single antigen and, in many cases, inform on disease exposure rather than immunity to the respecting pathogen. Attempting to correlate protection with a single point serological measurement, have shown that depending on the study population, pre-existing immunity and vaccine-induced immunity, such direct relationship between antibodies and protection is highly variable. This has led to the increasing reluctance of conducting serological analysis as they may fail to expand our knowledge in immune mechanisms conferring protection.In this study we showcase the power of serological profiling, specifically, establishing the antibody profiles to SARS-CoV2 and mapping the functional activity (isotype, neutralization) of various study populations. The study populations include male and female donors with/without mRNA vaccination, pregnant women, and neonatal cord blood. The results have led to several conclusions that the single assessment of antibody titers to just SARS-CoV2 spike or nucleocapsid would not have revealed: (1) antibodies to SARS-CoV2 nucleocapsid waned in our study populations over time thus increase the uncertainty on determining immune individuals; (2) distinct antibody profiles in neonatal cord blood vs. maternal blood; (3) distinct functional antibody profiles between the study populations; and (4) vaccination compared to disease induces a distinct functional profile and cross-reactivity with other SARS-CoV2 variants than the original strain. Our results show a clear need to advocate for enabling a full assessment of immunity by profiling both fine specificity and function, to potentially identify immune correlates of protection.

7108

CYTOKINE PROFILING REVEALS DISTINCTIVE IMMUNE RESPONSES IN DENGUE, ZIKA, CHIKUNGUNYA AND MAYARO VIRUS INFECTIONS

Juana del Valle-Mendoza[1], Hugh Watson[2], Yordi Tarazona-Castro[3], Wilmer Silva-Caso[1], Ronald Aquino-Ortega[1], Hugo Carrillo-Ng[3], Jorge Bazan-Mayra[4], Victor Zavaleta-Gavidia[4], **Miguel A. Aguilar-Luis**[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Evotec ID, Lyon, France, [3]Instituto de Investigacion Nutricional, Lima, Peru, [4]Direccion Regional de Salud Cajamarca, Cajamarca, Peru

Arboviruses, including Dengue virus (DENV), Chikungunya virus (CHIKV), Zika virus (ZIKV), and Mayaro virus (MAYV) are important causes of acute febrile illness (AFI) in high-risk regions in Peru. Differential diagnosis based on clinical manifestations is challenging due to overlapping symptoms. We conducted a pioneering study to compare cytokine profiles among these arboviruses, aiming to elucidate distinct immunological features for diagnostic and therapeutic insights. We conducted a cross-sectional study in patients with acute febrile illness from Cajamarca, Peru. Blood samples were collected for the diagnosis of arboviruses and the quantification of cytokines. Diagnosis of Dengue, Zika, Chikungunya, and Mayaro virus infections relied on specific IgM antibody detection via enzyme-linked immunosorbent assays (ELISA). Cytokine quantification was carried out by ELISA assays for IL-2, IL-6, IL-10, TNF-α, and IFN-γ. Comparative analysis of cytokine levels was performed between all viruses and controls. A total of 20 patients were recruited for each arbovirus and control group. Our study revealed similarities in clinical symptoms across arboviral infections, with headaches, myalgias, and arthralgias as the predominant symptoms. IL-2 levels were similar across the arboviruses; however, DENV and ZIKV patients had higher levels compared to controls. Elevated IL-6 levels were associated with CHIKV and ZIKV, while IL-10 levels were highest in DENV as compared to other arboviruses. TNF-α and IFN-γ were significantly elevated in DENV and ZIKV, and they were significantly higher in DENV compared to MAYV. Our findings provide valuable insights into the unique cytokine profiles of arboviral infections. We found similar levels of IL-2 across the arboviral groups, IL-6 was predominantly elevated in CHIKV and ZIKV, while IL-10 showed the highest levels in DENV. TNF-α and IFN-γ showed a similar pattern, with DENV and ZIKV patients expressing the highest levels. Understanding the distinct immunological signatures of these arboviruses is crucial for effective diagnostic and therapeutic approaches in high-risk regions.

7109

SERUM INTERLEUKIN-6 AND ZINC LEVELS ARE ASSOCIATED WITH SEVERITY IN COVID-19 PATIENTS FROM LIMA, PERU

Andrea Roman[1], Sandra Medina[1], Juana del Valle-Mendoza[1], **Miguel A. Aguilar-Luis**[1], Sungmin Kym[2], Ronald Aquino-Ortega[1], Yordi Tarazona-Castro[3], Hugo Carrillo-Ng[3], Eliezer Bonifacio-Velez de Villa[1], Wilmer Silva-Caso[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Chungnam National University School of Medicine, Daejeon, Korea, Republic of, [3]Instituto de Investigacion Nutricional, Lima, Peru

The individual's immune system can determine the progress of SARS-CoV2 infection and lethality. The modulation of the inflammatory response through various molecules, such as cytokines and trace elements, is crucial during the disease. In this context, the objective of the present study was to determine the serum levels of IL-6 and zinc and their association with the severity of the disease in patients with COVID-19 from Lima, Peru. Four groups of patients were analyzed. Hospitalized patients were divided into two groups: 26 admitted to ICU and 26 who did not require ICU. The other two groups included 36 patients who did not require hospitalization, 24 of which belonged to the outpatient group and 12 to the control group. Sixty-four and eight percent (64.8%) of the patients were male. The lowest IL-6 values were obtained in the outpatient group (2pg/mL) and the highest values in the ICU group (168.5 pg/mL). On the other hand, the highest zinc values were also obtained in the UCI group (3402.5 µg/dL).

7110

SERUM SPIKE SPECIFIC IGG3 SERVES AS A DISTINGUISHING IMMUNOLOGICAL MARKER BETWEEN SARS-COV-2 INFECTION AND VACCINATION

Marjahan Akhtar[1], Md. Rashedul Islam[1], Fatema Khaton[1], Imam Tauheed[1], Tasnuva Ahmed[1], Afroza Akter[1], Ishtiakul Islam Khan[1], Zahid Hasan Khan[1], Prasanta Kumar Biswas[1], Fahima Chowdhury[1], Ashraful Islam Khan[1], Sayera Banu[1], Tahmina Shirin[2], Taufiqur Rahman Bhuiyan[1], Firdausi Qadri[1]

[1]icddr,b, Dhaka, Bangladesh, [2]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh

Both SARS-CoV-2 infections and COVID-19 vaccines elicit immunological responses. However, it is difficult to distinguish the responses generated either from vaccination or infection. Here we have investigated SARS-CoV-2 spike receptor-binding domain (RBD)-specific IgG subclasses (IgG1, IgG2, IgG3 and IgG4) responses using ELISA in four different groups; (1) COVID-19 patients (n=39) with varying disease severity and (2) COVID-19 vaccinated individuals (n=30, adenovirus/mRNA based) (3) vaccinated after infection (n=39) (4) patients experiences breakthrough infection (n=19), in Bangladesh. We observed distinct IgG subclass responses in COVID-19 patients compared to COVID-19-vaccinated individuals. Specifically, COVID-19 patients exhibited elevated levels of both IgG1 and IgG3, with IgG3 dominating in the early phase (days 1-7) followed by a subsequent increase in IgG1. Conversely, COVID-19 vaccination predominantly induced IgG1 responses without a concurrent rise in IgG3. This effect was more evident when a significant rise of IgG1 but not IgG3 was observed

in patients who received COVID-19 vaccines after 90 days of infection. However, following breakthrough infection, we observed an increase in both IgG1 and IgG3. All of these findings collectively indicate that COVID-19 vaccination predominantly induces IgG1, whereas natural infection can elicit both IgG1 and IgG3 subclasses. These findings identify the importance of serum spike-specific IgG3 as an important distinguishing marker that can differentiate individuals based on their vaccination and natural infection history. More studies with larger sample size might be needed to establish this marker. This marker can be used as an important tool for longitudinal monitoring of vaccinations and for establishing SARS-CoV-2 correlates of protection.

7111

NO DISTINCT CYTOKINE, CHEMOKINE AND GROWTH FACTOR (CCG) BLOOD PROFILE ASSOCIATED WITH MONKEYPOX VIRUS CLADE IIB INFECTED PATIENTS

Eugene Bangwen, Nicole Berens-Riha, Nicky De Vrij, Ann Ceulemans, Isabel Brosius, Elise De Vos, Thao-Thy Pham, Marjan Van Esbroeck, Koen Vercauteren, Christophe Van Dijck, Wim Adriaensen, Laurens Liesenborghs

Institute of Tropical Medicine, Antwerp, Belgium

Previous literature, in particular on related orthopoxviruses, suggested a cytokine storm association with overt mpox disease. To date, only a handful of studies have investigated the modulation of circulating cytokine, chemokine and growth factor (CCG) profiles in monkeypox virus (MPXV)-infected patients with limited panels. The sole study on CCGs in clade I MPXV infections in 19 mpox patients showed that cytokine modulation correlated with disease severity. It remains unknown if a similar CCG profile is associated with clade II infections, as patients exhibit different clinical manifestations to both clades. We used a 65-plex CCG panel to analyze serum samples of 100 acute mpox patients from the 2022 outbreak and 26 pre-outbreak healthy controls. All 100 patients were men, median age 40 years (interquartile range: 33-46). Cluster analyses indicated no strong CCG profiles in mpox patients compared to healthy controls, but a trend towards certain cytokine modulations. Individual CCG analyses showed MIF, CXCL10, CCL8, CD30, IL2R, CXCL13, IL18, APRIL, CCL4, TNFRII, VEGFA, CXCL12, CXCL9, and CXCL11 to be significantly elevated in mpox patients, while TWEAK, CCL11, CCL2, CXCL5, and SCF were significantly suppressed. We did not detect significant differences in the expression of key pro-inflammatory cytokines such as IL-1α, IL-1 β, IL-6, IL-8 or anti-inflammatory cytokines such as IL-4, IL-10 and IL-13. Comparing with pre-outbreak samples of 10 mpox patients living with HIV before mpox infection, confirmed an increase in BLC, IL18, and MIF during mpox disease. A higher number of lesions correlated positively with BLC and TSLP expression, and negatively with CCL2. Presence of proctitis was associated with an increase in CD30 and LIF. Presence of systemic symptoms or ongoing fever were associated with an overexpression of IL2R, LIF, and CXCL11 and suppression of CCL24. In addition to well-known differences in clinical manifestations, clade I and clade IIb MPXV infections evoke marked differences in blood CCG profiles. The absence of discriminatory CCG profiles in mpox patients suggests limited clinical applications.

7112

MODULATION OF THE SPP1 GENE BY CHIKUNGUNYA VIRUS INFECTION *IN VITRO* AND ITS POSSIBLE IMPLICATION IN INFLAMMATION AND DISEASE SEVERITY

Danillo Lucas Alves Esposito, Benedito Antonio Lopes da Fonseca

University of Sao Paulo, Ribeirao Preto, Brazil

The SPP1 gene is responsible for encoding the osteopontin protein, which has several natural functions in our body, such as bone remodeling, angiogenesis, and tumor migration, in addition to play a role in chronic inflammatory and autoimmune diseases. Furthermore, this protein may also act as a Th1 cytokine on the regulation of the immune response by T cells, contributing as an inhibitor of the anti-inflammatory cytokine IL-10 and increasing the Th1-mediated (pro-inflammatory) response. In this study, expression of the SPP1 gene in monocytes that were infected *in vitro* with the Chikungunya virus (CHIKV) was compared to CHIKV infection of another co-circulating alphavirus in Brazil, Mayaro virus. Although the diseases caused by these viruses bear a strong resemblance, Mayaro disease typically results in a milder clinical presentation than Chikungunya, with less frequent recurrence of joint inflammation. Our transcript analysis revealed that the expression of the SPP1 gene was approximately 12-fold higher at early times after Chikungunya virus infection when compared either to the Mayaro virus and uninfected cells. Later in the infection, SSP1 gene was also observed to be positively modulated, although the expression showed a progressive decrease at later hours post-infection. In the case of Mayaro virus infection there was no significant difference in the SPP1 expression when compared to uninfected cells. This increased gene expression correlated positively with the levels of inflammatory cytokines and chemokines, such as IL-6, IL-15, and eotaxin. Our findings suggest that interventions in the production and secretion of osteopontin could attenuate the inflammatory effects induced by the Chikungunya virus, thereby presenting a potential target for development of drugs that counteract osteopontin functions. Also, therapy strategies for the Chikungunya disease, such as CRISPR-Cas9 and RNAi methodologies, may target the SSP1 gene to reduce the severe chronic manifestations of this disease.

INFLUENCE OF COUNSELLING ON POSITIVE STATUS DISCLOSURE AND VIRAL SUPPRESSION AMONG PEOPLE LIVING WITH HIV IN GHANA

Miriam Mensah[1], **Sampson Kafui Djonor**[2], Kekeli Akosua Seanefu[3], Vincent Ganu[4], Peter Puplampu[4], Margaret M. Lartey[5], Peter Worlanyo Abomah[6], Gladstone Agbakpe[6]

[1]Korle-Bu Teaching Hospital, Accra, Ghana, [2]Korle-Bu Teaching Hospital /University of Ghana, Accra, Ghana, [3]Laboratory Department, Faith Mission Hospital, CHAG, Accra, Ghana, [4]Infectious Disease Centre, Korle-Bu Teaching Hospital, Accra, Ghana, [5]Department of Medicine and Therapeutics, University of Ghana Medical School, Accra, Ghana, [6]Psychology Department, Methodist University, Accra, Ghana

Counselling is a key gateway to major HIV/AIDS services. Silence on HIV positivity non-disclosure remains dire, encouraging increase disease transmission and death. This study assessed the influence of counselling on HIV positive status disclosure and antiretroviral therapy (ART) adherence among people living with HIV (PLWHIV) at the Korle Bu Teaching Hospital (KBTH) in Ghana. The mixed-methods study design involved 423 participants. A semi-structured questionnaire with both close and open-ended questions was used to collect data from PLWHIV presenting at the Fevers Unit of KBTH. STATA 15.1 was used for data analysis. For open ended questions, thematic data analyses in Nvivo software were used to explore transcripts and appropriate themes generated. HIV positive status disclosure among the 49.3 ± 12.2years mean-aged population was 92.4%. Majority (61.5%) disclosed their status in the symptomatic phase of disease and disclosure to sexual partner was only 51.8%. Prevalence of HIV viral suppression (target not detected) was 52.2% with 68.4% high medication adherence. Having HIV pre-test counselling [aOR = 2.18, 95% CI 1.05 - 4.55, p=0.04] and age on ART (aOR = 0.94, 95% CI 0.89 - 1.00, p = 0.04) were associated with status disclosure. Not having HIV pre-test counselling (aOR = 2.17, 95% CI 1.28 - 3.67, p = 0.004), having enhancement counselling, rural residence, not having a partner/spouse as social support and not having assistance in taking medication were associated with increased odds of not having viral suppression. Qualitatively, counselling "educated", "encouraged", and "supported" ART adherence and status disclosure among PLWHIV, and gave them "hope" to cope with life. Status disclosure served as avenue for "financial assistance", "emotional support" and "reminders to take one's medication" towards attaining viral suppression. We found enough evidence to support the influence of counselling on HIV positive status disclosure, and the duo leading to ART and medication adherence - a call for their enhancement towards reduction of the disease transmission, and improving the quality of life of PLWHIV.

PERSISTENCE OF ANTI-YELLOW FEVER VIRUS IMMUNOGLOBULIN M ANTIBODIES POST-VACCINATION AND ITS REACTIVITY TO THE ENVELOPE DOMAIN III ANTIGEN OF THE YELLOW FEVER VIRUS

Elizabeth Berinyuy Nsai, Ngu Abanda
Centre Pasteur du Cameroon, Yaounde, Cameroon

Yellow fever (YF) is a vaccine-preventable, mosquito-borne viral infection endemic to tropical and subtropical parts of South America and Africa. In these parts, a live attenuated YF vaccine is routinely administered to children at 9-12months of age. If an infant vaccinee develops fever and jaundice years post-vaccination and anti-YF IgM antibodies are detected in their serum, it becomes unclear what these results represent. Does the IgM detection suggest a recent natural YF virus infection indicating vaccine failure or does it suggest the persistence of YF-IgM antibodies years post-vaccination? To better understand YF IgM sero-positivity post-vaccination, we tested archived sera from the ANRS 12225/12140-PEDIACAM study- a prospective observational cohort study of infants born alive to HIV+ and HIV- mothers enrolled from 3 hospitals in Cameroon. The infants were followed from birth to present and received the YF vaccine at 9-12months. To determine the presence and persistence of anti-YF IgM antibodies, we tested samples collected pre-vaccination, at 2-6months and 1-2years post-YF vaccination using the CDC YF IgM antibody capture 72hrs ELISA. We found that at 2-6months post-YF vaccination, 18/352(5.1%) of infants had anti-YF IgM antibodies while, 10/433(2.3%) of infants still had anti-YF IgM antibodies by 1-2years post-vaccination. Our results indicate that, YF IgM is rare by 6 months post-vaccination in infants who receive the YF vaccine at 9-12months. However, IgM persistence years post-YF vaccination could be observed in a minute proportion of infants. To further maximize the insight we could obtain from these samples, we assessed and compared the reactivity of YF IgM-positive vaccinee sera and YF natural infection sera to 3 recombinant YF antigens (Envelope protein, Envelope Domain III protein (EDIII), non-structural protein 1) using the multiplex immunoassay which makes use of antigen-coupled beads. The IgM antibodies from both sera groups exhibited stronger reactions to the YFV DIII envelope protein compared to other proteins, hence could serve as a more specific and sensitive marker for detecting IgM in both cases.

7115

AEDES AEGYPTI MOSQUITO SALIVA INHIBITS HUMAN T CELL PROLIFERATION: IMPLICATIONS FOR ARBOVIRAL DISEASE OUTCOME?

Laura Willen[1], Kristina Tang[1], Sreynik Nhek[2], Claudio Meneses[1], Christina Yek[2], Jessica Manning[1], Fabiano Oliveira[1]
[1]National Institutes of Health, Rockville, MD, United States, [2]International Center of Excellence in Research, NIAID, Phnom Penh, Cambodia

Dengue fever is one of the most rapidly spreading mosquito-borne viral diseases in the world and is caused by the bite of an infectious *Aedes* mosquito. To facilitate the blood feeding process, the mosquito salivates into the host skin, releasing several compounds known to limit host vasoconstriction, inhibit coagulation processes, and suppress pain receptors. Previous murine studies showed saliva of *Ae. aegypti* to be implicated in enhanced viral dissemination and increased pathogenesis of viral infections, while epidemiological studies have suggested a protective role for anti-*Ae. aegypti* saliva antibodies against symptomatic dengue. Here, we investigate the response of human peripheral blood mononuclear cells (PBMCs) to *Aedes* saliva, to better understand how anti-saliva immune responses influence dengue disease outcome. Preincubation of human PBMCs with salivary proteins of *Aedes* for three hours prior to being stimulated with Concanavalin A, a lymphocyte mitogen, inhibited CD3+ T cell proliferation by 30.8% and reduced IFN-γ and IL-2 secretion by 42.5% and 93.4%, respectively. Repeating this experiment with either denatured (30min at 70ºC) or digested (proteinase K) salivary proteins, abrogated the phenotype (7.1 and 3.6% inhibition of proliferation; 2.95% and 0% reduced IFN-γ secretion; and 41.6% and 14.2% reduced IL-2 secretion, respectively), supporting the hypothesis that saliva has a direct effect on T cell proliferation. Ongoing experiments using a SARS-CoV-2 peptide pool as stimulus on PBMCs of individuals with confirmed high neutralization titers against SARS-CoV-2, will elucidate whether saliva inhibits antigen-specific T cell proliferation. This is the first time that *Aedes* saliva is shown to have an inhibitory effect on human lymphocytes. Future mechanistic studies will uncover the implicated salivary components and potential differences between highly *Aedes* exposed vs. unexposed individuals. We aim to test if anti-saliva antibodies neutralize this saliva-induced inhibition, which will help characterize whether host differences in immune inhibition are associated with dengue disease outcome.

7116

HUMORAL IMMUNITY FOLLOWING VACCINATION IS SUFFICIENT TO PROTECT AGAINST RIFT VALLEY FEVER VIRUS ENCEPHALITIS

Karina Mueller Brown, Dominique J. Barbeau, Anita K. McElroy
University of Pittsburgh, Pittsburgh, PA, United States

Prevalent in Africa and the Arabian Peninsula, Rift Valley fever virus (RVFV) is a mosquito-borne virus that infects humans and livestock. In humans, RVFV infection typically presents as a self-limiting febrile illness. However, in a subset of individuals severe complications such as hepatitis, retinitis, encephalitis, or death can occur. While there are no RVFV vaccines currently licensed for human use, previous work using promising live attenuated vaccine candidates demonstrated that humoral immunity was sufficient to confer vaccine-mediated protection from lethal *hepatic* disease in C57/BL6 mice. Here, we investigated whether vaccination was effective in preventing lethal *central nervous system* (CNS) disease. Unlike traditional inbred mice such as C57BL6, CC057/Unc mice develop uniform late-onset encephalitis between 8 to 12 days post infection (dpi) when challenged with wild-type (WT) RVFV by foot pad injection. Attenuated RVFV vaccine candidates (DelNSsRVFV and DelNSs/DelNSmRVFV) were safe and immunogenic in CC057/Unc mice. Vaccinated mice also survived subsequent WT RVFV challenge and were fully protected from CNS disease. Furthermore, naïve mice that received passive transfer (PT) of serum from vaccinated animals 2 days post WT challenge were also protected against late-onset encephalitis, indicating that humoral immunity is sufficient for protection against RVFV encephalitis. Notably, protection through humoral immunity was dependent on PT dose and timing of PT administration. A decline in animal survival was observed when PT was administered 2 dpi at lower doses or when PT was given on days 3 to 6 post WT challenge. Overall, these data demonstrate that humoral immunity following vaccination is sufficient to protect against RVFV encephalitis and highlight the utility of attenuated RVFV vaccines in preventing diverse disease manifestations.

7117

DEFINING INNATE IMMUNE MEDIATORS REQUIRED FOR THE EFFECTIVE RIFT VALLEY FEVER VIRUS ANTIVIRAL RESPONSE

Tracey Freeman, Dominique J. Barbeau, Anita K. McElroy
University of Pittsburgh, Pittsburgh, PA, United States

Rift Valley fever virus (RVFV) is an arthropod-transmitted virus affecting humans and ruminants. RVFV infection most frequently manifests as an acute self-limiting disease, but in a subset of cases involves severe manifestations including hepatitis, encephalitis, and/or hemorrhagic fever. The determinants of infection severity are largely unknown. The NSs protein of RVFV is a critical mediator of virulence and is thought to exert its effects through antagonizing the host interferon response, suggesting a key role for innate immunity in controlling RVFV infection. When mice are infected with strains of RVFV that are deleted for the NSs protein they do not develop clinical illness; in contrast, 100% lethal hepatitis is observed in mice infected with WT RVFV. To evaluate the role of specific innate immune sensors and signaling mediators in modulating in vivo RVFV pathogenesis, we infected various immune mediator knockout mice with strains of RVFV that are deleted for the NSs gene. These attenuated NSs-deleted strains

were lethal in MAVS, STAT1, and IFNAR knockout mice. No lethality was observed in TLR3, TLR7, MyD88, TRIF, NLRP3, or TNF knockout strains, suggesting unique functions of MAVS, STAT1, and IFNAR in the RVFV antiviral response. Future investigations will aim to elucidate the contribution of hematopoietic versus stromal compartments of these innate immune mediators in protection from RVFV hepatitis.

IDENTIFICATION OF EPITOPE-SPECIFIC T CELL RESPONSES TO LASSA BY GENOME-WIDE ANTIGEN SCREENING AND CONSERVATION ACROSS ARENAVIRIDAE

YeJi Lee, Alessandro Sette, **Alba Grifoni**

La Jolla Institute for Immunology, La Jolla, CA, United States

CD4 and CD8 T cells play a key role in clearing Arenaviridae infections, even before the appearance of neutralizing antibodies. Thus, while vaccine strategies that would generate a rapid and durable neutralizing antibody response are desirable, a vaccine also inducing a rapid and durable T cell response would be of significant interest, especially if the T cell response could broadly target different viral species and isolates. Studies performed on Lassa survivors also show a robust and durable T cell response able to cross-recognize different Lassa lineages. Human data is however limited, and most studies so far focused on specific domains or immunodominant epitopes for GPC and NP. We have initiated a systematic study of all Lassa proteins (including GPC, N and L proteins), in terms of which epitopes are immunogenic in humans using a de-novo in-vitro stimulation approach. This approach will also determine the degree of conservation of Lassa human epitopes in other viruses of the Arenaviridae family (Old World and New World arenaviruses alike) Our approach re-reidentified epitopes previously shown in convalescent Lassa human samples and greatly expand the immunogenic regions induced by this virus in GPC, N and L proteins and identify several immunogenic and conserved regions, thus allowing to assess the feasibility of a panArenaviridae vaccine approach.

7119

FILOVIRUS VIRUS GLYCOPROTEIN - EPITOPE MAPPING, AND PSEUDOTYPING

Edgar Davidson[1], Sonya M. Jacobsen[1], Philipp A. Ilinykh[2], Alexander Bukreyev[2], James E. Crowe Jr.[3], Benjamin J. Doranz[1]

[1]Integral Molecular, Inc., Philadelphia, PA, United States, [2]University of Texas Medical Branch, Galveston, TX, United States, [3]Vanderbilt University, Nashville, TN, United States

Recent disease outbreaks highlight the need to characterize the immune response to filoviruses to develop vaccines and therapies. We have used extensive GP mutation libraries to map the epitopes for >200 monoclonal antibodies (MAbs) targeting the EBOV surface glycoprotein, GP. We have extended these studies to Marburg virus (MARV) by generating an Ala-scan library of MARV Δmucin GP (Uganda strain). Initial maps of anti-MARV MAbs include those of two non-neutralizing MAbs MR228 and MR235, targeting the wing region of MARV GP, that showed therapeutic protection in animal models (MR228) or that increased binding (MR235) by neutralizing MAbs. The variety of EBOV MAbs mapped, many from survivors of ebolavirus infection, include cross-neutralizing MAbs targeting the GP membrane-proximal external region (MPER); a broadly cross-reactive MAb that blocks GP interaction with its endosomal receptor Niemann-Pick C1; and MAbs who synergistically transform a non-neutralizing MAb into a potent neutralizer. The epitope maps have expanded our understanding of how the immune system recognizes EBOV GP, and allow correlation of epitopes with MAb neutralizing capabilities, to develop anti-EBOV therapeutics and vaccines. Mapping also identified mutations that increase the exposure of neutralizing epitopes, impacting future anti-ebolavirus vaccine strategies. To provide critical reagents for analyses of antibody or serum immune responses to ebolaviruses, we have developed a pseudotyped lentiviral reporter virus (RVP) system for EBOV and MARV, expressing bearing the appropriate viral GP. These replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout.

INHIBITORY EFFECTS OF PLANT-DERIVED COMPOUNDS ON ROTAVIRUS PATHOGENESIS

Redeemer Gyimah Asamoah

Noguchi Memorial Institute for Medical Research, Legon, Accra, Ghana

Acute diarrhea due to Rotaviruses remains a public health concern among newborns worldwide. Despite efforts to develop efficacious vaccines, the morbidity and mortality associated with rotavirus infections persist and this has necessitated the need for alternative therapeutic options. This study sought to investigate the inhibitory effects of specific terpenoids on rotavirus replication, with the goal of identifying potential candidates for antiviral therapy. Rotavirus infections manifest as acute gastroenteritis, characterized by symptoms such as fever, vomiting, abdominal pain, diarrhea, and dehydration, posing significant challenges to healthcare systems globally. Rotavirus infections represent a formidable challenge in pediatric healthcare, particularly in resource-limited settings where access to medical care and sanitation infrastructure may be limited. The burden of rotavirus-associated morbidity and mortality underscores the urgency of advancing strategies for prevention and treatment. Natural compounds such as Terpenoids provides a therapeutic alternative and presents an appealing avenue for the development of novel antiviral therapies. Fresh samples of avocado and guava leaves were assessed for their antiviral activity with crude extracts compared for their efficacy. Phytochemical analysis confirmed the presence of active compounds in both leaf extracts with the former exhibiting the highest inhibition percentage. This study provides compelling evidence for the potential utility of plant-derived phytochemicals as a source of pharmacologically active compounds. The superior inhibitory activity of Avocado leaf extract against rotavirus underscores its promise as a candidate for further investigation in the development of novel antiviral therapies.

7121

THE ARYL HYDROCARBON RECEPTOR/AXL PATHWAY AT THE CROSSROADS BETWEEN POLLUTION AND VIRAL INFECTIONS

Miguel A. Pelaez[1], Maria F. Torti[1], Carla Tomatis[2], Eugenio A. Carrera Silva[2], Cybele C. Garcia[1]

[1]Departamento de Química Biológica, Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina, [2]Instituto de Medicina Experimental, Academia Nacional de Medicina-CONICET, Ciudad Autónoma de Buenos Aires, Argentina

There is still a big gap in our knowledge regarding the molecular mechanism by which anthropogenic pollutants contribute to pathogenesis. Our laboratory has recently published data proving that the aryl hydrocarbon receptor (AHR), a ligand activated transcription factor that acts as an environmental sensor of xenobiotic chemicals, has a pro-viral role during infections with dengue (DENV), Zika (ZIKV), Junín (JUNV) and coronaviruses. AHR can regulate the expression of numerous genes, including some involved in the antiviral cellular response. In this work we aim to study the effect of AHR pharmacological modulation on Axl, a member of the TAM receptor family of proteins. Axl is a well-known entry co-receptor for different viruses and in vivo studies have shown that its expression is altered in rats exposed to secondhand smoke. We hypothesize that an AHR/Axl pathway plays a key role during viral infections. To study the effect of AHR modulation on Axl transcript and protein levels we pre-treated A549 cells with AHR endogenous agonist (L-Kynurenine) or with an AHR antagonist (CH223191) and then carried out the infection with DENV-2. We observed a 4-fold change increase and a 0.6-fold change decrease in Axl transcript levels respectively, measured by RT-qPCR. In concordance, we observed a 17% increase in Axl protein levels measured by flow cytometry in kynurenine-treated and infected cell cultures relative to the untreated

infected control. Finally, we carried out plaque forming unit assays to determine the effect of Axl modulation on the related arboviruses DENV-2 and ZIKV and the unrelated JUNV arenavirus replication. To do this, we pretreated A549 and Huh-7 cell cultures with a specific Axl inhibitor (R428) for 3 hours prior to infection. We observed a significant inhibition of viral replication, following a dose dependent response. Furthermore, we treated cell cultures with Gas-6, an Axl activating ligand, and observed a dose-dependent increase in viral titers. In conclusion, this work proposes an AHR/Axl pathway with a key role during viral replication and highlights the relevance of these pollutant receptors during viral infections.

SARS-COV-2 MAIN PROTEASE: MOLECULAR DYNAMIC STIMULATION WITH COMPOUNDS FROM AFRICAN NATURAL PRODUCTS

Diabate Oudou[1], Cheickna Cisse[2], Jeffrey G Shaffer[3], Abdoulaye Diawara[1], Mamadou Wele[1], Seydou Doumbia[4], Opeyemi Soremekun[5], Segun Fatumo[6]

[1]African Centre of Excellence in Bioinformatics (ACE-B), University of Sciences, Technics and Technologies of Bamako (USTTB), Mali, Bamako, Mali, [2]University of Sciences, Technics and Technologies of Bamako (USTTB), Mali, Bamako, Mali, [3]Department of Biostatistics and Data Science, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, USA, New Orleans, NY, United States, [4]University of Clinical Research Center (UCRC), University of Sciences, Technics and Technologies of Bamako (USTTB), Mali, Bamako, Mali, [5]The African Computational Genomics (TACG) Research group, MRC/UVRI and LSHTM, Entebbe, Uganda, Entebbe, Uganda, [6]Department of Non-communicable Disease Epidemiology (NCDE), London School of Hygiene and Tropical Medicine London, UK, UK, United Kingdom

The fast growth of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is causing a major threat to global public health, requiring the most urgent research for potential therapeutic agents. New targeted drugs are necessary to address the problem of resistance. The use of molecular dynamics (MD) simulations allows us to investigate the conformational details of biological systems as well as the interactions between proteins and ligands. In this work, we use molecular dynamic stimulation to validate some compounds from African Natural Products databases which have shown high affinity score with the main protease of SARS-CoV-2 by virtual screening. **Results:**Gypsogenic acid and Maslinic acid have revealed to have a high affinity with the main protease of SARS-CoV-2 by molecular dynamic analysis. Among the seven compounds used, two were shown very strong affinity for the SARS-CoV-2 main protease and those compounds are more likely to have anti-SARS-CoV-2 activities.

7123

PROMISING EFFECT OF SILYMARIN IN AN ANIMAL MODEL OF ARTHRITIS AND MYOSITIS INDUCED BY ALPHAVIRUS MAYARO AND CHIKUNGUNYA VIRUSES

Rafaela Lameira Souza Lima[1], Ariane Coelho Ferraz[1], Marília Bueno da Silva Menegatto[1], Maria Eduarda Diniz Starling[1], Oluwashola Samuel Olaolu[1], José Carlos de Magalhães[2], **Cintia Lopes de Brito Magalhães**[1]

[1]Federal University of Ouro Preto, Ouro Preto, Brazil, [2]Federal University of São João del Rey, Ouro Branco, Brazil

Mayaro virus (MAYV) and Chikungunya virus (CHIKV) are both members of the *Togaviridae* family causing similar diseases such as severe joint/muscle pain and fever. Our research group is focused on investigating factors contributing to the pathogenesis of MAYV and CHIKV, as well as identifying natural substances with potential antiviral activity. In a recent study, we demonstrated that silymarin, a complex of antioxidants obtained from *Silybum marianum*, exhibited antiviral activity against MAYV in cells. Subsequently, in animal model, we observed that silymarin displayed outstanding hepatoprotective, antioxidant, anti-inflammatory, and antiviral properties in liver of infected animals. Given that joint and muscle pain are prominent symptoms in Mayaro and Chikungunya fevers and that literature shows a potent antiviral activity of silymarin against these viruses, this study aims to evaluate in an animal model of arthritis and myositis induced by MAYV and CHIKV whether silymarin can reverse the damage to joints and muscles post-infection. To achieve this, 6-week-old BALB/c mice were infected with MAYV or CHIKV in the right hind paw pad (10^6 PFU) and the treated groups received 100 mg/kg/day of silymarin every 12 hours by gavage. Preliminary results from infected animals showed paw edema and inflammation, both of which were reduced in animals treated with silymarin. Euthanasia was performed on 7- and 12-days post-infection (dpi), and various organs/tissues including liver, spleen, brain, footpad, quadriceps, tibial, soleus, and extensor digitorum muscles were collected. CHIKV presence was assessed by qRT-PCR; in the quadriceps, tibial, and extensor digitorum muscles, no virus was detected in any of the groups. However, in the infected group that received silymarin, viral load was reduced in the liver, spleen, brain, and footpad at 7dpi, and in the liver, spleen, brain and soleous at 12dpi. The qRT-PCR results for MAYV are currently undergoing processing by our study group. These findings support further investigation into the potential benefits of silymarin in treating MAYV and CHIKV infections.

7124

DISCOVERY OF NOVEL HENIPAVIRUS INHIBITORS

Judith Straimer[1], James R. Manning[1], Johanna Jansen[1], Richard T. Eastman[1], Ryan Chan[1], Fred King[1], Yvonne Wang[1], Ahmed Rohaim[1], Tiffany Tsang[1], Colin Deniston[1], Cosmo Buffalo[1], Darlene Chen[1], Atul Sathe[1], Shreeya Hegde[1], Jeanne Dudley[1], Debapriya Sengupta[1], Zhenhang Chen[2], Alka Jays[3], Moushimi Amaya[3], Rachel O'Toole[4], Olivier Escaffre[4], Robert Cross[4], Bo Liang[2], Alexander Freiberg[4], Christopher Broder[3], Thomas Geisbert[4], Nadine Jarrousse[1]

[1]Novartis Biomedical Research, Emeryville, CA, United States, [2]Emory University, Atlanta, GA, United States, [3]Uniformed Services University, Bethesda, MD, United States, [4]The University of Texas Medical Branch, Galveston, TX, United States

The prototype species of henipaviruses, Hendra virus (HeV) and Nipah virus (NiV), are zoonotic, negative sense, single stranded RNA paramyxoviruses capable of infecting at least 18 species across seven orders of animals and are considered a serious pandemic risk by the CDC. Following an incubation period of 5-14 days, NiV infection in people will often present as a severe respiratory, vascular, and neurological disease. Outbreaks of NiV, in Bangladesh and Malaysia have led to high rates of human mortality (40->90%) with significant morbidity in survivors. Transmission of infection to people can be through contact with natural hosts (*Pteropus* fruit bats), excreta-contaminated food, or infected virus-shedding livestock or people. There are no currently approved vaccines or therapeutics to prevent or treat NiV or HeV infection for human use. Work with authentic NiV requires BSL-4 containment which represents a substantial challenge to drug discovery efforts. Here we report the successful application of recombinant Cedar henipavirus encoding nano-Luciferase (rCedV-nanoLuc), a BSL-2 approved surrogate system, to screen for compounds that inhibit NiV and HeV replication. We screened 1.7 million compounds and processed hits through a hit-finding flow chart which includes secondary assays such as a novel BSL-2 NiV minigenome reporter and a biochemical assay probing the polymerase activity of the NiV L-protein. Several counter-screens were also included to filter out hits that prevent viral replication through inhibition of host cell roles. Compounds that passed all filters were subsequently tested for inhibitory activity against authentic NiV. Finally, in order to further accelerate henipavirus antiviral drug discovery and enable structure-based approaches, we solved the cryo-EM structure of the L polymerase in complex with the P protein. Here, we present a comprehensive approach that uses a combination of cell-based NiV surrogate systems, high throughput biochemical assays and structural biology analyses to identify new direct-acting antiviral candidates for the treatment of highly pathogenic henipaviruses.

7125

ASSAY DEVELOPMENT OF FLAVIVIRUSES CELL-BASED LUCIFERASE REPORTER SYSTEM TO ENABLE HIGH THROUGHPUT DRUG DISCOVERY

Katherine Chan, Darlene Chen, Daniela Barriga, Yen-Liang Chen, Rich Eastman, Manjunatha Ujjini

Novartis Global Health, Biomedical Research, Emeryville, CA, United States

There is an urgent need for antiviral therapies against flaviviruses. More than 1 billion people are at risk and disease burden is rapidly rising due to climate change. To prepare for future pandemics, the flavivirus program within UTMB-Novartis Alliance for Pandemic Preparedness (UNAPP) was established to find broad spectrum inhibitors targeting RNA-dependent RNA polymerase (RdRp), protease and NS4B. We have developed and validated high throughput cell-based assay on an automation platform to screen and prioritize compounds for Structure Activity Relationship (SAR) optimization enabling novel drug discovery. Using various *in vitro* transcribed recombinant stable nanoluciferase flaviviruses (Dengue, Zika, YF and JEV), >1500 compounds were tested in duplicates. The protocol was optimized for MOI, signal window and robustness in 384-well format, with robust Z' score of >0.5 for all flaviviruses. Viral replication was measured at 3dpi via luminescence readout. A chain-terminator adenosine analogue, a potent RdRP inhibitor, was used as active control, showing consistent activity and robust correlation with historical high-content image-based data. We have optimized the assay on an integrated automated screening platform in a BSL2 enclosure with robotic arms enabling movement of 384-well plates between various pieces of equipment, improving assay quality, reproducibility and throughput. The transfer of compound into an infected assay plate was possible using an acoustic liquid handler. With the current capacity to test 90 compounds per week in concentration-response in all 4 dengue serotypes, we enabled compound optimization towards increased pan-serotype activity with minimal cytotoxicity for our second-generation dengue NS4B project. In addition, similar cellular nanoluciferase assays were developed for Zika, YF and JEV to enable broad spectrum flavivirus profiling of protease and RdRP inhibitors. These established assays provide a critical opportunity to identify a novel broad-spectrum lead candidates that can be developed into a promising therapy, thereby alleviating the disease burden in future outbreaks.

7126

ESTABLISHMENT OF A BSL-2 NIPAH MINIGENOME SYSTEM FOR ANTIVIRAL DRUG DISCOVERY.

Shreeya S. Hegde, Darlene Chen, Atul Sathe, Judith Straimer, Srinivasa Rao, Nadine Jarrousse

Novartis Global Health, Biomedical Research, Emeryville, CA, United States

Nipah virus (NiV) is a deadly and highly contagious zoonotic virus that emerged first in Malaysia and has a high mortality rate of 40 to 75% with severe morbidity in survivors. Nipah virus consists of a negative sense RNA strand (18.2 kb) consisting of L protein, an RNA-dependent RNA polymerase which forms a complex with phosphoprotein P. This complex is encapsidated by nucleocapsid N proteins allowing for viral replication. Owing to its high pathogenicity, NiV is classified as a BSL-4 virus. To enable work in a BSL-2 set up, we developed a noninfectious Nipah minigenome system as a valuable tool to identify potential inhibitors of Nipah replication for drug development. Utilizing only the minimum essential genetic elements required for viral replication, our current transient system is a 5-plasmid system consisting of N, P and L proteins and a minigenome construct that contains the NiV specific leader and trailer sequences flanking a nanoluciferase reporter gene and a T7 promoter. A T7 polymerase-encoding plasmid is co-transfected to generate the negative strand RNA mini genome. We successfully established a 384 well-plate transient assay in human host cells measuring luciferase expression 48hrs post transfection along with a parallel cytotoxic assay. We observed an AC_{50} as reported in literature for the tool compound in our NiV minigenome assay. Using this assay, we assessed NiV specific activity of inhibitors that were identified in a recombinant Cedar virus high throughput screen. To enhance assay robustness and decrease variability, also we developed and characterized a novel cell line stably expressing NiV N, P and L proteins that can be used to screen for novel inhibitors and support structural activity relationship (SAR) studies for Nipah drug development.

7127

RAPID-RESPONSE RNA-FISH ASSAY PLATFORM FOR CORONAVIRUS ANTIVIRAL HIGH-THROUGHPUT SCREENING

Ryan Chan, Christian Shema Mugisha, Vorada Cheunchob, Richard T. Eastman, Erika Flannery, Stephanie Moquin, Nadine Jarrousse, Manjunatha Ujjini

Novartis Global Health, Biomedical Research, Emeryville, CA, United States

Over the past 25 years, the global community has faced the challenges posed by three distinct outbreaks of coronaviruses. The first of these outbreaks was the severe acute respiratory syndrome coronavirus (SARS-CoV) epidemic, which occurred from 2002 to 2004 and tragically resulted in over 700 deaths. Following this, the Middle East respiratory syndrome coronavirus (MERS-CoV) epidemic emerged in 2012, causing over 2600 infections with a case-fatality rate of 36%. More recently, the world has become severely impacted by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) of the COVID-19 pandemic, responsible for causing nearly 7 million deaths worldwide. It is crucial to note that the threat of further coronavirus outbreaks continues to be a significant concern, as evidenced by the recent identification of the novel canine coronavirus CCoV-HuPn-2018 in several patients with pneumonia in Malaysia. The threat of the ever-evolving nature of viral infections as well as the lingering health and socioeconomic effects of the recent SARS-CoV-2 pandemic emphasize the urgent need for advanced antiviral drug screening tools to strengthen preparedness and preventive measures against future outbreaks. Here, we present the development and validation of a novel RNA-fluorescence *in situ* hybridization (FISH) assay as a high-throughput rapid response platform for antiviral drug discovery. The flexibility of RNA-FISH probe sets allows for synthesis to for any RNA viral genome, enabling detection of any viral replication inhibition of compounds within cells. Screening of 170 antiviral compounds in concentration-response demonstrates a strong R^2 correlation between the results obtained from our RNA-FISH assay and an immunofluorescence assay (IFA) in both human coronaviruses OC43 and 229E. Additionally, we successfully applied this methodology in the context of CCoV 1-71, opening new avenues for the evaluation of antiviral drugs to future emerging threats.

7128

UNVEILING THE ANTIVIRAL POTENTIAL OF WEDELOLACTONE AGAINST THE OROPOUCHE VIRUS

Marielena Vogel Saivish[1], Rafaela dos S. Peinado[2], Gabriela de Lima Menezes[3], Roosevelt Alves da Silva[4], Umberto Laino Fulco[3], Carolina C. Pacca[5], Raphael J. Eberle[6], Mônika A. Coronado[6], Mauricio Lacerda Nogueira[1]

[1]Faculdade de Medicina de São José do Rio Preto / The University of Texas Medical Branch, São José do Rio Preto / Galveston - TX, Brazil, [2]São Paulo State University, São José do Rio Preto, Brazil, [3]Universidade Federal do Rio Grande do Norte, Natal, Brazil, [4]Universidade Federal de Jatai, Jatai, Brazil, [5]Fundação Oswlado Cruz - Instituto Rene Rachou, Belo Horizonte, Brazil, [6]Institute of Biological Information Processing IBI-7: Structural Biochemistry, Forschungszentrum Jülich, Jülich, Germany

Oropouche virus (OROV), belonging to the *Orthobunyavirus oropoucheense* specie and *Peribunyaviridae* family, induces dengue-like febrile illness transmitted by the midge *Culicoides paraensis* and some mosquito species. Despite its typically mild symptoms, it can lead to severe complications such as neurological symptoms. With diagnostic challenges, particularly in impoverished endemic regions, OROV poses a potential threat for new epidemics, akin to other arboviruses like Dengue, Yellow Fever, and Zika virus. Exploring natural molecules for antiviral properties offers a promising avenue for therapies with minimal or no side effects. Wedelolactone (WDL) has shown significant inhibitory effects on viral proteins and replication,

positioning it as a promising candidate across various viruses. Our study delves into WDL's antiviral activity against OROV. In Vero cells, WDL exhibited an EC_{50} value of 18.92 ± 9.4 μM under post-infection treatment condition, showcasing its inhibitory effect against OROV infection. Additionally, *in silico* analyses shed light on WDL's potential inhibitory action on the N-terminal polymerase of OROV, suggesting its effectiveness at multiple stages of viral infection in mammalian cells. These findings underscore WDL's potential as a promising inhibitor against OROV infection.

2-PYRIMIDONE COMPOUND SERIES PREVENTS ACUTE VIREMIA AND CHRONIC CHIKUNGUNYA VIRUS IN A MOUSE MODEL OF INFECTION

Zachary Streblow[1], Nicole Haese[1], Corinne Augelli-Szafran[2], Takeshi Ando[1], Michael Denton[1], Samuel Medica[1], Craig Kreklywich[1], Mark Heise[3], Thomas Morrison[4], Omar Moukha-Chafiq[2], Ashish Pathak[5], Daniel Streblow[1]

[1]Oregon Health and Science University, Beaverton, OR, United States, [2]Southern Research, Birmingham, AL, United States, [3]University of North Carolina School of Medicine, Chapel Hill, NC, United States, [4]University of Colorado School of Medicine, Aurora, CO, United States, [5]NIH/NIAID, Rockville, MD, United States

Alphaviruses are arthropod-transmitted RNA viruses, including the NIAID Category B priority pathogens Eastern equine encephalitis (EEEV), Venezuelan equine encephalitis (VEEV) and chikungunya (CHIKV) viruses. In November of 2023, the first chikungunya virus vaccine became FDA approved for use in individuals 18 years of age and older who are at increased risk of exposure to CHIKV, although no FDA-licensed antiviral therapeutics are available to treat alphavirus infection or disease, thus demonstrating a need in the field of public health. We identified a small molecule antiviral hit using a screen against CHIKV. Derivatives of the hit were made by medicinal chemistry, and we identified a first-in-class, orally available, non-nucleoside small molecule (SRI-42718) that targets a conserved region in nsP4-RdRp. The SRI-42718 chemical series blocks both gRNA and sgmRNA synthesis as well as viral protein production. The compound has shown no adverse toxicity in mice as repeat dosing at 40 mg/kg, TID, is a well-tolerated treatment for up to 10 days. *In vivo* PK analysis indicates that the compound has good bioavailability by oral delivery in mice and nonhuman primates, and the compound was distributed to several mouse tissues including joints and muscles. Importantly, oral administration of the compound prevents viremia at a dose of 40 mg/kg three times per day (TID) in acutely infected mice. Viral tissue burden and virus-induced foot/ankle swelling (tissue disease) are also significantly reduced in treated animals compared to vehicle controls. A seven-day treatment of mice beginning at 28 days post infection during the persistent phase reduced the viral RNA level in joint-associated tissue. Combined, our data indicate that SRI-42718 is capable of blocking CHIKV replication *in vivo* during both the acute and persistent phases, which increases the therapeutic potential for this compound. SRI-42718 promises to be an important preclinical candidate and the compound has entered early drug development studies.

IN VITRO ANTI-SARS-COV-2 ACTIVITY OF CPM01 HERBAL TINCTURE AND ITS FRACTIONS

Frederick Ayertey[1], James O. Aboagye[2], Sylvester Kaminta[2], Peter P. Wormenor[2], Araba Abaidoo-Myles[2], Christopher Z. Abana[2], Anthony T. Boateng[2], Prince A. Nartey[2], Charlotte B. Bortey[2], Dzidzor Attoh[2], Helena Lamptey[2], Evelyn Y. Bonney[2], Kofi Donkor[1], Alex Asaase[1], George B. Kyei[2]

[1]Centre for Plant Medicine Research, Mampong-Akwapem, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana

The recent COVID-19 pandemic posed a significant challenge to public health worldwide and continue to threaten many lives. While vaccines are instrumental in curbing the spread of the virus, the need for effective treatment remains crucial in managing severe cases and emerging variants. CPM01, an herbal tincture developed by the Centre for Plant Medicine Research in Ghana as an immunomodulatory agent has garnered attention for its clinical efficacy in alleviating COVID-19 symptoms and expediting patient recovery without complications. The study sought to evaluate the anti-SARS-CoV-2 activity of CPM01 and its partitioned fractions *in vitro* in Vero E6 TMPRSS2 cells. The effect of CPM01 and partitioned fractions on SARS-CoV-2-induced cytopathy and virus inhibition was determined by crystal violet staining and fluorescence assay targeting the ORF3a protein of the virus respectively. The phytochemical content of CPM01 and fractions were quantified by colorimetry. The findings indicate that CPM01 and its chloroform fraction exhibited remarkable efficacy in preventing virus-induced cytopathic effect with a minimum inhibitory concentration of 0.31 μg/ml. The hexane and ethyl acetate fractions displayed promising virus inhibition, with minimum concentrations of 1.20 and 20.00 μg/ml respectively. The effective concentrations required to inhibit 50% (EC_{50}) of viral ORF3a were 5.55, 5.20 and 6.22 μg/ml respectively for CPM01, chloroform and hexane fractions. The total phenolic content (TPC) of CPM01 was determined to be 9.006±1.075 mg/100 mg GAE, while the total flavonoid content (TFC) was found to be 16.741±1.386 mg/100 mg QE. Even though the ethyl acetate fraction showed the lowest inhibition, it had the highest TPC and TFC, implying the anti-SARS-CoV-2 activity of CPM01 may not be dependent on its phenolic content alone. The findings highlight CPM01 as a potent anti-SARS-CoV-2 candidate with promising therapeutic potentials against COVID-19. However, further research involving mechanistic investigations and clinical trials, is imperative to comprehensively understand its role in managing COVID-19 and its evolving variants.

7131

GENERATION OF ANTIVIRAL RECOMBINANT PROTEINS TO OVERCOME MOSQUITO-BORNE VIRUS INFECTION

Erin Markle[1], Anak Agung Dew Megawati[1], Michelle Azuma[1], Alexander Franz[2], Loubna Tazi[1], Gregory Brennan[1], Stefan Rothenburg[1]

[1]University of California, Davis, Davis, CA, United States, [2]University of Missouri, Columbia, Columbia, MO, United States

Mosquito-borne virus infections impact more than 400 million people annually. With limited therapeutics available, the main control mechanism is vector control, however mosquitoes have become resistant to some insecticides. Other mechanisms to control arbovirus transmission include transgenic mosquitoes; however, the current methods are virus-specific or mosquito population replacement with lethal genes. Both control methods are insufficient because they are not broadly active against multiple viruses or long-lasting due to the ability for mosquito populations to rebound. Thus, alternative strategies that are broadly acting against multiple arbovirus families are needed. Host restriction factors are a large category of antiviral immune proteins, some of which can inhibit multiple virus families. For example, PKR and RNase L antiviral pathways are both activated by double stranded RNA (dsRNA), which is produced during the replication cycle of most viruses. However, viruses have evolved multiple strategies to evade these pathways to promote productive infection. To obtain broad antiviral activity, we generated recombinant enhanced antiviral restrictor (REAVRs) proteins containing the virus-sensing domains of PKR fused with the effector domains of RNase L. REAVRs showed high antiviral activity against dengue, Zika, and chikungunya virus when stably expressed in mammalian cells. Transgenic REAVR-expressing mosquitoes showed strong resistance against Zika virus infection and reduced virus dissemination. To improve efficacy of REAVRs, we have constructed a second generation of REAVRs with different vertebrate RNase L sensor domains and replacing PKR double-stranded (ds) RNA-binding domain with other sensor domains to further increase the breadth of viral families inhibited by REAVRs. We are currently characterizing the antiviral activities of these new REAVRs against a panel of arboviruses.

7132

USE OF AN INSECT CELL EXPRESSION PLATFORM FOR THE PRODUCTION OF NIPAH AND CRIMEAN-CONGO HEMORRHAGIC FEVER VIRAL FUSION, GLYCO-, AND NUCLEOPROTEINS

Isabelle E. Y. Eiser[1], Albert To[1], Lisa Hensley[2], Axel Lehrer[1]
[1]University of Hawaii, Honolulu, HI, United States, [2]Zoonotic and Emerging Disease Research Unit, National Bio and Agro-Defense Facility, USDA Agricultural Research Service (ARS), Manhattan, KS, United States

Development of recombinant production methods characteristic antigens of priority pathogens, such as Nipah Virus (NiV) and Crimean-Congo Hemorrhagic Fever Virus (CCHFV), are critical for public and global health research. Recombinant proteins have numerous research and biopharmaceutical applications including the use in surveillance of potential outbreaks, studying immunological responses to infection, and the development of vaccines and serological assays. NiV has caused over 600 human infections between 1998 and 2023 in Singapore, Malaysia, Bangladesh, and India with case fatality rates up to 70%. CCHFV has resulted in over 450 human cases since its identification in the mid 1900s, throughout Africa and Southeast Asia overlapping with NiV endemic countries, CCHFV has case fatality rates between 5% and 30%. Currently, it is suspected that cases of CCHFV are largely underreported with several epidemiological studies showing a seroprevalence around 11% in endemic countries. This underreporting can be due to the lack of affordable multianalyte assays available in these areas. There is an urgent need to develop more cost-effective multianalyte serological assays to assess human and animal seropositivity to NiV and CCHFV. High quality recombinant protein production using a scalable *Drosophila* S2 expression system and affinity purification offers an avenue for the development of affordable multiplex immunoassays in both high and low resource settings. Here we present first results of the production of NiV (pre)fusion (pf/F), attachment (G), and nucleocapsid (N) proteins as well as CCHFV receptor recognition glycoprotein (Gc and Gn) and nucleocapsid (N) proteins using our proprietary expression vector and *Drosophila* S2 cells. Recombinant proteins were purified using metal ion affinity chromatography. This research allows for production of antigens to be further used in the development of multiplex serological assays. These can then be used to better understand the prevalence of infection in humans and livestock in endemic and co-endemic areas of NiV and CCHFV, as well as other priority pathogens.

7133

INITIAL CLINICAL CHARACTERIZATION OF EGT710, A NOVEL CORONAVIRUS MPRO INHIBITOR, FOLLOWING ORAL ADMINISTRATION TO HEALTHY ADULTS

Jonathan Trolander[1], Fernanda Duraes[2], Begum Alaybeyoglu[1], Kamal Kumar Balavenkatraman[1], Lidiya Bebrevska[3], Renee Bergeron[4], Sakshi Bhardwaj[3], Frederique Chaperon[3], Suzanne Gaudet[1], Swati Aashish Ghanshani[5], Elisabete Goncalves[3], Feng Gu[6], Stephanie Moquin[6], **Steven J. Kovacs**[4]
[1]Novartis, Cambridge, MA, United States, [2]Nouscom AG, Basel, Switzerland, [3]Novartis, Basel, Switzerland, [4]Novartis, East Hanover, NJ, United States, [5]Novartis, Mumbai, India, [6]Novartis, Emeryville, CA, United States

EGT710 is a low molecular weight inhibitor of the coronavirus main protease (Mpro). It has activity against 8 coronavirus genera Mpro enzymes and potent cellular activity against SARS-CoV-2 variants. It has also shown efficacy in vivo in a mouse infection model. The safety, tolerability, and pharmacokinetics of EGT710 were investigated in a randomized (3:1), blinded, placebo-controlled study of healthy adults at a single center using a conventional single and multiple ascending dose design. Each cohort was 8 study participants (6 receiving EGT710; 2 receiving placebo). A relative bioavailability and food effect study were also included to evaluate the performance of a capsule and liquid (suspension) formulation in a separate cohort of 18 study participants using a Williams crossover design. A total of 70 received EGT710 and 18 received placebo across all parts of the study. Single doses up to 1100 mg and multiple doses up to 700 mg once daily for 7 days were safe and well tolerated. The most common adverse events involved general disorders and administration site conditions, none of which was considered related to the study treatment. There were no evident dose-dependent or dose-limiting adverse effects. Systemic exposure increased with dose. The two formulations showed comparable bioavailability. Administration of the suspension formulation with food modestly increased exposure to EGT710 and delayed the Cmax, suggesting EGT710 may be taken with or without food. The dose range investigated included therapeutic and supratherapeutic exposures, thus generating sufficient data to support dose and regimen selection for subsequent investigations of clinical efficacy in patients with acute coronavirus disease (using established antiviral PK/PD relationships). The data support once or twice daily administration of EGT710 without the need for a pharmacokinetic booster (e.g., ritonavir). The results support continued development of EGT710 as a treatment for coronavirus disease. The liquid formulation provides a unique option for patients who are unable to swallow or have difficulty swallowing.

7134

INVESTIGATION OF ANTIVIRAL ACTIVITY OF MEK INHIBITORS AGAINST YELLOW FEVER VIRUS USING IN VIVO MODEL

Ana Luisa C. Cruz[1], Natália L. Pessoa[1], Nidia E.C Arias[1], Samantha S F M Viegas[1], Anna Catarina D.S. Guimarães[1], Olindo A. Martins-Filho[2], Andréa Teixeira-Carvalho[2], Angelle Desiree LaBeaud[3], Claudio Antonio Bonjardim[1], **Betânia P. Drumond**[4]
[1]Federal University of Minas Gerais, Belo Horizonte, Brazil, [2]FIOCRUZ, Belo Horizonte, Brazil, [3]University of Stanford, Palo Alto, CA, United States, [4]BETANIA PAIVA DRUMOND, Belo Horizonte, Brazil

Yellow fever virus (YFV) causes an acute viral hemorrhagic disease, varying from very mild infection to severe and life-threatening illness, with mortality rate of 20-50%. YFV is endemic in tropical areas of Africa, and Central and South America, with massive outbreaks causing thousands of deaths in recent years, showing that YFV is still a serious public health concern despite the vaccination. To date there is still no specific antiviral treatment for YF. Here, we established the lethal dose (LD) of wild type YFV_BR_2018, a new YFV lineage, in knockout mice for interferon type 1 receptor (IFNAR $1^{-/-}$), and evaluated the potential activity of Selumetinib and Trametinib using this in vivo model. Four-weeks-old male and female C57BL/6 IFNAR$1^{-/-}$ mice were infected with 1.6 x 10^3 to 5.75 x 10^3 PFU of YFV_BR_2018, and monitored for 14 days. Mice infected with the higher dose had survival rates of 60% (females) and 40% (males). They clinical signs, as piloerection, hunched back, conjunctivitis, edema, paralysis, tremors, or penis inflammation. Infectious particles were found in the testicles of convalescent males. The deaths occurred between 8 and 11 days post infection. Then, 4- weeks-old male and female C57BL/6 IFNAR$1^{-/-}$ mice were infected with YFV_BR_2018 and treated with Selumetinib (50 mg/kg/day) or Trametinib (3 mg/kg/day) for 8 days. Neither Selumetinib nor Trametinib showed protection against mortality. It was possible to establish an infection model for the wild YFV_BR_2018 strain, with a mortality rate close to 50%. Although, antiviral effect against orthoflaviviruses have been shown for Selumetinib and Trametinib preliminary results do not indicate antiviral effect of tested inhibitors against YFV, based on mortality rate. Further analyses will be performed to address the effect of treatment on experimentally infected mice.

7135

EX VIVO ANALYSIS OF AN IL2/ANTI-IL2 COMPLEX FOR THE TREATMENT OF CHRONIC CHIKUNGUNYA ARTHRITIS IN A COLOMBIAN COHORT

Sarah R. Tritsch, Jose Forero Mejia, Alfonso Sucerquia Hernández, Christopher N. Mores, Aileen Y. Chang
George Washington University, WASHINGTON, DC, United States

Chikungunya virus (CHIKV) is an alphavirus that causes chronic arthritis in one-fourth of patients. No standard treatments exist for CHIKV chronic

arthritis. Our Colombian cohort is the largest longitudinally followed CHIKV patient cohort in the Americas. Immune analysis from this cohort revealed that low IL2 during acute infection predicted chronic joint pain. Chronic CHIKV arthritis is associated with altered gene pathways in regulatory T cell (Treg) function, decreased interleukin (IL)-2 production, and CD4+ effector T cell (Teff) synovial infiltration. Novel low-dose IL2 therapies preferentially activate Treg IL2 receptors with no apparent side effects reported in rheumatoid arthritis patients who received this treatment. Our previous studies in a CHIKV arthritis mouse model demonstrated that treatment with a complex containing low-dose IL2 and anti-IL2 monoclonal antibody (mAb) expanded and activated Tregs more than IL2 or the IL2 mAb alone, but also expanded Teffs and did not impact tarsal joint inflammation. The IL2 mAb alone amplified activated Tregs, increased expression of Treg suppression marker FoxP3, and improved histologic markers of inflammation, perhaps by augmenting the activity of endogenous IL2. To understand the mechanism of these IL2-related therapies in human CHIKV arthritis, PBMCs collected from our Colombian cohort of chronic CHIKV arthritis patients and a small group of healthy Colombian volunteers will be exposed to low doses of IL2 or the IL2/anti-IL2 mAb complex for 5 days. Flow cytometry of Treg populations, functional Treg suppression assays, and cytokine analysis will then be performed. This will be the first study to use an IL2/anti-IL2 mAb complex ex vivo using PBMCs from healthy donors or CHIKV arthritis patients. We hypothesize that IL2/anti-IL2 mAb complex treatment will significantly increase Treg immunosuppressive function via enhanced FoxP3-mediated CTLA4 suppression of Teff cells. This study is an important step toward determining the feasibility and safety of low-dose IL2-based treatments for CHIKV arthritis. This investigation is underway, and data will be available by August 2024.

7136

NOVEL IL2 FUSION PROTEIN FOR THE TREATMENT OF CHIKUNGUNYA VIRUS-INDUCED CHRONIC ARTHRITIS IN A MOUSE MODEL

Sarah R. Tritsch, Jose Forero Mejia, Alfonso Sucerquia Hernandez, Arnold Schwartz, Christopher N. Mores, Aileen Y. Chang

George Washington University, Washington, DC, United States

Chikungunya virus (CHIKV) is an alphavirus that causes persistent arthritis in one-fourth of patients. There are no standard treatments available for CHIKV chronic arthritis. Our preliminary data suggest that alteration of regulatory T cell (Treg) function and low IL2 levels play a role in CHIKV arthritis pathogenesis. Low-dose recombinant IL2 (rIL2) is an effective therapy for the treatment of autoimmune disease and may be of use in CHIKV arthritis flares. When rIL2 is complexed with an anti-IL2 monoclonal antibody (mAb), enhanced Treg differentiation is present in animal models. The mouse model for post-CHIKV arthritis involves footpad inoculation of wild-type C57BL/6 mice, which causes localized swelling and systemic infection. We previously treated CHIKV-infected mice with rIL2, anti-IL2 mAb, or rIL2/anti-IL2 complex. The complex increased peripheral IL2 and expanded and activated Tregs more than the other treatments, but also expanded effector T (Teff) cells and did not improve histological scores. We hypothesize that using a novel IL2 fusion protein in place of the complex will improve the outcomes by decreasing off-target Teff cell stimulation and improving histological inflammation markers. A fusion protein of IL2 and mouse IL-2Rα (CD25) joined by a non-cleavable linker extends the IL2 half-life and improves in vivo efficacy for Treg expansion and control of autoimmunity than rIL2. Mice infected with CHIKV or saline will be confirmed positive or negative by PCR. After the virus is cleared, mice will be treated with saline, rIL2, or the fusion protein for 5 days, at which time blood will be collected for cytokine analysis, spleen tissue harvested for flow cytometry analysis of T cell populations, and synovial tissue fixed for histology. This research provides a pre-clinical evaluation of fusion protein therapy for CHIKV arthritis and insights into using this novel therapeutic for alphavirus arthritis. This investigation is scheduled to begin in May 2024, and data will be available by September 2024.

7137

SYNTHESIS OF NOVEL QUINONES WITH ANTIVIRAL ACTIVITY AGAINST IMPORTANT HUMAN FLAVIVIRUSES

Henry Puerta-Guardo[1], Julio Aguiar Pech[2], Manuel Parra-Cardena[1], Guadalupe Ayora Talavera[1], Rocio de Lourdes Borges Argáez[2]

[1]Universidad Autonoma de Yucatan, Merida, Mexico, [2]Centro de Investigación Científica de Yucatan, Merida, Mexico

Flaviviruses such as the dengue serotypes (DENV 1 to 4), and Zika (ZIKV) viruses pose a significant global burden to human public health worldwide. Despite advances in drug development, there are no effective antivirals or vaccines available for the treatment of these rapidly spreading viruses. Natural products (e.g. flowers, leaves, herbal plants) are a potential source of chemical compounds from which it has been documented antiviral activities with good tolerability and minimal side effects. Quinones are abundant natural substances, mainly characterized by intramolecular unsaturated cyclic diketone structures, and includes benzoquinones, naphthoquinones, and anthraquinones. Quinones are known to contribute to various biological activities, including pharmacological effects such as anticancer, anti-inflammatory and antiviral properties. As quinones have different biological activities for different receptors, it is considered a privileged structure. Here, we enhanced the structural complexity of quinones by alkylation and/or acylation reactions increasing their Fsp^3, and evaluate their antiviral activity against DENV (1 to 4) and ZIKV *in vitro*. A library of 21 natural compounds were initially tested for their ability to cause cytotoxicity (μM) on mammalian cells *in vitro*. Then, concentrations that maintained a cell viability higher than 90% were used to inhibit the infection with DENV (1 to 4) and ZIKV using a cell-based neutralization assay. Preliminary results indicate that carminic acid, together with aloemodin and their derivatives A2, A3, A4, A8 and A9 were able to reduce the infection of mammalian cells with all DENV serotypes and ZIKV. Further experiments will help to elucidate the magnitude of their antiviral activity (EC_{50}) as well as the antiviral mechanisms by which viral inhibition occurs in mammalian cells. These results are promising as natural products must play an important role in contributing to antiviral drug development as alternatives to combat the increasing burden of mosquito-borne diseases worldwide.

7138

BIASES IN ATTRIBUTION METHODS FOR NOROVIRUS ACUTE GASTROENTERITIS

Dehao Chen[1], Kristin Nelson[1], Kayoko Shioda[2], Andrew F. Brouwer[3], Alicia N. M. Kraay[4], Andreas Handel[5], Ben Lopman[1], Elizabeth T. Rogawski McQuade[1]

[1]Emory University, Atlanta, GA, United States, [2]Boston University, Boston, MA, United States, [3]University of Michigan, Ann Arbor, MI, United States, [4]Bill & Melinda Gates Foundation, Seattle, WA, United States, [5]University of Georgia, Athens, GA, United States

The estimated global burden of acute gastroenteritis (AGE) attributable to norovirus varies by the method used to estimate the pathogen-specific burden of disease. One method ("detection-as-etiology" [DE]) considers any norovirus detection to be etiologic, such that the population attributable fraction (PAF) of AGE is norovirus prevalence; but many coinfections are often observed among AGE cases, so not all detection is etiologic, causing overestimation. Another method ("odds-ratio" [OR]) considers the PAF to be function of the odds ratio comparing detection of norovirus among AGE cases and healthy controls, but this method may be confounded by natural immunity acquired from prior norovirus infection, causing underestimation. To assess the biases in these attribution methods and develop an alternative method, we developed a norovirus transmission model accounting for repeated infection and natural immunity to estimate the incidence of symptomatic norovirus infection, from which a model-based (MB) PAF was calculated. We fit the model to the country-specific norovirus prevalence in AGE cases and controls in the multinational MAL-ED cohort study, understanding relationships between enteric infections and a variety of health outcomes, to estimate the transmission rates of

norovirus and other pathogens and solve for the endemic equilibrium. We used the equilibrium states to calculate country-specific PAFs for the DE and OR methods. We characterized the bias as the difference between the MB PAF and the other PAFs. The MB norovirus prevalence in the AGE cases and controls was generally consistent with the observed. The PAF of the DE method expectedly exceeded the others, while the OR PAF was unexpectedly larger than the MB. The biases in the DE and OR methods are similar across most countries, with average relative differences of +290% and +92%, respectively, compared to the MB. Modifications of the model to reflect the variations in natural history by country that were observed in MAL-ED may further refine the attribution bias estimates.

7139

TOSCANA VIRUS - FINDING THE NEW VECTORS

Nikola Polanska[1], Adrien Thiesson[2], Maxime Ratinier[2], Frederick Arnaud[2], Marketa Stejskalova[1], Marketa Rehbergerova[1], Alain Kohl[3], Petr Volf[1], **Magdalena Jancarova**[1]

[1]Charles University, Prague, Czech Republic, [2]IVPC UMR754, INRAE, Universite Claude Bernard Lyon 1, EPHE, PSL Research University, F-69007, Lyon, France, [3]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Arbovirus *Phlebovirus toscanaense* (TOSV) is an emerging but still neglected human pathogen that circulates in countries around the Mediterranean Sea. The manifestation of the disease varies from non-symptomatic forms through febrile illness to central nervous system disease. Although, it is one of the leading causes of meningitis and encephalitis, information about TOSV biology and epidemiology is limited. Based on the nucleotide sequences, TOSV is currently divided into 3 genetic lineages A, B and C; but the latter was only described based on partial sequences and virus isolate has never been obtained. Currently, there are only two species of sand flies (Diptera: Phlebotominae), *Phlebotomus perniciosus* and *P. perfiliewi*, considered as a proven TOSV vectors. However, the spread of TOSV to the new areas as well as the TOSV detection in several sand fly species suggested that the vector spectrum could be much broader. Here we aim to study in detail the vector competence of four sand fly species (*P. tobbi*, *P. sergenti*, *P. papatasi,* and *Sergentomyia schwetzi*) to two TOSV strains: 1500590 (TOSV A) and MRS20104319501 (TOSV B). Sand flies were infected by artificial feeding system with blood containing virus and fed females were collected and dissected at days 4, 8 and 14 after infection for virus quantification by infectious viral particles titration and RT-qPCR assay. First, we show that TOSV B appears to be more successful in development in sand flies than TOSV A. Moreover, *P. tobbi* with an infection rate of 66% and 53% at D4 and D8, respectively, seems to be the most susceptible species with a weak gut barrier to infection. In contrary, *P. sergenti* seems to be less susceptible to TOSV B with an infection rate of 5.5%, even though the virus disseminated in the head of all infected females. Additionally, *P. papatasi* and *S. schwetzi* appear to be refractory to TOSV B strain infection. In conclusion, our data suggest that two more sand fly species (*P. tobbi* and *P. sergenti*) are potential vectors of TOSV. In the context of climate changes and human activities, this information is crucial as sand flies are expected to expand to new areas, together with pathogens they carry.

7140

THE IMPACT OF CHRONIC SCHISTOSOMIASIS ON CO-INFECTIONS WITH DENGUE VIRUS IN MADAGASCAR

Jana C. Hey[1], Sreejith Rajasekharan[2], Raphael Rakotozandrindrainy[3], Anjarasoa R. Razafindrakoro[4], Matthieu R. Razafindralava[4], Zaraniaina T. Rasolojaona[4], Tahinamandranto T. Rasamoelina[4], Jacques Hainasoa[5], Rivo A. Rakotoarivelo[5], Christa Ehmen[6], Christina Deschermeier[7], Jürgen May[1], Lidia Bosurgi[8], Pietro Scaturro[2], Daniela Fusco[1]

[1]Department of Infectious Diseases Epidemiology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [2]Leibniz Institute of Virology, Hamburg, Germany, [3]Department of Microbiology and Parasitology, University of Antananarivo, Antananarivo, Madagascar, [4]Centre d' Infectiologie Charles Mérieux, Antananarivo, Madagascar, [5]Department of Infectious Diseases, University of Fianarantsoa Andrainjato, Fianarantsoa, Madagascar, [6]Diagnostics Development Laboratory, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, [7]Panadea Diagnostics GmbH, Hamburg, Germany, [8]Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Chronic schistosomiasis is highly prevalent in the tropics and can cause high morbidity. Research on the impact of this disease on morbidity caused by viruses circulating in the same areas, such as dengue virus (DENV), is scarce. Madagascar is a country highly endemic for schistosomiasis with only sporadic outbreaks of DENV. Our hypothesis is that chronic schistosomiasis might confer protection against DENV infections or dengue fever progression. A total of 990 serum samples, collected through a cross sectional study in schistosomiasis and DENV endemic regions of Madagascar have been collected and analyzed for Schistosome infection (59,5 %) and DENV/*Flaviviridae* seroprevalence (3,3 %/16,9 %) through an in-house PCR and pan-DENV IgG ELISA, respectively. Among them, 822 samples were used in a plaque reduction neutralization test (PRNT) to assess their potential to alter DENV infectivity. A significant reduction of the median plaque number in Schistosome-infected participants was observed and this effect remained significant when adjusting for other biological variables such as age and sex. In our Malagasy study population, we observed a low seroprevalence of DENV in a highly endemic schistosomiasis area. Our preliminary results corroborate our initial hypothesis of schistosomiasis interfering with DENV infections with the underlying molecular mechanisms remaining to be further investigated.

7141

MONITORING SURFACE CONTAMINATION WITH SARS-COV-2 AND INFLUENZA IN AN ADVANCED RESEARCH LABORATORY SETTING IN GHANA: A PROPOSAL FOR EFFECTIVE PREVENTIVE MEASURES

Roberta Dedei Afi Tackie, Ivy Asantewaa Asante, Joseph Ahia Quacoo, Vanessa Louise Magnusen, Juliet Sefakor Wordui, Nana Afia Asante Ntim, Joseph Asuam Nyarko, Victor Akyedzi Osei

Noguchi Memorial Institute for Medical Research, Accra, Ghana

The emergence of respiratory viruses such as SARS-CoV-2 and influenza presents significant challenges to public health. Understanding surface contamination and transmission dynamics within laboratory settings is crucial for implementing effective preventive measures. The aim of this study was to monitor laboratory surfaces contamination with SARS-CoV-2 and influenza viruses in an advanced research laboratory. We pre-moistened swabs with Virus Transport Medium and swabbed common shared surface areas in the laboratory environment, and its surroundings. Swabs were tested for the presence of SARS-CoV-2 and influenza viruses using real time RT-PCR with primers/probes and assays described by the CDC,USA . A total of 674 samples were collected from these surfaces between June 2023-April 2024 and tested. Out of this, 52% (352/674) were collected before commencement of work day and 48% (322/674) close of work. The distribution of swabbed surfaces were as follows: 16% (106/674) from lab benches, 8% (53/674) from biosafety cabinet used for RNA extraction, 8% (53/674) from biosafety cabinets used to prepare master mix only, 8% (53/674) from biosafety cabinets for template and positive controls addition only, 16% (106/674) from freezer door handles, 8% (53/674) from centrifuges and vortexes, 16% (108/674) from lab door handles and 5% (36/674) from a shared table used by all staff. Of the samples tested, 0.30% (2/674) SARS-CoV-2 RNA was detected from lab door handles before start of work day. The rest of the samples tested negative for SARS-CoV-2 and influenza. SARS-CoV-2 RNA was detected in the samples. Though not significant (p value = 0.397), the resultsshows the importance of such an attempt as it has implications for contamination and health of staff. Again, the fact that all other surfaces were negative for SARS-COV-2 shows strict adherence to decontamination procedures and good laboratory practices. This proactive approach will not only safeguard the health of research staff and limit contamination, but also provide valuable insights for similar settings globally. It is recommended that staff wash their hands prior to exiting laboratories.

MULTIFACTORIAL CHARACTERIZATION OF DENGUE TRANSMISSION DYNAMICS IN THE FRENCH CARIBBEAN ISLANDS TO BETTER PREPARE FOR FUTURE EPIDEMICS

Margot Garcia -- Van Smévoorde[1], Elodie Calvez[1], Geraldine Piorkowski[2], Xavier de Lamballerie[2], Georges Dos Santos[3], Raymond Césaire[4], Anubis Vega-Rua[1]

[1]Institut Pasteur de la Guadeloupe, Les Abymes, Guadeloupe, [2]Institut Hospitalo-Universitaire Méditerranée Infection, Marseille, France, [3]Centre Hospitalier Universitaire de Martinique, Fort-de-France, Martinique, [4]Centre Hospitalier Universitaire de Guadeloupe, Pointe-à-Pitre, Guadeloupe

Dengue is now the most widespread arboviral disease with incidence increasing more than 10-fold over the past 20 years, reaching a peak of 5.2 million cases in 2019, according to World Health Organization (WHO). The Americas are currently facing an unprecedented crisis, with more than 4 million cases of dengue recorded since the outbreak began in 2023, according to the Pan American Health Organization (PAHO). While it is endemic in all tropical and subtropical areas of the world, the Caribbean is one of the most affected regions, especially since the reintroduction of the *Aedes aegypti* vector in the 1970s. Since 2006, all four serotypes of dengue virus (DENV) have been detected during differents epidemics, with heterogeneous circulation in the French Caribbean islands (Guadeloupe and Martinique). During the recent outbreak in 2019-2021, three DENV serotypes were detected (DENV-1, DENV-2 and DENV-3), but curiously, their circulation was not homogeneous, with DENV-2 predominating in Guadeloupe, while DENV-3 was the main serotype circulating in Martinique. To investigate if genomic features of serotypes circulating in both islands were different, full genome sequencing was carried out on strains collected during the recent 2019-2021 outbreak in Guadeloupe and Martinique. Phylogenetic data revealed the homogeneous presence of genotype V for DENV-1, cosmopolitan genotype for DENV-2 and genotype III for DENV-3 in both French departments. To determine whether these differences in circulation of these viral strains are linked to a difference in vector transmission capacity, recent evaluations of vector competence of the 3 serotypes circulated during the 2019-2021 outbreak, as well as the current epidemic (DENV-2 only), were carried out on 6 populations (3 in Guadeloupe and 3 in Martinique) of *Aedes aegypti*, the local mosquito vector. Overall, these results confirm the active circulation of DENV in these regions, will help identify the factors inducing the epidemiological differences observed between the two islands and contribute to a better preparedness to cope with DENV emergences in the French Caribbean islands.

7143

A COMPREHENSIVE ANALYSIS OF COINFECTION DYNAMICS MODULATING MOSQUITO VECTOR COMPETENCE

Bri Marsico[1], Emily Gallichotte[1], Amy Sweeny[2], Gregory Ebel[1], Colin Carlson[3]

[1]Colorado State University, Fort Collins, CO, United States, [2]University of Sheffield & University of Edinburgh, Sheffield, United Kingdom, [3]Georgetown University, Washington, DC, United States

Arboviruses constitute a significant global health burden in part due to their complex ecologies and transmission dynamics. A growing area of interest towards controlling such pathogens are insect-specific-viruses (ISVs), as arbovirus-ISV coinfection has been shown to modulate vector competence, decrease viral titer, and block dissemination of medically important viruses. The biological mechanisms through which ISVs can impact arboviruses are poorly understood, but may include superinfection exclusion, sequestration of host factors, or effects on mosquito physiology. Studying these interactions can shed light on virus-virus interactions and vector competence within mosquitoes. However, such experimental approaches can be complex, and lack of standardization in data reporting makes comparison of outcomes across studies difficult to interpret. Through a comprehensive literature search we will collect and standardize coinfection experimental outcomes highlighting infection, dissemination, and transmission of arboviruses into a database. This database will support modeling networks for known ISV-arbovirus interactions in mosquitoes, which will be applied towards predicting ISVs that can suppress arboviral transmission. We will then test these predictions using *Aedes* sp. cell lines that have either competent or dysfunctional RNAi responses. Further testing will include additional *in-vitro* and mosquito colony experiments to validate modeling predictions and better understand ISV-arbovirus-vector interactions.

7144

MIDGUT ESCAPE OF YELLOW FEVER 17D VACCINE IN *AEDES AEGYPTI* AT AUGMENTED TEMPERATURES

Kaitlynn A. Williams, Gregory D. Ebel, Emily N. Gallichotte

Colorado State University, Fort Collins, CO, United States

Yellow fever virus (YFV) is spread to humans by *Aedes* mosquitoes and is endemic in tropical regions of Latin America and Africa. Climate change projections predict a range expansion of *Aedes aegypti* and an increased risk of transmission to humans. In endemic regions, YFV outbreaks are mitigated using the highly safe and efficacious live attenuated vaccine, YFV-17D. Previous studies have addressed the competence of *Ae. aegypti* for YFV-17D. While this vaccine replicates in the mosquito midgut, it does not disseminate efficiently compared to wild-type YFV strains. For many *Aedes*-arbovirus pairings, increased temperatures alter vector competence. However, the impact of temperature on *Ae aegypti* vector competence for YFV-17D is poorly understood. Therefore, we exposed *Ae. aegypti* to YFV-17D and held them at varying temperatures (29°C, 32°C, and 34°C). On days 7 and 14 post-infection, we collected midguts, and legs and wings, then measured viral RNA using qRT-PCR to determine midgut infection and escape. We found a temperature-dependent increase in YFV-17D midgut dissemination; 54% of mosquitoes at 34°C had YFV-17D in their legs and wings compared to 8% of mosquitoes at 29°C. While mosquitoes had increased rates of dissemination at 34°C, they also displayed increased levels of virus in their legs and wings at both time points. This suggests that higher temperatures lead to both increased midgut escape and YFV-17D replication in *Ae. aegypti*. Ongoing research will characterize mechanisms of enhanced midgut escape at increased temperatures and determine whether YFV-17D can infect and escape the salivary glands, allowing for transmission. Additionally, we will sequence the virus to determine whether YFV-17D attenuating mutations are maintained through midgut escape.

7145

A SPATIALLY RESOLVED AND ENVIRONMENTALLY INFORMED FORECAST MODEL OF WEST NILE VIRUS AND ST. LOUIS ENCEPHALITIS VIRUS IN COACHELLA VALLEY, CALIFORNIA

Aman Patel[1], Matthew J. Ward[1], Jennifer A. Henke[2], Nicholas B. DeFelice[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States, [2]Coachella Valley Mosquito & Vector Control District, Indio, CA, United States

St. Louis encephalitis virus (SLE) is endemic to California and was detected annually until 2003 when West Nile virus (WNV) was identified in California. SLE was not detected again in California until 2015, and has been endemic since the recent introduction.. WNV and SLE exist in a complex transmission cycle that uses the same amplifying host, i.e., birds, and mosquito vectors. WNV is known to be a faster replicating virus, achieving higher viremias in both birds and mosquitoes. SLE, while slower, appears to be able to reach detectable transmission levels during periods when WNV transmission is low in the system, but it is still unclear how infection with one disrupts the transmission of the other. Preliminary analyses suggest that since the reintroduction of SLE to California in 2015, WNV and SLE transmission have occurred simultaneously. Like the dominance of WNV after its introduction in 2003, SLE outcompeted WNV from late 2015 when introduced and in 2016, possibly due to bird naïveté. In-season dynamics between WNV and SLE in mosquitoes may be dependent on when each

virus emerges, as both have the potential to outcompete the other and spillover to humans. Thus, a better understanding of how interactions of SLE and WNV impact the transmission cycle may improve our ability to predict arboviral risk and spillover events. This study builds on our previously developed multi-model inference system of WNV in Coachella Valley, California, and aims to incorporate and mathematically explain the interplay between WNV and SLE. We developed and tested a spatially resolved ensemble model to understand how fluctuations in environmental conditions influence WNV mosquito infection rates in the Coachella Valley. Using 17 years of mosquito surveillance data, we will compare how environmental conditions associated with WNV amplification change related to the SLE observed infection rates. Accurate early season predictions of arboviral risk have the potential to allow local abatement districts and public health entities to implement early season interventions such as targeted adulticiding and public health messaging before human transmission occurs.

7146

A DOUBLE THREAT TO ARTEMISININ-BASED COMBINATION THERAPY (ACT). EFFICACY IN AFRICA: REDUCED SUSCEPTIBILITY OF *PLASMODIUM FALCIPARUM* TO BOTH ARTEMISININ AND LUMEFANTRINE

Colin J. Sutherland, Sade Pratt, Donelly A. van Schalkwyk
London School of Hygiene & Tropical Medicine, London, United Kingdom

Clinical management of uncomplicated malaria caused by Plasmodium falciparum is reliant on the effectiveness of artemisinin-based combination therapy (ACT). New parasite genotypes encoding variants of the pfk13 gene are now emerging in Africa, and these are less susceptible to the artemisinin component drugs of ACT. This then poses a risk of resistance-selection against ACT partner drugs. Parasites of Ugandan origin isolated from two ACT-treated UK travellers with documented treatment failure, adapted to long-term culture in 2022, were less susceptible to lumefantrine in vitro than parasites from successfully treated individuals. This suggests that changes in parasite susceptibility to lumefantrine may contribute to treatment failure in these patients. Thus, the major African ACT, artemether-lumefantrine (AL), may now be at risk. We present a comprehensive assessment of in vivo treatment outcomes, in vitro parasite susceptibility to artemisinin and lumefantrine, and genomic and genotyping data from UK travellers with imported P. falciparum infections presenting from 2022 to 2024. This series includes 16 cases that suffered a relapse of symptomatic parasitaemia within weeks of initial treatment with AL. Future drug strategies for more effective malaria chemotherapy in Africa will be proposed in the light of these findings. Finally, we will consider the wider public health implications of a potential emergence of reduced lumefantrine susceptibility among African populations of P. falciparum.

7147

COMBINATION OF REDOX MODIFIERS WITH ARTEMISININ RESULTS IN INCREASED PARASITE SUSCEPTIBILITY TO ARTEMISININS

Annie Roys[1], Ghizal Siddiqui[1], Carlo Giannangelo[1], Darren Creek[1], Natalie Counihan[2]
[1]Monash institute of pharmaceutical science, Melbourne, Australia, [2]Deakin University, Geelong, Australia

Resistance has been recorded for every class of antimalarial, including artemisinin combination therapies (ACTs), the current first line. Drug resistant parasites have been reported to have an increased ability to manage oxidative stress and maintain redox homeostasis following drug treatment, possibly due to an enhanced antioxidant system. We hypothesised that disrupting this redox balance by targeting the parasites' glutathione pathway will make parasites more susceptible to oxidative stress, and therefore re-sensitise them to existing antimalarials. This work aims to tackle resistance by identifying redox-modifying drugs that can be combined with artemisinin derivatives. Growth inhibitory studies and ring-stage survival assays were used to determine the antimalarial activity of different redox compounds and to identify compounds that could be synergistic with artemisinin in vitro. Real time analysis of parasite intracellular glutathione was observed using *P. falciparum* NF54*attB*$^{[hGrx1\text{-}\ roGFP2]}$ parasite line and a plate reader based redox assay. Untargeted and targeted thiol metabolomic were carried out to identify metabolic changes in drug treated parasites. We identified sulforaphane (SFN) to be a promising candidate, which alters parasite redox status and potentiates the activity of artemisinin. The combination of 15μM SFN with 700nM dihydroartemisin (DHA) in early ring-stage parasites resulted in a decrease in parasite survival compared to DHA alone (41% ± 7.3).15μM SFN resulted in an increased oxidative burden within parasites after 1 h incubation. Untargeted and targeted thiol metabolomics confirmed that SFN's antimalarial activity is entirely redox mediated and not as a result of major metabolic changes within the parasite The addition of SFN to existing antimalarial therapies would re-sensitise resistant parasites to existing antimalarials thereby extending their life span. Ongoing studies will elucidate the mechanism responsible for this synergistic activity and determine the safety and efficacy of this approach in drug-resistant in vivo models of malaria.

7148

VARIABILITY IN ANTIMALARIAL DRUG SUSCEPTIBILITY PATTERNS IN KISUMU AND MARIGAT DURING THE PERIOD OF INCREASING FREQUENCY OF ARTEMISININ RESISTANCE GENOTYPES

Doris W. Njoroge[1], Michal M. Ohaga[1], Dennis W. Juma[1], Redemptah A. Yeda[1], Agnes C. Cheruiyot[1], Benjamin H. Opot[1], Raphael O. Okoth[1], Jackline A. Juma[1], Edwin W. Mwakio[1], Kirti K. Tiwari[2], Timothy E. Egbo[2], Eric C. Garges[2], Hoseah M. Akala[1]
[1]KEMRI/ Walter reed army institute of research- Africa, Kisumu, Kenya, [2]Walter reed army institute of research- Africa, Kisumu, Kenya

Malaria remains a major public health threat globally affecting 241 million people annually. Persistent malaria burden has been attributed to rapid emergence and spread of parasite resistance to policy recommended drugs. Consequently, timeliness of detecting drug resistance in diverse transmission regions is critical. This established susceptibility of *Plasmodium falciparum* parasites from Kisumu and Marigat between 2018 and 2023 using in vitro testing, genomic analyses and passive monitoring of treatment outcomes. A total of 637 consenting individuals aged 6 months and over, presenting with uncomplicated malaria were treated with Coartem® according to weight band and monitored on Day 7 to assess treatment outcomes. Up to 5mL whole blood samples collected from each individual prior to start of medication were latter tested for in vitro susceptibility to 14 antimalarial drugs. Each sample was tested for species composition, single nucleotide polymorphisms (SNPs)in drug resistance genes, and presence of residual parasitemia on day seven using genomic analyses techniques. 475/ 637 individuals comprising 385 from Kombewa and 90 from Marigat tested positive for malaria by polymerase chain reaction (PCR) assay. In vitro susceptibility showed mean ±standard deviation values of 25.1±32.5ng/ml for chloroquine, 32.7±22.3 ng/ml for quinine, 2.9±2.3 ng/ml for artemether and 40.0±38.3 ng/ml for lumefantrine. 70% of the infections contained P. falciparum single species infection while 30 % were contained P. falciparum species alongside other nonfalciparum species as multiple species infections. SNPs analyses showed three nonsynonymous mutation Pfk13 gene V568G, T508N and N554S in two samples and 36% mutation in PfMDR1-Y184F. PfMDR1 N86Y and Pfcrt K76T were wild-type for the entire study period. None of the day 7 visit samples tested positive for malaria by molecular diagnosis suggesting that all infections resolved after treatment with coartem®. Continuous monitoring of changing parasite susceptibility by in vitro and molecular methods is essential for early detection of resistance.

7149

MALARIA DIAGNOSIS AND DRUG RESISTANCE IN A MILITARY HOSPITAL IN YAOUNDE, CAMEROON

Rania Nada[1], Isabelle Nakhla[1], Hanan El-Mohammady[1], Ethel Shang[2], O'Neal Youté[2], Pacome Tchuenkam[2], Bebongachem Ashu[2], Julius Nwobegahay[2]

[1]U.S. Naval Medical Research Unit – EURAFCENT, Cairo, Egypt, [2]Military Health Research Center, Yaounde, Cameroon

The burden of malaria remains high in Cameroon, with almost 35% overall mortality. We studied diagnosis and drug resistance genes (DRG) for malaria in Yaounde military hospital, Yaounde, Cameroon. Microscopy, HRP2 Rapid Diagnostic Test (RDT), qPCR, and sequencing for DRG were used in this study. From March 2021 to December 2023, we enrolled 3,000 acute febrile illness cases (median age 35 years, 49% males). Microscopy identified 1,267 (42.2%) cases and had a higher positive detection rate than RDT (762 cases, 25.4%). qPCR identified 557(32.4%) cases out of 1,698 tested. HRP2 RDT negative cases had a mean of 43.9% in microscopy and in qPCR positive cases, suggesting a high prevalence of *pfhrp2* gene deletion and evidence for shifting from RDTs based only on HRP2. Sequencing for *Pfcrt*, *Pfcytb*, *Pfk13*, *Pfdhfr*, *Pfdhps*, *Pfmdr1*, and *Pfatp6* antimalarial DRG was done on a random set of 250 microscopy positive samples. For *Pfk13*, no mutations were observed in the propeller region, however, multiple mutations including G112E (4%), L116I (1%), K189T (58%), K189N (4%), L258M (1%) and R225K (1%) were noticed outside this region. *Pfatp6* mutant alleles H243Y (9%), L402V (14%), E431K (18%) and D436Y (1%) were detected. Wild type allele *cytB* was present in all samples. *Pfdhfr* haplotype N51I/C59R/S108N was detected in 95% of the samples, whereas C59R/S108N was observed in an additional 3%. *Pfdhps* mutant alleles were I431V (14%), S436A (37%), A437G (79%), K540E (2%), A581G (11%) and A613S (12%). *Pfcrt* new mutation C44F was noticed in all samples, K49Q in 0.8%, the triple resistant genotype (M74I/N75E/K76T) in 1.6% and M74I/N75D/K76T in 0.8%. *Pfmrd1* resistant genotype (N86Y) was found in 11% and the mutant allele Y184F in 75% of the isolates. Mutations associated with artemisinin and atovaquone resistance were not detected, suggesting efficacy of these drugs in Yaounde, whereas mutations conferring sulfadoxine-pyrimethamine resistance predominate. Finally, we noticed a decline in the prevalence of mutant chloroquine resistance alleles compared to previous decade. This study indicates a high prevalence of antimalarial DRG polymorphisms.

7150

INVESTIGATING *PLASMODIUM FALCIPARUM EX-VIVO* DRUG RESPONSES TO ARTEMISININ-BASED COMBINATION THERAPIES (ACTS) PARTNER DRUGS IN GHANA

Samirah Saiid[1], Edem Adika[2], Osumanu Ahmed[3], Priscilla Acquah-Jackson[3], Mina Ansong[3], Clinton Nhyira Osei[3], Josie Okai[3], Mona-Liza Sakyi[3], Collins Morang'a[3], Enoch Amoako[3], Ignatus Dorvi[3], Francis Dzabeng[3], Elrmion Senyah Adjei[3], Gordon Awandare[3], Alfred Amambua-Ngwa[4], Yaw Aniweh[3], Lucas Amega-Etego[3]

[1]Department of Biochemistry, Cell, and Molecular Biology, University of Ghana, Accra, Ghana, [2]Dundee University, U.K, United Kingdom, [3]West African Center for Cell Biology of Infectious Pathogens (WACCBIP), Accra, Ghana, [4]Medical Research Council (MRC), The Gambia at London School of Hygiene and Tropical Medicine, U.K, United Kingdom

Antimalarial drug resistance poses a threat to malaria control. While artemisinin-based combination therapies (ACTs) are presently the most effective frontline antimalarials, signs of resistance are emerging in Africa. This includes resistance to artemisinin driven by mutations in *Plasmodium falciparum kelch13* gene and reduced efficacy of ACT partner drugs, but the extent of resistance to partner drugs such as AQ and LUM is not well understood. We assessed the *ex-vivo* sensitivity of clinical isolates cultured from individuals attending LEKMA or University of Ghana hospitals with confirmed malarial fever. We also determined the prevalence of known antimalarial drug resistance markers in these isolates using ONT-based amplicon sequencing. Mean 50% inhibitory concentrations (IC_{50}) results were below standard thresholds for resistance to CQ, DHA and AS, except one isolate that had mean IC_{50} values of 26.20 nM and 38.30 nM, above cutoffs for DHA and AS respectively. This isolate did not carry any validated *kelch13* mutations. Two isolates (4.08 %) and seven isolates (14.29 %) showed reduced susceptibilities to LUM and PPQ, respectively. About 29.50 % and 45.50 % isolates carried the combined *dhfr:dhps* quintuple mutant (IRNI-AGKAA) and quadruple mutant (IRNI-SGKAA) respectively. These combined mutant haplotypes are known to confer increased resistance to SP. In conclusion, we demonstrated that parasites are still sensitive to CQ, DHA and AS. However, there is emerging tolerance to LUM and PPQ that needs further investigation.

7151

AMPLICON DEEP SEQUENCING OF *PFKELCH13* GENE IN PATIENTS WITH *PLASMODIUM FALCIPARUM* MALARIA DURING THE THERAPEUTIC EFFICACY STUDY TRIALS FROM 2020 TO 2022 IN SENEGAL

Amy GAYE[1], Mouhamad Sy[1], Tolla Ndiaye[1], Yaye D. Ndiaye[1], Mamadou A. Diallo[1], Baba Dieye[1], Awa B. Deme[1], Mamadou S. Yade[1], Abdoulaye Tine[1], Djiby Sow[1], Aita Sene[1], Bassirou Ngom[1], mariama Toure[1], Ndogaye Gadjaga[1], Mamane N. Garba[1], Khadim Diongue[1], Ibrahima M. Ndiaye[1], Fatou B. [1]International Center for Research and Training on Applied Genomics and Health Surveillance (CIGASS), Dakar, Senegal, [2]National Malaria Control Programme, Avenue Aimé Césaire, Dakar, Senegal,, Dakar, Senegal, [3]U.S. President's Malaria Initiative, USAID, Dakar, Senegal, Dakar, Senegal, [4]Department of Immunology and Infectious Diseases, Harvard TH Chan School of Public Health, Boston MA, USA 02115, Boston, MA, United States

Senegal has used artemisinin-based combination therapy (ACT) to treat uncomplicated *Plasmodium falciparum* infection since 2006. Artemisinin (ART) resistance is mediated by mutations in the *Pfkelch13* (*PfK13*) gene and parasite genomic background modulates this resistance. Therapeutic Efficacy Studies (TES) demonstrate that ACTs including artemether-lumefantrine (AL) and artesunate-amodiaquine (ASAQ) remain efficacious in Senegal. The appearance of ART resistance in Africa increases the urgency for ART resistance surveillance in Senegal. We used TES samples from Senegal to identify *PfK13* mutations among *P. falciparum* infections detected after day 0 (D0) of ACT treatment. We used amplicon sequencing of 400 TES samples from Kédougou, Kolda, and Kaolack (2020 - 2022). Participants were treated with AL or ASAQ on D0 with 28 (AL) or 42 (ASAQ) day follow up. Samples came from individuals that were parasite positive after D0, with priority given to pairs of samples (D0 and day of failure or DF). The 400 samples include 34 from 2020 (17 D0 + 17 DF); 22 from 2021 (11 D0 + 11 DF); and 56 from 2022 (28 D0 + 28 DF). We included an additional 288 DF samples from 2022. Samples were subjected to targeted amplicon sequencing of pooled and indexed samples. Sequencing data were aligned to the reference (PF3D7_1343700) sequence and four mutations in the propeller domain were identified from among the 400 samples. These variants and their frequencies included: V566L (0.25%), A578S (0.74%), V589I (0.25%), V637I (0.5%). An additional four mutations were found outside the propeller domain: T149S (0.25%), K189T (15%), K189N (1%), R255 (0.25%). None of these mutations are validated as associated with ART resistance. While new *PfK13* mutations need to be phenotypically tested for partial ART resistance, the appearance of DF infections may also result from partner drug resistance. Ongoing molecular surveillance for known and emerging malaria drug resistance mutations is important for detection of emerging risk and to identify novel mutations that may contribute to ART resistance in different genomic backgrounds.

7152

DISSECTING THE ROLE OF *PLASMEPSIN II AND III* IN PIPERAQUINE RESISTANT *PLASMODIUM FALCIPARUM* LINES

Breanna Walsh, Robert L Summers, Dyann Wirth, **Selina Bopp**
Harvard T.H. Chan School of Public Health, Boston, MA, United States

Artemisinin (ART) combination therapies (ATC) are the current first line anitimalarials used world-wide. Resistance to both ART and the partner drugs like piperaquine (PPQ) are occurring and spreading in South East Asia. Major genetic determinants associated with recrudescence attributed to the partner drug PPQ are increased copy numbers of *plasmepsin II* and *III* and as well as mutations in the *chloroquine resistance transporter* (*pfcrt*). While mutations in *crt* were shown to be protective in vitro, experimental data on the role of plasmepsins in PPQ resistance is sparse. We have previously presented a bimodal growth response to increasing PPQ concentrations in PPQ resistant *Plasmodium falciparum* isolates from Cambodia in the absence of *crt* mutations. We chose the area under the curve (AUC) instead of the conventional half-maximal effective concentration (EC_{50}) used in drug assays to quantify the bimodal response. To specifically determine the role of plasmepsins in the response to PPQ, we used a relevant Cambodian isolate with a duplication in *plasmepsin II* and *III* but no mutation in *pfcrt*. Using this clonal isolate, we generated *plasmepsin II*, *plasmepsin III* and *plasmepsin II/III* combination KO lines with the CRISPR/Cas9 system. Our data demonstrate that a reduction in in *plasmepsin II* or *III* decreases the AUC three or six fold, respectively, compared to the parental line indicating direct involvement of *plasmepsin II* and *III* in the PPQ response at high concentrations. We detected a three to six fold increase in free heme in parasites treated with PPQ but no major differences between hemoglobin catabolism in parasite lines with different *plasmepsin* copy numbers. In contrast, changing the homeostasis of the food vacuole with pH modulators (CCCP or concanamycin A) did reduce survival under high PPQ exposure up to 50%. We demonstrated that increased *plasmepsin* copy number enhances survival under high PPQ pressure in Cambodian parasites and likely contributes to the emergence of resistance.

7153

POPULATION PHARMACOKINETICS OF ARTEMETHER-LUMEFANTRINE PLUS AMODIAQUINE IN PATIENTS WITH UNCOMPLICATED *PLASMODIUM FALCIPARUM* MALARIA

Junjie DIng[1], **Richard M. Hoglund**[1], Rob van der Pluijm[1], James J. Callery[1], Thomas J. Peto[1], Rupam Tripura[1], Mehul Dhorda[1], Chanaki Amaratunga[1], Lek Dysoley[2], Ho Dang Trung Nghia[3], Caterina Fanello[1], Marie A. Onyamboko[4], Anupkumar R. [1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Cambodian National Malaria Control Program, Phnom Penh, Cambodia, [3]Oxford University Clinical Research Unit, Hospital for Tropical Diseases, Ho Chi Minh City, Vietnam, [4]Kinshasa School of Public Health, University of Kinshasa,, Kinshasa, Congo, Democratic Republic of the, [5]National Institute of Malaria Research, Indian Council of Medical Research, New Delhi, India, [6]Lao-Oxford-Mahosot Hospital Wellcome Trust Research Unit (LOMWRU), Vientiane, Lao People's Democratic Republic, [7]Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [8]Dev Care Foundation, Dhaka, Bangladesh

Uncomplicated falciparum malaria is commonly treated with an artemisinin-based combination therapy (ACT), which has contributed to the reduction of the worldwide burden of malaria. Resistance to the artemisinin component and to the partner drug in ACTs has been observed in Southeast Asia, and artemisinin resistance has recently also emerged in eastern Africa. 'Triple' ACTs, consisting of two partner drugs with different mechanisms of action and similar pharmacokinetic profiles, could help to counter the effects of artemisinin resistance and prolong the efficacy of partner drugs. When adding a new compound to a combination, assessments of potential drug-drug interactions are needed to verify that all components attain therapeutic levels while remaining safe. The analyses presented here used data from two randomized, controlled interventional trials conducted in 7 Asian and 1 African countries, in which artemether-lumefantrine was given with or without amodiaquine to patients with malaria. Both studies included a cohort with dense pharmacokinetic sampling, combined with sparse data from the rest of the patients. Concentration-time data of artemether, dihydroartemisinin, lumefantrine, desbutyl-lumefantrine, amodiaquine, and desethylamodiaquine were analysed using nonlinear mixed effect modelling, implemented in NONMEM. Pharmacokinetic models developed for all drugs showed that amodiaquine does not impact the pharmacokinetics of lumefantrine. The model demonstrated showed good predictive performance and goodness-of-fit. No clinically relevant drug-drug interactions were identified, indicating that dose adjustment is not necessary for the triple combination. Also, three different models describing the pharmacokinetics of artemether, lumefantrine, amodiaquine, and their respective metabolites were successfully developed. These models could be used to simulate the effects of altered dosing of this triple combination.

7154

MODEL-GUIDED STRATEGIES FOR MITIGATING ANTIMALARIAL DRUG RESISTANCE: BENEFITS OF EARLY ADOPTION OF TRIPLE ARTEMISININ-BASED COMBINATION THERAPIES IN UGANDA AND TANZANIA

Tran Dang Nguyen[1], Robert J. Zupko[2], Carter C. Farinha[1], Philip Rosenthal[3], Agaba B. Bosco[4], Samwel Lazaro[5], Deus Ishengoma[6], Maciej F. Boni[1]

The emergence and spread of drug-resistance mutations in Plasmodium falciparum pose a significant threat to malaria control efforts worldwide. As resistance to artemisinin-based combination therapies (ACTs) continues to evolve, there is an urgent need to evaluate alternative treatment strategies to mitigate the impact of drug resistance. We used a mathematical model to simulate the spread of drug-resistant mutations, particularly the 561H, 469Y, and 675V mutations, associated with resistance to artemisinin, under different treatment scenarios. We compared the outcomes of continuing with artemether-lumefantrine (AL) as the first-line therapy, switching to the triple ACT artemether-lumefantrine-amodiaquine (ALAQ) at different timepoints, temporarily adopting artesunate-amodiaquine (ASAQ) as an interim measure, and other available drugs (e.g. DHAPPQ, extended doses for AL to 5 days) deployments in Uganda and Tanzania. Our model predicts that an immediate switch from AL to ALAQ would result in the lowest number of treatment failures over the next five years (2024-2029). Delaying the transition to ALAQ by four years could double or even triple the number of treatment failures. Furthermore, the earlier the adoption of ALAQ, the more effective it would be in delaying the spread of the kelch13 variants, with predicted frequencies of 0.35 (immediate deployment) and 0.5 to 0.65 (4-year delay) in Tanzania for 2029. For countries where ALAQ will not be available soon, temporarily switching to ASAQ (3-day treatment) emerged as a viable second-best option.

7155

INCREASING VALIDATED ARTEMISININ PARTIAL RESISTANCE MARKERS CONFIRMED IN ETHIOPIA DURING NATIONAL SENTINEL-BASED *PLASMODIUM FALCIPARUM* MOLECULAR SURVEILLANCE

Bokretsion Gidey Brhane[1], Abebe Alemu Fola[2], Helen Nigussie[3], Moges Kassa[1], Henok Hailgiorgis[1], Yonas Wuletaw[1], Boja Dufera[1], Adugna Abera[1], Heven Sime[1], Gudissa Assefa[4], Hiwot Solomon[4], Geremew Tasew[1], Getachew Tollera[1], Mesay Hailu[1], Jonathan J. [1]Ethiopian Public Health Institute, Addis Ababa, Ethiopia, [2]Brown University, Providence, RI, United States, [3]Addis Ababa University, Department of Microbial, Cellular and Molecular Biology., Addis Ababa, Ethiopia, [4]Ministry of Health, Addis Ababa, Ethiopia, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Ethiopia aims to overcome a recent resurgence of malaria cases and eliminate local malaria transmission by 2030. With the emergence of artemisinin partial resistance (ArtR) in Africa, molecular surveillance is critical to monitor the relevant drug resistance markers. This study reports the results of sentinel site-based molecular surveillance for antimalarial drug resistance mutations. Between 2020 and 2022, dried blood spots (DBS) were collected from febrile outpatients ≥6 months old with microscopically confirmed falciparum malaria at 12 sentinel sites across a range of transmission settings. Molecular inversion probe (MIP) sequencing was used to target mutations associated with artemisinin and partner drug resistance: *kelch13, pfmdr1, pfcrt, pfdhfr,* pfdhps genes, target genome-wide markers to assess complexity of infection (COI) and parasite relatedness. A total of 1,200 patients positive for *P. falciparum* was assessed. Median age was 20 years (IQR: 14-30), and 489 (40.8%) were female. In the Kelch 13 propeller, the R622I mutation is reported mutation reported at high prevalence (>16%, range (0-58.8%) with variability across regions. A 675V mutation (WHO-validated) was were reported for the first time in Ethiopia (<5%) in Gambella region. Additional validated (441L, 574L) and candidate markers (527H, 537A) were detected in low frequency. Moreover, several partner drug resistance markers were identified; mutations in *mdr1* (184F), *dhps*, *dhpr* and *crt* were nearly fixed across the country. Majority (87.2%) of genotyped samples carried monogenomic infections (COI=1) and were highly-related to evidence of genetic clustering at the health facility level. Principal component analysis showed evidence of parasite clustering at the regional clustering regional level with district clustering of Gambella parasites. These analyses confirm the high prevalence and expansion of 622I mutation and identify other validated markers (675V and 441L) that require further investigation. Detection of multiple ArtR suggest intensive monitoring of ACT efficacy in vivo for early identification of partner drug resistance and ACT failure.

7156

UNDERSTANDING THE BIPHASIC DOSE-RESPONSE CURVE ASSOCIATED WITH PIPERAQUINE RESISTANCE IN *PLASMODIUM FALCIPARUM*

The recent failure of dihydroartemisinin plus piperaquine (DHA+PPQ) antimalarial combination therapy in Southeast Asia poses a significant threat to malaria control efforts. A unique *in vitro* characteristic of PPQ-resistant *P. falciparum* is a bimodal dose-response curve indicating increased parasite survival under high drug concentrations. Due to the unique shape of the dose- response curve, area under the curve (AUC) has replaced the traditional IC_{50} when assessing susceptibility to PPQ. Previous work identified that a combination of novel substitutions in the chloroquine transporter (PfCRT) paired with multiple copies *plasmepsin II/III* (*pm2/3*) are required to generate this bimodal curve, with additional copies of *pm2/3* associating with an increased AUC. To further investigate factors driving this novel phenotype, we modified the standard 72h drug exposure to adjust the stage at which parasites were initially exposed to PPQ (early ring, late ring, trophozoite, or schizont) as well as duration of drug exposure. We performed these experiments using the parents of a previously conducted genetic cross as well as several PPQ-resistant isolates which are unique both in PfCRT genotype as well as *pm2/3* copy number. Our results reveal that exposing late-stage parasites to PPQ eliminates the bimodal nature of the dose-response curve (AUC: $p < 0.001$) without any significant change in PPQ susceptibility (limited point IC_{50}: 22.4nM vs 23.5nM; $p = 0.235$). Furthermore, we paired additional phenotypes and measurements with the disappearance of the biphasic portion of the dose-response curve to further understand the biological factors which contribute to this novel phenotype.

Artemisinin partial resistance (ART-R) has emerged in eastern Africa and threatens the efficacy of artemisinin combination therapies. In an attempt to identify novel antimalarials with improved properties, we studied synthetic endoperoxides inspired by artemisinins, but potentially not subject to ART-R. We compared susceptibilities of *Plasmodium falciparum* isolates to dihydroartemisinin (DHA), the active metabolite of clinically relevant artemisinins, the synthetic trioxolane artefenomel, which has potent activity but formulation and PK challenges and RLA-4735, a trioxolane designed to address ART-R and solubility/formulation challenges. We collected 39 isolates from eastern Uganda in 2019 and 166 isolates from northern and eastern Uganda in 2023-24, all from subjects with symptomatic *P. falciparum* infection. Susceptibilities were determined using the *ex vivo* ring-stage survival assay (RSA: % survival, relative to controls, 66 h after a 6-hour 700 nM pulse of compound), and a 72 h growth inhibition assay (IC_{50}), with SYBR Green detection. For 2019, RSA median survival was 0% for DHA, artefenomel, and RLA-4735. Median IC_{50}s were 1.5 nM (range 0.5 - 3.3 nM) for DHA, 0.5 nM (0.04 - 3.3 nM) for artefenomel, and 2.6 nM (1.1- 7.4 nM) for RLA-4735. For 2023-24, RSA median survival was 5.3% (range 0.0%-39.1%) for DHA, 0.0% (0.0%-1.9%) for artefenomel, and 0.0% (0.0%-3.23%) for RLA-4735, and median IC_{50}s were 3.8 nM (0.4 - 12.8 nM) for DHA, 3.0 nM (0.01 - 31.7 nM) for artefenomel, and 3.6 nM (0.05 - 23.4 nM) for RLA-4735. RSA median survival was higher in 2023-24 than 2019 for DHA, consistent with spreading ART-R, but not for artefenomel or RLA-4735. Also, median IC_{50}s were higher in 2023-24 than in 2019 for DHA and artefenomel, but not for RLA-4735. In summary, RLA-4735 demonstrated potent activity with both the RSA and IC_{50} assays against Ugandan *P. falciparum* isolates over time, including against isolates with reduced DHA susceptibility. We speculate that reduced iron reactivity and prolonged parasite residence time due to exceptionally high protein binding explain the potent antimalarial activity and lack of susceptibility to ART-R of RLA-4735

7158

HIGH EFFICACY OF ARTEMETHER LUMEFANTRINE AND ARTESUNATE PYRONARIDINE WITH SINGLE LOW DOSE PRIMAQUINE IN ADULT PATIENTS WITH *PLASMODIUM FALCIPARUM* IN A SETTING WITH HIGH PREVALENCE OF MARKERS OF PARTIAL ARTEMISININ RESISTANCE AND *PFHRP2 OR 3* GENE DELETION IN ETHIOPIA: A SINGLE BLIND RANDOMIZED CONTROLLED TRIAL

The emergence and expansion of *Plasmodium falciparum* (*Pf*) parasites with reduced sensitivity to artemisinins in East Africa threatens progress in malaria control. *Pf* parasites with *pfkelch13* 622I variant are uniquely reported in the Horn of Africa and may co-occur with deletions in *hrp2* and *hrp3* gene that allow parasites evade diagnosis by rapid diagnostic tests (RDT). In this study, *Pf* infected adult patients were followed for 42 days following the WHO therapeutic efficacy surveillance protocol, between December 2021 and July 2022, in a randomized two-arm prospective efficacy trial (Artemether-Lumefantrine [AL, n=101] or Pyronaridine-Artesunate [PA, n=98] plus primaquine [PQ]). Recurrent infections and paired samples were genotyped by targeting *Pfmsp2* and *Poly-α*, digital PCR was used to genotype *pfhrp2/3* gene deletion, and *pfkelch13* and *pfmdr1* genes were sequenced on Illumina iSeq100. No early treatment failures were observed in both arms. All but one patient in the AL arm cleared their microscopy detectable parasites by day 3 whilst late parasitological failure (LPF) was observed in 11 patients (day 21-42) of which 8 were confirmed recrudescences. PCR-adjusted treatment success were 97.8% (AL) and 98.9% (PA) on day 28 and 94.2% (PA) on day 42. The *pfkelch13* 622I variant was detected in 62.5% (5/8) of the paired recrudescent infections but not in confirmed reinfections. The *pfmdr1* NFD haplotype (86, 184, 1246) linked with lumefantrine failure was detected in all LPF samples. At recruitment, 41.6% (82/197) of infections were HRP2-based RDT negative of which 68.3% (56/82) were *pfhrp2* gene deleted. Although numbers were small, the *pfkelch13* 622I variant was detected more in *hrp2/3* gene deleted (71.4%, 5/7) than wild type (50%, 7/14) infections. Both AL and PA with PQ were efficacious for the treatment of uncomplicated *Pf* malaria in adults in a setting with rapid expansion and co-occurrence of parasites with *pfkelch13* 622I mutation and *hrp2/3* gene deletions. The findings in this study call for further detailed investigation to include children, assessing efficacy without adding PQ, and preparing for action such as multi-first line treatments.

The 8-aminoquinolines are the only licenced drug class for the treatment of relapsing malaria. Key members of the class include currently licenced primaquine and tafenoquine; as well as legacy compounds: pamaquine and pentaquine. The hypothesised mode of action for primaquine comprises a 2-step biochemical relay: (1) Cytochrome P450 (CYP)-mediated (predominantly CYP 2D6) metabolism into reactive intermediates; and (2) redox cycling of metabolites with CYP reductase (CPR) to form anti-parasitic levels of Reactive Oxygen Species (ROS). This work investigated whether this mechanism is class-wide; scrutinising CYP-mediated metabolism of, and subsequent ROS production from the 8-aminoquinolines. This study provides a thorough exploration into the physicochemical and pharmacological properties of 8-aminoquinolines and clinically relevant combination partners. Key DMPK analyses include hepatic metabolism with HμREL® co-culture clearance assay and investigations into CYP-specific metabolism, inhibition, and induction. Preliminary data into the pharmacodynamic mechanisms of 8-aminoquinoline action includes the measurement of CYP-mediated ROS using Pan-CYP and CYP-specific inhibitors and measures of cellular oxidative stress including Haem Oxygenase-1, as well as interrogation of *in vitro* efficacy using a *Plasmodium cynomolgi* liver stage assay. Evidence is presented in support of a divergent bioactivation step (1), and convergent ROS-mediated step (2) in the mechanism of action across the 8-aminoquinoline class, with tafenoquine not showing hepatic metabolism or CYP-mediated ROS production. Tafenoquine licencing now requires compulsory co-administration with chloroquine due to treatment failure with alternative regimen, piperaquine-dihydroartemisinin. This study suggests that these drug-drug interactions are unlikely to be CYP-mediated for both primaquine and tafenoquine. Ongoing research is underway to confirm the potentiating effect of chloroquine, and inhibitory effect of dihydroartemisinin on the redox-related efficacy of 8-aminoquinolines.

7160

THERAPEUTIC EFFICACY AND SAFETY OF ARTEMETHER LUMEFANTRINE (AL) AND ARTESUNATE AMODIAQUINE (ASAQ) FOR THE TREATMENT OF UNCOMPLICATED FALCIPARUM MALARIA IN KAGERA REGION, TANZANIA 2023

The World Health Organization (WHO) recommends pre-emptive antimalarial diversification to limit drug pressure and, when drug efficacy falls below 90%, a change in national policy. Artemisinin partial resistance (APR) and low uncorrected artemether-lumefantrine (AL) efficacy, are each indicative of increased pressure on lumefantrine. In 2022, Tanzania confirmed APR in Kagera region, and <90% AL efficacy in Pwani region. Low uncorrected efficacies have also been reported in Kagera, Pwani, Tanga (2022); and Tabora (2023) regions. We conducted this TES to

assess APR in Kyerwa district, neighboring Karagwe district and Kayonza district, Rwanda, which reported APR in 2015 and 2018. Children aged 6 months to 10 years were recruited in Kyerwa, treated with AL or artesunate-amodiaquine (ASAQ), and followed for 28 days to assess drug efficacy as per the 2009 WHO protocol. The primary outcome measure was polymerase chain reaction (PCR)-corrected efficacy using a 3/3 *msp1/ msp2/glurp* approach with gel electrophoresis. Parasite clearance rate and day 7 lumefantrine concentration levels were assessed. From June 2023 to January 2024, 176 participants (88 AL, 88 ASAQ) were enrolled; 87 (98.8%) AL and 88 (100%) ASAQ reached an endpoint. Respective uncorrected and corrected Kaplan-Meier efficacies for AL were 73.6% and 96.6% and 100.0% and 100.0% for ASAQ. Day 3 parasitemia was observed in 27 (15%): 8 (9.2%) AL, 19 (21.6%) ASAQ. The median parasite clearance half-life was 3.19 hours for AL and 3.04 hours for ASAQ. There was no association between day 7 lumefantrine concentration and malaria reinfection risk (hazard ratio=1.25, p=0.614). Genotyping for *k13* is ongoing to confirm APR. With high day 3 parasitemia, low uncorrected efficacy, and regional findings of APR in neighboring Rwanda and Uganda, which both use AL as first-line, a switch from AL to an alternate first-line ACT (ASAQ, Dihydroartemisinin Piperaquine) in Tanzania treatment guidelines should be considered as per WHO guidance. ASAQ's 100% efficacy and antagonistic selective resistance mechanism make it a strong replacement candidate for AL.

7161

THE UTILITY OF QPCR ESTIMATION OF PARASITE DENSITY IN EVALUATING THE EFFECT OF SULFADOXINE-PYRIMETHAMINE AS PERENNIAL MALARIA CHEMOPREVENTION

Sutherland[1], Serge-Brice Assi[3], Abibatou Konaté[3], Paterne Gnagne[3], William Yavo[3], Bigoga Jude[2], Akindeh Nji[2], Wilfred Mbacham[2], R Matthew Chico[1], Khalid B. Beshir[1]

[1]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Fobang Institute for Innovation in Science and Technology and The Biotechnology Center, The University of Yaounde I, Yaounde, Cameroon, [3]National Institute of Public Health and UFR of Pharmaceutical and Biological Sciences, Department of Parasitology-Mycology, Félix Houphouët-Boigny University, Abidjan, Côte D'Ivoire, [4]College of Public Health, University of South Florida, Tampa, FL, United States, [5]Centre for translational Medicine and Parasitology, Department of Immunology and Microbiology, University of Copenhagen and Department of Infectious Diseases, Copenhagen University Hospital, Copenhagen, Denmark

Perennial malaria chemoprevention (PMC) is a strategy recently updated by the World Health Organization to protect infants from malaria infections contributing to the overall reduction of disease burden. To evaluate these guidelines, the Plus Project investigates the effect of PMC with sulfadoxine-pyrimethamine (SP) in countries such as Cameroon and Côte d'Ivoire. qPCR is a more sensitive diagnostic method than point of care rapid diagnostic tests (RDT) and microscopy despite not readily operationalized for use in national programs. Thus, those can lead to false or missed diagnosis and underestimating the number of malaria cases. Therefore, this study aims to assess the sensitivity of qPCR and how programmatic tools compare with this molecular diagnostic method in measuring the impact of PMC. This study is nested within a larger study conducted in Côte d'Ivoire (regions Seguela and Cani) and Cameroon (regions Mbankomo and Soa) between July and August of 2023. A subset of samples from children aged aged between 10 weeks and 6 months (Côte d'Ivoire) or 6 and 9 months (Cameroon) were selected from 'cases' (children having the opportunity to take the expanded PMC-SP dosing) and controls (children who received standard of care). All children were tested for malaria using RDTs and microscopy, followed by blood spots collected on filterpaper. A highly sensitive qPCR method targeting *Plasmodium falciparum cytochrome ß* gene was employed to confirm and estimate parasite density. Additionally, conducted *Plasmodium* speciation to further explore the presence of non-Pf malaria cases. A total of 230 and 59 patients were positive by both RDT and microscopy in Côte d'Ivoire and Cameroon, respectively. Among those samples, 67.8% and 64.4% were positive by qPCR, with an estimated median parasite density of 401 (range: 6 - 110,256) and 501 parasites per microlitre (range 5 - 29,338), respectively. Further analysis will be conducted to evaluate the correlation between microscopy density and Ct values. The study will provide data on the diagnostic capacity of RDT and microscopy, and the utility of qPCR as an additional tool to evaluate the impact of interventions.

7162

COMPARATIVE EVALUATION OF ANTIMALARIAL DRUG EFFICACY IN THREE STUDY SITES IN MALI

Fatoumata Ousmane Maiga, Laurent Dembele, Ousmaïla Diakite, Abdoulaye A. Djimde

University of Sciences, Techniques and Technologies of Bamako (USTT-B), Bamako, Mali

Malaria remains a significant public health threat in Africa. The increasingresistance of *Plasmodium falciparum* parasites to available antimalarial treatmentsunderscores the urgent need for new therapeutic strategies. Some drugs previouslywithdrawn due to observed resistance are now being reconsidered for their potential utilityin certain regions due to the dynamic landscape of parasite resistance. This study aims toassess the efficacy of 15 antimalarials, categorized into three groups: drugs withdrawn due toresistance, currently used drugs, and new drugs under investigation. The goal is to explore theevolving efficacy of these treatments in the face of changing resistance patterns andpotentially reintegrate withdrawn drugs into effective treatment regimens. *P. falciparum* parasites were collected from three sites in Mali (Kolle, Bougoula-Hameau, and Faladje) and analyzed in a laboratory in Bamako. Each drug was tested on freshlycollected parasites, followed by a staining process using SYBR Green and Mitotracker. Thedrugs' efficacy was assessed by measuring parasite viability with flow cytometry, whichprovided data to estimate each drug's 50% inhibitory concentrations (IC50). We anticipate significant variability in the efficacy of antimalarial drugsacross the study sites, reflecting the genetic diversity of *P. falciparum* strains and their levelsof resistance. New-generation medications are expected to show higher efficacy againstresistant strains, offering promising prospects for malaria treatment. This study will provide critical insights into the efficacy of antimalarial drugs indifferent study sites. It has the potential to inform on the current status of used antimalarialsand support the development of tailored strategies with new ones.

7163

MINIMUM INOCULUM OF RESISTANCE STUDIES TO SUPPORT ANTIMALARIAL DRUG DISCOVERY

Tanaya Sheth[1], Jin Jeon[1], Kate J. Fairhurst[1], Tomas Yeo[1], Vandana Thathy[1], Ionna Deni[1], Leticia Tiburcio Ferreira[1], Kelly Rubiano[1], Josefine Striepen[1], Kyra A. Schindler[1], Heekuk Park[1], Anna Adam[2], Maelle Duffey[2], Anne-Catrin Ulhemann[1], Didier Leroy[2], David A. Fidock[1]

[1]Columbia University Irving Medical Center, New York, NY, United States, [2]Medicines for Malaria Venture, Geneva, Switzerland

Malaria remains a significant global health burden with an estimated 249 million cases and 608,000 deaths as of 2022. The emergence and spread of *Plasmodium falciparum* parasites resistant to multiple first-line drugs makes it imperative to develop new therapeutics with novel modes of action. Minimum inoculum of resistance (MIR) studies applied to candidate drugs provide a powerful tool to quantitatively assess the risk of resistance and measure its phenotypic impact in vitro. These experiments often extend to the identification of resistance mediators, a subset of which are drug targets. Here, we present our MIR studies on five different targets: dihydroorotate dehydrogenase (PfDHODH), ATPase4 (PfATP4), translation elongation factor 2 (PfeEF2), acetyl CoA synthetase (PfACS),

and phosphatidylinositol-4 kinase (PfPI4K), targeted by the compounds DSM265, KAE609, M5717, MMV019721 and MMV390048, respectively. Data from these results can be used to predict whether resistance would be quickly selected in the field. Compounds with robust MIR data can be used as a positive control for studies to assess the resistance liabilities of candidate therapeutics.

7164

RISK OF SELECTION AND TIMELINES FOR THE CONTINUED SPREAD OF ARTEMISININ AND PARTNER DRUG RESISTANCE IN AFRICA

Oliver J. Watson[1], Salome Muchiri[2], Graziella Scudu[2], Abby Ward[2], Gina Cuomo-Dannenburg[1], Tom Brewer[1], Aaron M. Woolsey[2], Peter Winskill[1], Lucy Okell[1]

[1]MRC Centre for Outbreak Analysis & Modelling, Imperial College London, London, United Kingdom, [2]Clinton Health Access Initiative, Boston, MA, United States

The introduction of artemisinin combination therapies (ACTs) has significantly reduced the burden of *Plasmodium falciparum* malaria, yet the emergence of artemisinin resistance (ART-R) as well as partner drug resistance threatens these gains. Recent confirmations of *de novo* ART-R markers in Africa, in particular in Rwanda, Uganda and Ethiopia, underscore the urgency of addressing this issue in Africa. Our objective is to characterise this evolving resistance landscape and understand the speed with which ART-R will continue to spread in Africa. We use a mathematical modelling approach to evaluate the risk posed by ART-R and explore scenarios for how ART-R will continue to spread in Africa. We incorporate current best estimates of both ART-R and partner drug resistance by bringing together WHO, WWARN and MalariaGen Pf7k data on antimalarial resistance in combination with a literature review to estimate model parameters known to impact the selection of ART-R for each malaria-endemic country. We identify 12 malaria endemic countries in Africa to prioritise for surveillance and future deployment of alternative antimalarial strategies, based on quickly selecting for ART-R once established. In scenarios designed to explore the continued spread of deletions in Africa, we identify 9 high-threat countries (Djibouti, Ethiopia, Kenya, Malawi, Rwanda, Sudan, Tanzania, Uganda, Zambia) that are most at risk of ART-R both spreading to and subsequently being rapidly selected for. In these 9 countries, under a range of scenarios, we predict that ART-R will spread out from the current hotspot in Central Africa, and within 30 years will replace the majority of parasites (>50% frequency). Our results provide a refined and updated prediction model for the emergence of ART-R in an effort to help guide antimalarial policy and prioritise future surveillance efforts and innovation. These put into stark context the speed with which antimalarial resistance may spread in Africa if left unchecked, confirming the need for swift and decisive action in formulating antimalarial policies focused on containing ART-R in Africa.

GENOMIC SURVEILLANCE OF *PLASMODIUM FALCIPARUM* IN GOLD MINING AREAS IN THE BRAZILIAN AMAZON BASIN

Mariana Aschar[1], Paoola Vieira[2], Daniel Ward[3], Jamille Gregório Dombrowski[1], Ronaldo Cesar Borges Gryschek[1], Taane Clark[3], Susana Campino[3], Silvia Maria Di Santi[1]

[1]USP, São Paulo, Brazil, [2]Health Department of Para, Para, Brazil, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom

There is an association between gold mining activities, deforestation and increase in the number of malaria cases, as observed in the Brazilian Amazon. In Brazil, about 140,000 cases of malaria were reported in 2023, and the state of Pará contributed 17% of this burden. In this state there was a 21% increase in gold mining areas and a concerning 132% increase in the number of *Plasmodium falciparum* cases. Difficulties in accessing diagnosis and low adherence to treatment increase vulnerability to malaria, contributing to resistance of parasites to antimalarials. Deletions in the *pfhrp2/3* genes can impact the performance of rapid diagnostic tests. These factors pose challenges to malaria control and elimination. We analyzed 49 blood samples from patients infected with *P. falciparum* in gold mines located in Pará, Brazil. After DNA extraction, the samples were analyzed through semi-nested PCR and the fragments obtained were resolved by gel electrophoresis. The prevalence of deletions in *pfhrp2/3* genes was 6.12%. We assessed the prevalence of drug resistance markers in *P. falciparum* by carrying out a targeted amplicon sequencing protocol using the MinION platform from Oxford Nanopore Technologies. Multiplex PCR with specific primers for each gene was followed by sequencing. Mutations associated with *P. falciparum* resistance were detected in all isolates, with mutations for chloroquine (*pfcrt* K76T, C72S, and *pfmdr1* Y184F), for pyrimethamine (*pfdhfr* N51I and S108N), and for sulfadoxine (79% with double mutations - *pfdhps* A437G and A581G and 21% with triple mutations - A437G, A581G and K540E). No mutations associated with artemisinin resistance (*pfkelch13*) were found. Although no mutations associated with resistance to artemisinin have been detected, the misuse of antimalarials or illegal medicines poses a threat to the emergence of resistance to this antimalarial or partner drugs. Furthermore, deletions in the *pfhrp2/3* genes significantly impact the use of rapid diagnostic tests, which are crucial for diagnosis, especially in remote areas. These findings highlight the importance of ongoing genomic surveillance in malaria-endemic regions.

7166

LEVERAGING A *PLASMODIUM FALCIPARUM* GENETIC CROSS TO IDENTIFY CANDIDATE DETERMINANTS OF MULTIGENIC RESISTANCE TO QUININE AND CHLOROQUINE

Mariko Kanai[1], Sachel Mok[1], Tomas Yeo[1], Melanie Shears[2], Leila S. Ross[1], Jin H. Jeon[1], Sunil K. Narwal[1], Meseret T. Haile[1], Abhai K. Tripathi[2], Godfree Mlambo[2], Jonathan Kim[1], John Okombo[1], Eva Gil-Iturbe[1], Kate J. Fairhurst[1], Talia Bloxham[1], Jessica L. Bridgford[1], Heekuk Park[1], Felix D. Rozenberg[1], Matthias Quick[1], Filippo Mancia[1], Marcus C.S. Lee[3], Jennifer L. Small-Saunders[1], Anne-Catrin Uhlemann[1], Photini Sinnis[2], **David A. Fidock**[1]

[1]Columbia University, New York, NY, United States, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]University of Dundee, Dundee, United Kingdom

The emergence of *Plasmodium falciparum* strains showing partial resistance to artemisinin (ART) in multiple countries in east Africa poses a substantial threat to malaria treatment. ART derivatives constitute the core component of first-line combination therapies to treat uncomplicated malaria and are used to treat severe disease. Should ART resistance spread, alternative drugs will be required, yet the options are limited. The WHO recommends quinine (QN) as an option for treating severe malaria when artesunate or artemether are not available or are contraindicated. Moderate *P. falciparum* resistance to QN has been reported, but its genetic basis has remained elusive. We conducted a genetic cross between the QN-resistant Cam3.II parasite and the drug-sensitive NF54 parasite, using human liver-chimeric FRG-NOD mice. This cross yielded 120 independent recombinant progeny. Phenotypic analysis of progeny, combined with whole-genome sequence data, enabled us to apply quantitative trait loci mapping to identify regions associated with QN resistance. Our results identified a segment on chromosome 7, which for both IC_{50} and IC_{90} analyses included *dmt1* that encodes a putative drug/metabolite transporter. IC_{50} (but not IC_{90}) analyses also associated the QN response with mutant *pfcrt*, located 200 kb upstream of *dmt1*. Genetic disruption of *dmt1* sensitized Cam3.II parasites to QN, and transport studies with proteoliposomes reconstituted with recombinant mutant DMT1 showed evidence of QN transport. These data implicate *dmt1* as a component of a multigenic basis of QN resistance. We also identified a peak on chromosome 12, whose genes include mutant *ftsh1* that is a potential resistance mediator. This chromosome 12 peak was also associated with CQ resistance in addition to the dominant *pfcrt* peak on chromosome 7. Our data reveal a multigenic basis of QN resistance and identify a potential new modulator of mutant *pfcrt*-mediated CQ resistance.

THE GULART STUDY: A CROSS-SECTIONAL SURVEY OF ARTEMISININ PARTIAL RESISTANCE AND SPECIES DIVERSITY IN FIVE NORTHERN UGANDAN DISTRICTS

Elizabeth R. Zhang[1], Peace Amito[2], Natasha Turyasingura[1], Frida Aryemo[3], Christopher Nyeko[3], Sandra Ajolorwot[3], Vivian Nakiwu[3], Melody Deblasio[4], Jack Carew[1], Amy Bei[1], Richard Echodu[2], Sunil Parikh[1]

[1]Yale School of Public Health, New Haven, CT, United States, [2]Department of Biology, Faculty of Science, Gulu University, Gulu, Uganda, [3]Gulu University Multifunctional Research Laboratories, Gulu, Uganda, [4]Yale College, New Haven, CT, United States

Partial resistance to artemisinin derivatives, vital drugs in the treatment of malaria, has emerged in multiple East African countries and is linked to mutations in the *Plasmodium falciparum* (*Pf*) Kelch 13 protein (*Pfk13*). Published studies in Uganda have relied on convenience sampling, which are unable to provide an estimation of community-level prevalence. We employed a GIS-based two-stage cluster randomized cross-sectional survey of n=598 asymptomatic children <5 years in five districts of Northern Uganda: Gulu (n=180), Amuru (n=113), Lamwo (n=101), Pader (n=90), and Omoro (n=114) from Aug 2022 to Jan 2023. In addition, we sampled n=102 patients presenting with uncomplicated malaria at the Gulu Regional Referral Hospital (GRRH). In the asymptomatic community cohort, 54.2% were male, and the mean age was 1.9 yrs (SD=1.4). 44.1% (n=263) were positive for *Pf* by PfHRP2-based RDT and 54.3% (n=325) were positive for any *Plasmodium spp.* infection by real-time PCR. While the majority (66.8%; n=217/325) were positive for *Pf*, we found a strikingly high burden of *P. ovale* species (*Po*): 31.4% (n=102) were *Po* mono-infections and 22.2% (n=72) were *Pf-Po* co-infections. An additional 4.0% were *Pm* (n=13) and 0.6% (n=2) were *Pv* infections. Of the n=102 diagnosed as uncomplicated malaria cases at GRRH, a surprising n=32 were *Po* mixed or mono-infections by RT-PCR. Apart from *Pf* and *Po*, no other species were detected among symptomatic patients. Our study reveals a striking community-based prevalence of *Po* in children sampled in all districts, including in individuals presenting for care with symptomatic disease at GRRH. In addition, *PfK13* was successfully amplified by PCR for n=158/217 of *Pf*+ community samples. Thus far, C469Y has been identified by high-resolution melting (HRM) in our community samples. Further work, namely HRM and NGS, is underway to complete characterization of circulating *PfK13* haplotypes in the community. Together, these data present a complex scenario in Northern Uganda which necessitate urgent changes in malaria diagnostic and treatment policies in the region.

7168

DIAGNOSIS OF *PLASMODIUM* SPECIES USING A.I. TECHNIQUES VERSUS STANDARD MICROSCOPY

Sanjai Nagendra[1], Roxanna Hayes[1], Dayeong Bae[2], Krystin Dodge[1]

[1]Labcorp, Burlington, NC, United States, [2]Noul Company Limited, Seoul, Korea, Republic of

Malaria diagnosis using standard techniques is challenging and time-consuming, leading to discrepancies and delays. Innovative technologies utilizing advanced technologies are changing the diagnostic landscape. The miLab™MAL, an automated malaria diagnostic solution, was compared with standard microscopy at Labcorp® reference laboratories. 409 samples submitted for parasitic examination were prepared with thick and thin smears and Noul's malaria diagnostic solution, miLab™MAL, and evaluated for positivity, negativity, and speciation. 399/409 samples were manually negative, while 397/409 were negative by miLab™MAL. Two samples initially classified as negative manually were found positive by miLab™MAL. Upon re-examination of the peripheral smear, very rare trophozoites, constituting less than 0.1% of the erythrocytes, were identified in both samples. In nine out of ten cases, *Plasmodium falciparum* was identified by both methods. In one case, *Babesia sp.* was identified by microscopy, but miLab™MAL identified *Plasmodium falciparum*. Our studies show that miLab™MAL was accurate in identifying the presence or absence of *Plasmodium*. All positive samples detected by microscopy were also identified with miLab™MAL. The miLab™MAL also showed greater sensitivity than the manual method. All cases negative for *Plasmodium* by microscopy were also negative by the miLab™MAL method (100% specificity), indicating that intraerythrocytic inclusions were not confused with malarial parasites. The miLab™MAL correctly identified *Plasmodium falciparum* species in 11/12 cases compared to the 10/12 cases by standard microscopy. Because machine learning tools for Babesia were not programmed into the miLab™MAL, this led to the discrepancy. Based upon the study's findings, miLab™MAL can be used to screen out negative *Plasmodium* samples. Since the positivity rate for malaria in reference laboratory specimens is low, resources can be saved using this technology. Due to the limited number of positive samples (n=12), further studies in malaria-endemic areas are necessary to assess the reliability of *Plasmodium* speciation.

7169

GENOTYPING OF PLASMODIUM FALCIPARUM MEROZOITE SURFACE PROTEIN 2 (PFMASP-2) REVEALED DIFFERENT ALLELIC PROFILES IN BLOOD AND SALIVA SAMPLES FROM MFOU HEALTH DISTRICT IN CAMEROON

Loïc T. J. Keumo, Hillary M. S. Tene, Francis Zeukeng, Rose G.F. Leke, Jude D. Bigoga

University of Yaounde I, Yaounde, Cameroon

Monitoring Genetic diversity of malaria parasites might help address constant emergence of resistance of *Plasmodium falciparum* to antimalarials. the usefulness of Pf*MSP2* to monitor *P. falciparum* polymorphism is hampered by the lack of non-invasive sample collection method. In the current study we sought to assess the suitability of saliva as a biological material to assess the diversity of *P. falciparum*. To this end, we collected total of 27 saliva and 50 blood specimens from malaria positive patients at Mfou health district, Cameroon. Genomic *Plasmodium* spp. DNA was extracted from blood and saliva samples, and used in nested-PCR to detect the presence of *P. falciparum* and the different alleles of *Pfmsp-2*. The presence of *P. falciparum* was confirmed by nested PCR with a positivity rate of 94% (47/50) and 88.88% (24/27) in blood and saliva samples respectively. Altogether, 14 different alleles of the *Pfmsp-2* gene with bands ranging between 279-1178bp were detected in blood. The genetic diversity and multiplicity of Infection (MOI) of *Pfmsp-2* was 10.61% and 2.81 respectively in blood samples. In contrast, only 6 alleles of the *Pfmsp-2* gene with bands ranging between 450-708pb were detected in saliva samples. Here, the genetic diversity of *Pfmsp-2* gene and the multiplicity of infection were 35.29% and 1.33 respectively. Quadruple allelic infections (4 types of alleles) were predominant (29,78%) in blood, while single allelic infections (1 allele) were predominant in saliva (86,67%). These results demonstrated the use of saliva as specimen for investigating genetic diversity endemic area. Furthermore, our findings depict an extensive genetic diversity of Pfmsp-2 observed in Mfou and it could herald the rise and spread of drug resistant strains of *P. falciparum* which could have implication in MSP2-based vaccines efficacy in this locality.

7170

POINT-OF-CARE TEST OF BLOOD *PLASMODIUM* RNA WITHIN A PASTEUR PIPETTE USING A NOVEL ISOTHERMAL AMPLIFICATION WITHOUT NUCLEIC ACID PURIFICATION

Lyu Xie[1], Zhi Zheng[1], Jiyu Xu[1], Lihua Fan[1], Xiaodong Sun[2]

[1]Peking Union Medical College, Beijing, China, [2]Yunnan Institute of Parasitic Diseases, Yunnan, China

We present Pasteur Pipette-assisted Isothermal Probe Amplification (pp-IPA), a novel molecular point-of-care test (POCT) for malaria detection in resource-limited settings. In this approach, specific, tailed probes capture released 18S rRNA of *Plasmodium* onto the inner wall of an oligo-conjugated Pasteur pipette through sandwich hybridization. After

washing off impurities and unbound probes, the bound tailed probes are ligated to form complete dumbbell-shaped templates for subsequent isothermal amplification using a pair of primers, bypassing nucleic acid extraction and reverse transcription. The entire assay takes 60 - 80 min to complete requiring only a Pasteur pipette and a water bath. Experimental results confirm pp-IPA's analytical sensitivity to be $1.28*10^{-4}$ parasites/µl, a sensitivity 3 - 4 orders of magnitude higher than existing molecular POCT methods for malaria, with 100% specificity against various blood-borne pathogens causing malaria-like symptoms. Additionally, pp-IPA needs only liquid-transfer skill for operation and the cost for per test is around $0.25. pp-IPA's simplicity, affordability, high sensitivity/specificity, and minimal equipment requirement make it a promising point-of-care pathogen identification tool in resource-constrained regions.

7171

MOLECULAR AND SEROLOGICAL ANALYSIS OF AFEBRILE *PLASMODIUM FALCIPARUM* INFECTION IN SOUTHERN MOZAMBIQUE: A PROSPECTIVE COHORT

Arlindo Chidimatembue[1], Arnau Pujol[2], Henriques Mbeve[1], Meritxell Molinos[1], Nelo Ndimande[1], Eduard Rovira-Vallbona[2], Manuel Garcia[2], Pedro Aide[1], Quique Bassat[2], Francisco Saute[1], Alfredo Mayor[2]

[1]Manhica Health Research Centre (CISM), Maputo, Mozambique, [2]ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain

Afebrile *Plasmodium falciparum* (*Pf*) infections have a debilitating impact on health and represent a hidden source of transmission that can compromise malaria elimination efforts. Understanding the dynamics and biological factors that maintain parasite-host interactions at the subclinical level would contribute to the ongoing debate on the relevance of afebrile infections as a barrier to malaria elimination, and guide the use of interventions to reduce this silent reservoir. In this study, healthy Mozambican individuals were screened at household level using a rapid diagnostic test (RDT) to detect Pf infection. Positive cases were confirmed microscopically and followed up for 28 days (daily visits for the first 4 days and weekly visits until the 28th day) during the 2020-23 rainy season. Antimalarial treatment was administered either upon reaching the end of the follow-up period or in response to clinical symptoms occurred before day 28. Blood samples and basic clinical-demographic information were collected at every visit. Samples were analysed using a combination of genetic and serological tools. The longitudinal analysis used data from 146 of the 177 enrolled individuals, excluding individuals with less than 3 observations on days 7, 14, 21 and 28. Seventeen of the 146 participants (11.6%) spontaneously cleared the infection and 11 (7.5%) developed fever during the follow-up. In 34 participants (23.3%), parasite densities and HRP2/LDH levels decreased dramatically and stabilized at low levels (i.e. below the geometric mean of the clearance samples), whereas in 28 participants (19.2%) they increased and stabilized at high density levels (i.e. above the geometric mean of the fever samples). In 56 participants (38.4%), parasite densities and HRP2/LDH levels were maintained at intermediate levels. Thus, approximately half (57.6%) of the afebrile RDT-detected infections maintained densities with high transmission potential. Ongoing molecular and serological characterization will provide further insight into the parasitological and immunological factors linked to disease progression in areas of low malaria transmission.

7172

MALARIA PREVALENCE AMONG PATIENTS ATTENDING TWO HEALTH CENTRES IN IKWUANO L.G.A, ABIA STATE, NIGERIA USING BLOOD AND URINE SAMPLES

Onyinye M. Ukpai, Jennifer C. Okoye

Michael Okpara University of Agriculture, Umudike, Umuahia, Nigeria

Malaria, a life threatening disease caused by the protozoa of the genus Plasmodium is transmitted to man through the bites of infected female Anopheles mosquitoes. The study was done between July and December, 2023 to determine the prevalence of malaria among patients attending Amawom and Umudike health centres using the conventional microscopy and RDT kit methods. Two mls of venous blood and 200 ul of urine were collected from 200 patients who gave their consent using sterile syringes for blood and sterilized dry mouthed cork screwed plastic containers for urine. Blood was dispensed into EDTA bottles and gently mixed. Blood samples were examined using conventional microscopy for thin and thick blood smears and Carestart TM strip for blood while urine test was done with SD Bioline strip. The overall prevalence of malaria with microscopy was 24.0% while RDT for blood and urine were 12.0% and 10.5% prevalences respectively. More males (27.3%) than females (20.8%) were infected. The age group 20-30 years recorded more infection (32.6%). The need for development of new, simple, quick, accurate non invasive and cost-effective diagnostic tests for malaria can be complemented by the use of RDTs, especially RDT for urine for non-invasive approach, since the results of RDTs used in the study have shown their usefulness as a rapid and simple tool for malaria diagnosis. This also promises to be a useful diagnostic tool that can be deployed for use in poor resource settings where regular supply of electricity and absence of an expert microscopist can be challenges to the use of microscopy

7173

STRENGTHENING THE QUALITY OF MALARIA MICROSCOPY THROUGH A CASCADE TRAINING MODEL IN TANZANIA

Saidi Mgata[1], Stella Makwaruzi[1], Saidi Haji[2], Bimkubwa Kombo[2], Michael Gulaka[1], Gibonce Bwana[3], Bakari Mohamed[4], Geofrey Makenga[1], Marguerite M. Clougherty[5], Albert Ikonje[6], Daniel Mbwambo[7], Abdallah Lusasi[7], Samwel Lazaro[7], Shija J. Shija[2], Chonge Kitojo[6], Sarah-Blythe Ballard[8], Naomi Serbantez[6], Sigsibert Mkude[1]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [3]National Public Health Laboratory, Ministry of Health, Dar es Salaam, Tanzania, United Republic of, [4]Zanzibar Malaria Elimination Program, Ministry of Health, Dar es Salaam, Tanzania, United Republic of, [5]Population Services International (PSI), Washington DC, WA, United States, [6]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [7]National Malaria Control Programme, Ministry of Health, Dodoma, Tanzania, United Republic of, [8]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of

In 2023, >1 million malaria microscopy tests were conducted in high-burden Mainland Tanzania and 35,550 were conducted in Zanzibar, an elimination-targeted area. However, there were no certified expert microscopists, and only 70.1% of health facilities (HFs) performed satisfactorily on malaria microscopy during Malaria Service Delivery and Quality Improvement (MSDQI) evaluations. We assessed the impact of a cascade model to expand the cohort of certified microscopists at HFs. A cohort of 12 microscopists underwent WHO-External Competency Assessment of Malaria Microscopy (ECAMM) expert certification. This expert cohort was further expanded with those passing advanced malaria diagnostic refresher training (MDRT) and ultimately served as MSDQI supervisors, quality improvement mentors, and administrators of laboratory external quality assurance (EQA) proficiency testing (PT), and basic MDRT. We used EQA PT and MSDQI evaluations to assess microscopy performance improvement of those trained with the cascade model. The 12 expert microscopists conducted 9 MDRT trainings, resulting in a total of 177 trained microscopists, and expanding the expert cohort by 25. In Zanzibar, 85 PT rounds conducted by this expert cohort demonstrated significantly improved scores from 84% to 92% in parasite identification (PID), 18% to 54% in species identification (SID), and 32% to 45% in parasite counting (PC) ($p<0.001$ for all PT). In mainland, 11 PT rounds demonstrated improved scores from 93% to 100% in PID, 64% to 77% in SID, and 43% to 50% in PC, but did not reach significance. In the same period, microscopy performance in 14 Mainland HFs receiving supervision and mentorship from the expanded cohort significantly improved MSDQI scores from 40% to 92% in smear preparation and staining ($p<0.001$); 60%

to 100% in slide examination; 33% to 71% in PT enrollment ($p<0.001$); and 33% to 57% in internal quality control performance. This cascade training model rapidly established a cohort of expert microscopists who, in turn, significantly expanded the cohort of trained microscopists and contributed to significant improvements in HF PT nationwide.

7174

MALARIA MICROSCOPY EVALUATION AND QUALITY ASSURANCE IN RURAL CLINICS IN WESTERN KENYA

Jonathan S. Schultz[1], Oliver Towett[2], Wycliffe Odongo[3], Kizito Obiet[2], Brian Seda[2], Victoria Seffren[3], Simon Kariuki[2], Kephas Otieno[2], Dennis Bii[2], Daniel McDermott[4], Sarah Staedke[4], Titus K. Kwambai[1], Julie R. Gutman[3]

[1]Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Kisumu, Kenya, [2]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [3]Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

While rapid diagnostic tests are widely used, they have several limitations, and blood smear (BS) examination by microscopy remains the gold standard for malaria diagnosis. However, poor quality reagents, limited technical capacity, and turnaround times all threaten the ability to reliably provide accurate results in public health facilities (HF) in malaria endemic areas of Kenya. To assess the quality of malaria microscopy, we evaluated the concordance of BS results at 28 HF with expert microscopy in Siaya County, western Kenya. At each HF, the quality of reagents, slide preparation, standard operating procedures availability, and infrastructure (electricity and microscope) were documented. Approximately 20 patients per HF assessed for malaria by microscopy between January and March 2024 were randomly selected to have their BS re-examined by an expert microscopist. Two expert examinations were conducted for each patient, one on-site re-examination of the routine HF-prepared slide using the HF microscope (slide 1), and the second off-site at the Kenya Medical Research Institute (KEMRI) malaria laboratory, where a second dried but unstained slide was stained and examined (slide 2) as the gold standard. Concordance between the routine HF results and expert re-examined HF slide at the HF (slide 1) and expert stained HF slide at KEMRI (slide 2) were evaluated, and sensitivity and specificity calculated. Overall BS positivity was 35% (166/480). There was 85% (405/480) concordance between the routine HF results and slide 1 expert re-reading, with a range of 50% (10/20) to 100% (20/20), by HF. There was 81% (336/411) concordance between the HF results and slide 2, with a range from 65% (7/13) to 100% (10/10). Compared to slide 2, the routine HF results had sensitivity and specificity of 72% and 87%, respectively. HF with the lowest concordance had poor BS quality 21% (6/28), contaminated reagents 7% (2/28), and low-quality microscopes with intermittent electricity 4% (1/28). While overall concordance was high, the variability in results and moderate sensitivity highlight the need for ongoing monitoring of malaria microscopy quality at public HF.

7175

AN EFFECTIVE CASCADING CLASSIFIER FOR PATIENT-LEVEL MALARIA DIAGNOSIS ON THE MILAB™ PLATFORM WITH FOCUS-STACKING TINY VISION TRANSFORMER

Hyunghun Cho, DongShik Ham, Seongjin Park, Adam Balint, Dayeong Bae, Minjong Kim, Younghoon Song, DaeSeon Jeong

Noul Co., Ltd., Yongin-si, Korea, Republic of

Determining a proper diagnosis can take varying lengths of time and effort. In the case of malaria, inspecting a smeared blood slide through a microscope is the most common method of diagnosis. AI solutions, such as those conducted with the miLab™ platform, have been proposed to inspect the blood cells digitally, and cascading classifiers have shown great performance. However, clumped or blurry cells are still difficult for the AI to classify correctly. These hard samples require review by an expert to provide an accurate diagnosis; however, this comes at the cost of increased time and monetary cost to provide a diagnosis. This study introduces a new deep-learning model based on a pre-trained vision transformer; fine-tuned on hard samples. Reducing the workload of a human expert, TinyViT, a state-of-the-art but small model, can augment the workflow of the miLab™ platform and decrease the number of cells required to be reviewed. To circumvent the shallow depth of field limitations, focal stacking using multiple auto-focused images was used to generate the input image. Experts have extensive experience examining images prepared using different staining qualities. To mimic this experience, we apply realistic microscopy image augmentations to improve generalization when fine-tuning the pre-trained model. Adding additional steps to the existing pipeline introduces unnecessary overhead; therefore, this method is used only when there are few equivocal cells to review. We have internally validated that extending cascading classifiers improved malaria readout performance. The number of cells designated for user review decreased, reducing the time experts need to confirm cells, even if using a more accurate AI model takes extra operation time. Appending TinyViT to the end of the miLab™ process improved the overall performance to 97% and reduced the number of false positives and negatives while not significantly increasing processing time. As a result, 80% less resources can be spent confirming cells, and it can instead be spent by on-site experts helping more people, improving accessibility, and maintaining a good patient-provider experience.

7176

DETECTION OF *PLASMODIUM VIVAX* IN NORTHERN KENYA VIA MICROSCOPY CONFIRMED BY MOLECULAR SPECIATION

Stephen Aricha[1], Regina Kandie[1], Mildred Shieshia[2], Rosebela Kiplagat[1], Dan Otieno[3], Beatrice Machini[1]

[1]Ministry of Health, Kenya, Nairobi, Kenya, [2]PMI-USAID, Nairobi, Kenya, [3]WHO, Nairobi, Kenya

In Kenya, *Plasmodium falciparum* is the predominant parasite responsible for malaria infections, mainly in western Kenya. Presence of *P. vivax* can complicate both diagnosis and treatment, posing a challenge for malaria control in endemic counties. We describe confirmed detection of *P. vivax* cases in northern Kenya in the aftermath of heavy rains, Sept-Dec 2023. We conducted a retrospective review of data from the Kenya Health Information Systems between December 2023-February 2024 in the five northern counties of Isiolo, Marsabit, Mandera, Samburu and Wajir to ascertain increase in malaria cases. In the peripheral clinics, blood smears with morphological features inconsistent with *P. falciparum* at time of diagnosis were encouraged to be sent for confirmation by expert microscopy and PCR at the National Malaria Reference Laboratory (NMRL). In the five northern counties, 7,860 confirmed cases of malaria were reported between Dec 2023-Feb 2024, up from 2881 cases—a 173% increase from the same period in the previous year. So far, NMRL has processed 9 samples sent for species confirmation—six were confirmed as *P. vivax*, and three as *P. falciparum.* Additional samples remain but NMRL has not processed them due to limited reagents. Detection of *P. vivax* in the northern counties that border Ethiopia is of great concern, suggestive of potential cross-border transmission. Strengthening diagnostic and speciation capacity by microscopy is critical, especially because rapid diagnostic tests used in Kenya do not detect *P. vivax*. Complementing microscopy with molecular diagnostics can also improve speciation in a timely manner. Recent malaria outbreak investigations in Wajir and Marsabit counties also found >40 cases of *P.* vivax. Ongoing malaria surveillance, particularly on *P. vivax*, through strengthened microscopy and molecular confirmation in the northern counties is critical to inform national malaria program decisions and improve response, especially as weather patterns change to become more conducive to malaria transmission.

7177

EVALUATION OF THE PERFORMANCES OF RAPID DIAGNOSTIC TESTS TO DETERMINE THE PREVALENCE OF *PLASMODIUM FALCIPARUM PFHRP2* GENE DELETIONS IN THE HEALTH DISTRICT OF NANORO, BUKINA FASO

Ipéné Mylène Carenne Bayala[1], Awa Gnémé[1], Paul Sondo[2], Eulalie Compaoré[1], Bérenger Kaboré[3], Elisée Kambou[4], Solange Millogo[4], Chantal Kouevi[1], Marc Tahita[3], Franck Hien[3], Karim Derra[3], Elie Rouamba[3], Hamidou Ilboudo[3], Halidou Tinto[3]

[1]University Joseph KI-ZERBO, ouagadougou, Burkina Faso, [2]Nanoro Clinical Research Unit/University Joseph KI-ZERBO, ouagadougou, Burkina Faso, [3]Unité de Recherche Clinique de Nanoro, ouagadougou, Burkina Faso, [4]University Nazi Boni, ouagadougou, Burkina Faso

Malaria diagnostic methods rely essentially on rapid diagnostic tests (RDTs) based on histidine-rich protein 2 in peripheral health centers and microscopy only performed in reference centers. Nowadays, the reliability of RDT results would be threatened by the appearance of strains that do not secrete *pfhrp2* antigen, making these parasites undetectable by RDTs. The objective of this study was to evaluate the performances of RDTs and to determine the prevalence of *Plasmodium falciparum pfhrp2* gene deletions in the health district of Nanoro. The study population consisted of children under Seasonal Malaria Chemo Prevention (SMC) coverage and aged 6-59 months. At each visit for chemo-prevention, blood samples were taken for the preparation of thick drops and blood smears. A rapid diagnostic test was also done to assess malaria infection on site. Blood was spotted on a filter paper for the detection of *pfhrp2* gene deletions using PCR.A total of 1059 children with a mean age of 34 months (range 6-59) participated in this study. The analysis of RDT performance indicators allowed us to obtain a specificity of 84.00% and a sensitivity of 77.06%. False positives were estimated at 15.99% compared to 22.94% false negatives. On a total of two hundred (200) samples analyzed by PCR, we obtained a prevalence of 2.58% of *pfhrp2* gene deletion. This study is one of the first to reveal the presence of *pfhrp2* gene deletions in Burkina Faso. With approximately 2.6% prevalence, this value is below the threshold of 5% set by the WHO to consider a change in the type of RDT. Therefore, HRP2 RDTs are still indicated for the diagnosis of malaria in Burkina Faso. However, a large-scale study to monitor the temporal dynamics of these *Plasmodium falciparum* strains that do not produce the *pfhrp2* antigen is necessary in Burkina Faso.

STRENGTHENING THE LABORATORY DIAGNOSIS OF MALARIA IN GUINEA: THE KEY ROLE PLAYED BY WHO-CERTIFIED LOCAL EXPERTS

Fakouma Camara[1], Mamadou Sitan Keita[1], Souleymane BERETE[1], Eliane Mbounga[2], Lamine Bangoura[2], Alioune Camara[3], Kolou Bie PIVI[3], Mandjou Diakite[4], Olivier Byicaza Nk[1], Daouda N'Diaye[1], Amadou Tidiane Diallo[1], Sékouba Cisse[1], Ibrahima Tanou Bah[1], Elizabeth Fitch[5], Richard Reithinger[6], Datolo Kone[1]

[1]RTI International, Conakry, Guinea, [2]President's Malaria Initiative, USAID, Conakry, Guinea, [3]National Malaria Control Program, Conakry, Guinea, [4]Direction Nationale des Laboratoires, Conakry, Guinea, [5]RTI International, RTP, NC, United States, [6]RTI International, Washington, DC, United States

Malaria continues to represent a substantial health burden in Guinea. In 2021, USAID | Guinea StopPalu+ facilitated the WHO certification of 10 local malaria microscopists from referral hospitals supported by the project. Since then these experts have been used to oversee and lead malaria diagnosis training workshops for laboratory technicians, as well as conduct regular supportive supervisions to monitor the quality of malaria diagnosis at health facilities. Here we describe how the quality of malaria diagnosis in Guinea has been strengthened, including elaborating on best known practices and lessons learned. We describe observations and findings from two cycles of quarterly supportive supervision visits to 22 specialized microscopy laboratories in 19 of the country's 39 districts. Visits included direct observations by the supportive supervision team of technicians performing laboratory malaria diagnosis, key informant interviews, a review of laboratory registers, and an assessment of laboratory competence against WHO-provided reference microscopy slides. Substantial improvements were seen across various domains following two cycles of supportive supervision. In terms of the External Quality Assessment, the correct diagnosis of malaria improved from 89% to 98%, correct species identification improved from 65% to 83%, and correct parasite quantification improved from 49% to 55%. Microscope maintenance improved from 86% to 91%, and the specialized technical interventions improved from 0% to 27%; similarly, the availability of key commodities improved substantially (e.g., the availability of Giemsa and immersion oil improved from 77% to 100% and 91% to 100%, respectively). Facilities that conducted internal quality control efforts increased from 27% to 36%. Two cycles of supportive supervision by 10 WHO-certified local malaria microscopists led to substantial improvements in the malaria diagnostic capacity of laboratory technicians in 22 laboratories. Additionally, key improvements in quality service provision were made, including with regards to the availability of commodities and functional equipment.

ECONOMIC EVALUATION OF MALARIA DIAGNOSTIC STRATEGIES FOR MALARIA CAMPS IN REMOTE VILLAGES OF ODISHA STATE, INDIA

Sooyoung Kim[1], Anne Kessler[2], Mohammed A. Haque[3], Timir K. Padhan[3], Danielle C. Ompad[4], Sanjib Mohanty[3], Jane M. Carlton[2], Praveen K. Sahu[3], **Yesim Tozan**[5]

[1]New York University School of Global Public Health, Department of Public Health Policy and Management, New York, NY, United States, [2]Center for Genomics and Systems Biology, Department of Biology, New York University, New York, NY, United States, [3]Department of Molecular & Infectious Diseases, Community Welfare Society Hospital, Rourkela, Odisha, India, [4]New York University School of Global Public Health, Department of Epidemiology, New York, NY, United States, [5]New York University School of Global Public Health, Department of Global and Environmental Health, NEW YORK, NY, United States

In India, malaria predominantly affects tribal populations in remote areas of Odisha state. The deployment of 'malaria camps' (MCs) with a mass screening-and-treatment (MSAT) intervention was shown to be effective in reducing PCR-positive Plasmodium infection prevalence. *Plasmodium falciparum* histidine-rich protein-2 (*pfhrp2*) gene deletions may, however, lead to false-negative RDT results, posing a challenge to MSAT's sensitivity to detect true malaria cases. We evaluated the incremental cost-effectiveness (ICER) of two alternative malaria detection strategies in the context of MSAT, following standard guidelines for cost-effectiveness analysis. A decision tree model was developed with three arms with arm 1 representing the comparator screening strategy which is the existing HRP-2-based RDT and arms 2 and 3 being the alternative screening strategies with an LDH-based RDT and an isothermal (LAMP-based) molecular diagnostic strategy, respectively. The number of DALYs averted and the associated incremental costs were estimated to calculate ICER from both a healthcare provider and a societal perspective. Deterministic and probabilistic sensitivity analyses were both conducted to ensure the robustness of the findings. The ICER of Arm 2 was estimated at $0.98/DALY averted (95% CrI=[$0.64/DALY averted, $2.04/DALY averted]) from the healthcare provider perspective, and at $0.40/DALY averted (95% CrI=[cost-saving, $3.00/DALY averted]) from the societal perspective. The ICER of Arm 3 was $114.05/DALY averted (95% CrI=[$65.03/DALY averted, $352.04/DALY averted]) from the healthcare provider perspective and was $113.43/DALY averted (95% CrI=[$64.37/DALY averted, $351.25/DALY averted]) from the societal perspective. Transitioning to either an LDH-based RDT or a LAMP-based molecular diagnostic represents a cost-effective alternative to the current HRP-2-based RDT utilized in the MSAT component of the MCs. Notably, the LDH-based RDT exhibited a significantly less incremental cost while averting more disease burden compared to the LAMP-based method.

EFFICACY AND SAFETY OF ARTEMETHER + LUMEFANTRINE AND ARTESUNATE + AMODIAQUINE FOR UNCOMPLICATED MALARIA IN EQUATORIAL GUINEA

Matilde Riloha Rivas[1], Maria Consuelo Oki[2], Juan Carlos Momo Besaha[2], Policarpo Ncogo[3], Jose Raso Bijeri[1], Elizabeth Nyakarungu[2], Luz García[4], Adrian Eho May[1], Jesus Nzang[1], Valero Ondo[3], Florentino Abaga Ondo[3], Wonder P. Phiri[2], Carlos A. Guerra[5], Guillermo A. García[5], Claudia A. Daubenberger[6], Pedro Berzosa Díaz[4]

[1]National Malaria Control Program, Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea, [2]MCD Global Health, Malabo, Equatorial Guinea, [3]Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea, [4]National Centre of Tropical Medicine, Institute of Health Carlos III, Madrid, Spain, [5]MCD Global Health, Silver Spring, MD, United States, [6]Department of Medical Parasitology and Infection Biology, Swiss Tropical and Public Health Institute, University of Basel, Basel, Switzerland

Malaria remains a significant public health challenge in Equatorial Guinea, particularly among children and pregnant women. With the country's national malaria control program, endorsing Artemether + Lumefantrine (AL) as the first-line treatment since 2017, continuous surveillance is essential to monitor ongoing efficacy and detect early signs of drug resistance. This study aims to evaluate the therapeutic efficacy and safety of the national first-line (AL) and second-line (Artesunate + Amodiaquine, ASAQ) malaria treatments in young malaria patients in Equatorial Guinea. This prospective cohort study will be conducted from March 2024 to July 2024 in three sentinel sites: Malabo (Bioko Island), Bata, and Ebibeyin Districts (located on the mainland of Equatorial Guinea). After obtaining informed consent from parents and guardians, we will consecutively enroll febrile children aged 6 months to 10 years diagnosed with uncomplicated *Plasmodium falciparum* malaria. Each site will parallel-test AL and ASAQ[CD1] [PJBD2] , given orally for a complete 3-day treatment course. The study aims to recruit treatment cohorts of 88 patients each for AL and ASAQ, summing to a total of 528 participants across all sites. Treatment efficacy will be assessed through close monitoring of clinical and parasitological outcomes for a 28-day follow-up period. The study will employ thick and thin blood smear malaria microscopy, PCR and sequencing to understand successful treatment rates, and to distinguish recrudescence from newly acquired infections. Drug safety evaluations will focus on the incidence and nature of adverse events associated with these treatments. Results will provide an evidence base for malaria drug policy in EG, hopefully supporting AL as the first line treatment and evaluating the role of ASAQ as a second-line therapy, ensuring optimal care for malaria patients in Equatorial Guinea.

7181

EVALUATION OF FOR EFFICACY OF ARTEMISININ-BASED COMBINATION THERAPIES ON *PLASMODIUM FALCIPARUM*, PLASMODIUM MALARIAE AND PLASMODIUM OVALE INFECTIONS IN MALI

Souleymane Babouya Kone, Souleymane Dama, Bakary Fofana, Bouran Sidibe, Niawanlou Dara,Mohamed Lamine Alhousseini and Abdoulaye Djimde

PMRTC, Bamako, Mali

Most cases of malaria are caused by *Plasmodium falciparum*. Non-falciparum species (*P. vivax*, *P. ovale*, *P. malariae…)* can cause malaria infections as well. Little work exists on the efficacy and clearance of non-falciparum species; andall strategies are oriented on the P. *falciparum* species. The purpose of this study was to clearance and efficacy of ACT on *P. malariae*, *P. ovale* and *P. falciparum* on data from the WANECAM1 network in Mali.The database of the WANECAM1 study was used to perform the analysis for this thesis. The 28-day WHO *in vivo* protocol was used for estimation of therapeutic responses. The WWARNParasite Clearance Estimator Software was used for the estimation of the parasite clearance half-life. The classic parasite clearance time was estimated by taking the median of the parasitaemianegativation time.Out of a total of 4172 volunteers. The median parasite clearance half-life times were 2.9 h, 4.79 hand 4.74 h respectively for *P. falciparum*, *P. malariae* and *P. ovale*. There was a significantdifference between the half-life times of *P. falciparum* compared to those of *P. malariae* and *P.ovale* ($p<0.001$) while there was no significant difference between the half-life times of non-falciparum species. The classical parasite clearance time was 24h and 36h. Adequate clinical andparasitological response (ACPR) was 79.81% for *P. falciparum*, while ACPR were 99.32% and98.18% for *P. malariae* and *P. ovale*, respectively, with a significant difference statistically ($p <0.05$).We conclude that the parasite clearance half-life of *P. falciparum* species was faster compared to*P. malariae* and *P. ovale* species.The ACTs used in the study were more effective on *non-falciparum* species than on *P. falciparum*.

Over the past several decades, natural products have an extensive history as pioneering agents for drug development. In particular, many of the promising antimalarials know to date are the natural products and/or their derivatives. Recently, we have discovered and developed prodiginine chemotype as novel class of orally efficacious antimalarial agents. Our work has shown that a number of the prodiginine derivatives were equally effective against a panel of *Plasmodium falciparum* pan-sensitive and multi-drug resistance strains at low nanomolar concentrations, suggesting potential to discover a new drug target to combat malaria parasites. In addition, these compounds inhibited formation of hypnozoites and schizonts in both radical cure and prophylactic modes at low concentrations. Herein, we present the detailed optimization and structure-activity relationships of prodiginine chemotype with enhanced antiplasmodial activities against both the asexual blood and liver stage malaria parasites and improved metabolic and pharmacokinetic profiles. This material has been reviewed by the Walter Reed Army Institute of Research. There is no objection to its presentation and/or publication. The opinions or assertions contained herein are the private views of the author, and are not to be construed as official, or as reflecting true views of the Department of the Army or the Department of Defense. Research was conducted under an IACUC-approved animal use protocol in an AAALAC International-accredited facility with a Public Health Services Animal Welfare Assurance and in compliance with the Animal Welfare Act and other federal statutes and regulations relating to laboratory animals.

The global impact of malaria remains staggering despite extensive efforts to eradicate the disease. The challenges for a sustainable elimination include the failing effectiveness of front-line artemisinin-based combination therapy (ACT) due to emerging resistance and safety concerns associated with limited radical cure options for relapsing *Plasmodium vivax*. There is an urgent need for novel, effective, affordable and safe antimalarial drugs to overcome drug resistance, and ideally, such agents would be efficacious against both blood stage and liver stage malaria infections. We have developed a novel antimalarial acridone chemotype with dual stage efficacy against both liver stage and blood stage malaria, as well as single-dose cure ability and potential to prevent relapsing infection. Our novel acridone chemotype represents a broad-spectrum approach with potential to vanquish many challenges. Extensive and comprehensive preclinical evaluations of our late lead acridone candidate will be presented.

7184

DRUG INTERACTION BETWEEN DIHYDROARTEMISININ-PIPERAQUINE AND SULFADOXINE-PYRIMETHAMINE IN PREGNANT WOMEN RECEIVING MALARIA CHEMOPREVENTION

Michelle E. Roh[1], Norah Mwebaza[2], Zoe Geng[3], Leonard Opio[4], Bishop Opira[4], Moses W. Mwima[4], Timothy Ssemukuye[4], Nikoletta Fotaki[5], Abel Kakuru[4], Moses R. Kamya[6], Grant Dorsey[7], Philip J. Rosenthal[7], Francesca T. Aweeka[3], Liusheng Huang[3]

[1]Institute for Global Health Sciences, University of California, San Francisco, San Francisco, CA, United States, [2]Department of Pharmacology and Therapeutics, Makerere University, Kampala, Uganda, [3]Department of Clinical Pharmacy, University of California, San Francisco, San Francisco, CA, United States, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]Department of Life Sciences, University of Bath, Bath, United Kingdom, [6]Department of Medicine, Makerere University, Kampala, Uganda, [7]Department of Medicine, University of California, San Francisco, San Francisco, CA, United States

Comparative trials of intermittent preventive treatment in pregnancy (IPTp) have shown that dihydroartemisinin-piperaquine (DP) is a more efficacious antimalarial, but sulfadoxine-pyrimethamine (SP) is associated with better fetal growth. We hypothesize that DP+SP for IPTp may be superior to either therapy alone. However, potential drug-drug interaction between DP and SP requires investigation. We completed pharmacokinetic (PK) studies nested in a placebo-controlled, double-blinded randomized trial of pregnant women living in Busia District, Uganda who were randomized to IPTp with SP, DP, or DP+SP every 4 weeks starting at 16- or 20- weeks gestation. For intensive PK, serial sampling from day 0-23 was performed after the 28th gestational week IPTp course in 87 participants (27 DP, 36 SP, 24 DP+SP). For sparse PK, paired day 28 (trough) samples were analyzed in 198 participants (98 SP, 98 DP+SP) after the 20th and 28th gestational week IPTp course. Sulfadoxine (SDX), pyrimethamine (PYR), and piperaquine (PPQ) levels were determined using liquid chromatography tandem mass spectrometry. Non-compartmental analyses were used to determine PK parameters. Intensive PK analyses demonstrated that coadministration of DP+SP significantly reduced geometric mean C_{max} and $AUC_{day0-23}$ of SDX (by 25% [90% CI: 13%–33%] and 25% [11%–33%]) and PYR (by 26% [17%–34%] and 34% [26%–42%]) (all $p<0.05$). Sparse PK analyses indicated that co-administration of DP+SP significantly reduced trough SDX levels after the 28th, but not the 20th gestational week IPTp course (31% [10%–47%] versus 6% [-19%–26%] reduction; p-interaction=0.025). PYR levels were reduced with coadministration of DP+SP at both the 20th and 28th gestational week IPTp course (reductions of 18% [5%–30%] and 33% [22%–43%]; p-interaction=0.027). Co-administration of DP+SP moderately reduced PPQ C_{max} and $AUC_{day0-23}$ by 13% [-11%–32%] (p=0.34) and 19% [4%-32%] (p=0.046). Thus, coadministration of DP+SP significantly reduced SP exposure with a greater magnitude during the 3rd vs. 2nd trimester. Further investigation is needed to define optimal dosing strategies for IPTp with DP+SP.

7185

MICROVOLUME ANALYSIS OF ANTIMALARIAL DRUGS FOR PEDIATRIC PHARMACOKINETIC-PHARMACODYNAMIC STUDIES

Liusheng Huang[1], Florence Marzan[1], Michelle Roh[1], Norah Mwebaza[2], Grant Dorsey[1], Philip Rosenthal[1], Francesca Aweeka[1]

[1]University of California San Francisco, San Francisco, CA, United States, [2]Infectious Disease Research Collaboration and Makerere University, Kampala, Uganda

It is desirable to quantify antimalarial drugs in microvolume samples to support pharmacokinetic studies in pediatric populations, due to the limited volume of blood. We used capillary tube sampling to obtain plasma or dried blood spots (DBS), which were processed with protein precipitation, liquid-liquid extraction, or solid phase extraction, and analyzed by liquid chromatography tandem mass spectrometry (LC-MS/MS). We have developed plasma methods to determine concentrations of artemether and dihydroartemisinin (50 µL), piperaquine (25 µL), hydroxychloroquine and its metabolites (20 µL), amodiaquine (AQ) and desethylamodiaquine (DEAQ, 10 µL), lumefantrine and desbutyl lumefantrine (5 µL), sulfadoxine (SDX), and pyrimethamine (PYR, 5 µL). We also explored methods to determine piperaquine, lumefantrine, AQ and DEAQ concentrations from DBS. Here we present a method for determination of AQ, DEAQ, SDX, and PYR concentrations from 10 µL plasma. The method was developed on a Waters Acquity UPLC system (I class) coupled with Sciex TripleQuad 6500^{+} tandem mass spectrometry (MS/MS) managed with the software Analyst® 1.6.3. Plasma samples (10 µL) were processed by solid-phase extraction with an HLB micro-elution plate. Chromatographic separation was achieved on an ACE® Excel C_{18} analytical column (50 x 2.1 mm, 1.7 µm) eluted with water (A) and acetonitrile (B), both containing 0.1% formic acid at a flow rate of 0.8mL/min in gradient mode. The injection volume was 5 µL for AQ and DEAQ and 1 µL for SDX and PYR. The instrument time per sample was ~2 min. The calibration ranges were 0.1 – 100 ng/mL for AQ, 0.2 – 200 ng/mL for DEAQ. 0.2 – 200 ng/mL for PYR, and 20 – 20,000 ng/mL for SDX. Precision and accuracy were within 15%. The recoveries were 93.4±0.5 %, 87.8±2.2 %, 97.9±4.8 %, and 95.1±3.2 %, respectively. Matrix effect was negligible. DEAQ was unstable in plasma, with ~50% degradation overnight. The method was used to analyze 366 clinical samples, among which 82% have quantifiable AQ/DEAQ and 83% have quantifiable SDX/PYR. In summary, LC-MS/MS enables microvolume sampling and subsequent drug analysis to support clinical studies in pediatric populations.

7186

PRIMAQUINE PHARMACOKINETICS AND RADICAL CURE EFFICACY IN *PLASMODIUM VIVAX*-INFECTED ADULTS IN THAILAND

Michele D. Spring[1], Pattaraporn Vanachayangkul[2], Sabaithip Sriwichai[3], Worachet Kuntawunginn[3], Chanikarn Kodchakorn[3], Montri Arsanok[3], Ta-aksorn Winita[3], Parat Boonyarangka[3], Paphavee Lertsethtakarn[3], Thunyarat Anothaisintawee[3], Krit Harncharoenkul[3], Krisada Jongsakul[3], Jeffrey Livezey[3]

[1]SUNY Upstate Medical University, Syracuse, NY, United States, [2]Armed Forces Research Institute of Medical Sciences, Thailand, Thailand, [3]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Clearing dormant *Plasmodium vivax* hypnozoites with the anti-malarial drug, primaquine (PQ), may be hampered by ineffective metabolism of the drug into its active metabolites, particularly in individuals with polymorphisms in the cytochrome P450 2D6 enzyme. We conducted a clinical trial in Thailand designed to both assess efficacy of radical cure PQ (15 mg/day for 2 weeks) and to identify biomarkers of *P. vivax* hypnozoites. *P. vivax*-infected adults were randomized to one of two arms: EARLY group receiving PQ with concomitant oral artesunate (AS) for five days and the DELAYED group receiving PQ alone, six weeks after AS treatment. Both arms stayed in study housing for the first 28 days both to minimize risk of re-infection and obtain samples for retrospective analyses of hypnozoite biomarkers.

Recurrences of *P. vivax* over the 6-month study period were diagnosed by blood smear, both at study-specific time points and if clinical symptoms developed, and then confirmed with 6-species polymerase chain reaction (PCR) testing. Relapses were treated with PQ and chloroquine (CQ). For all volunteers, urine PK samples were collected for 24 hours after the first dose of PQ and at scheduled timepoints throughout the 2-week course. Thirty *P. vivax* patients were enrolled, with 28 receiving radical cure PQ: 12 with AS+PQ, 10 with PQ alone and 6 who received only AS, relapsed before six weeks, then received CQ+PQ. One volunteer in PQ+AS group, none in PQ alone, and three in the PQ+CQ had *P. vivax* recurrences, giving efficacy of 92% (1 of 12), 100% (0 of 10) and 50% (3 of 6), respectively. Urine PQ PK parameters for each volunteer and per drug regimen will be presented. Methemoglobin (metHgb), generated during PQ administration and a suggested signal of efficacy, was highest in the PQ+AS group (peak 4.6%, range 0-11%) versus PQ alone (3.6%, range 0-8.3%) or PQ+CQ group (2.8%, range 0-4.9%). These results will contribute to our knowledge of PQ metabolism parameters as predictors of radical cure efficacy, particularly when able to be combined with future hypnozoite biomarker data.

7187

DISCOVERY OF NOVEL ANTIPLASMODIAL COMPOUNDS USING RING FUSION OF INDOLE ALKALOIDS

Raphaella Paes[1], Alexis A. Bragg[2], Beau R. Brummel[2], Erin Solomon[2], Christian Baigorria[1], Debopam Chakrabarti[1], Robert W. Huigens III[2]

[1]University of Central Florida, Orlando, FL, United States, [2]University of Florida, Gainesville, FL, United States

To mitigate the threat of emerging resistance to available antimalarials, new screening libraries are needed to discover novel chemotypes. Compound collections of commercial or "in-house" origin are often limited in diversity and stereochemical complexity. To address the lack of chemical diversity in current drug discovery efforts, we have developed an innovative "Complexity to Diversity" ring distortion approach to rapidly generate a diverse and unique library of complex small molecules from stereochemically complex indole alkaloids. Through the process of ring distortion, the complex ring systems of natural products are re-engineered utilizing ring fusion, cleavage, and expansion using various chemical reactions. Previous work in our lab has shown success in generating antiplasmodial compounds through ring distortion of vincamine and yohimbine - taking inactive starting compounds to products with submicromolar EC_{50}s against the multidrug resistant Dd2 parasite line with excellent selectivity. Using the ring-distortion approach of reserpine, a library of 83 compounds were synthesized and tested for antiplasmodial activity and selectivity. From these efforts, a reserpine derivative, AB-2-81 with potent antiplasmodial activity (EC_{50} 131 ± 21 nM) with high selectivity (SI >191) was identified. This work validates the value of ring distortion in re-engineering of natural products to develop new class of antiplasmodials.

7188

IN SILICO, IN VIVO AND *IN VITRO* TOXICITY ASSESSMENT OF NOVEL HETEROCYCLICS WITH ANTIMALARIAL ACTIVITY

Maria del Pilar Crespo-Ortiz, Maria Elena Burbano, Mauricio Barreto

Universidad del Valle, Cali, Colombia

The emergence of resistance against most frontline antimalarials underpins the need for novel drugs. However, toxicity is a bottleneck for the further development of many inhibitory molecules. Although many *in silico* and *in vitro* approaches are available, *in vivo* models tend to simulate the real conditions more closely. Combined strategies may improve the detection and selection of molecules worth of further testing lowering time and costs. The aim of this study was to test the potential of *Galleria mellonella* (Insecta: Lepidoptera) as a low-cost *in vivo* model combined with *in silico* and *in vitro* assays to assess the toxicity of compounds with potential antimalarial activity. A total of 20 heterocyclics from an in-house library, showing inhibitory effects on *Plasmodium falciparum* parasite cultures (IC_{50} <1 μM) were selected for toxicity testing. *In silico* analysis was performed using SwissADME (Brent alerts) and ProTox-II. *In vitro* toxicity for cell membranes was assessed by hemolytic activity in human red blood cells (RBC) and the half-lethal doses (LD_{50}) were determined using six-instar larvae of *G. mellonella*. The larvae were initially injected with 500mg/kg and if >60% survived after five days, the assay was performed using higher doses up to 2000 mg/kg. Ten compounds showed no Brent alerts, Protox analysis revealed that 8 (out of 10) compounds showed predicted hepatotoxicity, 3 immunotoxicity, 6 carcinogenicity and 4 mutagenesis. None of the compounds was cytotoxic. In most cases the predicted likelihood of toxicity was low (consensus score:< 0.7), 3 compounds with higher predicted immunotoxicity and predicted toxicity level 4 (1000mg/kg) showed to be less toxic in the *Galleria* model. Most active compounds showed not induction of RBC damage at >200 μM, however two diphenyl-pyrazolines induced RBC hemolysis at lower concentrations (>50 μM). LD_{50} in *G. mellonella* classified most compounds as low or no toxic whereas *in silico* predicted toxicity was higher. *Galleria* model provides a more accurate representation of *in vivo* toxicity as *in silico* accuracy relies on the structural similarity of the novel compounds with those in the database.

7189

PARASITE CLEARANCE AND PROTECTION FROM *PLASMODIUM FALCIPARUM* INFECTION: CLINICAL RESULTS FROM A THREE-ARM, PARALLEL, DOUBLE-BLINDED, PLACEBO-CONTROLLED, RANDOMIZED TRIAL OF PRESUMPTIVE SULFADOXINE-PYRIMETHAMINE VERSUS SULFADOXINE-PYRIMETHAMINE PLUS AMODIAQUINE VERSUS ARTESUNATE MONOTHERAPY AMONG ASYMPTOMATIC CHILDREN 3-5 YEARS OF AGE IN CAMEROON

The World Health Organization's (WHO) 2022 malaria chemoprevention guidelines recommend providing sulfadoxine-pyrimethamine (SP) to asymptomatic children living in high-transmission malaria areas as a perennial malaria chemoprevention (PMC). We will present results from a three-arm, parallel, double-blind, placebo-controlled, randomized trial in Cameroon designed to measure the effect of parasite genotypes associated with SP resistance on the efficacy of SP and SPAQ among asymptomatic children between 3-5 years of age (NCT06173206). Our sample size has 80% power to detect a significant difference in duration of protection in the presence or absence of the I431V mutation, derived from 1000 simulations and these assumptions: 6 infections per person per year, 40% microscopy prevalence, 10% loss-to-follow up, 30% *Pfdhps* I431V frequency, 28-day protection against *Pfdhps* I431 parasites, 15-day protection against *Pfdhps* 431V parasites, 85% genotyping success at *Pfdhps* codon 431. Children are randomly assigned to one of three directly-observed treatment groups: (i) SP group (n=450) receive daily artesunate (AS) placebo on days -7 to -1, then active SP plus placebo amodiaquine (AQ) on day 0, and placebo AQ on days 1 and 2; (ii) SPAQ group (n=250) receive placebo AS on days -7 to -1, then active SPAQ on day 0, and active AQ on days 1 and 2; and (iii) AS group (n=200) receive active AS on days -7 to -1, then placebo SP on

day 0 and placebo AQ on days 0 to 2. On days 0, 2, 5, 7, and thereafter weekly until day 28, children provide blood for thick smear slides. For future qPCR, dried blood spots are collected on the same days and weekly thereafter to day 63. We will report unblinded results including: (i) time-to-parasite clearance among SP and SPAQ recipients who were positive on day 0 by qPCR and followed to day 63; (ii) mean duration of SP and SPAQ protection against infection, and (iii) mean duration of symptom-free status among SP and SPAQ recipients who were parasite free on day 0 by qPCR. Our conclusions will reflect on the utility of the new WHO malaria chemoprevention efficacy study protocol follow-up to day 28 versus day 63.

7190

PARASITE CLEARANCE AND PROTECTION FROM *PLASMODIUM FALCIPARUM* INFECTION: CLINICAL RESULTS FROM A TWO-ARM, PARALLEL, DOUBLE-BLINDED, PLACEBO-CONTROLLED, RANDOMIZED TRIAL OF PRESUMPTIVE SULFADOXINE-PYRIMETHAMINE VERSUS ARTESUNATE MONOTHERAPY AMONG ASYMPTOMATIC CHILDREN 3-5 YEARS OF AGE IN ZAMBIA

[1]College of Public Health, University of South Florida, Tampa, FL, United States, [2]Department of Infection Biology, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Tropical Diseases Research Centre, Ndola, Zambia, [4]Centre for Translational Medicine and Parasitology, University of Copenhagen,, Copenhagen, Denmark, [5]Centre for Translational Medicine and Parasitology, University of Copenhagen, Copenhagen, Denmark, [6]Department of Infection Biology, London School of Hygiene and Tropical Medicine, London, UK, London, United Kingdom, [7]Department of Disease Control, London School of Hygiene and Tropical Medicine, London, United Kingdom

The World Health Organization's (WHO) 2022 malaria chemoprevention guidelines recommend the provision of sulfadoxine-pyrimethamine (SP) to asymptomatic children who reside in areas of high malaria transmission as perennial malaria chemoprevention (PMC). We will present results from a two-arm, parallel, double-blind, placebo-controlled, randomized trial in Zambia that is designed to evaluate the effect of parasite genotypes on the efficacy of single-dose SP among asymptomatic children between 3-5 years of age (NCT06166498). Our sample size has 77.4% power to detect a significant difference in duration of protection in the presence or absence of *Pfdhps* K540E, derived from 1000 simulations with the following assumptions: 10 infections per person per year, 37.8% prevalence by microscopy, 10% loss to follow up, 80% frequency of *Pfdhps* K540E, 30-day protection against *Pfdhps* 540K parasites, 18-day protection against *Pfdhps* 540E parasites and 85% genotyping success at *Pfdhps* codon 540. Children are randomly allocated to one of two groups for directly-observed treatment. Over seven consecutive days (days -7 to -1), children in the SP group (n=400) receive placebo artesunate (AS), then active SP (day 0). In contrast, children in the AS group (n=200) receive active artesunate for seven consecutive days, followed by placebo SP (day 0). Then, on days 0, 2, 5, 7, and weekly thereafter until day 28, children provide finger-prick blood for thick smear slides. Dried blood spots are collected on these same days for future qPCR analysis, and collected weekly thereafter until day 63. Children who become symptomatic are treated with artemether-lumefantrine if positive by malaria rapid diagnostic test. We will report unblinded results including: (i) time-to-parasite clearance among SP recipients who were positive on day 0 by qPCR and measured to day 63; (ii) mean duration of SP protection against infection, and (iii) mean duration of symptom-free status among SP recipients who were parasite free on day 0 by qPCR. Our conclusions will reflect on the utility of WHO's new malaria chemoprevention efficacy study protocol with its follow-up to day 28 versus day 63.

7191

PACRALIMA NITIDA FRUIT-RIND AND LEAF EXTRACTS EXHIBITED ANTIPLASMODIAL AND IMMUNO-MODULATORY EFFECTS AGAINST *PLASMODIUM BERGHEI*-INFECTION IN SWISSMICE

Ehimwenma Sheena Omoregie[1], Francis A. Obuseh[2], Faith Aghayere[1], Merit Ayevbuomwan[1], Francis Irabor[3]

[1]University of Benin, Benin City, Nigeria, Benin City, Nigeria, [2]Defense Centers for Public Health Portsmouth, Portsmouth, VA, United States, [3]Benson Idahosa University, Benin City, Nigeria, Benin City, Nigeria

Malaria has continued to remain a public health challenge, especially in some tropical and sub-tropical regions of the world. Although, a significant reduction in mortality and morbidity was recorded between 2005 and 2015, decreased susceptibility of *Plasmodium falciparum* to the current first-line antimalarial drug, artemisinin-based combination therapy (ACT), has been reported in Southeast Asia and other continents which further complicate the severity of the disease, especially in low-income countries like Nigeria. Numerous strategies have been employed to combat artemisinin resistance and one of them is the intensified efforts toward the discovery of novel drugs from plant sources that may be alien to the parasite. This study therefore evaluated the antiplasmodial and immuno-modulatory effects of chloroform-methanol extracts of *Pacralima nitida* fruit-rind and leaf in *P. berghei-infected* mice. The bioactive constituents of the plant were extracted using standard protocol. Extracts obtained were assessed for antiplasmodial activity by the standard four-day suppressive test on *P. berghei* (*ANKA*) infected mice (Swiss strain). The absorption spectra from the HPLC chemical finger-prints of the extracts revealed several peaks representing bioactive phytochemicals while the results from the animal study showed that the extracts were dose-dependently ($p < 0.05$) active against *P. berghei* parasite in comparison with the untreated infected mice (negative control). Dose-dependent decreases ($p < 0.05$) in some oxidative stress indices of the extracts-treated groups as against the infected control were observed. The pro-inflammatory cytokines levels were assessed and were found to be significantly low in the extracts-treated groups relative to the infected control. Results from the study suggest that methanol extracts of *P. nitida* fruit rind and leaf possess appreciable antiplasmodial properties with some immuno-modulatory effect against the *P. berghei* parasite.

7192

EFFECT OF SEASONAL MALARIA CHEMOPREVENTION IN STUNTING CHILDREN IN KOULIKORO, MALI

Soumba Keita[1], Mahamoudou Touré[1], Fousseyni Kané[1], Daouda Sanogo[1], Moussa Keita[2], Cheick Oumar Doumbia[1], Cheick Oumar Tangara[1], Nafomon Sogoba[2], Mahamadou Diakité[3], Seydou Doumbia[1]

[1]University Clinical Research Center/ University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali, [2]Malaria Research and Training Center/ICER-Mali/University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali, [3]University Clinical Research Center/Malaria Research and Training Center/University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, Bamako, Mali

Seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine plus amodiaquine (SP+AQ) is an effective and promising strategy for controlling malaria morbidity and mortality in areas of intense seasonal transmission. Despite its effectiveness several controversies regarding the occurrence of clinical malaria among eligible children and challenges of the strategy in the context of high prevalence of malnutrition in area where it is implemented make questionable the benefit of SMC in malnourished children compared to those with normal nutritional status. This study investigated the risk of clinical malaria among stunting versus normal children eligible for SMC in Koulikoro, an area where the frequencies of the two diseases are high during the rainy season. A total of 2613 children eligible for SMC were enrolled just before the first round of SMC in July 2020. At baseline *Plasmodium falciparum (P.f)* infection and nutritional status was assessed for study participants and children were classified in

two comparison groups: normal and stunted. All participants were followed from the start to the end of SMC through passive case detection to determine the incidence of clinical malaria define as fever and malaria RDT or blood smear positive. The risk of malaria in both groups was estimated using the Wald test. The overall prevalence of asymptomatic malaria and stunting were 11.2% and 62% respectively. Ended, 847 children as normal and 89 as stunted. During the SMC season the overall incidence was 25.6%. Comparing the first occurrence of *P.f* parasitemia during the SMC season, the cumulative incidence of malaria was 20.6% in the normal group (n=336) vs. 33.7% in the stunted group (n=332). Stunted children had significantly more first malaria episodes RR= 1.97 (95% CI, 1.73-2.25). These results suggest a reduction of the effect of SMC treatment in preventing clinical malaria among stunted children compared to normal children. Thus, a combined intervention targeting the two diseases could increase the effectiveness of SMC in area where the two diseases are highly seasonal.

EXPERIENCES FROM DIGITALIZING INSECTICIDE-TREATED NETS (ITNS) MASS DISTRIBUTION CAMPAIGNS IN ZAMBIA

Japhet Chiwaula[1], Christopher Lungu[2], Rueben Kaponde[3], Belendia Serda[2], Ketty Ndhlovu[1], Dingani Chinula[3], Edwin Mteba[3], Reuben Zulu[1], Mercy Ingwe[1], Ignatius Banda[1], John Banda[1], Busiku Hamainza[1]

[1]National Malaria Elimination Programme, Lusaka, Zambia, [2]PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, [3]USAID Evidence for Health, Lusaka, Zambia

The Zambia National Malaria Elimination Programme conducts universal mass distribution of insecticide-treated nets (ITNs) every three years. In 2023/2024, Zambia used an Electronic Data Management Information System (EDMIS) to implement the ITN campaign for the first time. Prior to this, paper-based data collection was used, resulting in numerous challenges. Here we describe the development of EDMIS and lessons learned during its use to support deployment of ITNs targeting an estimated 20 million Zambians. A two-month consultation process was used that involved an assessment of the data infrastructure architecture. A data collection form was developed to collect information on household members, sleeping spaces, GPS coordinates, ITNs allocated and distributed, and data quality and validation checks. Over 10,000 phones and a HPE ProLiant DL380 Gen10 Plus server were procured to manage data entry, storage, and analyses. To address possible upload challenges and loss of data, paper-based registers were used as backup. A total of 20,664,899 persons in 3,883,195 households were registered, 17.45% less than the 4,560,912 projected households. As at March 27, 2024, 10,178,609 ITNs (one net per two people) were distributed and captured on EDMIS countrywide, translating to 89.4% of the enumerated population protected. During the process, bottlenecks were identified and support for about 10,000 data users was provided at full operating capacity. However, about 20% of data failed to upload to DHIS2 while in the field during registration and distribution, which was attributed to internet challenges in rural areas. This delayed the campaign by three months. The lessons learned and best practices established during the implementation of the EDMIS will contribute to the success of future campaigns, particularly by building staff capacity at district level in IT skills. However, with unpredictable outcomes in the digital space, the paper registers remain important in the execution of ITN campaigns.

7194

IMPROVING INTEGRATED COMMUNITY CASE MANAGEMENT (ICCM) BY COMMUNITY HEALTH WORKERS - AN EXAMPLE OF MALARIA MANAGEMENT IN NCHELENGE DISTRICT, ZAMBIA

Gift Hapenga[1], Chilowekwa Shike[1], Tawonga Manda[1], Jennifer Somtore[2], Rabson Zyambo[3], Tamara Ngona[4]

[1]USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project, Lusaka, Zambia, [2]U.S. President's Malaria Initiative (PMI), Lusaka, Zambia, [3]USAID, Lusaka, Zambia, [4]Ministry of Health-NMEC, Lusaka, Zambia

In Zambia, the 2021 national malaria prevalence was estimated to be 23%, according to data from the malaria indicator survey. Luapula Province, which includes Nchelenge District, had the highest prevalence at 63%. The Ministry of Health (MOH) plans to train 40,000 Community Health Workers (CHWs) nationwide by 2025 in integrated community case management (iCCM) including malaria. Between 2021 and 2023, trained CHWs increased from 382 to 405 in Nchelenge District. Although CHWs were being trained, many were not sufficiently equipped with malaria commodities, as it was reported in May 2021 that the availability of rapid diagnostic tests (RDTs) and the first-line antimalarials were at 0% and 5% respectively (56.7% reporting rate). During the regional supply chain review meeting with the MOH and partners in 2021, contributing factors to the commodity availability at CHW level, such as health facilities (HFs) not including CHWs' needs, low reporting rates, and low data quality, were identified. Following the findings, the USAID Global Health Supply Chain Program-Procurement and Supply Management (GHSC-PSM) project partnered with the MOH to establish a consistent supply of commodities by working with provincial and district MOH staff to ensure that approved order quantities for HFs include CHWs' needs for iCCM and introduced a commodity ordering and tracking tool (COTT) for community level reporting for stock levels, consumption, losses, and adjustments. The tool provides an efficient way for CHWs to manage and track essential commodities with limited oversight and has now been integrated into the MOH-led iCCM trainings. These initiatives enhanced the availability of RDTs to 85%, and first-line antimalarials to 75% (80.6% reporting rate) in May 2023, at CHW level, and contributed to an increase in malaria case detection by CHWs from 79 cases in May 2021 to 5,366 cases for timely treatment in May 2023. These results indicate the importance of considering CHW expansion in commodity management. Strengthening CHW supply chain management skills may have helped the monitoring and maintenance of adequate commodities.

7195

QUANTIFYING FOR ROLE OF IMPORTATION ON SUSTAINED MALARIA TRANSMISSION IN SOUTHEAST UGANDA

Adrienne Epstein[1], Okiria Aramanzan[2], Isaiah Nabende[2], Tonny Max Kayondo[2], Michael Obbo[2], Robert Tumwesigye[2], Innocent Willing[2], Monica Mbabazi[2], Brian Asiimwe Kagurusi[2], Bryan Greenhouse[1], Grant Dorsey[1], Emmanuel Arinaitwe[2], Isabel Rodriguez-Barraquer[1]

[1]UCSF, San Francisco, CA, United States, [2]IDRC, Kampala, Uganda

Importation of malaria parasites through human movement poses a threat to control. However, understanding the role of importation is challenging because it is difficult to differentiate between local and imported infections in areas with some level of transmission. We aim to quantify the role of importation on malaria in Kamwezi, Uganda, a region characterized by spatial variation in burden. We enrolled 400 households in a 2-year longitudinal study in summer 2023, collecting travel and movement histories, data on malaria episodes, and blood samples during bimonthly visits. Passive surveillance captured symptomatic infections at a local health facility alongside the cohort. Our outcomes included parasite positivity (asymptomatic infections) and symptomatic malaria cases. Regression models analyzed the association between travel and outcomes, stratifying by village-level transmission intensity. After four survey rounds involving

5,821 visits of 1,872 individuals, 3.8% (224) had recent malaria illness, and 16.6% (264) tested positive for asymptomatic infection at baseline. 8.3% (488) of individuals reported overnight travel and 6.9% (404) reported evening movement. We did not find evidence for an association between travel and asymptomatic infection, nor did we find an association between travel and symptomatic malaria in higher transmission villages. We found evidence supporting an association between travel and symptomatic malaria (incidence rate ratio = 2.45, 95% confidence interval 1.45-4.08) in lower transmission villages, such that travel accounted for 10% of malaria cases, with travel to higher transmission areas elevating risk. Furthermore, we found that movements during evening to higher transmission villages were associated with malaria illness. By the conference, 18 months of follow-up will be complete, allowing a probabilistic model estimating importation probability for all cases. We will also generate genotype data to differentiate between local and imported infections. Understanding these factors is crucial for developing interventions to reduce the impact of importation on sustained transmission.

7196

MALARIA ELIMINATION IN CABO VERDE: AN OVERVIEW ABOUT FOR HISTORY, CASE DATA FROM FOR LAST 35 YEARS (1985-2023) AND CHALLENGES AHEAD

Adilson De Pina[1], Jonas Gomes[2], António Moreira[3], El Hadji Niang[4], Gillian Stresman[5]

[1]Malaria Elimination Program, Ministry of Health, Praia, Cape Verde, [2]National Institute of Public Health, Cabo Verde, Praia, Cape Verde, [3]National Malaria Program, Ministry of Health, Praia, Cape Verde, [4]Laboratoire d'Ecologie Vectorielle et Parasitaire, Faculté Des Sciences et Techniques, Université Cheikh Anta Diop, Dakar, Sénégal, Dakar, Senegal, [5]Department of Epidemiology, College of Public Health, University of South Florida, Tampa, FL, 33612, United States of America, Tampa, FL, United States

On January 12th, 2024, Cabo Verde was officially certified by the WHO as a malaria-free country after six consecutive years without local cases. This study analyses the malaria history of Cabo Verde, from 1953 to certification in 2024, brings some lessons learned and discusses challenges for the future as a malaria-free country. A literature review was conducted; descriptive analyses were done with the last 35 years' data (1988-2022), and cases were mapped using the Quantum GIS Software. Six reference stages and three periods of malaria interruption can be highlighted. The first interruption was for five years (1968-1972), the second for three years (1983-1985), followed by outbreaks, and finally, certification in 2024. From 1988 to 2022, 3,089 malaria cases were reported, being 2,381 (77.1%) local and 708 (22.9%) imported. To achieve elimination, after the last malaria outbreak in Cabo Verde in 2017, the NMCP reviewed the strategies and developed the new NSP for Malaria Elimination 2020-2024. It included implementing active and reactive foci investigations and effecting the vector control. The vector control strategies, included larval source management, indoor residual spraying (IRS) and environmental modification. Concerted efforts focusing on behavioural change and social mobilization were also crucial aspects in achieving elimination, associated with the robust epidemiological surveillance system in place, capable to detect timely, treat correctly and the follow-up of all cases. With the certification, Cabo Verde became an African country reference in the health sector organization, multisectoral and partnership in malaria control. Maintaining the certification imposes several challenges to the country's sustainability and perennially. The lessons learned and experiences about malaria control and elimination in Cabo Verde is an opportunity and hope to the others African countries that can benefit to save more lives and improve the quality of life of populations.

7197

ARE THERE GENDER DIFFERENCES IN FOR GAPS IN MALARIA TREATMENT CASCADE IN GHANA? IMPLICATIONS FOR MALARIA ELIMINATION

Harriet Affran Bonful[1], Irene Akwo Kretchy[2], Yakubu Alhassan[3], Deborah Atoborah[4], Augustina Koduah[2], Afia Frimpomaa Asare Marfo[5], Mercy Naa Aduele Opare-Addo[5], Kwabena F.M. Opuni[6]

[1]Department of Epidemiology and Disease Control, University of Ghana School of Public Health, Legon, Ghana, [2]Department of Pharmacy Practice and Clinical Pharmacy, University of Ghana School of Pharmacy, Legon, Ghana, [3]Department of Biostatistics, University of Ghana School of Public Health, Legon, Ghana, [4]Centre for Gender Studies and Advocacy (CEGENSA), University of Ghana, Legon, Ghana, [5]Department of Pharmacy Practice, Faculty of Pharmacy and Pharmaceutical Sciences, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [6]Department of Pharmaceutical Chemistry, University of Ghana School of Pharmacy, Legon, Ghana

Effective case management is critical to Ghana's malaria elimination agenda. Identifying gender differences in the malaria treatment cascade will help tailor interventions to address specific needs that will maximize benefits from scarce resources. We set out to explore gender differences in the malaria treatment cascade in Ghana. This was a nationally representative community-based survey among participants 18 years and older, in six randomly selected regions. The outcomes included gender differences in malaria treatment cascade of one-month and six-month prevalence of self-reported malaria. Overall, 3022 participants were engaged, including 1547 females, with a median age of 32(25-43) among males vs. 31(24-41) among females. The one-month self-reported malaria prevalence was 20.8% (19.4 - 22.3), 20.3% among males vs. 21.3% among females. A higher prevalence was observed among females in the Greater Accra region (17.5% vs. 10.5%) and the Central region (28.8% vs. 19.3%), $p<0.05$. Of the 628 malaria cases, 60% were tested, and 95.5% tested positive. Among the positive cases, 72,2% were prescribed orthodox medication, predominantly ACTs, 15.3% took complementary and alternative medicine (CAM), and 11.9% took both orthodox and CAM treatments. Stratified by sex, significant differences were not observed in the malaria treatment cascade except that, more females with negative tests took orthodox treatments, (38.5% vs. 0%, $p<0.05$), as well as CAM products (61.5% vs. 50.0%, $p <0.05$). Self-reported malaria in the past 6 months was 57.4% (55.6 - 59.1), and of 1733, 59.4% were tested, (males: 58.1% vs. females: 60.7%). Malaria RDT testing was significantly higher among females than males, 66.2% vs. 58.9%, ($p<0.05$). Fewer females tested positive (94.6% vs. 97.3%). Of the 695/1,733 cases, (40.1%) positive malaria cases treated with orthodox medicines, significantly more females (42.3%) were treated with orthodox medicines compared to males (37.8%), $p<0.05$. Exploring the factors that account for the relative gender differences in the treatment cascade gaps can potentially enhance malaria elimination efforts in Ghana.

7198

ONE HEALTH BY USING GREEN SYNTHESIS OF NANOPARTICLES TO IMPROVE COMMUNITY ENVIRONMENT

Agnes Antoinette Ntoumba

University of Douala, Douala, Cameroon

Mosquitoes are main vectors of parasitic diseases such as dengue, malaria,filariasis,Japanese encephalitis, chikungunya and so on . These diseases cause death in humans and animals.The constant use of chemical insecticides against mosquitoes has led to a physiological resistance . Nanotechnology is a rapidly growing field due to its unique functionality and a wide range of applications. The aqueous extract of fresh leaves of *Ocimum basilicum* have been used to synthetize nanoparticles. The synthesized nanoparticles was characterized by using ultraviolet spectrophotometry, X-Ray diffraction, and Fourier transform infrared spectroscopy methods.The wavelengths between 400-600nm confirmed experimentally the formation of silver nanoparticles. They were crystalline in nature and constituted by the following chemical groups: Alcohols, amines,

alkyls, aldehydes and ketones. The larvicidal effect against *Anopheles gambiae* has been tested. The LC50 determinated after 24 h and 48 h. The results showed an increase in potency with time. The mortality of AgNPs *O. basilicum* having concentration of 2.0 to 2.5 ppm after 24 h. The LC_{50} for AgNPs *O. basilicum* were 1.54 ppm after 24 h, while after 48 h the LC_{50} reached 0. 95ppm.The green synthesis of silver nanoparticles using *O. basilicum* water extract were effective against *Anopheles gambiae* larvae. Their insecticide properties that do not require the presence of any harmful material. This method is eco-friendly, low-cost, and safe for human health and his environment Biocontrol agents derived from this methodology could be considered as a suitable alternative to control vector-borne diseases in developing countries.

7199

PREVALENCE OF GLUCOSE-6-PHOSPHATE DEHYDROGENASE DEFICIENCY IN A MALARIA-ENDEMIC REGION OF COLOMBIA: IMPLICATIONS FOR RADICAL CURE OF *PLASMODIUM VIVAX*.

Lina Zuluaga-Idárraga[1], Alexandra Rios[1], Juan Esteban Martinez[1], Daniel Camilo Aguirre[1], Alberto Tobón-Castaño[1], Tatiana Maria Lopera Mesa[1], Ivan Cardenas[2], Mario Olivera[3], Milton Cardozo[4], Guillermo Gonzalvez[4], Maria Paz Ade[5], Roberto Montoya[6], Erika Venegas[7], Heidi Mihm[7], Sonia Herrera[8], Michelle Hsiang[8], Jaclyn Flewellin[8], Lawrence Barat[8], Leopoldo Villegas[8]

[1]Universidad de Antioquia, Medellín, Colombia, [2]Ministerio de Salud y Protección Social, Bogotá, Colombia, [3]Instituto Nacional de Salud, Bogota, Colombia, [4]Pan American Health Organization (PAHO), Bogotá, Colombia, [5]Pan American Health Organization (PAHO), Washington, MD, United States, [6]Pan American Health Organization (PAHO), Washington, DC, United States, [7]U.S. Agency for International Development (USAID), Bureau for Latin America and the Caribbean, Washington, DC, United States, [8]U.S. President's Malaria Initiative (PMI) Impact Malaria project, Washington, DC, United States

Glucose-6-phosphate dehydrogenase deficiency (G6PDd) is a common genetic condition with important implications for radical cure of *Plasmodium vivax* (*Pv*), the most common malaria species in Colombia and Latin America (LA). G6PDd is associated with a higher risk of hemolytic events when using 8-aminoquinoline drugs. The prevalence of G6PDd and its relation to *Plasmodium sp*ecies infection is poorly known in this region. A cross-sectional study was conducted in Quibdó, Colombia. Participants were randomly selected among the general population (GP) (n=1267), indigenous communities (IC) (n=194), and outpatients with suspected malaria (OSM) (n=542). Participants were screened for G6PD levels using a quantitative finger-prick blood test and were classified as deficient, intermediate, or normal phenotype. *Plasmodium sp.* infections were determined by polymerase chain reaction (PCR). G6PDd and *Plasmodium* infection prevalence were calculated for each population and risk factors for G6PDd were explored. The study was conducted between July and November 2023. The prevalence of G6PDd was 10.4%, 0%, and 7.0% in the GP, IC and OSM, respectively. The prevalence of *Plasmodium sp.* infection was 17.8%, 40.7%, and 47.8% in GP, IC, and OSM, respectively. Among GP and IC, *Pv* was more frequent than *Pf* (GP Pv=11.2% & Pf=0.1%; IC Pv=26.2% & Pf=0.1%), and most *Pv* infections were asymptomatic. Being Afro Colombian (Prevalence ratio (PR) 6.81; 95% CI [3.21 - 18.08]) and male (PR 1.71; 95% CI [1.29 - 2.29]) were risk factors to be G6PDd, while being G6PDd resulted in lower *Plasmodium* infection (PR 0.41; 95% CI [0.25 - 0.63]). Afro-Colombian populations in Quibdó have a high G6PDd and thus, a higher potential risk of hemolysis, suggesting that a G6PD test must be implemented before the use of a high dosage of primaquine or tafenoquine. Effective malaria control is a big challenge in the study area due to the high burden of asymptomatic infections, caused by *Pv*. G6PDd was not found among the studied IC, which harbors the highest burden of *Pv* suggesting an opportunity for the adoption of new interventions for radical cure in this population.

7200

MASS DRUG ADMINISTRATION FOR MALARIA IN LOS CHILES, COSTA RICA: ITS IMPLICATIONS FOR ELIMINATION

Isaac Vargas[1], Sara Arce-Bonilla[1], Yadel Centeno[2], Jennyffer Gonzalez-Luna[3], Hazel Herra[3], Claudia Rosales-Galeano[3], Grettel Mora[3], Melissa Ramirez-Rojas[1], Rodrigo Marin[1], **Leopoldo Villegas**[2]

[1]Ministerio de Salud, San Jose, Costa Rica, [2]InterAmerican Development Bank, Washington DC, DC, United States, [3]Ministerio de Salud, Los Chiles, Costa Rica

Despite the significant achievements, malaria is still a public health problem in Costa Rica (CR). Malaria cases are concentrated in a few regions from which, Los Chiles foci have been responsible for the 81% of the CR cases in 2022. To contribute to the elimination of malaria in the main active foci (Los Chiles) in Costa Rica, a MDA was proposed by the MOH and partners. Three localities were selected San Gerardo, Coquital, and Medio Queso; and two farms that overall reported 64% of the cases in Los Chiles canton (97% Plasmodium falciparum, Pf)). We reported the results of a non-interventional, observational study conducted between January and June 2023. Two MDAs cycles were implemented among people who provided verbal consent and without any contraindications. A preparatory phase (Jan-Mar 2023) included an updated census, protocol design, planning, and door-to-door sensitization of the selected communities. Chloroquine (CQ) full treatment was given supervised for 3 days to the selected population in 861 households, and 2 farms. Overall, the average CQ completeness (full CQ 3d course) in the MDA1 (Apr 1-7) and MDA2 (Jun 5-9) among the selected 3 localities was 82% and 59.2%, respectively. In contrast, the average CQ completeness among participants in the farms was 33.4% in MDA1 and 47.7% in MDA2. Among all groups, the CQ refusal rate was increased 5x times - from 3.1% in MDA1 to 15.8% in MDA2. Adherence to more than two CQ doses was 88% and 89% in MDA1 and MDA2, respectively. Malaria cases dropped to zero after the end of MDA1 for 12 months; surveillance activities (passive/active case detection) have been maintained. The addition of a MDA in Los Chiles was successful in eliminating malaria transmission in the target areas for 12 consecutive months. To our knowledge, this is the first MDA for malaria conducted in Latin America after the updated WHO recommendations for chemoprevention strategies in June 2022. MDA (and other chemoprevention strategies) should be considered, assessed its feasibility, and incorporated more frequently at NMCPs to accelerate elimination targets.

7201

TARGETED TREATMENT WITH PRIMAQUINE FOR THE ELIMINATION OF *PLASMODIUM VIVAX IN A BORDER AREA OF THE GREATER MAEKONG SUB REGION*

Pattamaporn Petchvijit[1], Piyarat Sripoorote[1], Waraporn Thongyod[1], Nattawan Rachaphaew[1], Pyae Linn Aung Pyae Linn Aung[1], Amnat Khamsiriwatchara[2], Saranath Lawpoolsri[3], Kritsana Suk-aum[4], Peeriya Watakulsin[5], Wang Nguitragool[6], Wanlapa Roobsoong[1], Liwang Cui[7], Jetsumon Sattabongkot[1]

[1]Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [2]Center of Excellence for Biomedical and Public Health Informatics (BIOPHICS), Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [3]Department of Tropical Hygiene, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [4]Center of Vector Borne Disease Control 2.3, Ministry of Public Health, Tak, Thailand, [5]Office of Disease Prevention and Control 2, Ministry of Public Health, Phitsanulok, Thailand, [6]Department of Molecular Tropical Medicine and Genetics, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand, [7]Division of Infectious Diseases and International Medicine, Department of Internal Medicine,, Tampa, FL, United States

Plasmodium vivax malaria's high incidence hampers the Greater Mekong Sub-region's (GMS) 2030 malaria elimination goals. Thailand's adoption of the 1-3-7 surveillance framework for rapid case detection and containment

is commendable, yet insufficient due to challenges like hypnozoite-induced relapses and poor adherence to the 14-day primaquine (PQ) regimen. Hence, additional control measures are imperative to meet elimination targets. This study integrated the 14-day PQ treatment with reactive case detection activities as part of the 1-3-7 surveillance approach, termed Targeted Primaquine Treatment (TPT). Three districts with the highest reported *P. vivax* incidence along the Thailand-Myanmar border were selected as study sites. Within each district, two villages with similar geographical and malaria prevalence profiles were assigned as treatment or control groups. While individuals in the control group received standard malaria prevention and control measures (SMPC), eligible individuals in the treatment group received TPT (PQ 0.25mg/kg/day for 14 days) under directly observed treatment, in addition to SMPC, with the target of 150 index cases per group. The impact of TPT will be assessed by comparing two indicators (incidence and prevalence) before and after TPT in both groups. From October 2023 to March 2024, 55 index cases were identified across the two groups, with over 300 individuals receiving the 14-day PQ regimen. The TPT will continue until July 2024 to cover the peak malaria transmission in these areas. Preliminary analysis with available results detected an impact of TPT on the infection rate in the treatment group but minimal change in the control group. Notably, no severe adverse effects related to PQ were reported. In conclusion, early results of TPT shows potential in reducing the burden of vivax malaria. Its integration into existing malaria elimination efforts, such as the 1-3-7 strategy, requires minimal additional resources. Thus, TPT offers a viable strategy to enhance *P. vivax* malaria elimination, not only in Thailand but also in the broader GMS and Southeast Asia regions where *P. vivax* remains prevalent.

7202

ADVANCING MALARIA DIAGNOSTIC AND TREATMENT ACCESSIBILITY: A COLLABORATIVE APPROACH TOWARDS ACHIEVING NATIONAL TARGETS IN BENIN

Deborah Golan[1], **William Houndjo**[2], Julien Aissan[2], Vivien Akan[2], Emmanuel Koffi Yovo[1], Aimeric Zoungrana[1], Celestin Danwang[1], Lundi-Anne Omam[1], Almighty Nkengateh[1], Didier Agossadou[1], Cyriaque Affoukou[2], Achille Bernard BATONON[2], Olajumoke Adekeye[1]

[1]Clinton Health Access Initiative, Cotonou, Benin, [2]National Malaria Control Program, Cotonou, Benin

In Benin, significant improvements have been made in combating malaria, evidenced by a notable decrease in incidence rates by over 20% in 2023. However, this positive development is counteracted by a 17% rise in malaria lethality, escalating from 1.2 to 1.4 per 1000 cases. Nonetheless, hospital lethality has remained steady at 1.6%. These statistics underscore a pressing issue in malaria-related fatalities and emphasizes the urgent necessity for enhanced commodity access, especially for severe malaria cases. To address the challenges related to commodity access, the National Malaria Control Program has undertaken various initiatives, including supply chain activities focused on supervision, healthcare facility training, central-level quantification activities and supply data reviews. While these efforts have led to a continuous decrease in stock outs across the country since 2021, the availability of testing and treatment remains moderate, fluctuating between 70% and 80%. This level falls below the national target of 95%. Availability of testing and treatment commodities were addressed with comprehensive data reviews aiming at strengthening malaria surveillance activities and leveraging data insights to strengthen commodities access. Since 2023, one annual coaching session has been conducted, empowering healthcare providers to deliver accurate and timely malaria diagnosis and treatment. Building upon the successes of the previous year's efforts, which were primarily centered around healthcare facility training, this coaching approach has evolved this year to include 40 hospitals. By broadening the scope of the coaching to include hospitals, the National Malaria Control Program aims to extend its reach and impact, especially regarding severe malaria, and ensuring that diagnostic and treatment accessibility is optimized across all levels of the healthcare system. To further strengthen this initiative, results from the collaborative efforts of the data reviews will be used to directly inform the content and focus of coaching sessions, ensuring alignment with evolving challenges and priorities.

7203

IMPROVING DATA QUALITY AND SUPPLY CHAIN SERVICE DELIVERY THROUGH TARGETED CAPACITY BUILDING IN RESOURCE-CONSTRAINED SETTINGS: A CASE STUDY OF TWO SELECTED LOCAL GOVERNMENT AREAS IN KANO STATE, NORTHERN NIGERIA

Bravo B. Otohabru[1], Zumnan Tangshak[1], Abdullahi D. Muhammad[1], Chinedu Chukwu[1], Isaac Adejo[1], Thomas A. Hall[2], Frederick Ifijeh[1], Dozie Ezechukwu[1], Ezinne O. Onuba[3], Sonachi S. Ezeiru[3], Talatu Y. Kassim[4], Godwin N. Ntadom[4], Bolakale K. Issa-Kawu[4], James Ssekitooleko[5], Daniel R. Bott[6]

[1]Management Sciences for Health, Abuja, Nigeria, [2]Management Sciences for Health, Baltimore, MD, United States, [3]Catholic Relief Services, Abuja, Nigeria, [4]National Malaria Elimination Programme, Abuja, Nigeria, [5]The Global Fund, Geneva, Switzerland, [6]Local Fund Administrator, PWC, Abuja, Nigeria

Variances between dispensed-to-user data from the pharmacy and the number of patients accessing malaria prevention and treatment services have remained a source of concern in Kano State Nigeria. This mismatch can result in inaccurate quantification leading to overstocking or understocking of health facilities resulting in wastage which affects commodity security. For improved supply chain data management and accountability, formal refresher training is needed to retain institutional capacity amidst high attrition of personnel because of transfers, retirements, and migration. The Targeted capacity building (TCB) model was introduced to bridge the attrition gap of trained personnel without adequate resources for robust refresher training in all facilities. Twenty-four health facilities and 30 staff were selected in two local government areas (LGAs) with data triangulation variance greater than 10% and less than -10% indicating weak performance. A TCB session was planned to focus on the root causes and how to reduce the variance between the data sources. To ensure knowledge is retained after the training, a performance monitoring plan was developed with health facility workers and LGA personnel for follow-up. Before TCB, the cumulative average variance between dispensed to user data and the number of clients accessing malaria services recorded on the facility register and other registers collating malaria services between January and June 2023 was -44% and 25% respectively. These values improved to -22% and 8% for the respective LGAs following TCB from July to December 2023. The findings support the approach of using targeted capacity building in resource-limited areas, focusing on facilities and LGAs with performance issues. Continued analysis should be done to ascertain if the TCB approach can be sustained and continuously used.

7204

UTILIZATION OF MALARIA CORE TEAM STRATEGY ENHANCES STATE GOVERNMENT STAFF CAPACITY AND IMPROVES EFFICIENCY. A CASE STUDY OF OGUN STATE, SOUTHWEST NIGERIA

Isaac Adejo[1], Victoria Erinle[1], Chinedu J. Chukwu[1], Linda Okafor[1], Thomas Hall[2], Bravo Otohabru[1], Oluwatosin Olotu[3], Ralph Enushai[3], Frederick Ifijeh[3], Emmanuel Obi[4], Temitope Ipinmoye[4], Sonachi S. Ezeiru[4], Issa B. Kawu[5], Godwin N. Ntadom[5], James Ssekitooleko[6]

[1]Management Sciences for Health, Abuja, Nigeria, [2]Management Sciences for Health, Arlington, VA, United States, [3]Management Sciences for Health, Abeokuta, Ogun State, Nigeria, [4]Catholic Relief Services, Abuja, Nigeria, [5]National Malaria Elimination Programme, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Management Sciences for Health (MSH), a sub-recipient of Catholic Relief Services, implemented the Global Fund Malaria Grant, New Funding Model (NFM3) in 11 states in Nigeria from 2021-2023. One perennial challenge which the MSH project team sought to address during this period was that the State Malaria Elimination Programs (SMEP) staff lacked the capacity

to coordinate project activities and provide technical assistance to health workers, leading to a lack of ownership of grant interventions and making sustainability nearly impossible. MSH project team introduced the Malaria Core Team (MCT) strategy to enhance the capacity of SMEP personnel to address identified gaps. The MCT consists of SMEP technical staff and MSH state-based technical staff. MSH staff coached and mentored the government personnel in providing on-the-job training to service providers, through joint site visits. SMEPs now take ownership of grant interventions and ensure accountability for malaria health products, promoting sustainability. MCT members monitor project activities without MSH staff support and provide training to health workers using MSH-designed and national tools. Four SMEP personnel participated in a 2021-2023 MCT visit to Ogun State, visiting 180 health facilities, mentoring 450 workers, and advocating for smooth implementation, ensuring 40% of project-supported facilities were visited. The strategy of MSH, which involves working closely with governments, has significantly improved service delivery and reporting at the facility level. The Malaria Core Team's monitoring and supervisory visits have improved service providers' compliance with National Malaria Treatment guidelines, particularly in secondary health facilities. These visits have helped providers become more familiar with the guidelines and current treatment practices, especially for severe malaria. The MCT has resolved issues such as non-reporting, poor documentation, and poor data quality, reducing the risk of serious problems.

7205

INTEGRATING ACTIVE SURVEILLANCE AND ENTOMOLOGY FELLOWSHIP FOR SUSTAINABLE MALARIA CONTROL AND ELIMINATION IN SOUTHERN ANGOLA

André Domingos[1], Generoso Wangama[2], José Franco Martins[3], Cani Pedro Jorge[3], Luzala Garcia[3], Fernanda Guimarães[3], Paulo Máquina[4], Manuel Lando[5], Ana Direito[6], Xavier Badia[7], Gonçalo Alves[7], **Teresa Nobrega**[6]

[1]Provincial Public Health Department, Ondjiva, Angola, [2]SADC E8 fellowship, Cuangar, Angola, [3]National Malaria Control Programme, Ministry of Health, Luanda, Angola, [4]SADC Elimination 8, Luanda, Angola, [5]The Mentor Initiative, Ondjiva, Angola, [6]The Mentor Initiative, Luanda, Angola, [7]The Mentor Initiative, Haywards Heath, United Kingdom

Synergy initiatives aimed at enhancing malaria surveillance for elimination in border regions of Southern Angola started in 2017. The Ministry of Health is strengthening efforts for a sustainable path for a malaria elimination together with its regional partners. Under the Elimination 8 funded program, a strategy for active surveillance, including malaria case-based notification tracker system, was rolled out. Recently, a training program was conducted in Cunene and Cuando Cubango Provinces focusing on building capacity and sustainability of interventions for active surveillance. Fifty-three health workers of selected health facilities and focal points of 5 districts were trained on DHIS2 tracker, data driven decision making, vector control and entomology as path to scale up interventions. In addition, a fellowship program was set up to implement an entomological surveillance programme building local capacity. The intensification of capacity building interventions and integration with fellowship activities will allow to increase the scope of sentinel sites and enhance foci classification, investigation and response. This collaborative effort, led by the Ministry of Health, aimed to strengthen malaria information systems and case-based reporting to identify local transmission foci. This integrated approach not only enhances intervention effectiveness but also strengthens overall health system capacity, ensuring long-term sustainability and resilience against disease resurgence in the region. This abstract highlights the significance of interlinking active surveillance programs with entomology fellowships to achieve sustainable malaria control and elimination goals.

7206

THE IMPACT OF 1-3-7 FOCUS INVESTIGATION SURVEILLANCE IN A PRE-ELIMINATION SETTING IN SOUTHERN ZAMBIA: A ZONAL-RANDOMIZED TRIAL

Anne C. Martin[1], Japhet Matoba[2], Caison Sing'anga[2], Mukuma Lubinda[2], Michael Musonda[2], Ben Katowa[2], Tamaki Kobayashi[1], Harry Hamapumbu[2], Edgar Simulundu[2], William J. Moss[1]

[1]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma, Zambia

Since 2016, eleven countries have been certified as malaria free, but none of these are in continental Africa, where elimination challenges are unique. Recommended elimination strategies, like 1-3-7 focus investigation, feature heightened case-based surveillance and focal community response to index cases. A passively detected malaria "index" case, be reported within one day, classified within three days, and followed up in its community with focal response within seven days. To date, no study has measured the effect of 1-3-7. Choma District, located in Southern Province, Zambia is a very low transmission setting (under-5 RDT prevalence is 3.3%). The MUSEMO study was a 24-month zonal-randomized study in two health center catchments areas in Choma District to measure the impact of 1-3-7 on the prevalence and incidence of malaria. 1-3-7 was deployed in a randomly-selected half of the zones in the study area. Surveys measured malaria prevalence in index-case communities 7 and 35 days after index case diagnosis to compare 1-3-7, "intervention", and non-1-3-7, "control" zones through multi-level logistic regression. Health facility data reported weekly zonal incidence and Poisson regression estimated changes in incidence rate across intervention and control areas. Community qPCR prevalence increased between the 7 and 35-day visits from 1.9% to 2.8%, but there was no significant difference across arms. The weekly zonal incidence as reported through surveillance was 81% lower in the zones using 1-3-7 surveillance (ratio of IRR: 0.19, 95% CI: [0.08,0.43], p-value <0.01). The increase in community-level prevalence suggests there is ongoing local transmission in the weeks after an index case, and that current focal 1-3-7 response does not interrupt this. The decrease in catchment-wide incidence provides evidence that the surveillance component of 1-3-7 may drive improved awareness of localized malaria risk and planning and response to mitigate it. These findings support the use of the 1-3-7 surveillance approach to focus investigation and to add additional focal response strategies to day-7 activities.

7207

VILLAGE HEALTH TEAMS IMPROVING THE MANAGEMENT OF MALARIA IN CHILDREN UNDER 5 YEARS IN UGANDA'S WEST NILE REGION: A CASE OF MOYO DISTRICT

Felix Manano[1], Dorah Taranta[1], Angela Kateemu[1], Franklin Amuli[2], Robert Abiriga[1], Allan Matovu[1], Benjamin Binagwa[1], Edward Mugwanya[1], Nancy Brady[3], Amy Casella[3], Aliza Hasham[3]

[1]USAID/PMI Uganda Malaria Reduction Activity; JSI, Kampala, Uganda, [2]Moyo District Health Office, Ministry of Health, Kampala, Uganda, [3]USAID/PMI Uganda Malaria Reduction Activity; JSI, Boston, MA, United States

Malaria remains a significant health challenge in low- and middle-income countries, particularly affecting children under 5 years and pregnant women. In Uganda's West Nile Region, malaria prevalence is 22%. Moyo District in West Nile has been grappling with high malaria test positivity rates, ranging from 62% (January 2023) to 91% (December 2023). To address the problem, in September 2023, all 466/466 village health team members (VHTs) in Moyo were trained on case identification and fever management through integrated community case management (iCCM) of malaria, pneumonia, and diarrhea in children under five years of age. A cascaded training approach was used through the levels of service delivery in the district, starting from the district to the VHT. Training focused on case management and reporting of data and was followed by quarterly VHT meetings and mentorships to ensure compliance and accountability for commodity refills. At the start of the intervention, the

National Medical Stores (NMS) supplied 11,691 malaria commodities to 30 health facilities in Moyo, of which 70% (8,133) went to the VHTs. The availability of commodities for iCCM in Moyo ensured that malaria test and treatment ratios remained above the 95% national target. Following the iCCM training, VHT knowledge scores increased to an average of 75% from 39% at baseline. The number of children under five years attended to by VHTs within the community increased to 2,872 from 1,694 before the intervention. Fever cases attended to by VHTs also increased to 2,595 from 1,552. The success of this approach underscores the potential of VHT-led iCCM to significantly improve access to malaria case management services, particularly in hard-to-reach communities.

7208

MODELING THE IMPACTS OF SEVERE STORMS ON MALARIA INCIDENCE IN MOZAMBIQUE FROM 2016-2023

Kelly M. Searle, Euna M. Khan, Hengcheng Zhu, Mitchel Croal, Jaideep Srivastava, Lin Zhang

University of Minnesota, Minneapolis, MN, United States

Increases in frequency and severity of extreme weather events (e.g. cyclones, tropical storms, and severe storms) are a hallmark of climate change, and impact established programs to control and eliminate malaria. Mozambique is already experiencing these, with increases in tropical storms, tropical cyclones, and floods over the past 10 years impacting the entire population and currently does not have the capacity to respond to all of the infectious disease challenges that result. The National Malaria Control Program (PNCM) is charged with implementing and maintaining the infrastructure to support P. falciparum prevention, control, and elimination programs throughout the country. In this resource poor setting, the progress of these programs is under constant threat when infrastructure is damaged due to severe weather events because emergency response is limited to the highest impacted areas. Areas outside of direct impact, have not received support in the aftermath, and not specifically for malaria. We integrated malaria surveillance data and climate data for both named and unnamed storms to determine geographic areas in Mozambique that are at an increased risk of malaria due to infrastructure damage following severe weather events. We used databases from the World Meteorologic Organization database of named tropical storms and cyclones to identify the locations and tracts of the eyes of the storms. We quantified the areas impacted by these storms using NASA satellite precipitation data matched to the time and locations of the eyes of the storms. We integrated temperature data from NASA satellites also. We used daily precipitation data, monthly temperature data, and daily wind data (from NASA weather stations) to detect storms that don't reach the classification to be a named storm. We used these data with the malaria incidence data aggregated to the District level to quantify the population at risk in these areas following severe storms using a Bayesian time-series model. This study will present preliminary findings of our models for at the national level in Mozambique.

7209

EFFECTS OF COMMUNITY MALARIA CASE MANAGEMENT TO THE OVERALL MALARIA INCIDENCE IN BUSIA COUNTY KENYA 2022

Edwin Oluoch Onyango

Busia, Busia, Kenya

The objective of the study was to determine whether Case Management of Malaria (CCMm) by Community Health Volunteers (CHVs) affect the trends of malaria incidence in Busia Kenya from 2018 to 2023. The study determined the annual proportion and trends for malaria cases tested and treated at health facilities and Community Units and correlated the trends with annual malaria incidence out-patient malaria cases, weather patterns, climate change, and commodity availability at the community level. This was a retrospective cross-sectional involving the analysis of routinely collected malaria data as reported on the Kenya Health Information Systems. The proportion of Suspected Malaria Cases being tested by Community Health Volunteers compared to those tested at Health facilities increased from 11% in 2019 to 45% in 2022. The rate of malaria infections per month remained almost constant, with peak infections occurring in May annually, except in May 2020. Over time the contribution of CCMm in overall malaria case management and incidence has increased, with more malaria cases being treated in the Community as of mid 2022. The incidence of Malaria has remained high over the years. The study concluded that CCMm improves access to Malaria treatment services but does not reduce the Annual Malaria Incidence in Busia County.

7210

MALARIA AND ANAEMIA PREVALENCE AND ASSOCIATED FACTORS AMONG PREGNANT WOMEN INITIATING ANTENATAL CARE IN GHANA

Gifty D. Ampofo[1], Joseph Osarfo[1], Doris D. Okyere[1], Ekoue Kouevidjin[2], Matilda Aberese-Ako[1], Harry K. Tagbor[1]

[1]University of Health and Allied Sciences, Ho, Ghana, [2]University Cheikh Anta Diop, Dakar, Senegal

Malaria infection in pregnancy is associated maternal anemia and low birth weight. Although there are improving levels of implementation of recommended malaria and anemia control interventions in Ghana, there is no commensurate reduction in maternal anemia prevalence and low birth weight. A health facility-based cohort study was conducted between 2018 and 2020 to identify current risk factors of low birth weight and maternal anemia in 2 regions of Ghana. The baseline malaria infection and anemia prevalence and associated factors is reported here. Five thousand, one hundred and ninety-six pregnant women of all parities, ages and gestational ages were enrolled at first antenatal care visit in Ashanti and Volta regions of Ghana. Descriptive and inferential statistics were conducted on data collected on socio-economic and demographic characteristics, obstetric history, ITN ownership and use, presenting complaints and laboratory results of full blood count, G6PD and sickling status, malaria parasite, HIV, syphilis, Hepatitis B, schistosoma and helminth infections using STATA version 16. The mean (SD) age and gestational age were 27.3 (6.5) years and 15.5 (8.37) weeks respectively. ITN use was 59.8% compared to 80.8% ownership. Overall malaria parasite prevalence was 5.7%; higher in Ashanti (10.24% [95% CI: 8.92 - 11.68]; mean parasite density = 982/µl) compared to Volta (2.63% [CI: 2.07 - 3.29]; mean parasite density = 18226/µl). Overall anemia prevalence was 55.2%; higher in Volta region (65.6% [95% CI: 63.78 - 67.31]) than in Ashanti (42.6% [95% CI: 40.53 - 44.60]). Women with malaria infection were more likely to be resident in Ashanti, primipara, of lower wealth status and reported at least a clinical symptom. Women were more likely to be anemic if resident in Volta region, had malaria infection, were younger than 25years, booked ANC later and of lower wealth index (P<0.001). Although malaria infection prevalence is relatively low it still poses a risk to maternal anemia. Maternal anemia is high and of serious public health importance appearing to be related more to geographic location and wealth index.

7211

THE RELATIONSHIP BETWEEN PLACENTAL MALARIA AND PREECLAMPSIA

SARAH BOUDOVA[1], Titus Divala[2], Randy Mungwira[2], Tamiwe Tomoka[3], Miriam Laufer[4]

[1]Thomas Jefferson University, Philadelphia, PA, United States, [2]Blantyre Malaria Project, Blantyre, Malawi, [3]University of Malawi, Blantyre, Malawi, [4]University of Maryland School of Medicine, Baltimore, MD, United States

Pre-eclampsia (PreE) and malaria are leading causes of perinatal morbidity and mortality in sub-Saharan Africa. Placental malaria (PM) has overlapping pathophysiology with PreE, causing abnormal angiogenesis in the placenta. Placental damage from PM may predispose patients to PreE. Previous studies have demonstrated an association between hypertensive disorders of pregnancy and PM but are limited by a failure to characterize the PM (acute v. earlier in pregnancy) and type of hypertensive disorder (PreE, eclampsia, all hypertensive disorders of pregnancy). Utilizing placental specimens and clinical data collected during a randomized

controlled clinical trial of intermittent preventive therapy during pregnancy in Malawi, we aimed to examine the association between PM and PreE. All individuals from the parent study with singleton pregnancies and placental histopathology and PCR available were included in this analysis. All patients were HIV-uninfected and primi- or secundigravid. No patients had chronic hypertension or advanced maternal age. Chi-squared tests were performed. Among the 751 individuals meeting inclusion criteria, 125 (16.7%) had evidence of PM. Of those, 105 had hemozoin pigment present, indicative of an infection earlier in pregnancy. Out of the 751 participants, 31 (5.0%) had PreE, 6 had eclampsia (1.0%) and 82 (13.1%) had any type of hypertensive disorder of pregnancy. There was no statistically significant difference in rates of PreE, eclampsia or hypertensive disorders of pregnancy based on the presence of PM or hemozoin pigment. Although, individuals with hemozoin pigment had nearly twice the rate of preeclampsia as those without (6.7% v. 3.7%, p=0.16). We suspect that placental infection in the 1st or 2nd trimester, rather than acute infection at the time of delivery may increase the risk of PreE. This study is limited by its sample size, and is likely underpowered to detect a difference in PreE rates based on PM. Further studies characterizing the relationship between PM and hypertensive disorders of pregnancy are warranted, with particular focus on the role of antimalarial treatments in reducing the risk of PreE.

7212

MALARIA-GUT MICROBIOTA INTERACTIONS WITHIN THE CONTEXT OF GEOGRAPHIC REGIONS, NUTRITION, PARASITIC CO-INFECTION & AGE IN RWANDA

Jean d'Amour Mutoni[1], Matthias Van Hul[2], Aline Uwimana[3], Anthony Puel[2], Amandine Everard[2], Hélène Alexiou[4], Leon Mutesa[1], Jean-Paul Coutelier[2], Nadine Rujeni[1], Patrice D. Cani[2]

[1]University of Rwanda, Kigali, Rwanda, [2]Université catholique de Louvain, Brussels, Belgium, [3]Rwanda Biomedical Center, Kigali, Rwanda, [4]Haute Ecole Leonard de Vinci, Brussels, Belgium

Malaria, caused by *Plasmodium* species, is a major health problem affecting the global south disproportionately. The gut microbiota (GM) play a critical role in health and disease including infections such as malaria. Evidence shows a significant interplay between the host GM and both the transmission and severity of malaria. Malaria-GM interactions may be shaped by several factors including, but not limited to, geographic location, nutrition, co-infections such as soil-transmitted helminths (STH) and age. Therefore, we used a multidimensional approach to explore interactions between malaria and the GM in Rwanda. Between 11/2021 and 09/2022, we conducted a study in three malaria-endemic provinces of Rwanda: East, South and West. We recruited 169 participants (85 females and 84 males) aged between 2-78 years. In addition to questionnaire-derived data, malaria diagnosis by rapid diagnostic test (RDT) and blood smear was followed by STH screening in stool by formalin-ether technique to make comparison groups. Fecal microbiota was analyzed using 16S rRNA gene sequencing. We discovered a significantly differential beta-diversity ($p < .002$, PERMANOVA) which may be explained by a 20-30% lower fiber intake ($p<.001$, ANOVA) observed in the West compared to both the other provinces. Relative abundance of *Faecalibacterium* and *Succinivibrio* was significantly higher in the West than in the East/South ($p<.001/p<.02$, Kruskal-Wallis) and lower in the West than in the South ($p<.01$, Kruskal-Wallis) respectively. Unlike age, infection status was not linked to GM composition differences. Moving forward, we are collecting samples with a better representation of asymptomatic and severes cases to perform metagenomic and micronutrional analyses.

7213

A REVIEW OF 15 YEARS OF CRYPTIC MALARIA IN THE UNITED KINGDOM

Parisha Katwa[1], Sophie Leinster[1], Philip G. Veal[1], Hilary A. Kirkbride[1], Peter L. Chiodini[2]

[1]UK Health Security Agency, London, United Kingdom, [2]UK Health Security Agency Malaria Reference Laboratory, London, United Kingdom

Autochthonous malaria transmission has not been observed in the United Kingdom since 1953. Nearly all malaria cases diagnosed in the UK are imported, in individuals who acquire their infection during travel to a malaria-endemic region. Cryptic malaria cases where there is no history of recent travel of that nature and for which initial epidemiologic investigations cannot identify a plausible mode of acquisition are rare in the UK, making up less than 1% of cases since 2000. All cryptic malaria cases in the UK are investigated according to published national guidance. We reviewed 15 years of cryptic malaria in the UK between 2009 and 2023, to identify trends, compare investigation outcomes and inform updates to national cryptic malaria guidance. Nine cases of cryptic malaria, 8 *Plasmodium falciparum* and one *P. malariae*, were reported in the UK between 2010 and 2023, with the highest annual total of 3 cases in 2023. All cases were reported in Southern England, with the majority reported in London. Additional investigations were undertaken by the UK Health Security Agency's national Travel Health team, Malaria Reference Laboratory, local health protection teams and the national Medical Entomology team, to identify the potential source of infection for each case. Other stakeholders were included where appropriate. Five cases were classified as possible 'baggage' or 'airport' malaria, one as recrudescence in a semi-immune person due to pregnancy, one as a probable case of transfusion-transmitted malaria due to *P. malariae* and no clear sources were identified for the remaining two cases. Autochthonous transmission was excluded in all cases. Although it is considered unlikely that malaria will become endemic again in the UK, climate change could facilitate a re-emergence of natural transmission of malaria. Thorough investigation of cryptic malaria cases is essential in identifying potential sources of infection, and to ensure accurate and timely surveillance, which is vital to detect and prevent autochthonous malaria in the UK.

7214

KNOWLEDGE, ATTITUDES, AND PRACTICES OF MALARIA TREATMENT IN RWANDA: A CROSS-SECTIONAL STUDY

Pierre Gashema[1], Aileen Jordan[2], Eric Saramba[3], Lambert Nzungize[4], Neeva Wernsman Young[5], Corine Karema[6], Jean Baptiste Mazarati[4], Jonathan J. Juliano[7], Jeffrey A. Bailey[5], Kristin Banek[8]

[1]Center for Genomic Biology, INES-Ruhengeri, Ruhengeri, Rwanda, College of Medicine and Veterinary Medicine, University of Edinburgh UK,, Kigali, Rwanda, [2]College of Medicine and Veterinary Medicine, University of Edinburgh UK,, Edinburgh, United Kingdom, [3]College of Medicine and Health Sciences, University of Rwanda, Kigali, Rwanda, [4]Center for Genomic Biology, INES-Ruhengeri, Ruhengeri, Rwanda, Kigali, Rwanda, [5]Department of Pathology, Brown University, Providence, RI, USA, Providence, RI, United States, [6]Quality Equity Health Care, Kigali, Rwanda, Kigali, Rwanda, [7]Division of Infectious Diseases, School of Medicine, University of North Carolina, Chapel Hill, NC, USA, North Carolina,, FL, United States, [8]Institute for Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, NC, USA, North Carolina, FL, United States

Malaria remains a significant public health threat. Prompt diagnosis with effective treatment is a key malaria intervention and its success depends on communities having knowledge of and adhering to malaria treatment guidelines. Rwanda, the first African country to confirm partial artemisinin resistance, must promptly address this threat by ensuring optimal malaria treatment practices in the community. This study measured the malaria knowledge, attitudes, and practices (KAP) among febrile patients seeking treatment at government clinics, aiming to identify factors influencing malaria treatment practices across Rwanda. A cross-sectional study was

conducted in six health centers in areas of high malaria transmission in Rwanda. Patients or caregivers of children seeking treatment for fever were enrolled and interviewed using semi-structured questionnaires. The frequency and proportions of the KAP indicators were determined using descriptive statistics. From December 2023 to February 2024, 406 participants were enrolled, and 56% were female, most lived rurally (80%), and 50.2% attended primary school. Malaria knowledge was high: symptoms (86.7%), transmission (82.7%), and control (73.7%). Only 71.2% owned insecticide-treated nets (ITNs), 50.5% received indoor residual spraying (IRS). 44.3% (180/406) sought malaria treatment in the last 6 months; of those, 46.1% completed medication in 3 days, 36.7% stopped in 2 days, 10.6% over 3 days, 2.8% unsure. Furthermore, 26.8% (109/406) took antimalarials for fever without diagnosis; 54.1% got them from drug outlets/pharmacies. Malaria knowledge and positive attitudes towards treatment and prevention strategies among participants were high across all health centers. However, these positive attributes did not translate into malaria prevention and treatment behaviors. Specifically, poor adherence to malaria treatment was observed, which is likely potentiating the emergence of resistance. In an era of developing drug resistance, there is an urgent need to identify and implement effective interventions to boost malaria treatment and adherence practices in Sub-Saharan Africa.

QUANTIFYING THE RELATIONSHIP BETWEEN MALARIA IN PREGNANCY AND MATERNAL ANEMIA USING ROUTINE ANTENATAL CARE-BASED SURVEILLANCE DATA IN TANZANIA

Abigail R. Goodship[1], Sequoia I. Leuba[1], Joseph T. Hicks[1], Abdallah Lusasi[2], Sijenunu Aaron[2], Samwel L. Nhiga[2], Mzee M. Nassoro[3], Frank Chacky[2], Patrick G.T. Walker[1]

[1]Imperial College London, London, United Kingdom, [2]Ministry of Health, National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [3]Ministry of Health, Division of Reproductive and Child Health, Dodoma, Tanzania, United Republic of

Whilst malaria is associated with an increased risk of severe anemia, especially in first-time mothers, the relationship is not well characterized. To address this gap, we used routine antenatal care (ANC) surveillance data from mainland Tanzania (January 2016-September 2023) from pregnant women attending their first ANC visit. We evaluated trends in maternal malaria and severe anemia (hemoglobin (Hb) <85g/L) prevalence using descriptive statistics and used binomial mixed-effects logistic regression to estimate adjusted severe anemia prevalence, accounting for variation in Hb testing coverage. National malaria prevalence was 6.8% and severe anemia prevalence was 1.7%. Of the 17.2 million women attending first ANC, 91.8% were tested for malaria, but only 63.4% were Hb tested. Health facilities Hb testing <75% of attendees (compared to ≥ 75%) had higher malaria prevalence (8.37% vs 5.87%) and a higher percentage of women visiting after the first trimester (34.0% vs 25.2%), suggesting those who were not tested for severe anemia were likely those most at risk of severe anemia. After adjusting for variation in Hb testing coverage, our estimate of severe anemia cases increased 46.5% (unadjusted n = 184994, adjusted n = 271089). We found a weak positive correlation between malaria and adjusted severe anemia prevalence in different regions over time (Spearman's $\rho = 0.371$, $p<0.05$). From age-disaggregated data, we found that as malaria prevalence increased, the relative risk of severe anemia increased in younger women. When malaria prevalence in under 20s was 0, the risk of severe anemia in pregnant women under 20 compared to women over 25 was 0.98 (95% Confidence Interval (CI): 0.92, 1.04), and as malaria prevalence reached 30%, the relative risk increased to 1.44 (95% CI: 1.31, 1.58). Our work shows the value of routine ANC data in providing temporal and spatial granularity on ANC coverage and prevalence of malaria and severe anemia in pregnancy. This analysis will be used to inform Tanzanian maternal health policy on resource allocation and intervention coverage to reduce maternal malaria- and severe anemia-related morbidity and mortality.

7216

MALARIA HIGH RISK POPULATION ASSESSMENT IN ZANZIBAR, MAY-AUGUST 2023

Geofrey Makenga[1], Sarah Gallalee[2], Humphrey Mkali[1], Mwinyi Issa Khamis[3], Abdulhamid Ramadhan[3], Mohamed Ali Kitwasi[3], Stella Makwaruzi[1], Saidi Mgata[1], Michael Gulaka[1], Nicodemus Govella[1], Fabrizio Molteni[4], Sarah-Blythe Ballard[5], Chonge Kitojo[6], Naomi Serbantez[6], Marguerite M. Clougherty[7], Sigsibert Mkude[1], Jennifer Smith[2], Shija J. Shija[3], Cara Smith Gueye[2], Roly Gosling[7]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Malaria Elimination Initiative, Institute for Global Health Sciences, University of California San Francisco, USA, California San Francisco, CA, United States, [3]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [4]Swiss Tropical Public Health Institute, Dar es Salaam, Tanzania, United Republic of, [5]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [6]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [7]Population Services International (PSI), Washington DC, WA, United States

In malaria elimination settings, cases tend to cluster geographically and occur among certain subpopulations. Clustering is often related to certain factors such as occupation or mobility, which increase an individual's risk for malaria infection. The U.S. President's Malaria Initiative supported a case-control study to identify malaria high-risk populations (HRPs) in Zanzibar. Patients presenting with symptoms of malaria at selected facilities were recruited from historically high burden shehias in two urban districts (Mjini and Magharibi B) and two rural districts (Kati and Micheweni). Between May and August 2023, the study recruited 197 cases and 557 controls matched by age group and sex. Logistic regression was used to explore associations between risk factors and the epidemiological outcome of local malaria infection, classified as no travel outside Zanzibar in the prior three weeks. In urban districts, night watchmen/police (odds ratio [OR] 5.3, 95% confidence interval [CI]: 2.7-10.6, $p<0.001$), construction workers (OR 3.0, 95% CI: 1.8-5.0 $p=0.007$), and farmers (OR 1.6, 95% CI: 1.1-2.2, $p=0.01$) were found to be at risk for malaria infection. Other high-risk behaviours in urban districts included night-time activities (OR 2.8, 95% CI: 1.8-4.3, $p<0.001$), meals taken outside (OR 2.0, 95% CI: 1.1-3.4, $p=0.01$), and recent travel within Zanzibar (OR 3.3, 95% CI 1.5-7.1, $p=0.002$). In rural districts, night-time activities (OR 3.8, 95% CI: 1.5-9.9, $p=0.006$) and taking meals outside (OR 2.7, 95% CI 1.1-6.6, $p=0.03$) were risk factors for malaria; however, there were no significant associations between occupational group and infection. There was no statistical association between malaria infection and net use in urban districts, but in rural districts, prior night net use was protective (OR 0.38; 95% CI: 0.2-0.8 $p=0.015$). In urban populations, some occupations were associated with increased risk of malaria infection, while only behaviors were associated with increased risk of malaria infection in rural populations. These findings suggest intervention targeting occupational groups could reduce malaria risk among HRPs in urban areas.

7217

ASYMPTOMATIC MALARIA RESERVOIRS IN HONDURAS: A CHALLENGE FOR ELIMINATION

Hugo Valdivia[1], Gustavo Fontecha[2]

[1]U.S. Naval Medical Research Unit SOUTH, Lima, Peru, [2]Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras

Malaria elimination efforts have resulted in substantial progress during the last 25 years. In central America, Honduras has decreased the incidence of malaria to less than 2,408 cases in 2023 and aspires to reach elimination by 2030. However, reaching the elimination goal requires an evaluation of existing strategies, understanding the prevalence of asymptomatic and submicroscopic infections, and the incorporation of novel intervention tools tailored toward decreasing transmission in the country.
We conducted an active surveillance study during November 2023 in the community of Kaukira (Gracias a Dios Department), which is a major focus

of malaria transmission in Honduras. Households were randomly selected, and all eligible individuals were invited to participate. Participants provided sociodemographic and epidemiological data, and a finger prick sample for a rapid diagnosis test (RDT), photoinduced electron transfer PCR (PET-PCR), and conventional PCR testing.
A total of 138 participants were enrolled from 81 households. Most subjects were female (n=91, 65.9%) with a mean age of 42 years and all tested negative by RDT. Molecular testing detected 17 malaria positive samples (12.3%) with 15 of these typed, resulting in eight cases of *P. falciparum*, six cases of *P. vivax* and one mixed infection. Parasitemia levels were low, ranging from 100 parasites/µL to less than 0.25 p/µL. None of the positive cases were symptomatic during enrollment. Statistical analysis revealed that individuals who had previously lived with someone diagnosed with malaria were three times more likely to test positive for malaria (Fisher exact test p<0.05, OR 3.3, 95%CI:0.9-11.4).
Our study highlights ongoing transmission of malaria in Kaukira due to the presence of human asymptomatic malaria reservoirs which can hamper malaria elimination efforts. Furthermore, the association between previous malaria exposure in the household and current infection underscores the need for targeted interventions. Finally, our results highlight the need for highly sensitive detection methods as part of the surveillance strategy to achieve the goal of malaria elimination.

7218

EVIDENCE OF DECLINING MALARIA TRANSMISSION IN ZIMBABWE, 2014-2023

Busisani Dube

US President's Malaria Initiative, Harare, Zimbabwe

While global malaria progress has stalled in recent years, Zimbabwe has reported declines in annual incidence. We sought to examine the malaria epidemiological trend and assess if changes were a result of decreased outpatient attendance, testing, or reporting. We used R to extract and analyze malaria data reported in the national health management information system from 2014-2023. Between 2014-2023, a mean of 95% of health facilities submitted monthly data reports on time, but only 44% of reports had all malaria variables completed. Confirmed malaria cases reported by health facilities and community health workers (CHWs) decreased from 552,305 in 2014 to 244,247 in 2023 (56% decrease), resulting in a 59% decrease in reported annual malaria incidence, from 39 to 16 cases per 1,000 individuals. On average, 44% of cases were diagnosed by CHWs, increasing from 23% in 2015, when CHW coverage increased, to 57% in 2023. Over 70% of cases were reported between February and June, aligning with the rainy season. Three of the 10 provinces, Manicaland, Mashonaland Central, and Mashonaland East reported 75% of total annual malaria cases. The malaria case fatality rate decreased from 0.156% to 0.124% (21% decrease). The number of all-cause outpatient visits decreased 34%, from 12.6 million visits in 2014 to 8.3 million in 2023; however, the increased proportion of cases diagnosed by CHWs did not account for decreased outpatient attendance. Test positivity decreased 43%, from 37% in 2014 to 21% by 2023. When adjusted for potentially decreased testing (provider discretion and rapid diagnostic testing stockout) and reporting completeness, the overall trend of testing decreased by 23%. Even when corrected for missing data and testing rates, reported malaria cases have decreased in Zimbabwe.

7219

IMPACT OF THE INTERRUPTION OF SEASONAL MALARIA CHEMOPREVENTION IMPLEMENTATION ON MALARIA INCIDENCE IN BANDIAGARA, MALI

Drissa Coulibaly[1], Souleymane Traore[1], Kindie Kouriba[1], Fayçal Maiga[1], Ladji Diarrassouba[1], Abdoulaye K. Kone[1], Karim Traore[1], Amadou Niangaly[1], Ismaila Thera[1], Helen Powell[2], Mark A. Travassos[2], Mahamadou A. Thera[1]

[1]Malaria Research and Training Center, University of Sciences Techniques and Technologies, Bamako, Mali, [2]Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Malaria remains a major public health threat, with 249 million cases and 608,000 deaths in 2022. Most deaths were in the African region in children under five (WHO, 2023).Seasonal malaria chemoprevention (SMC) is an effective control strategy that has led to a significant reduction in morbidity. A decline in malaria incidence in Bandiagara, Mali, a vaccine testing site, following the combined implementation of control strategies that included SMC was observed in 2017-2018 compared to the previous decade. Since 2016, SMC has been a nationwide measure in Mali. This study aimed to assess the impact of a 2021 interruption of SMC in Bandiagara on malaria incidence. SMC resumed in 2022.A cohort of 240 children in three age strata (3 months-5 years, 6-10 years and 11-18 years) was followed from July 2021-December 2022 in Bandiagara, an area with intense seasonal malaria transmission. We measured malaria incidence in number of episode person-years for 2021 and 2022. Overall, malaria incidence was higher in 2021 compared to 2022 with, respectively, 2.04 and 0.96 episodes, IRR=2.12 (95% CI: 1.75- 2.55; p<0.001). The incidence in the 3 months-5 years age strata was, respectively, 1.7 and 0.5 episodes in 2021 and 2022, IRR=3.5 (95% CI: 2.3-5.7; p<0.001). For the 6-10 years strata, the incidence was higher in 2021, with 1.8 episodes vs 1.1 episodes in 2022, IRR=1.56 (95% CI: 1.13- 2.15; p=0.0025). For children 11-18 years, the incidence was also higher in 2021, with 2.5 episodes vs 1.1 episodes in 2022, IRR=2.31 (95% CI: 1.73- 3.08; p<0.001). In 2021, the malaria incidence for children aged 6-10 years was similar to children 3 months-5 years, IRR=0.96 (95% CI: 0.68- 1.37; p=0.42). That year, children under 10 years old had a lower malaria incidence than children above 10 years, IRR=0.68 (95% CI: 0.49- 0.94; p=0.0084).The high malaria incidence in 2021 is likely a consequence of the SMC interruption and indicates the need for further support for SMC efforts. Interestingly, SMC interruption also impacted malaria incidence in children outside the targeted age group, suggesting the need for further investigation of malaria spread and vulnerability in pediatric populations.

7220

CONDUCTING AND OVERCOMING PEDIATRIC CLINICAL TRIALS CHALLENGES IN LOW AND MIDDLE INCOME COUNTRY SETTINGS: EXPERIENCE IN THE DEMOCRATIC REPUBLIC OF CONGO

Clovis Mwamba Llunga, Didier Kalemwa, Stefan Schneitter, **Elisabeth Reus**

The Swiss Tropical and Public Health Institute, Allschwil, Switzerland

Africa carries the major burden of malaria worldwide with children being the most affected. Despite increased efforts in pediatric drug development, a notable lack of approved pediatric formulations for anti-malarial drugs in young infants remains. Products intended for older children are often administered to young infants increasing the risk of misdosing and adverse reactions. Clinical trial conduct in children in low and middle-income countries (LMIC) poses challenges due to restricted funding, specific clinical needs, ethical and regulatory protections and lack of infrastructure. In 2020, we initiated the CALINA study in a regional, regulatory clinical trial naïve, Congolese hospital. The study evaluated a new dosage of arthemether-lumefantrine (5mg/60mg) in the treatment of uncomplicated malaria in neonates and infants < 5 kilograms of body weight. To enable this, a decentralized trial approach was set-up. This included training

and weekly communication with the referral health centers, enabling a community network, obtaining participant feedback and getting buy-in from local authorities. Between 2020 to 2023, 14'350 infants presented with suspected malaria at the peripheral centers for consultation (10km radius from the study site); 284 infants were pre-screened out of which 50 were transferred to the main hospital and screened at site. This lead to 21 infants being included in the study, with no loss to follow-up, the highest recruiting study site. Through understanding of the patient pathway and efficient site set-up and management, the study demonstrated the complexity and success in recruiting a highly vulnerable population in LMIC settings. Although, the return on investment for such intensive set-up is disputable, a conventional trial configuration does not necessarily work when reaching vulnerable patients. A decentralized approach set-up to the endemic sites with a focus on patient pathway is key to successful recruitment. The need for expertise, capacity strengthening and constant site support to ensure operational efficiency is paramount for successful completion of such trials.

7221

SCOPING REVIEW OF NEUROLOGICAL SEQUELAE DUE TO *PLASMODIUM FALCIPARUM* AND *VIVAX* CEREBRAL MALARIA, 1980-2023

Joanna Whisnant, Ewerton Cousin, Taren Gorman, Quince Hara, Cathleen Keller, Olivia Nesbit, Stephanie R.M. Zimsen, Jonathan Mosser

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Malaria is a deadly vector-borne disease transmitted by Anopheline mosquitos with the majority of disease burden being caused by the parasites Plasmodium falciparum and vivax (*P.f.* and *P.v.*). Cerebral malaria (CM) is considered the most severe complication due to its high mortality rate and potential to leave survivors with residual neurological sequelae. We aim to describe the current data landscape of *P.f.* and *P.v.* CM neurological sequelae prevalence and duration by conducting a scoping review. Three databases (Pubmed, SciELO, Web of Science) were searched from 1980-2023 as were reference lists. Representative populations in locations endemic for *P.f.* or *P.v.* at the time of the study were included. We pre-registered the review protocol (PROSPERO ID CRD42023431162). We found 2,589 sources, 2,008 of which were excluded during title/abstract screening. After full text screening, 76 of the remaining 169 papers were excluded due to study overlap. 11 studies identified from the references of other malaria systematic reviews were also included. A total of 104 articles were extracted and analyzed, covering 26 countries. Most studies (76; 71.0%) were conducted in Sub-Saharan Africa, 17 in South Asia (15.9%), 10 in Southeast Asia, East Asia, and Oceania (9.35%), and 4 in North Africa and Middle East (3.74%). Across time, 18 (16.8%) studies took place in the 1980s, 49 (45.8%) in the 1990s, 33 (30.8%) in the 2000s, and 7 (6.54%) in the 2010s. There were no studies conducted in Latin America, the Caribbean, or in 2020-23. Although 47.7% (51) of studies provided information on the sequelae acquired, only 29.0% (31) included sequelae duration. 5 (4.67%) studies included data on *P.v.* CM, of which only 2 focused solely on *P.v.* The lack of studies in *P.v.*-prominent areas combined with the absence of more recent data indicate significant gaps in the current research. This work will be updated through 2024 and serve as the basis for a further systematic review and quantitative synthesis. As some countries approach elimination, studies on prevalence and duration of CM neurological outcomes are needed to accurately quantify malaria burden and track elimination progress.

7222

PLASMODIUM OVALE CURTISI AND P.O WALLIKERI CO-CIRCULATION AMONG MALARIA INFECTED PATIENTS IN THREE HEALTH FACILITIES IN DSCHANG, WEST REGION OF CAMEROON.

Pacome Valery KOM TCHUENKAM[1], Varun R. Potlapalli[2], Innocent Mbulli ALI[1], Meredith S. Muller[2], Darlin Bean Nguene Kaunda[1], Eva Mai KEMING[1], Kyaw THWAI[2], Oksana Kharabora[2], Jessica T. LIN[2], Jonathan J. Juliano[2]

[1]Department of Biochemistry, Faculty of Science, University of Dschang, Dschang, Cameroon, [2]Institute of Global Health and Infectious Diseases, University of North Carolina School of Medicine, Chapel Hill, NC, United States

Malaria is a vector-borne parasitic disease that continues to be a global public health threat to humans. Four different species of Plasmodium have been identified to cause malaria in African settings: *P. falciparum*, *P. malariae, P. ovale sp., and P. vivax*. Previous cross-sectional surveys in 2013 and 2017 have indicated the circulation of *P. vivax* in Cameroon prompting further investigation into the circulation of falciparum and non-falciparum species among patients presenting with symptoms consistent with acute uncomplicated malaria. This study evaluated the presence of malaria infection among these individuals using molecular methods in the West region of Cameroon. A cross-sectional facility-based study was carried out among 431 clinically suspected cases of malaria in 2020 from three health facilities in Dschang. Socio-demographic and clinical data were collected from all consenting patients. In addition, blood spots on Whatman chromatographic paper (number 03) were collected from the patients. These blood samples were subjected to DNA extraction and a real time PCR-based assay which detects the Plasmodium 18s rRNA gene. Samples positive for *P. ovale* were further characterised as *P.o curtisi* or *P.o wallikeri* using realtime PCR assay and custom primers. Among 431 samples, 215(49.9%) were positive for *P. falciparum*, 12(2.8%) for *P. ovale* in mixed infections with *P falciparum*, and 5(1.2%) mono infections. 1 for *P. malariae*(0.2%) mono infection and 3 for *P. falciparum* and *P. malariae* mixed infection (0.7%). 195(45.2%) samples were negative for any Plasmodium species. Speciation real time PCR detected 9 *P.o curtisi* and 5 *P.o wallikeri* infections. 3 samples identified as mixed, indicating co-circulation of *P. ovale* species in Dschang. Risk factors for infection will be assessed by bivariate analysis. Non-falciparum infection was present, but relatively uncommon in acutely febrile patients in 2020. No *P. vivax* infections were detected different from previous reports in the same region from 2017. The variation in non-falciparum prevalence needs to be further evaluated to determine the impact these species will have on malaria control.

7223

NOSOCOMIAL MALARIA: RISK OF MALARIA AFTER HOSPITALIZATION AT JINJA REGIONAL REFERRAL HOSPITAL, UGANDA: A COHORT STUDY

Arthur M. Mpimbaza[1], Nelson Ssewante[1], Jane S. Nassiwa[1], Steve Kiwuwa[1], Melissa Conrad[2], Phil J. Rosenthal[2], Joan N. Kalyango[1]

[1]Makerere University, Kampala, Uganda, [2]University of California San Francisco, San Francisco, CA, United States

In endemic settings, public hospitals may provide ideal grounds for malaria transmission, infection and disease. We determined risk of malaria among patients hospitalized with non-malaria illness at Jinja Regional Referral Hospital (JRRH), Uganda. This is an ongoing prospective cohort study. Eligible patients (negative malaria test at admission, requiring prolonged hospitalization, and provision of consent) are consecutively screened and enrolled at the Accident and Emergency Unit of JRRH. Upon enrollment, study participants undergo clinical assessment and a blood sample is collected for malaria testing (blood smear, RDT, and PCR). This assessment is repeated on days 7, 14, 21, 28, 35, and 42 after hospitalization, on the discharge day, and on non-scheduled days if fever is reported. Risk of malaria infection is reported as incidence. Associated factors are to

be determined using regression models. From July 2023 to March 2024, 301 patients have been screened; 133 excluded and 168 enrolled. Of 168 participants who have completed follow-up, 18 (11%) tested positive for malaria infection. Of the 18 positive patients, 15 (83%) were male, 14 were RDT and microscopy positive and four were RDT positive only. The median age and time to infection was 33 years (IQR 20-40) and 19 days (IQR 14, 24), respectively. Two patients turned positive on day 7, two on day 13, and rest after day 14. The geometric mean parasite density was 1086 (95% CI 290, 4058) parasites/ul of blood. One patient was symptomatic and *P. falciparum* accounted for all infections. Only one patient had a medical condition (tetanus), the rest had different fracture types. The cumulative incidence of malaria infection among patients hospitalized with non-malaria illness is high. Protective measures need to be considered among hospitalized patients in endemic regions. The magnitude of the problem, including possibility of transmission of non-malarial mosquito-borne diseases among hospitalized patients, needs to be further studied. Complete results will be presented at the conference.

7224

AN EXPERIMENTAL HUMAN BLOOD-STAGE MALARIA MODEL FOR STUDYING *PLASMODIUM KNOWLESI* INFECTION

Jeremy S. Goodwin-Gower[1], Rebecca Webster[1], Jacob A. Tickner[2], Hayley E. Mitchell[1], Jenny M. Peters[1], Stacey Llewellyn[1], Adam J. Potter[1], Ria Woo[1], Susan Mathison[3], Nischal Sahai[3], Helen E. Jennings[1], Fiona H. Amante[1], Bridget E. Barber[1]

[1]QIMR Berghofer Medical Research Institute, Herston, Australia, [2]Queensland Pediatric Infectious Diseases Sakzewski Laboratory, Brisbane, Australia, [3]UniSC Clinical Trials, Sunshine Coast, Australia

The zoonotic parasite *Plasmodium knowlesi* has emerged as a major threat to malaria control in Southeast Asia. *P. knowlesi* is now the only cause of indigenous human malaria in Malaysia and is increasingly reported in neighbouring countries. Human experimental induced blood stage malaria (IBSM) models of *P. falciparum*, *P. vivax*, and *P. malariae* have provided insights into parasite biology and disease pathogenesis, and enabled evaluation of diagnostics and therapeutic interventions for these species. The aim of this study was to develop an IBSM model for *P. knowlesi*. First, the laboratory-adapted YH1 *P. knowlesi* strain, previously adapted to grow in human erythrocytes, was further adapted to grow in human serum and expanded *in vitro* to produce a new malaria cell bank (MCB) designated YH1-HS. We are now undertaking a volunteer infection study to evaluate the safety and infectivity of this new *P. knowlesi* MCB, and to characterise replication rates, host response to disease, and pharmacodynamic response to artemether-lumefantrine. We will enrol up to 4 malaria-naïve healthy adults in cohorts of 1 participant each. Participants will be intravenously inoculated with *P. knowlesi*-infected erythrocytes. The first participant will receive ~2,800 viable parasites, with participants in subsequent cohorts receiving a higher dose of parasites depending on results from preceding cohorts. Definitive antimalarial treatment with artemether-lumefantrine will be initiated when parasitemia, as measured by qPCR, reaches ≥10,000 parasites/mL, or on day 21 if qPCR remains negative. This study will provide insights into *P. knowlesi* biology and host response to disease, in addition to establishing a model to evaluate therapeutic interventions against this emerging parasite. Data will be presented.

7225

MOLECULAR EPIDEMIOLOGY OF RESIDUAL PLASMODIUM SPP. TRANSMISSION IN A PERUVIAN AMAZON BASIN COMMUNITY

Macarena Vittet[1], Pamela Rodríguez[2], Mitchel Guzman-Guzman[2], Joseph M. Vinetz[3], Dionicia Gamboa[2], Hugo O. Valdivia[4], Danielle Pannebaker[4], Juan F. Sanchez[4]

[1]Vysnova Partners Inc., Alexandria, VA, United States, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Yale School of Medicine, New Heaven, CT, United States, [4]U.S. Naval Medical Research Unit SOUTH, Lima, Peru

Plasmodium vivax remains a health threat in the Peruvian Amazon. Malaria caused by P. vivax often manifests as submicroscopic infections, serving as reservoirs that could hinder elimination efforts and contribute to persistent transmission. Active disease surveillance is essential for detecting asymptomatic cases, estimating risk for military populations, and informing public health interventions.We conducted a prospective malaria cohort study in Santa Rita, a rural community in the Peruvian Amazon basin, from March 2021 to January 2022. The study included a baseline screening and eleven follow-ups among individuals aged three months and older. We collected socio-demographic, clinical, and epidemiological information, along with whole blood for malaria microscopy and molecular testing, and serum samples for serology. We enrolled 351 subjects with a mean age of 27.2 ± 20.5 years and a female to male ratio of 1:1. The mean number of follow-ups per subject was 7.5 with 77.8% (273/351) completing their first follow-up to 51.6% (181/351) by the twelfth follow up.Five subjects tested positive by microscopy for P. vivax (1.4% prevalence) and one for P. falciparum (0.28% prevalence). A subset of 153 participants (1,597 samples) that were visit at least nine times and/or had a positive microscopy result underwent RT-qPCR. A prevalence of 30.06% (46/153) for P. vivax and 0.65% (1/153) for P. falciparum was found. Among the 153, 47 tested positive for malaria by TaqMan real-time PCR at least once during the follow-up period and 10 participants tested positive by the same detection method more than five times during their follow-up visits, with the highest recording positivity in 10 out of 12 follow-up visits. Our study showed a high submicroscopic/microscopic malaria ratio of 24.8 in Santa Rita and a group of persistently positive asymptomatic individuals. This may hinder malaria elimination efforts and contribute to malaria transmission in the community. Furthermore, our results emphasize the need of diagnostic methods with higher sensitivity to detect infections on a submicroscopic level to strive toward successful elimination strategies.

A NATIONAL MOLECULAR SURVEILLANCE PROGRAM FOR THE DETECTION OF *PLASMODIUM SPP.* AND *P. FALCIPARUM* MARKERS OF ARTEMISININ RESISTANCE IN PAPUA NEW GUINEA - 2019-2023.

Samuel McEwen[1], Tamarah Koleala[2], Rebecca Narokobi[1], Marie Elliot[2], Annie Dori[1], Dulcie Latu-Ninda[1], Alexa Murrary[1], Rachael Farquhar[1], Willie Porau[3], William Pomat[2], Nakapi Tefuarani[4], Leo Makita[5], Alyssa Barry[6], Maria Ome-Kaius[2], Leanne Robinson[1], Moses Laman[2]

[1]Burnet Institute, Melbourne, Australia, [2]Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, [3]Centra Public Health Laboratory, Port Moresby, Papua New Guinea, [4]University of Papua New Guinea, Port Moresby, Papua New Guinea, [5]National Department of Health, National Malaria Control Program PNG, Port Moresby, Papua New Guinea, [6]Deakin University, Geelong, Australia

Background: Papua New Guinea (PNG) has the highest burden of malaria in the Western Pacific Region and is committed to regional malaria elimination targets. Strengthening surveillance and laboratory capacity is therefore a high priority in PNG to enable the National Malaria Control Program (NMCP) and Provincial Health Authorities (PHA) to make evidence-based decisions within their local context. STRIVE is a partnership-based implementation research and surveillance strengthening project that has established a molecular-informed sentinel surveillance system integrating real-time data dashboards and mapping tools that can be readily accessed and

utilised by the NMCP and provincial partners in a user-friendly manner to support planning, stratification and containment. Method: Eight sentinel health facilities capture febrile illness case data and collect dried blood spot on filter paper from a subset of patients. Samples are sent to a central laboratory and screened using polymerase chain reaction (PCR) that amplifies a conserved region of the 18S rRNA gene. Species-specific quantitative PCRs (qPCR) are then performed on positive samples and a qPCR specific for the kelch-13 C580Y gene is performed on *P. falciparum* positive samples. Result: Between 2019-2023, molecular surveillance confirmed the presence of Plasmodium spp. infections in 53.4% of febrile illness cases observed at the 8 sentinel sites. *P. falciparum* and *P. vivax* predominated, detected in 31.6% and 15.5% of cases respectively, with *P. malariae* and *P. ovale* rarely observed in 0.3% and 0.1% of cases respectively. Kelch13 C580Y mutations were detected in *P. falciparum* cases in at all sites, with the highest proportion in Buimo catchment in Lae, Morobe Province. In late 2022, an outbreak of *P. falciparum* was detected in the highlands fringe site, informing and guiding local response measures. Discussion: Establishing a molecular surveillance program to guide national and local decision-making in PNG has been feasible and is providing the priority evidence the NMCP requires for targeted therapeutic efficacy monitoring and responding to outbreaks in non-endemic settings.

EXPLAINING TRENDS IN PLASMODIUM FALCIPARUM TRANSMISSION IN AFRICA SINCE 2000

Tasmin L. Symons[1], Adam Saddler[1], Paulina Dzianach[1], Jailos Lubinda[1], MIchael McPhail[1], Annie Browne[1], Punam Amratia[2], Susan F. Rumisha[2], Daniel J. Weiss[1], Peter W. Gething[1]

[1]Telethon Kids Institute, Perth, Australia, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of

Concern has grown in recent years about the slowing rate of progress against malaria in Africa, with population growth in many places outpacing reductions in per capita incidence. The reasons for this are much speculated upon, but ultimately poorly quantified. In this analysis, spatio-temporal trends in key drivers of African malaria since 2000 - donor-funded intervention coverage, but also urbanisation, health-system strengthening, and an increasingly changing climate - are reconstructed using mathematical and statistical models. A geostatistical model then links these drivers to the Malaria Atlas Project's database of infection prevalence observations (>55k geolocated points), to estimate their individual and cumulative impact on trends in malaria prevalence and incidence since 2000. We find that within established transmission boundaries malaria control is responsible for the majority of change in burden this century, but that the impact of vector control has waned in recent years as coverage has failed to reach targets. Our results suggest improvements in horizontal interventions - strong health-systems offering accessible and efficacious treatment to those in need - have played a critical role in reducing malaria prevalence in children under five, but more needs to be done to target remote populations with low access to healthcare. Counterfactual analysis removing the impact of direct malaria control (ITNs, ACTs, IRS, SMC) reveals a changing baseline - socioeconomic development in Africa has fundamental altered inherent environmental and personal receptivity. Changes in receptivity attributable to the climate, meanwhile, are highly stochastic, highlighting vulnerabilities both at transmission fringes (where intervention coverage is low), and within high-burden settings (where intervention coverage levels are most threatened by indirect effects of climate change).

CASE STUDY: ROYAL THAI ARMY SOLDIERS DEPLOYED FOR UN PEACEKEEPING OPERATIONS IN SOUTH SUDAN IN 2023 EXPERIENCE HIGH RATES OF *P. FALCIPARUM* AND *P. OVALE* MALARIA UP TO NINE MONTHS POST-DEPLOYMENT

Sutchana Tabprasit[1], Watcharee Yokanit[1], Porruthai Kittikanar[1], Kamonwan Siriwatthanakul[1], Min Kramyoo[1], Paphavee Lertsethtakarn[2], Sidhartha Chaudhury[2], Jeffrey R. Livezey[2]

[1]Royal Thai Army – Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [2]Walter Reed Army Institute of Research – Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Peacekeeping operations in sub-Saharan Africa continue to be impacted by malaria both in-country and among returning service members. The Royal Thai Army (RTA) deploys an Engineering Company to Juba and Rumbek, South Sudan to conduct peacekeeping operations as part of the UN Peacekeeping Mission in South Sudan. Each deployment is approximately 12 months long and units are rotated yearly. The unit is provided doxycycline one week before travel and mefloquine via direct observation therapy during deployment and for four weeks after returning. Malaria diagnosis is conducted using rapid diagnostic tests and treatment is provided according to WHO guidelines. In 2023, the 273-person RTA unit experienced a high rate of prophylaxis failure with 27 Soldiers (9.9%) diagnosed and treated for malaria while deployed and another 37 Soldiers (13.6%) testing positive for malaria following return from deployment, including 18 cases of *P. ovale* (Po), 14 cases of Pf, 4 cases of mixed Pf/Pv, and 1 case of Pv; this constituted the largest single apparent Po cluster observed in a military unit in recent history. Eight malaria cases (all Pf) were identified within one week of returning from deployment during a unit-wide microscopy screening. The remaining 29 cases (6 Pf, 4 Pf/Pv, 18 Po, and 1 Pv) were identified 1-9 months following return from deployment and when Soldiers became symptomatic and sought medical care. Given that both Pf and Po are relatively rare in Thailand it is likely such infections were originally acquired in South Sudan. This case study highlights two significant areas of concern. First, there was a high rate of sub-clinical (18 of 273) and sub-microscopic (10 of 273) Pf malaria in returning Soldiers who were given mefloquine prophylaxis. Second, there was a high rate of latent Po infection among deployed Soldiers (18 of 273) that was only detected weeks to months after returning from deployment. These findings highlight shortcomings to existing malaria prophylaxis and screening strategies for military units deploying to endemic areas and underscore the importance of active surveillance and/or presumptive treatment when these units return.

7229

SPATIO-TEMPORAL EPIDEMIOLOGY OF URBAN MALARIA OVER DIFFERENT TRANSMISSION SEASONS IN ACCRA, GHANA.

Francis Dzabeng[1], Victor Edem Kornu[1], Clinton Nhyira Osei[1], Charles Mensah[1], Anna Beltrame[2], Keziah L. Malm[3], Yaw Aniweh[1], Gordon A. Awandare[1], Lucas Amenga-Etego[1], Gillian Stresman[2]

[1]West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, [2]College of Public Health, University of South Florida, Tampa, FL, United States, [3]National Malaria Elimination Programme, Ministry of Health, Accra, Ghana

Urban malaria has largely been ignored, but evidence is emerging that urban areas in Africa are receptive to malaria transmission. In Ghana, despite urban communities of greater Accra being considered low malaria risk and some areas earmarked for a push for elimination, pockets of moderate malaria transmission remain. This study aims to use three surveys spanning different transmission cycles to better understand the spatiotemporal malaria epidemiology in the Greater Accra Region of Ghana to support appropriate interventions towards malaria elimination. For each cross-sectional survey, 13 health facilities, stratified by malaria risk, and 100 households per catchment area were randomly selected. This was repeated at 3 time points throughout the transmission season.

All consenting household members were tested for malaria and anaemia and completed a questionnaire. QGIS™ and R/Rstudio software were used to map malaria cases and the number of malaria episodes. Spatio-temporal analysis with Anselin local Moran's I and Getis-Ord Gi* statistics were conducted. Preliminary results from the dry season survey include 2930 individuals sampled from 1313 households (average household size of 3.6). Of these, the average age was 29.8 (SD 18.7), with 42.9% males and 52.1% females. The overall malaria prevalence was 2.2% (95% CI: 1.7 - 2.8) but ranged from 0.8 to 5.9 per facility catchment area. The prevalence of anaemia was 7.1%% (95% CI 6.2-8.1) but ranged from 1.8 to 18.2% per facility catchment area. Low utilisation of insecticide-treated bednets (10%) the night before the survey was reported. The predominant forms of vector control employed in households were fumigation (15.9%) and mosquito repellents (5.1%). Our preliminary data confirms a low but heterogeneous prevalence of malaria infections during the dry season in Accra and a low-reported use of vector control methods typically employed in rural settings. Combined with the seasonal patterns observed, these results will fill an important gap in understanding urban malaria risk in Accra and other similar settings and help inform intervention strategies appropriate for this context.

7230

DESCRIPTION OF INPATIENT MALARIA CASE MANAGEMENT AT HEALTH FACILITIES IN SOUTHEASTERN TANZANIA, 2023

Godwin Machibya[1], Geofrey Makenga[1], Michael Gulaka[1], Stella Makwaruzi[1], Saidi Mgata[1], Nicodemus Govella[1], Antar Fereji[1], Alexandar Jacob[1], Michael Kimario[1], John Richard[1], Cyprian Lungu[1], Daud Saire[1], Marguerite M. Clougherty[2], Albert Ikonje[3], Chonge Kitojo[3], Sarah-Blythe Ballard[4], Naomi Serbantez[3], Sigsibert Mkude[1], Samwel Lazaro[5], Abdallah Lusasi[5]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Population Services International (PSI), Washington DC, WA, United States, [3]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [5]National Malaria Control Programme, Ministry of Health, Dodoma, Tanzania, United Republic of

In Tanzania, malaria service quality is assessed through Malaria Services and Data Quality Improvement (MSDQI) supportive supervision (SS). In 2023, PMI supported the National Malaria Control Program in Tanzania to investigate factors associated with malaria hospitalization and mortality rates using facility registers and SS data in Lindi, Mtwara, Pwani, and Ruvuma regions. A descriptive analysis of inpatient MSDQI data from 36 (28%) health facilities was conducted. Selection prioritized facilities with high malaria case counts and/or poor performance during previous MSDQI rounds. Stock availability of emergency medicines used to treat severe malaria complications, diagnostic accuracy, and health worker competence managing severe malaria cases were assessed. Scores from record review and MSDQI assessments were categorized as poor (below 50%), moderate (50- to 75%), and good (75% and above). From January to December 2023, the facilities reported 109,132 admissions, of which 10,834 (9.9%) were for severe malaria (31% of all [34,948] malaria cases) and 134 malaria deaths (1.2% case fatality rate [CFR] among severe admissions). Among the 10/36 (29%) facilities reporting severe malaria cases and malaria deaths, "good" scores were obtained by 97% for injectable artesunate preparation and administration; 70% for severe malaria treatment dose per patient weight; 54% for adequate emergency medicine stock, such as anticonvulsants and oxygen; 64% for management of associated emergency conditions; and 64% for adherence to national guidelines for treating complications associated with severe malaria. Despite an overall low CFR, serious remaining gaps in the inpatient management of severe malaria highlight the need for a comprehensive assessment of emergency commodity availability and ongoing support to improve service delivery. Improving healthcare providers' skills in managing severe malaria at the primary level could lower mortality rates and enable prompt treatment of complications.

7231

MAPPING MALARIA SEASONALITY IN SUB-SAHARAN AFRICA: METHODOLOGY AND INSIGHTS

Michael McPhail[1], Francesca Sanna[1], Tasmin Symons[1], Michele Nguyen[2], Charlie Whittaker[3], Punam Amratia[4], Peter W. Gething[1], Daniel J. Weiss[5]

[1]Telethon Kids Institute, Perth, Australia, [2]Nanyang Technological University, Singapore, Singapore, [3]Imperial College London, London, United Kingdom, [4]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [5]Curtin University, Perth, Australia

Seasonality is an important aspect of the epidemiology of malaria, and seasonal signals are evident in many metrics that measure transmission intensity and burden of disease. Understanding intra-annual variation, especially when attributable to epidemiologically-sensible environmental signals, can provide insight vital for accurate burden estimation, near-term predictions of outbreaks, evaluating the efficacy of seasonally-timed interventions, and the strategic planning of intervention campaigns and of clinical trials. Furthermore, understanding and combating malaria in highly seasonal areas will be critical for reducing global burden of this disease, as some of the highest burden areas are highly seasonal.

We have developed a geostatistical modelling framework to describe the intra-annual variation in the monthly proportion of P.*falciparum* incidence for sub-Saharan Africa between 2000 and 2020. Our model is trained using a comprehensive new data base of publicly available malaria time-series observations and incorporates a range of temporally dynamic environmental covariates. We derive key seasonal characteristics from the predictions of this model including season timing (onset, peak, and duration), seasonal intensity, and the number of seasons. We use inter-year variation of these characteristics to gauge temporal variation.

We present a range of products including maps of the derived characteristics: season timing, seasonal intensity, and inter-year variance. We discuss the apparent spatial structure in the arrangement of these characteristics, and the demarcation of seasonal and non-seasonal locations. Additionally, we provide insight into the influence of environmental factors; including maps illustrating the spatially heterogeneous relationship between the observed signals and the underlying climatic drivers. These findings provide useful insight into malaria seasonality and have the potential to improve the cost-efficacy of seasonally timed campaigns, which is critical those individuals currently living in areas with seasonal malaria.

7232

LONG-ACTING FORMULATION OF IVERMECTIN FOR EFFECTIVE MALARIA CONTROL: INSIGHTS FROM AN AGE-STRUCTURED MODELLING STUDY.

Angélique Porciani[1], André Sagna[2], Christophe Roberge[3], Sophie Le Lamer-Déchamps[3], Nicolas Moiroux[1], Roch Dabiré[4], Fabrice Anyrekun Somé[4], Sié Hermann Pooda[5], Karine Mouline[1], Ramses Djidjou-Demasse[6]

[1]IRD, Montpellier, France, [2]IRD, Bobo-Dioulasso, Burkina Faso, [3]Medincell, Jacou, France, [4]IRSS, Bobo-Dioulasso, Burkina Faso, [5]University of Dedougou and CIRDES, Bobo-Dioulasso, Burkina Faso, [6]IRD-Institut polythechnique de Thies, Thies, France

Despite a great decrease of malaria cases and deaths starting from the twenties, a stagnation, and even an increase in the last years, highlight the limits of available tools for controlling the disease. A novel approach, complementary to existing ones, is to render Anopheles blood meals toxic by treating hosts using systemic insecticides like ivermectin. Efficacy of this strategy is hampered by the short remanence of approved oral dose, and thus, the requirement of repeated dosing to achieve full coverage. Hence, long-Acting Ivermectin Formulations (LAIFs) would increase efficacy with costs and logistical reliefs. In the frame of the IMPACT project, a LAIF candidate from the BEPO® technology has been selected using cattle model. Pharmacokinetics and pharmacodynamics (PK/PD) data showed sustained entomocidal efficacy for at least 3 months after a single injection. Here, we developed a mathematical model to predict associated

transmission blocking effects. Unlike other mathematical models in this context, we incorporated continuous structural variables, including humans age, and time post-LAIF injection (for both humans and vectors). Hence, we captured the longitudinal dynamics of (i) ivermectin systemic concentrations in the human bloodstream, and (ii) ivermectin associated effects on mosquitoes' life span after a blood meal on treated human.
Using our experimental PK/PD data, the model was run in a context of perennial transmission with a baseline of 30% clinical case prevalence and 80% Plasmodium prevalence in the population. Different scenariii were tested where efficacy duration, formulation dose and proportion of the population treated were adjusted. A 70% coverage of the 6-60 years old with LAIF at a dose of 1mg/kg (three months efficacy) would decrease malaria case prevalence from 30 to 19% (36% decrease) for 89 days. Translated to entomological parameters, this corresponds to a 65% decrease of infectious Anopheles' population. Using our model, we therefore demonstrated that MDA using our candidate LAIF would meet the WHO requirements of more than 20% decrease of clinical case prevalence for novel malaria vector control tools.

7233

BACTERIAL VAGINOSIS IS ASSOCIATED WITH INCREASED RISK OF PLACENTAL MALARIA

Erin J. Dela Cruz[1], Michelle E. Roh[1], Abel Kakuru[2], Mwayi Madanitsa[3], Crispin Mukerebe[4], James Dodd[5], Jenny Lee[1], Lorenzo Ramirez[1], Odongo Bakar[2], Harriet Adrama[2], Jimmy Kizza[2], Peter Olwoch[2], Matthew Chico[6], Feiko O. ter Kuile[5], Peter J. Turnbaugh[1], Moses R. Kamya[2], Grant Dorsey[1], Philip J. Rosenthal[1]

[1]University of California, San Francisco, San Francisco, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Malawi University of Science and Technology, Thyolo, Malawi, [4]National Institute for Medical Research, San Mwanza, Tanzania, United Republic of, [5]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

Bacterial vaginosis (BV) is a common cause of vaginal discharge characterized by a shift in the microbiota from a *Lactobacillus*-dominant community towards a diverse set of anaerobic and facultative species. BV is associated with increased risk of adverse birth outcomes (low birth weight, preterm birth, chorioamnionitis) and reproductive tract infections (STI acquisition, HIV transmission). Although malaria and BV are considered independent risk factors for adverse birth outcomes, there are no published studies examining the vaginal microbiota within the context of malaria in pregnancy. Here, we demonstrate a novel association between BV and/or decreased vaginal lactobacilli during pregnancy and increased risk of placental malaria (PM). We analyzed data from an ongoing double-blinded randomized trial of intermittent preventive treatment during pregnancy (IPTp) in Uganda. In multigravida with evidence of malaria parasitemia during pregnancy, we found that BV at delivery was associated with increased odds of moderate-to-severe past-chronic PM, defined as histopathology with ≥ 10% HPF with hemozoin pigment deposited in fibrin (aOR=2.3 [95% CI: 1.4-3.8]). In a subset of participants, we used 16S rRNA amplicon sequencing to characterize the vaginal microbiota during pregnancy (at 12-20 and 32 weeks gestation). Among multigravida, we found a positive correlation between microbial diversity (suggestive of BV) and PM severity. BV-associated taxa—*Atopobium* and *Gardnerella*--were significantly more abundant with increasing PM severity. To test whether the vaginal microbiota was correlated with PM in an independent cohort, we analyzed data from an IPTp trial in Malawi and Tanzania (IMPROVE). In participants assessed for BV at 16-28 and 32-35 weeks gestation, vaginal fluid Gram stain with decreased *Lactobacillus* morphotypes was associated with increased risk of PM (OR=1.6, 95% CI: [1.0-2.4]). Overall, our data support a previously undescribed link between vaginal microbiota and PM. Further studies are needed to determine whether interventions targeting the vaginal microbiota impact severity of PM and related birth outcomes.

7234

ASSESSMENT OF THE INFECTIVITY OF MALARIA PARASITES FROM ASYMPTOMATIC SCHOOL CHILDREN TO *ANOPHELES* MOSQUITOES IN A HIGH TRANSMISSION AREA IN GHANA

Mawusi Adepa Mawuli[1], Linda Eva Amoah[2], Neils Ben Quashie[2], Isaac Sraku[1], Yaw Asare Afrane[1]

[1]University of Ghana Medical School, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana

Asymptomatic malaria is prevalent in Ghana. Majority of these infections are sub-microscopic, and carriers would normally not seek treatment. They would therefore serve as infectious reservoirs for malaria transmission. This study assessed the infectivity of parasites from asymptomatic children to *Anopheles* mosquitoes in a high transmission area in Ghana. Ninety-eight healthy children were screened for malaria by microscopy and nested polymerase chain reaction using sequence specific primers targeting the 18rna of the *Plasmodium* gene. Presence of sub-microscopic gametocyte was determined by amplification of the *Pf*g377 gene by reverse transcriptase polymerase chain reaction. Whole blood samples from the asymptomatic children were used in a direct membrane assay using laboratory raised colonies of *Anopheles gambiae.* Infectivity was determined by the presence of oocysts in mercurochrome-stained dissected midguts viewed under the light microscope. Mosquito infection rate as well as oocyst density were recorded. Out of the 98 children who were screened, 73 (74.49%) were asymptomatic for malaria. Out of these, 13.70% (10/73) carried microscopic densities of parasites. Parasite density (geometric mean (95% CI)) amongst these participants was 2,560(1,383.29-6,903.39(parasites/µl). Molecular analysis indicated that 82.46% (57/73) had malaria parasites. Amongst these, 64.38% (47/57) were classified as having sub-microscopic infections. None of the participants carried gametocytes by microscopy, however *Pf*g377 gene amplification was observed in 33.33% (19/57) participants. Blood samples from 4 out of these 19 individuals (21.05%) were infectious to mosquitoes. These infections were observed in 9 midguts out of a total of 862(1.04%) midguts dissected for all feeding experiments. The total oocyst density observed was 28. Prevalence of asymptomatic malaria infections was high, and were associated with carriage of sub-microscopic densities of gametocytes which were infectious to mosquitoes. The asymptomatic children would therefore serve as a reservoir for onward transmission of malaria within the community.

7235

G6PD DEFICIENCY VARIANTS AND MALARIA: INSIGHTS FROM A HOSPITAL BASED STUDY IN AWKA, SOUTHEAST NIGERIA

Moses N. Ikegbunam, Uchechukwu Nwokike, Chibueze Ihekwereme, Ogechukwu Frances Nworji

Nnamdi Azikiwe University, Awka, Nigeria

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency, which is prevalent in malaria-endemic regions, has been linked to a reduced risk of severe malaria due to impaired parasite growth in deficient erythrocytes. Conversely, it poses a high risk of hemolytic anemia in patients treated with the antimalarial drug primaquine. This study aims to investigate the prevalence of G6PD deficiency variants, their impact on hemoglobin levels, malaria parasite density, and their implications for malaria treatment policy in Awka, Anambra State, Nigeria. **Methods**: A subset of 100 malaria patients at Chukwuemeka Odimegwu Ojukwu Teaching Hospital in Awka, Nigeria, underwent screening for common G6PD mutations (A376G and G202A), which are particularly prevalent among individuals of West African descent. Malaria infection was confirmed using Rapid Diagnostic Test kits. The G6PD gene region was amplified using PCR, and Sanger sequencing techniques were employed to study the polymorphisms associated with G6PD variants.
Results: Molecular analysis revealed that the B variant (normal) was predominant, with 83% of the participants possessing this variant, while

17% had the mutant A+ (A376G) variant associated with mild G6PD deficiency. None of the participants tested positive for the A- (A376G/G202A) variant associated with severe G6PD deficiency. Both the B variant and the A+ variant (moderate) showed no significant impact on the hemoglobin and parasitemia levels of the study participants.
Conclusion: This study found only a low prevalence of the G6PD A+ (moderate variant) mutation among the participants, with no significant impact on their hemoglobin and parasitemia levels. This suggests that the observed G6PD deficiency variants may not have substantial implications for the management of malaria in this population.

7236

DECLINE IN THE INCIDENCE OF MALARIA IN BENIN IN 2023: INVESTIGATION OF ASSOCIATED FACTORS AND HOW TO MAINTAIN THE TREND

Emmanuel Koffi YOVO[1], Julien Aïssan[2], Achille Couao-Zotti[2], William HOUNDJO[2], Macoumba Toure[3], Lundi-Anne Omam[1], Didier Agossadou[1], Rock Aikpon[2], Arnaud le Menach[4], Olajumoke Adekeye[1], Cyriaque Afoukou[2], Achille Batonon[2]

[1]Clinton Health Access Initiative (CHAI), Cotonou, Benin, [2]National Malaria Control Program (NMCP), Ministry of Health (MoH), Benin, West Africa, Cotonou, Benin, [3]Clinton Health Access Initiative (CHAI), Dakar, Senegal, [4]Clinton Health Access Initiative (CHAI), Paris, France

Consecutively over past 4 years, Benin has observed a steady upward trend in incidence of malaria, despite the various interventions implemented to control the disease. For the first time in 2023, a drop in incidence was observed. The poor quality of routine epidemiological surveillance data and the low care seeking behavior were the main hypotheses put forward for this decline.Routine malaria data collected monthly and hosted on DHIS2, the repository for all health system data in Benin were analyzed. We analyzed indicators related to confirmed malaria cases with assessment of the temporal and spatial trend from 2020 to 2023 in relation the specificities in some interventions scaled-up nationwide for the first time in 2023.The number of confirmed malaria cases rose by 10.3% from 2020 to 2021(that is from 2.19 million cases to 2.42 million cases), then an upward trend was maintained between 2021 and 2022, with the number of cases rising from 2.42 million to 2.67 million (this is an increase of 10.2%). Between 2022 and 2023, an opposite trend was observed, with a 22.1% drop in the number of confirmed cases, from 2.67 million to 2.08 million. Compared to 2022, the number of tested cases increased by 1.5% and the positivity rate fell by 16%. This drop maybe attributable to the combined effect of several interventions: i) a new monthly data quality assessment method with the used rapid diagnostic test (RDT) cassettes verification as proof, which improves indicators relating to data quality; both campaigns of ii)the seasonal malaria chemoprevention (SMC) implemented in eligible areas in the northern side of the country; and the mass mosquito net distribution campaign, achieved good coverage of targets nationwide; and iii) the intensification of community-based interventions with the commitment of civil society organizations through the Zero Malaria Alliance. Malaria incidence in Benin declined in 2023, probably due to the synergistic effect of three majors' interventions put in place to control the disease. These interventions need to be reinforced in 2024 to maintain the improvement trend in malaria epidemiological surveillance indicators in Benin

7237

MODELING THE TEMPORAL INCIDENCE OF FEVER AND CLINICAL MALARIA IN DANGASSA, DISTRICT OF KATI, MALI FROM 2014 TO 2016

Oumar Oumar Thiero[1], Kola Cisse[2], Soumba Keita[3], Aissata Massambou Sacko[2], Seydou Doumbia[3]

[1]Tulane/FMOS, NEW ORLEANS, LA, United States, [2]FMOS/DER SP, Bamako, Mali, [3]FMOS/UCRC, Bamako, Mali

Malaria remains one of the leading causes of morbidity and mortality in much of sub-Saharan Africa. Our objective was to study the temporal variations of the incidence of malaria and fever in Dangassa from October 2014 to December 2016 and to make an analytical comparison of these incidences.
Our study was conducted in Dangassa on the right bank of the Niger River with year-round access to the river water. This was a longitudinal study consisted of following healthy participants between cross passages: - 526 participants from October 2014 to June 2015 - 825 participants from June 2015 to November 2015 - 1234 participants from November 2015 to June 2016 - 987 participants from June 2016 to December 2016.
The Poisson regression model with the number of person months offset was used to estimate the person-month incidence of fever and malaria as a function of age class, season and sex parameters.
Results: The incidence rate of fever in the 5 to 9 year age group was 1.81 times that of children under 5 with a significant p ($p = 0.001$). Malaria during the high transmission season was 2.3 higher than the low transmission season with a significant p ($p < 0.001$).
Conclusion: This study has a significant variation in the variation of the incidence of fever and malaria in particular according to the age group of the season with a strong tendency during the period from June to November corresponding to the period of strong transmission in Mali.

7238

UNDERSTANDING RELATIONSHIPS BETWEEN ENVIRONMENTAL TEMPERATURE, RAINFALL, AND MALARIA IN CHILDREN UNDER 5 YEARS OF AGE IN SENEGAL

Donal Bisanzio[1], Carrie Ngongo[2], Abdou Gueye[3], Gabriella Corrigan[1], Algaye Ngom[3], Mamoudou Aw[3], Cheikh Gassama[4], Tidiane Gadiaga[5]

[1]RTI International, Washington, DC, United States, [2]RTI International, Seattle, WA, United States, [3]RTI International, Dakar, Senegal, [4]RTI International, Darkar, Senegal, [5]Ministère de la Santé et de L'Action Sociale, Dakar, Senegal

Malaria transmission is greatly affected by weather conditions; thus, climate change is one of the main factors that could affect future trend of malaria cases in endemic countries. This research aimed to investigate the effect of temperature and precipitation on malaria in children under 5 years of age (U5) in five regions of Senegal (Diourbel, Kédougou, Kolda, Sédhiou, and Tambacounda). Monthly, district-level data on population and reported U5 children with malaria were gathered from the Senegal's national health management information system (HMIS) between 2018 and 2022. Monthly temperature and precipitation were estimated using remote sensing data from MODIS and from the Global Precipitation Climatology Centre. Time series analyses were performed to describe the trend of malaria incidence and weather indicators. The relationship between malaria incidence and weather indicators was investigated using generalized additive random effect models. From January 2018 to December 2022, 121,030 malaria cases in CU5 were reported in the HMIS for the study area. Malaria incidence declined from 68.2 cases per 1,000 CU5 to 18.6 cases per 1,000 CU5 (-72.1%) from 2018 to 2022, with a substantial decrease in 2020 and 2021. From 2018 to 2021 average temperatures decreased (MD: -4.2%; IQR: -2.7%; -5.7%) linked with increased precipitation (MD: 10.8%, IQR: 1.1%; 16.7%). In 2022, precipitation diminished (MD: -24.8%, IQR: -16.9%; -30.3%) and temperature increased (MD: 5.2%, IQR: 3.4%; 7.6%). Malaria incidence was significantly associated with weather conditions occurring in the previous 5 months. The association between malaria incidence and rainfall was larger than with temperature. Understanding climate-malaria links could help health systems to adapt their surveillance and intervention systems to address malaria vulnerability and adapt to a changing climate.

Chan School of Public Health, Cambridge, MA, United States

Molecular surveillance is emerging as a critical tool for malaria genomic epidemiology, and the integration of genetic metrics could synergize with and improve malaria transmission studies. In Senegal, we showed that clinical incidence and genetic metrics such as the frequency of multiple strain infections or complexity of infection (COI, the number of strains per infection) have a complex relationship. Specifically, relations between genetic metrics and clinical incidence differ sharply in regions with an annualized incidence greater than 10 cases per thousand year (‰) versus regions with less than 10‰. We hypothesize that changes in parasite genetics in higher transmission areas (>10‰) largely reflect differences in bulk transmission intensity, while those in lower transmission areas (<10‰) are more sensitive to differences in transmission heterogeneity (variation in transmission structure among populations, individuals, and vectors). To explore this hypothesis, we use GenEpi, a model which layers parasite genetics over a detailed, agent-based malaria transmission model (EMOD) to identify the parameter regimes where parasite genetics is more sensitive to changes in bulk transmission intensity or transmission heterogeneity. Here, we describe the model design and calibration strategy that will be used to address these questions. This involves: 1) fitting the model to the observed incidence and genetic metrics of three moderate-to-high transmission (>100‰) sites in Senegal, 2) comparing model predictions to genetic data collected from three low transmission settings (≲ 10‰), and 3) modeling different forms of transmission heterogeneity to determine whether they could be responsible for any deviations between modeled and observed values. Distinguishing genetic signals associated with transmission heterogeneity from those with bulk transmission intensity could inform tailored intervention campaigns designed to disrupt the transmission structure of a target population and, hence, be of great value to national malaria control programs.

PLASMODIUM FALCIPARUM GENE SIGNATURES OF MALARIA DISEASE SEVERITY IN KENYAN CHILDREN

Beauty Kolade[1], Kristen Wilding[1], Qiuying Cheng[2], Ivy Hurwitz[2], Evans Raballah[3], Samuel B. Anyona[3], Kristan A. Schneider[4], Ananias A. Escalante[5], Axl G. Cepeda[5], Benjamin Mcmahon[1], Douglas J. Perkins[2]

[1]Los Alamos National Laboratory, Los Alamos, NM, United States, [2]Center for Global Health, University of New Mexico, Albuquerque, NM, United States, [3]University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, [4]Department of Applied Computer and Biosciences, University of Applied Sciences Mittweida, Mittweida, Germany, [5]Biology Department/Institute of Genomics and Evolutionary Medicine (iGEM), Temple University, Philadelphia, PA, United States

We present signatures of disease severity from our analysis of *Plasmodium falciparum* (*Pf*) transcriptomes (n=60) obtained from pediatric patients with malarial anemia in a holoendemic transmission region: Siaya, Kenya. The statistical signal was enriched with several strategies including the exclusion of patients coinfected with HIV and/or bacteremia, to reduce alternative sources of variance. LASSO model selection identified 13 genes associated with low hemoglobin (Hb) levels and five associated with high Hb levels with a univariate *P*-value (by Welch two-sample t-test) less than 0.1. The majority of the 13 genes associated with poor outcomes (*i.e.*, low Hb) are central to known virulence mechanisms in blood-stage malaria and several have been investigated as potential malaria drug targets, *i.e.*, histone H3, mitochondrial ATP synthase, type I signal peptidase, plasmepsin X, STPP-2B (calcineurin), *Pf*EMP1 and RIFIN. LASSO model selection applied to particular subsets of the genes, such as kinases, metabolic genes, secretion systems, and those interacting with erythrocytes identified additional genes that may be linked with disease severity. Sequedex, a metagenomic analysis technique based on signature peptides, identified redox-related functional groups in the human host transcriptome that were elevated in severe disease (Hb<6.0 g/dL) but had no functional categories for *Plasmodium*. To better understand how genetic variation and gene expression patterns of highly divergent genes such as *Pf*EMP1 in the dataset were associated with low Hb levels, *Pf* transcriptomes were mapped onto the 14 *Plasmodium* chromosomes of the Kenya reference isolate (pfKE01) derived from plasmoDB. Our methodology included using peptide 10-mer analysis to address low complexity regions and genome duplications, read mapping with Bowtie2, and gene assignment using HTSeq. Using this approach, we aim to gain an enhanced understanding of the relationship between gene expression patterns and malaria severity.

7241

PLASMODIUM FALCIPARUM GENETIC DIVERSITY IN THE BLOOD STAGE VACCINE CANDIDATE ANTIGEN PFCYRPA IN SENEGAL

Aboubacar Ba

Institut Pasteur de Dakar, Dakar, Senegal

Malaria represents a public health burden. Current estimates revealed a plateaued curve of the disease-associated morbidity and mortality, while approved vaccines are yet to show strain-transcendent protection. Our present study evaluates the breadth of genetic diversity of one of the malaria vaccine candidates in early phase I clinical trials, *P. falciparum* Cysteine-Rich Protective Antigen (PfCyRPA) and also predicts the functional impact. Samples used in this study were collected from informed consents patients diagnosed with symptomatic malaria infections in Kédougou, Senegal. *P. falciparum* gDNA was extracted prior to *PfCyRPA* amplification. *PfCyRPA* genomic sequencing were obtained through targeted deep amplicon sequencing using the NovaSeq 6000 platform and sequence reads analyzed using the Geneious Prime Software. Non-synonymous single nucleotide polymorphisms were called relative to the 3D7 reference sequence using a minimum variant frequency of 0.02 and minimum coverage of 1000 reads. To predict the functional impact, PfRh5-CyRPA complex was constructed using Pymol (PDB ID: 4U0Q and 6MPV) and structural predictions with mAb binding was performed. A total of 93 *Pf* clinical isolates were included in this experiment. Overall, we identified 15 distinct SNPs, of which only four (F41L, V165I, N270T and V292F) have previously been reported. The majority of the novel SNPs were rare and only identified in a single isolate, except for R236N (N=4), R50C (N=2), I196F (N=2) and K211Q (N=2). Furthermore, our structural threading analysis revealed 3 novel SNPs occurring near epitopes bound by inhibitory monoclonal antibodies, potentially impacting immune evasion, while other SNPs were predicted to impact *PfCyRPA* structure or interactions with its binding partner PfRH5. Our data demonstrate that *PfCyRPA* exhibits a relatively greater genetic diversity than previously described. The structural

studies reveal that novel SNPs could have functional implications on *PfCyRPA* recognition by inhibitory antibodies, complex formation, or structural modelling, all hypotheses that we are exploring functionally.

EFFECTS OF RECOMBINATION ON LINKAGE DISEQUILIBRIUM IN THE EPIDEMIOLOGY OF PLASMODIUM FALCIPARUM MALARIA

Kien Tran, Nguyen Tran, Maciej Boni
Temple University, Philadelphia, PA, United States

When multiple beneficial alleles are present in a population, there is no general evolutionary result guaranteeing that recombination will speed up or slow down the emergence and evolution of genotypes carrying multiple beneficial alleles. Translated to infectious disease control, this evolutionary ambiguity means that when multiple types of drug resistance are present, we cannot be sure whether recombination will act more strongly (1) to bring together single-resistant genotypes into multi-drug resistant (MDR) genotypes, or (2) to break apart MDR genotypes into single-resistant genotypes. We introduce a new version of an established and validated individual-based malaria transmission model where we have added individual mosquito bites, interrupted feeding by mosquitoes, and individual recombination events of different Plasmodium falciparum genotypes inside the mosquito's salivary glands. Recombination among P. falciparum genotypes occurs from two sources of variation: multi-clonal infections and interrupted feeding by mosquitoes, and the results from our modeling analysis show that 80% to 95% of recombinant falciparum genotypes are created from single uninterrupted bites on hosts with multi-clonal infections. However, higher rates of interrupted feeding accelerate the emergence of double-resistant genotypes from single-resistant genotypes through recombination. A comparison of drug-resistance management strategies with this new model shows that, over a 15-year timeframe, triple ACT strategies show the largest reductions in treatment failures, multiple first-line therapy approaches show the second-largest reductions, and ACT cycling approaches show the smallest reductions in future treatment failures.

7243

ASSESSING CHANGES IN *PLASMODIUM FALCIPARUM* GENETIC DIVERSITY IN NIGERIA POST-ACTS IMPLEMENTATION

Fehintola Victoria Ajogbasile[1], Andrés Aranda-Diaz[1], Ying-An Angie Chen[2], Christian Happi[3], Bryan GreenHouse[1]
[1]University of California San Francisco (UCSF), San Francisco, CA, United States, [2]National Cheng Kung University, Tainan, Taiwan, [3]Redeemer's University, Ede, Nigeria

Understanding parasite genetic diversity over time and across regions can help gauge the impact of ACTs on parasite populations. We utilized a high-resolution method that employs targeted sequencing of microhaplotypes to evaluate changes in Plasmodium falciparum transmission intensity in Nigeria, 15 years post-ACTs introduction. We utilized 593 DBS samples from children aged 12-60 months collected from therapeutic efficacy studies performed across six States at four time points between 2010 and 2020. We extracted genomic DNA and performed amplicon sequencing of 100 highly diverse microhaplotypes. The median expected heterozygosity (He) of the microhaplotypes was 0.56 (interquartile range: 0.43-0.73) across all States and not significantly different across time. A majority (61%) of the microhaplotypes had He>0.5 indicating sustained genetic diversity over time and across States, comparable to findings in Mozambique. Notably, 85% of infections were polyclonal, with mean complexity of infection (COI) of 3.4, suggesting high within-host diversity. The mean intra-host relatedness among parasite clones was 0.63, suggesting significant inbreeding and a major role of cotransmission in maintaining polyclonal infections within all populations; this however, resulted in an effective COI of 1.95. Spatio-temporal pairwise comparison using identity by descent showed low proportion (<3%) of significantly related parasites across all States, consistent with the high genetic diversity observed across all States regardless of the Year. This is in line with previous studies from Nigeria. Our study indicates no genetic evidence of reduction in malaria transmission intensity over the study period, aligning with national survey reports from 2010 and 2018. The persistent high genetic diversity and lack of decline in transmission underscore the need for ongoing surveillance of the malaria parasite's genetic landscape. This analysis suggests that merely increasing the coverage of existing interventions may not suffice. Instead, exploring new strategies or enhancing existing ones to effectively combat malaria in Nigeria is imperative.

7244

MALKINID (MALARIA KINSHIP IDENTIFIER): A LIKELIHOOD MODEL FOR IDENTIFYING PARASITE GENEALOGY RELATIONSHIPS BASED ON GENETIC RELATEDNESS

Wesley Wong[1], Lea Wang[2], Stephen S. Schaffner[3], Xue Li[4], Ian Cheeseman[4], Timothy J.C. Anderson[4], Ashley Vaughan[5], Michael Ferdig[6], Sarah K. Volkman[1], Daniel L. Hartl[7], Dyann F. Wirth[1]
[1]Harvard TH Chan School of Public Health, Boston, MA, United States, [2]Harvard University, Cambridge, MA, United States, [3]Broad Institute, Cambridge, MA, United States, [4]Texas Biomedical Research Institute, San Antonio, TX, United States, [5]Seattle Children's, Seattle, WA, United States, [6]University of Notre Dame, Notre Dame, IL, United States, [7]Harvard University, Cambrdge, MA, United States

Pathogen genomics is a potent tool for tracking infectious disease transmission. In malaria, sexual reproduction and recombination in mosquitoes can generate genetically related progeny whose genomes contain identical-by-descent (IBD) segments. In theory, IBD can be used to distinguish genealogical relationships (parent-child [PC], full-sibling [FS], etc) to reconstruct transmission history or identify parasites for genotype-to-phenotype quantitative-trait-locus (QTL) experiments. We developed a new likelihood model, *MalKinID* (Malaria Kinship Identifier), based on genomic data from three laboratory-based genetic crosses (yielding 440 PC and 9060 FS comparisons). *MalKinID* uses the genome-wide IBD proportion and the per-chromosome max IBD segment block and IBD segment count distributions to identify parasite genealogical relationships. *MalKinID's* performance was assessed using empirical lab-cross data and simulated, point importations. *MalKinID* accurately identified lab-generated F_1 progeny with >80% sensitivity and showed that 0.39 (95% CI: 0.28, 0.49) of the second-generation progeny of an NF54 and NHP4026 cross were F_1s and 0.56 (0.45, 0.67) were backcrosses of an F_1 with the parental NF54 strain. For simulated, outcrossed point importations, *MalKinID* accurately reconstructs genealogy history with high precision and sensitivity. The F1-scores for PC, FS, second-degree, and third-degree relatives were 0.95 (0.84, 1.0), 0.94 (0.72, 1.0), 0.84 (0.60, 1.0) and 0.84 (0.64, 0.94), respectively. However, when importation involves inbreeding, such as during serial cotransmission, the precision and sensitivity of *MalKinID* declined, with F1-scores of 0.76 (0.56, 0.92) and 0.23 (0.0, 0.4) for PC and FS and <0.05 for second-degree and third-degree relatives. *MalKinID* lays the foundations for identifying different parasite genealogical relationships, which can be used to reconstruct transmission lineages in outcrossed parasite populations or used to separate progeny for QTL experiments.

7245

PLASMODIUM FALCIPARUM ADAPTS TO FRONTLINE DRUG CHANGES THROUGH NEW HAPLOTYPES AT OLD TARGETS

Angela M. Early[1], Stéphane Pelleau[2], Lise Musset[3], Daniel E. Neafsey[4]
[1]Broad Institute of MIT and Harvard, Cambridge, MA, United States, [2]Institut Pasteur, Paris, France, [3]Institut Pasteur de la Guyane, Cayenne, French Guiana, [4]Harvard T.H.Chan School of Public Health, Boston, MA, United States

Populations of *Plasmodium falciparum* regularly confront orchestrated changes in frontline drug treatment that drastically alter the parasite's selection landscape. When this has occurred, the parasite has successfully adapted to the new drugs through novel resistance mutations. These novel

mutations, however, may emerge in a genetic background already shaped by prior drug selection. In some instances, selection imposed by distinct drugs has targeted the same loci in either synergistic or antagonistic ways, resulting in genomic signatures that can be hard to attribute to a specific agent. Here, we use two approaches for detecting sequential bouts of drug adaptation: haplotype-based selection testing and temporal changes in allele frequencies. Using a set of longitudinally acquired samples from French Guiana, we determine that since the introduction of the new drug artemether-lumefantrine (AL) there have been rapid hard selective sweeps at both known and novel loci. We additionally identify genomic regions where selection acted in opposing directions before and after widespread AL introduction. At four high-profile genes with demonstrated involvement in drug resistance (*crt*, *mdr1*, *aat1*, and *gch1*), we saw strong selection before and after drug regime change, however, selection favored different haplotypes in the two time periods. Similarly, the allele frequency analysis identified numerous coding variants whose frequency trajectory changed sign under the new drug pressure. These selected alleles were enriched for genes implicated in artemisinin and/or partner drug resistance in other global populations. Overall, this suggests that subtle changes throughout the genome impact drug resistance, and this may explain the observation that some *P. falciparum* populations experience novel evolutionary trajectories—rather than a return to "wildtype"—after drug removal.

7246

HMMIBD-RS, AN ENHANCED IMPLEMENTATION OF *HMMIBD* FOR PARALLELIZABLE IDENTITY-BY-DESCENT DETECTION FROM HAPLOID GENOMES

Bing Guo, Timothy D. O'Connor, Shannon Takala-Harrison
University of Maryland School of Medicine, Baltimore, MD, United States

Identity-by-descent (IBD) is a key tool in malaria parasite population genomics to infer genetic relatedness, selection signals, and population demography. The hidden Markov Model-based probabilistic method *hmmIBD* has been widely used to infer IBD in species with high recombination rates and low marker density, such as *Plasmodium falciparum* (*Pf*). In previous work, we found that *hmmIBD* had higher accuracy in detection of IBD segments compared to identity-by-state-based methods. However, the power of the *hmmIBD* algorithm is currently limited by its non-parallelizable implementation, and the assumption of uniform recombination rate across the genome, limiting its application to large data sets or to genomes with variable recombination. Here, we present a new tool, *hmmibd-rs,* that reimplements the original *hmmIBD* algorithm in a memory-safe language, Rust. The tool allows the direct input of a common genotype data format (BCF), the specification of a non-uniform recombination rate map, and the utilization of multi-core CPU for parallelization, with performance increasing almost linearly with the number of threads. Using simulation, we showed that *hmmibd-rs,* can detect IBD segments from 30,000 simulated *Pf*-like 100-centimorgan (cM) chromosomes in 9 hours using 64 threads, compared to 3-4 weeks when using single-threaded *hmmIBD*, demonstrating scalability for large data sets such as MalariaGEN Pf7 (n > 20,000 isolates). We also found that the incorporation of a recombination rate map into *hmmibd-rs* largely reduced detection of false positive IBD segments (≥ 2 cM) in low recombining regions and moderately decreased false negative rates in high-recombining regions in genomes simulated with non-uniform recombination rates, compared to *hmmIBD*, which uses an average rate. Ongoing work will apply this new tool to the MalariaGEN Pf7 data set to measure the computation time used for IBD detection and determine the extent to which the incorporation of variable recombination rates (estimated from population samples or existing genetic cross data) impacts downstream inferences of parasite demography in different malaria transmission settings.

7247

GENETIC SURVEILLANCE REVEALS THE CLONAL REPLACEMENT DYNAMICS AND SPATIAL STRUCTURE OF *PLASMODIUM FALCIPARUM* IN SÃO TOMÉ AND PRÍNCIPE

YingAn A. Chen[1], Peng-Yin Ng[1], Daniel Garcia[1], Ju-Hsuan Wang[1], Yu-Wen Huang[1], Aaron Elliot[2], Brian Palmer[2], Arlindo Carvalho[3], Lien-Fen Tseng[4], Cheng-Sheng Lee[1], Kun-Hsien Tsai[5], Bryan Greenhouse[2], **Hsiao-Han Chang**[1]
[1]National Tsing Hua University, Hsinchu, Taiwan, [2]University of California, San Francisco, San Francisco, CA, United States, [3]University of Sao Tome and Principe, Sao Tome, Sao Tome and Principe, [4]Taiwan Anti-Malarial Advisory Mission, Sao Tome, Sao Tome and Principe, [5]National Taiwan University, Taipei, Taiwan

Despite ongoing efforts to eliminate malaria in São Tomé and Príncipe (STP), there has been an increase in case numbers in recent years. Understanding the composition of the remaining transmission is crucial for tailoring effective elimination strategies. In this study, we collected amplicon sequencing data from 980 samples and integrated it with longitudinal surveillance data from 2010 to 2016 to examine the genetic composition of the parasite population. The mean multiplicity of infection (MOI) was 1.3, and the proportion of polyclonal infections was 11%, indicating that transmission intensity was low. Notably, the temporal trends of these genetic metrics did not align with incidence rates. In low transmission settings, where parasite population size is small, genetic metrics are expected to be highly influenced by stochastic fluctuations in the composition of circulating infections. Our results suggest that temporal changes in genetic metrics may not necessarily reflect changes in transmission intensity. Furthermore, while the majority of samples (87%) were genetically linked to other samples, suggesting limited genetic diversity, we observed continuous turnover in genetic clusters accompanied by changes in drug-resistance haplotypes during the study period. Principal component analysis suggests that the STP samples were genetically similar to those from Central and West Africa, pointing to the possibility of importation. The parasite diversity was lowest at the end of the study period, which is indicative of successful malaria control efforts. In summary, our study reveals dynamic changes in the parasite population in STP, highlighting the need to not only prioritize targeted interventions against hotspots of transmission but also to implement reactive case detection and collect travel histories to prevent the introduction of new parasites into this island nation as it approaches elimination. This study also serves as a case study for implementing genetic surveillance in a low transmission setting.

7248

APPLICATION OF HIGHLY MULTIPLEXED AMPLISEQ TARGETED NGS ASSAYS FOR GENOMIC SURVEILLANCE USE CASES FOR *P. FALCIPARUM* AND *P. VIVAX* IN ASIA, AFRICA AND LATIN AMERICA

Johanna H. Kattenberg[1], Mathijs Mutsaers[1], Nguyen Van Hong[2], Luis E. Cabrera-Sosa[3], Florence Ouédraogo[4], Bénédicte Palata[5], Nguyen Thi Hong Ngoc[2], Nguyen Huong Binh[2], Papy Mandoko[5], Dionicia Gamboa[3], Hamtandi M. Natama[4], Anna Rosanas-Urgell[1]

Malaria remains a major global health problem. Research has advanced our knowledge of malaria epidemiology and ecology, but emerging drug and diagnostic resistance highlight the urgency of continuous surveillance. Genomic surveillance, a field of study using genetics to track diseases, aids in decision-making and policy for malaria control and elimination. While genomic surveillance of viral and bacterial pathogens is becoming mainstream, genomic tools are not routinely used in malaria surveillance, partly due to the size and complexity of the parasite genome. Here we

present a set highly-multiplexed sequencing assay (AmpliSeq) which have been developed for cost-effective targeted deep sequencing of *P. falciparum* or *P. vivax* of specific genomic regions of interest. These assays combine phenotypic and population genetic markers to study parasite dynamics, which has been successfully piloted in several countries, including Burkina Faso, Democratic Republic of Congo, Peru, Vietnam, and in travelers and migrants in Belgium.We demonstrate genetic surveillance use cases, such as drug-resistance of *P. falciparum* in Vietnam, Burkina Faso and DRC, the increasing rate of *hrp2/3* deletions in Peru, and the origin of imported *P. vivax cases* in Belgium. High-resolution identity-by-descent relatedness analysis in Vietnam indicated a high level of *P. vivax* parasite connectivity in coastal provinces, and a distinct highly-related population in a remote highland province. An imported clonal *P. vivax* outbreak in a Peruvian Amazon border community was detected. In addition, we are investigating *Pfcsp* diversity in a vaccine trial site in Burkina Faso. This approach can effectively differentiate and characterize parasite isolates over time and space, and is easily adaptable to diverse epidemiological contexts. It can guide, surveillance and implementation of core control interventions such as vector control, chemotherapy and prophylaxis, and vaccine deployment strategies, among others. The priority is to make this tool available to key actors in endemic countries to increase ownership and ensure data usage for decision-making and policy.

7249

TEMPORAL GENOMIC ANALYSIS REVEALED MAINTAINED GENETIC DIVERSITY AND COMPLEXITY OF INFECTION AMONG PLASMODIUM FALCIPARUM INFECTIONS IN MAINLAND TANZANIA:2021-2022

[1]National Institute for Medical Research, Dar es Salaam, Tanzania, United Republic of, [2]Brown University, Providence, RI, United States, [3]Nelson Mandela African Institute of Science and Technology, Arusha, Tanzania, United Republic of, [4]University of North Carolina, Chapel Hill, NC, United States, [5]National Malaria Control Program, Dodoma, Tanzania, United Republic of, [6]National Malaria Control Programme, Dar es Salaam, Tanzania, United Republic of, [7]National Malaria Control Programme, Dodoma, Tanzania, United Republic of, [8]University of Nairobi, Nairobi, Kenya

Plasmodium falciparum infections in endemic countries exhibit high genetic diversity, posing challenges to malaria control efforts. Recent studies have reported the heterogeneous genetic diversity of P. falciparum in mainland Tanzania, highlighting the need for integrated approaches in malaria surveillance. Understanding the temporal dynamics of genetic diversity and the complexity of infection (COI) is crucial for effective malaria control and elimination strategies. Here we present the preliminary analysis for countrywide temporal dynamics of P. falciparum genetic diversity and COI of malaria parasites in 13 regions of Mainland Tanzania from 2021 to 2022. About 34,550 individuals were screened by malaria rapid diagnostic tests (RDTs) through cross-sectional surveys conducted between February and July 2021-2022, of which 14,871 were malaria positive. DNA extraction was done using the Chelex 100+Tween20 method and sequenced by molecular inversion probes (MIPs). The data was analyzed using MIPtools and R software. The mean COI was 1.53 (ranging from 1.55 in 2021 to 1.51 in 2022) and did vary across years (p-value =0.02), indicating the persistence of heterogeneous genetic diversity within the country. The proportion of polyclonal infections was 40.4% in 2021 and 46.1% in 2022. The mean COI was heterogeneous across the studied regions, with the lowest mean COI of 1.27 in Dodoma and the highest being 2.01 in Kagera. The COI correlated with regional transmission intensities (correlation ratio = 1). The expected heterozygosity was 0.28 in 2021 and 0.36 in 2022, indicating little genetic diversity. The principal component analysis did not detect parasite population structure over time. The results reveal a striking persistence of moderate genetic diversity and complexity of infection over time, indicative of ongoing supper infection/co-transmission within individual hosts. Further analysis will be performed to fully assess temporal parasite genetic diversity to support effective malaria management and elimination in the country.

7250

DIVERSITY AND MULTIPLICITY OF *PLASMODIUM FALCIPARUM* INFECTIONS AMONG ASYMPTOMATIC SCHOOL CHILDREN IN ANKAZOABO, SOUTHEN MADAGASCAR

Fanomezantsoa Ralinoro[1], Omega Raobela[2]

[1]National Malaria Control Program, Antananarivo, Madagascar, [2]National Malaria Control Programme, Antananarivo, Madagascar

< Malaria remains a major public health problem in Madagascar. Understanding *Plasmodium falciparum* population diversity and transmission dynamics provides information on the intensity of malaria transmission, which is needed for assessing malaria control interventions. This study aimed to determine P. *falciparum* allelic diversity and multiplicity of infection (MOI) among asymptomatic school-age children between five to fifteen year-old in Ankazoabo district, South of Madagascar in December 2023.From 360 asymptomatic study participants, a total of 99 samples positive for *P. falciparum* were included for molecular analysis. Samples were characterized by nested PCR and genotyping the polymorphic regions of *msp-1* and *msp-2*. For *msp-1*, 86.87 %(86/99), and *95.95*% (95/99) for *msp-2* were detected. In *msp-1* ,K1 was the predominant allelic family detected in 80.23% (69/86) of the isolates followed by MAD20 and RO33. For *msp-2,* the frequency of IC/3D7 and FC27 were 82.11%(78/95) and 70.53%(67/95) respectively. Fifty three percent of isolates had multiple genotypes and the overall mean of multiplicity of infection (MOI) was 2.3. Correspondingly, the excepted Heterozigosity(He) value for *msp-1*(He=0.54) and *msp-2*(He=0.51).The findings of this study revealed higher genetic diversity of the *msp-1* and *msp-2* allele families in *P.falciparum* isolates in this malaria endemic area. However continued monitoring of status of the local genetic diversity profile in *P.falciparum* population is required to support malaria control and elimination strategies. >

7251

REVEALING NOVEL GENETIC VARIANTS IN THE MALARIA TRANSMISSION BLOCKING VACCINE CANDIDATE PFS25

Malaria remains a significant global health challenge, causing nearly a quarter of a billion cases worldwide in 2022. The approval of 2 new liver-

stage vaccines is a major advance, but there remains an urgent need for more effective vaccines that target other stages of the parasite's life cycle. Transmission-blocking vaccines (TBVs) offer promise for malaria elimination by reducing transmission within communities through targeting the sexual stages. However, the genetic diversity of the parasite antigens presents a significant obstacle to vaccine development. We employed next-generation amplicon deep sequencing to identify Pfs25-associated non-synonymous SNPs in 209 *Plasmodium falciparum* samples from four African countries: Senegal, Tanzania, Ghana, and Burkina Faso. Using a very sensitive threshold of 1% variant frequency, we identified 24 SNPs including 25 novel variants, and assessed their population prevalence and variant frequency in complex infections. Five variants were detected in multiple samples (L63V, V143I, S39G, L63P, and E59G), while the remaining 21 were rare variants found in individual samples. Analysis of country-specific prevalence revealed varying proportions of mutant alleles, with Ghana exhibiting the highest prevalence (55.3%), followed by Senegal (27.6%), Tanzania (6.9%), and Burkina Faso (6.9%). We further categorized SNPs based on their frequency, identifying dominant variants with frequencies exceeding 25% and rare variants with frequencies below 2%. Threading analysis of the Pfs25 protein structure revealed SNPs in two categories: 1) SNPs that have the potential to influence the binding between Pfs25 and antibodies and can lead to immune evasion, and 2) SNPs that can potentially modify the structure of Pfs25 protein. Our results show that while Pfs25 remains a relatively highly conserved gene, we identified additional SNPs beyond the 9 previously reported. Most of these newly discovered SNPs display low variant frequency and population prevalence. Further research exploring the functional implications of these variations will be important to elucidate their role in malaria transmission.

AMPLICON AND SNP GENOTYPING OF *P. FALCIPARUM* AND *P. VIVAX* CASES IDENTIFIES HIGHLY RELATED SAMPLE CLUSTERS AS BHUTAN APPROACHES ELIMINATION

Emma Rowley[1], Kelsey Murt[1], Jean-Paul Courneya[1], Bing Guo[1], Biraj Shrestha[1], Mariusz Wojnarski[2], Risintha Premaratne[3], Xong Hong Li[3], Kesang Wangchuck[4], Sonam Wangdi[3], Kim Lindblade[5], Tobgye Tobgye[6], Shannon Takala-Harrison[1]

[1]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [2]Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, [3]World Health Organization, Global Malaria Program, Geneva, Switzerland, [4]Royal Center for Disease Control, Ministry of Health, Thimphu, Bhutan, [5]PATH, Geneva, Switzerland, [6]Vector Borne Disease Control Program, Ministry of Health, Thimphu, Bhutan

Bhutan is slated for malaria elimination by 2025, and cases have declined sharply over the last 20 years. Approaching elimination, malaria cases are often imported and occur in border regions. Understanding genetic relatedness between parasites can help distinguish imported from local cases. DNA was extracted from dried blood spots for 114 *Plasmodium vivax* and 30 *Plasmodium falciparum* isolates collected from individuals with clinical infection in Bhutan from 2016 to 2021. *P. falciparum* genotyping was conducted using the 129-amplicon AMPLseq panel, and *P. vivax* genotyping using a SNP barcode comprised of 130 variable sites. The resulting amplicon and SNP genotypes were compared to the same sites extracted from publicly available whole genome sequence data (MalariaGEN Pf7 and Pv4 for *P. falciparum* and *P. vivax*, respectively) from isolates collected in India, Bangladesh, and Myanmar. Isolates with poor genotyping coverage and polyclonal isolates without a clear predominant clone were excluded, resulting in 64 genotyped *P. vivax* isolates and 12 *P. falciparum* isolates for analysis. Dcifer was used to estimate genetic relatedness, and InfoMap community network detection was performed to identify clusters of highly related parasites. We identified two clusters of identical *P. falciparum* isolates, each with 100% identity at the 104 genotyped amplicons, and 7 clusters of identical *P. vivax* isolates, with 100% identity at the 130 variable sites. One *P. vivax* and one *P. falciparum* cluster contained isolates from non-consecutive collection years, suggesting persistence of parasite clones over time in this very low transmission area. Neither *P. vivax* nor *P. falciparum* isolates from Bhutan clustered with isolates from neighboring countries, likely due to limited representation of sequences from border regions in the MalariaGEN database. This lack of data from immediately adjacent districts limits our ability to infer whether cases were imported or locally-acquired based on genotyping data alone; such inferences will require integration with additional epidemiologic data on the timing of diagnosis, travel history, and patient proximity.

PULSED MICROWAVE IRRADIATION INDUCES APOPTOSIS LIKE CELL DEATH IN *PLASMODIUM FALCIPARUM* VIA FAS/FASL DEATH RECEPTOR PATHWAY

Lina Margarita Solis Castillero, Carmenza Spadafora, Ricardo Correa, Lorena Coronado

INDICASAT AIP, Panama, Panama

Pulsed Microwave Irradiation Induces Apoptosis-Like Cell Death in *Plasmodium falciparum* via FAS/FASL Death Receptor PathwayMost of the signaling pathway events involved in the apoptotic process of protozoa remain unknown, and *P. falciparum* is no exception. A previous study by our research group demonstrated that the parasite *P. falciparum* exhibits regulated cell death markers when exposed to microwaves (MW). In this study, we investigated the presence of proteins in *P. falciparum in vitro* following exposure to pulsed MW irradiation at 2.45 GHz frequency. After MW exposure, we used a commercial human dot-blot array to identify 43 target proteins associated with programmed cell death (PCD). We compared protein expression levels between control and treated samples using ImageJ, a digital image analysis software. Notably, MW-treated samples showed significantly higher signal intensity for the death receptor Fas and its ligand FasL, which are known to activate the caspase cascade in multicellular organisms and in some eukaryotic single-celled microorganisms. We also observed increased expression of HSP70, HSP60, BID, and BAX, proteins that participate in the Fas/FasL mediated apoptosis pathway leading to mitochondrial outer membrane permeabilization (MOMP) and cell death. Interestingly, *P. falciparum* possesses metacaspases encoded by the PfMCA1, 2, and 3 genes. Our results suggest that the activation of death receptor FAS/FASL like in *P. falciparum* triggers the activation *of P. falciparum* metacaspases. We propose that FAS/FASL like proteins are present *in P. falciparum* and play a significant role in the parasite's apoptosis-like cell death.

7254

SETTING A MRDT-BASED STRATEGY FOR MONITORING THE OCCURRENCE OF *PLASMODIUM FALCIPARUM HRP2* AND *HRP3* DELETIONS IN MADAGASCAR

Dina Ny Aina Liantsoa Randriamiarinjatovo[1], Seheno Razanatsiorimalala[1], Arsène Indriambelo[2], Viviane Razafindravao[3], Laurence Randrianasolo[1], Milijaona Randrianarivelojosia[1]

[1]Institut Pasteur de Madagascar, Antananarivo, Madagascar, [2]Université de Toliara, Toliara, Madagascar, [3]Centre Médicale Betela Andaboly, Toliara, Madagascar

In the island of Madagascar – where *Plasmodium falciparum*, *P. vivax*, *P. ovale*, and *P. malariae* coexist, the malaria rapid diagnostic test (mRDT) has become an essential tool for improving malaria case management since 2006. The most used mRDT in the Malagasy health system detects both the pan-specific LDH and the *P. falciparum* HRP2. However, the deletion of the *pfhrp2* gene threatens the accuracy of the HRP2-based test. There therefore is a need to set a robust method for monitoring the occurrence of *pfhrp2* and *pfhrp3* gene deletions. During malaria detection in August 2023 in 373 children aged from 5 to 14 years in Ankililoaka in the dry southwestern part of the island, blood samples were collected by finger-prick for mRDT and molecular analysis using dried blood spots. Of the 194 (52%) mRDT positive samples, 105 were mRDT pan LDH and HRP2 positive, 76 mRDT HRP2 positive but pan LDH negative, and 13 mRDT pan LDH positive but HRP2 negative. These 13 HRP2 negative samples

were PCR analyzed. Five samples contained *P. falciparum* and one case of *pfhrp2* and *pfhrp3* double deletions (0.5%), and two cases of *pfhrp3* single deletions (1.1%) were confirmed. Our results demonstrated the occurrence of *pfhrp2/3* deletions among *P. falciparum* isolates from the southern part of Madagascar at a low level. Above all, the standard operating procedures for detecting *P. falciparum hrp2/3* deletions were successfully established for developing a national survey to guide the national malaria control program on the mRDT choice.

7255

GUT MICROBIOTA-INDUCED IMMUNE TOLERANCE IMPAIRS SYSTEMIC IMMUNITY AGAINST SEVERE MALARIA

Rafael Polidoro[1], Marcos V. Rangel-Ferreira[1], Olivia J. Bednasrki[1], José Carlos Alves-Filho[2], Nathan W. Schmidt[1]

[1]Indiana University School of Medicine, Indianapolis, IN, United States, [2]University of São Paulo, Ribeirão Preto, Brazil

Severe malaria caused by *Plasmodium* spp. infection leads to hundreds of thousands of deaths annually. Our lab uses *P. yoelii* and C57BL/6 mice from diverse vendors to study the influence of gut microbiota on malaria severity. Recently, we showed microbiota-dependent germinal center contraction and reduced antibody quality post-infection, leading to hyperparasitemia. This phenotype is replicated by introducing cecal material from hyper-parasitemic mice into regular and germ-free mice. While the causality is established, the intricate mechanisms remain unclear. Here, we found that susceptible mice had increased T regulatory cells in their Peyer's Patches and spleens after infection, correlated with reduced IFN-γ production. When exposed to sub-colitis doses of DSS, malaria-resistant mice developed colitis, while susceptible mice were resistant to weight loss, confirming the tolerogenic nature of their microbiota. Both groups showed similar levels of intestinal damage and bacterial translocation post-infection, suggesting malaria-dependent microbiota-independent gut injury. Moreover, modulation of splenic adenosine immunosuppressive pathways involving A2AR and CD39 is enhanced by tolerogenic microbiota in different leukocytes during malaria infection. Treatments to repair the gut barrier or to antagonize A2AR after intestinal damage post-infection significantly mitigate parasitemia, weight loss, and mortality while enhancing immunity. These findings highlight the vital role of the gut microbiota in shaping systemic immunity during infections, underscoring the potential of therapeutic interventions targeting the gut barrier to mitigate malaria severity and enhance outcomes.

7256

AGEING OF *PLASMODIUM FALCIPARUM* MALARIA SPOROZOITES ALTERS THEIR MOTILITY, INFECTIVITY AND REDUCES IMMUNE ACTIVATION *IN VITRO*

Roos van Schuijlenburg[1], Samaneh Azargoshasb[2], Clarize M. de Korne[1], Jeroen C. Sijtsma[1], Sascha Bezemer[1], Alwin J. van der Ham[1], Els Baalbergen[1], Fiona Geurten[1], Laura M. de Bes-Roeleveld[1], Severine C. Chevalley-Maurel[1], Matthias N. van Oosterom[2], Fijs W.B. van Leeuwen[2], Blandine Franke-Fayard[1], Meta Roestenberg[1]

Sporozoites (SPZ), the infective form of *Plasmodium falciparum* (Pf), can be inoculated into the human host skin by Anopheline mosquitoes. These SPZ migrate at ± 1µm/s to find a blood vessel and travel to the liver where they infect hepatocytes. At the skin they are still low in number and vulnerable to immune attack by antibodies and macrophages. This is why whole SPZ and SPZ proteins are used as the basis for most malaria vaccines. Mosquitoes inoculate SPZ into a human host between 14 and 25 days after infectious blood meal. However, it is unknown whether residing time within the mosquito affects the SPZ. We aimed to unravel how the age of *Pf* SPZ in salivary glands (14, 17, or 20 days post blood meal) affects their infectivity and the ensuing immune responses. We investigated SPZ numbers, viability, motility using dedicated sporozoite motility orienting and organizing tool software (SMOOT) and infectivity of HC-04.j7 liver cells. *In vitro* co-culture assays with SPZ stimulated monocyte-derived macrophages (MoMϕ) and $CD8^+$ T-cells, analyzed by flow cytometry, were used to investigate immune responses. We found that SPZ age did not result in different SPZ numbers or viability. However, we observed a markedly different motility pattern, whereby motility decreases from 89% at day 14 to 80% at day 17 and 71% at day 20 (p=<0.0001). Similarly, infectivity of day 20 SPZ dropped to 50% as compared with day 14 SPZ (p=0.004). MoMϕ were better able to take up day 14 SPZ (7.6%) than day 20 SPZ (4.1% p=0.03) and displayed an increased expression of pro-inflammatory CD80, IL-6 (p=0.005) and regulatory markers PDL1 (p=0.02), IL-10 (p=0.009) upon phagocytosis of younger SPZ. Interestingly, co-culture of these cells with $CD8^+$ T-cells revealed a decreased expression of activation markers CD137 and IFNγ as compared to their day 20 counterparts. These findings suggest that older (day 17-20) *Pf* SPZ are less infectious and have decreased immune regulatory potential. Our data shows a first step in enhancing our understanding of how mosquito residing time affects *Pf* SPZ and could impact our understanding of the *Pf* infectious reservoir and the potency of whole SPZ vaccines.

LEVERAGING BIRTH COHORTS TO TRACE COMPLICATED MALARIA RISK AND ITS IMMUNOLOGICAL CORRELATES AT EACH INFECTION IN INFANCY

Florian A. Bach[1], Abel Kakuru[2], Grant Dorsey[3], Moses Kamya[2], Prasanna Jagannathan[1]

[1]Stanford University, Stanford, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]University of California, San Francisco, CA, United States

Infections with *P. falciparum* range from asymptomatic to life-threatening. Protection from severe disease is usually acquired in the first few years of life, though it is unknown how this protection is encoded immunologically. Uncovering this mystery holds promise for developing and evaluating interventions that prevent severe disease and death. We leveraged three birth cohorts from high-transmission settings in Uganda for a detailed view of malaria risk and associated immunological changes in infancy. Monthly, active case finding allowed the faithful capture of each infection in more than 900 children aged 8 weeks to 2 years. Across thousands of *P.falciparum* infections, we find that the risk of complicated malaria is highly dynamic in early life. First infections tended to have lower parasitemias and were mostly uncomplicated. Median parasitemia increased in subsequent infections but reached a plateau after about three infections. The probability of symptoms, given a parasitemic episode remained constant in early life. In contrast, complicated disease risk peaked around malaria episode 5 and then quickly, exponentially declined thereafter,while median parasitemia remained unchanged. In multivariate analyses, the order of infection, more than age or parasitemia, significantly predicted complicated malaria risk in our cohort. Single-cell analysis of *P.falciparum*-specific T cells revealed changes in activation and differentiation associated with high and low-risk infections. Our data suggest that protection from severe disease is acquired after just a few malaria episodes. This occurs even when median parasitemias remain unchanged, and thus represents a mechanism of disease tolerance. This tolerance mechanism is likely distinct from clinical immunity, as the probability of developing symptoms remained constant in this cohort.

7258

REACTIVITY OF ANTIBODIES AGAINST MALARIA AND OTHER PARASITIC DISEASES TO THE ANTIGENS N, S AND S1 SUBUNIT RDB951 USED IN COVID-19 SEROLOGY

Mauhaun Taheri, Diana Martin, Vitaliano A. Cama

CDC, Atlanta, GA, United States

In response to the SARS-CoV2 (COVID) pandemic, several antibody (Ab) sero-surveillance assays were developed. However, studies suggesting that samples from malaria endemic areas have Ab that cross react with

COVID serology assays may limit their utility in these settings. We used a multiplex bead assay (MBA) to assess if Ab from parasite positive samples from United States (US) patients reacted against three COVID antigens: nucleocapsid (N), the spike protein (S) or its subunit RDB951 (R). The study tested 816 pre-COVID samples: 704 from the US with Ab positive results (Ab+) for malaria or 13 other parasitic diseases, 91 from Africa with Ab+ for filariasis, and 21 from US individuals with no reactivity for parasitic diseases. Controls were 33 samples collected during the COVID pandemic. Resulting data were assembled in contingency tables and analyzed by Chi-square/ Fisher's exact tests. Among pre-COVID samples, Ab+ against the COVID antigens were found in 14 (1.7%) samples for N, 26 (3.2%) for S, and none for R. No sample was Ab+ for N and S. Among the 33 samples from the COVID period, 10 (30.3%) had Ab+ for N, 20 (60.6%) for S and 19 (57.6%) for R, and 18 (54.5%) had simultaneous Ab+ for S and R. Among pre-COVID US samples positive for a parasitic disease, significant associations were found between filariasis positive samples (6/72, 8.3%) and Ab+ to S ($p=0.015$). Among 35 malaria Ab+ samples, one sample had Ab+ for N, and another had Ab+ for S. Among the 91 African pre-COVID samples, only 6 had Ab+ for N and 2 for S. Meanwhile, the COVID pandemic control group had Ab+ against the N, S and R antigens that were significantly associated with the COVID period ($p<0.001$). The MBA data showed that US malaria positive sera were not associated with Ab+ for COVID antigens N, S or R, and that Ab developed against other etiologies, as determined by MBA in pre-COVID samples, could contribute to some cross reactivity against either the N or S antigens but not likely against the R antigen.

7259

A NOVEL MURINE MODEL FOR INVESTIGATING THE PATHOGENIC ROLE OF COAGULATION IN MALARIA-ASSOCIATED ACUTE RESPIRATORY DISTRESS SYNDROME

Nicole M. Nazario, Margaret Taylor, Julie M. Moore
University of Florida, Gainesville, FL, United States

Malaria-associated acute respiratory distress syndrome (MA-ARDS) is a complication of severe malaria, characterized by pulmonary complications such as edema, inflammation, hemorrhages, and alveolar damage. The role of coagulation in the pathogenesis of MA-ARDS is poorly understood. Aiming to understand the pathogenic pathways that lead to lung malaria, including dysregulated coagulation, we developed an experimental murine model that lacks endothelial tissue factor (TF), the primary initiator of the extrinsic coagulation cascade. We hypothesized that altered TF expression would suppress the inflammatory response, oxidative stress, and endothelial disruption, resulting in reduced vascular leakage in the lung. We further hypothesized that sexual dimorphism would influence disease severity, with males being more susceptible. We assessed disease progression in P. berghei NK65 infected (IV, 105) endothelial tissue factor-deficient ($F3^{flox/flox}$ Tie-2^{Cre}) mice. Parasitemia, anemia, and body condition were measured longitudinally over 16 days. At 16 days post-infection, lung tissues were weighed and processed for histology and molecular analysis. Body condition score as measured by activity and behavior was significantly reduced in males relative to females regardless of TF expression. Females lacking endothelial TF had significantly lower parasite burden in comparison to males, while tissue factor intact female and male mice had similar parasitemia. Lung index, anemia, and body weight in all experimental groups were similar. Ongoing studies are examining lung histology and the expression of inflammatory, anti-oxidant, pro- and anti-coagulant associated genes to further assess the extent to which TF expression and sex influence lung pathology in this model.

7260

COMPARING MIXTURE MODELING APPROACHES FOR CLASSIFYING LONG-TERM MALARIA SEROLOGICAL MARKERS IN NORTHERN LAOS

Estee Y. Cramer[1], Benjamin Benjamin Rogers[1], Francois Rerolle[2], Emily Dantzer[2], Bouasy Hongvanthong[3], Isabel Byrne[4], Lindsey Wu[4], Adam Bennett[2], Chris Drakely[4], Nicholas G. Reich[1], Andrew A. Lover[1]
[1]School of Public Health and Health Sciences, University of Massachusetts Amherst, Amherst, MA, United States, [2]Malaria Elimination Initiative, The Global Health Group, University of California, San Francisco, CA, United States, [3]Centre of Malariology, Parasitology, and Entomology, Vientiane, Lao People's Democratic Republic, [4]Department of Infection Biology, London School of Hygiene & Tropical Medicine, London, United Kingdom

In Lao People's democratic (Lao PDR), malaria is hypo-endemic and *Plasmodium vivax* is a common cause of malaria infection; current diagnostic tools are insufficient for detection of malaria infection. Serological assays can be a valuable tool for elucidating infection timelines and estimating the likelihood of *P. vivax* hypnozoite presence. Challenges in serology include defining antigenic targets, and classification of individuals based on semi-quantitative assays. This study presents a comparison of two statistical models to classify parasite exposure based on Luminex assays. We also apply regression models to quantify factors associated with historical exposure. A cross-sectional study in Lao PDR was conducted in four providences. Participants provided biological samples and demographic information. The prevalence of four putative long-term markers was classified using two mixture models: (1) deterministic finite mixture model (dFMM), and (2) novel probabilistic finite mixture model (pFMM) using a Weibull distribution in a Bayesian framework. Thirty-eight individuals (0.8%) were PCR-positive for current parasitemia. The seronegative proportion of the population by model is as follows for each marker: PvAMA1 (59.3% by dFMM, 11.9% [80% CrI: 3.5, 31.8] by pFMM); PvMSP119 (18.0% by dFMM, 17.4% [80% CrI: 1.0, 42.9] by pFMM); PfAMA1 (57.5% by dFMM, 23.6% [80% CrI: 21.6, 25.5] by pFMM); PfMSP119 (58.2% by dFMM, 26.9% [80% CrI: 24.7, 29.2] by pFMM). Seroprevalences based on the pFMM model are consistent with expectations in this region which is approaching elimination. Factors including age, geography, sex, and occupation were associated with individual-level seropositivity (cumulative exposures). This was consistent with expectations of long-term markers. While serology is a useful tool, the lack of validated classification methods leads to arbitrary cut-points under strong assumptions. This pFMM provides a complimentary and nuanced framework to interpreting serological data. A probabilistic approach can better capture the uncertainty found in this inherently complex data.

7261

TARGETS OF CSP-BASED MALARIA VACCINES: WHAT WE MISSED IN 1987 AND WHAT IS MISSING NOW

Franklin Yengdem Nuokpem[1], Comfort Kotey[1], Josiah Darko Affum[1], Daniel Dosoo[1], Georgina Agyekum[2], Eric Kyei-Baafour[2], Yaw Bediako[1], Kwadwo Asamoah Kusi[2], Gordon Awandare[1], Yaw Aniweh[1]
[1]West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana

The current circumsporozoite protein (CSP) based licensed malaria vaccines can be improved by the inclusion of novel CSP targets. In the wake of increasing relevance of non-*falciparum* species, a cross-species vaccine is desirable. In this study, we profiled the CSPs of *Plasmodium falciparum, Plasmodium malariae,* and *Plasmodium ovale* in terms of protein sequence and structure, and naturally-acquired CSP-specific IgG in malaria-exposed individuals. We sought to uncover cross-species conserved domains to prioritize in the design of a cross-species vaccine. Also, we probed potentially protective CSP motifs by comparing immune responses between malaria "protected" and "at-risk" cohorts. Sequence alignments were done using Clustal Omega. Protein structures were predicted using

ColabFold and compared using TM-align. Total IgG, IgG avidity, and IgG subclass measurements against full-length proteins (PfCSP, PmCSP, PoCSP) and peptides (20mer with 10aa overlap) were done by indirect ELISA. Western/dot blotting was done to confirm ELISA results and identify immunodominant CSP peptides. Sequence and structural similarities were low across full-length proteins; highest in the C-terminus. We observed the conservation of essential sequences cross-species; the PEXEL motif, the protease cleavage site, and region II+. There was similar anti-PfCSP and PoCSP and a lower anti-PmCSP total IgG levels. We uncovered 16/27(PfCSP), 16/26(PmCSP), and 13/26(PoCSP) seropositive peptides by dot-blot. IgG profiles of the PEXEL (N-terminus), minor repeat (junctional), major repeat (central repeat), and region II+ (C-terminus) peptides reveal high and diverse peptide recognition in the malaria "protected" cohort; IgG was polarized to peptides of the central repeat and the C-terminus in the at-risk cohort. Our study reaffirms CSP-specific antibody feedback inhibition in naturally malaria-exposed individuals. We propose cross-species targets; the PEXEL, protease cleavage site, and region II+. Our data suggests that a potent anti-CSP response is high and diversified across CSP domains. This study contributes to the design of effective vaccines.

7262

INVESTIGATING THE ASSOCIATION BETWEEN MALARIA INFECTION AND AUTOANTIBODY PRODUCTION IN MURINE AND HUMAN STUDIES.

Rinter Kimathi[1], Francis Ndung'u[2], Kim S. Midwood[3], Paul Garside[4], Hannah E. Scales[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Kemri Wellcome trust Kilifi, Kilfi, Kenya, [3]University of Oxford, Oxford, United Kingdom, [4]University of Glasgow, Glasgow, United Kingdom

The relationship between malaria and autoimmunity remains controversial, with previous studies showing that infection promotes or inhibits inflammatory conditions. We, therefore, set out to investigate the link between *Plasmodium* infection and autoimmunity using murine models and studies in patient cohorts. The development of rheumatoid arthritis associated anti-citrullinated protein autoantibodies (ACPA) responses were assessed in *Plasmodium chabaudi* infected mice. Subsequently, we evaluated the impact of these heightened ACPA responses on the development of a model of experimental arthritis in mice following infection with *P. chabaudi* infection. We demonstrate that infection with *P. chabaud*i leads to increased ACPA peaking at two weeks post infection; and remaining high even after parasite clearance compared to naïve mice. Under the conditions used in our study these autoantibodies did not appear to influence the outcome of experimental autoimmune arthritis. Extending our findings to humans, we measured the levels of ACPA in individuals residing in areas of either low or moderate malaria transmission. Using microarray, we assessed the range of autoimmune markers exhibited by ACPA high individuals and flow cytometry was also used to assess T cell phenotypes associated with an autoimmune profile. As in the murine studies, individuals living in higher malaria transmission areas had elevated levels of ACPA. Individuals with higher ACPA exhibited diverse autoantibody profiles, suggesting a general increase in autoreactivity. We also noted lower FOXP3 regulatory T cell levels in individuals with higher ACPA levels compared to those with lower responses. These data suggest that malaria infection induces a range of autoantibody responses in both mice and humans. In our murine model, the pre-existing ACPA response following a single infection did not influence the development of experimental autoimmune arthritis. However, the impact of multiple malaria infections on the risk of developing autoimmune disease warrants further investigation.

7263

PROTEIN SEQUENCE AND STRUCTURE, AND ANTIBODY PROFILE OF THE AMA1 FROM THREE *PLASMODIUM* SPECIES.

Josiah Darko Affum[1], Franklin Yengdem Nuokpem[1], Comfort Kotey[1], Daniel Dosoo[1], Silas Nkansah Yeboah[1], Georgina Agyekum[2], Eric Kyei-Baafour[2], Gordon Awandare[1], Kwadwo Asamoah Kusi[2], Yaw Aniweh[1]

[1]West African Centre for Cell Biology of Infectious Pathogens, University of Ghana, Accra, Ghana, [2]Noguchi Memorial Institute for Medical Research, Accra, Ghana

The need for an effective malaria vaccine is imperative. The prevalence of non-*falciparum* species in the clinical setting calls for the design of broad-spectrum intervention tools. To achieve this in vaccine design, it is necessary to establish species-specific immune mechanisms. The Apical membrane antigen (AMA1) is an advanced vaccine candidate with its potential evidenced by neutralizing antibodies. In this study, we investigated sequence and structural conservation between AMA1 proteins of *P. falciparum, P. malariae,* and *P. ovale* using *in silico* techniques and characterized IgG responses in six different populations in Ghana. Protein sequence comparison was done using Clustal Omega (significant at similarity >30%). Protein structures were predicted by homology modeling using Swiss-Model. Monoclonal antibody cross-reactivity was determined by Western blot. Our study cohorts include community, hospital (follow-up days 0,7,21), and a malaria "protected" and "at-risk" cohort sampled in the same geographic area. Total IgG, IgG subclasses, and IgG avidity were measured by indirect ELISA , and data was analyzed in R. There was high sequence similarity(>50%) and structural concordance(TM>0.9) between all antigens. All antigens were recognized by malaria-hyperimmune IgG in Western blot with intensities of PfAMA1>PmAMA1>PoAMA1. Using PfAMA1-generated monoclonals, we observed cross-reactivity between PfAMA1 and PmAMA1 for MAb N3-1D7. Comparing immune response against the three antigens, PfAMA1 recorded the highest IgG levels and seropositivity in all sample groups corresponding with species transmission intensity. Across the three antigens, anti-PfAMA1 IgG avidity was highest only in our clinical follow-up cohort on day zero. Dominating IgG subclasses were IgG1 and IgG2. This study affirms species transmission intensity in Ghana and the conservation of AMA1 in terms of sequence and structure. This is the first study that profiles and compares cross-species immune responses against AMA1 in naturally immune individuals. This study contributes to anti-AMA1 immunology towards vaccine design.

7264

MALARIA EXPOSURE RISK AND NATURALLY ACQUIRED IMMUNITY AMONG STUDENTS FROM SOUTHERN AND NORTHERN GHANA

Nana Akua O. Koranteng[1], Adwoa A. Afari[2], Beatrice Asantewaa[2], Mathias Naporo[3], Helena Lamptey[1], Michael F. Ofori[1], Zakaria Seidu[4]

In Ghana, malaria remains a significant public health issue, with different regions experiencing varying levels of transmission intensity. This study examined the differences in malaria exposure and the development of naturally acquired immunity between students from Ghana's northern and southern regions. A cross-sectional study was conducted on a group of 189 healthy students from the Nyankpala Campus of the University for Development Studies (UDS) using a structured questionnaire to assess their malaria exposure history, risk, and prevention-seeking behavior. In addition, the study measured their IgG levels against *P. falciparum* 3D7 crude antigens, HB3VAR06, and IT4VAR60 using an indirect ELISA. This study uncovered that though individuals from the northern regions showed

a nearly significant difference in malaria susceptibility (p=0.054), there were no notable differences in malaria prevention-seeking behaviors compared to those from the southern region. Furthermore, no significant differences were observed in the levels of IgG antibodies against crude antigens, however, variations were found in the levels of IgG antibodies against HB3VAR06 antigens. The HB3VAR06-specific IgG levels were relatively higher among individuals from the north (p=0.027), whereas those from the south had higher levels of IT4VAR60-specific IgG but not significant (p=0.155), suggesting that individuals from the two regions may have been exposed to different VAR clones of the parasite. In general, the levels of naturally acquired IgG antibodies showed no correlation with the risk of malaria exposure. The result of this study provides valuable insights into the prevalence and risk factors associated with malaria in the study population and a potential geographical selection of parasites between southern and northern Ghana.

Malaria is a disease of major global health concern. *Plasmodium falciparum* is the deadliest human *Plasmodium* parasite. An effective malaria vaccine would be an important additional tool in the fight against malaria. Merozoite proteins of Plasmodium falciparum have been studied for malaria vaccine development. One of such antigens is the Plasmodium falciparum Cytosolically Exposed Rhoptry Leaflet Interacting protein 1 (*Pf*CERLI1). *Pf*CERLI1 is essential for red blood cell invasion by merozoites; antibodies against *Pf*CERLI1 are inhibitory to red blood cell invasion. In this study, we determined the immunodominant regions of PfCERLI1 to prioritize as targets for vaccine development. Five overlapping peptides were designed and synthesized to cover three-quarters of the full-length protein. Full-length protein structure was predicted using ColabFold. The predicted structure was visualized and edited in PyMol. Initial peptide seroreactivity using hyperimmune IgG purified from Ghanaian adults was determined by dot blot. Total IgG was measured using indirect ELISA. Sera samples were obtained from Madina (community samples and malaria-diagnosed hospital samples) and Lekma (clinical follow-up with days 0,7,21). All *Pf*CERLI1 peptides are reactive to naturally-acquired IgG. Our findings reveal varying levels of recognition among *Pf*CERLI1 peptides. Notably, peptides 5 and 7 exhibited immunodominance in the Madina cohort in both community and clinical samples. All anti-peptide IgG increased with age moderately in the clinical cohort. Adjusted for age, we observed higher total IgG levels in the community cohort compared to the hospital cohort except for peptide 3. In the clinical cohort, peptides 3, 4, and 5 were immunodominant at all time points. We observed significant IgG decay at day 7 for all peptides except 3 and 7. Our results show a correlation of peptide IgG with the development of anti-malaria immunity in naturally-exposed individuals. We are inclined to conclude that *Pf*CERLI1 is an essential target for vaccine design. Understanding the immunodominant regions of *Pf*CERLI1 brings us closer to a targeted and effective malaria vaccine.

The immune response to *Plasmodium falciparum* (Pf) is complex, involving innate responses that induce regulatory mechanisms, which determine infection outcomes and acquired immunity. In malaria-naive adults inoculated with Pf sporozoites via needle injection in Barcelona, we conducted analyses including genome-wide gene expression, cytokine and antibody profiling, and dendritic cell (DC) phenotyping. There were minimal responses on days 1 and 7. However, low density infections at day of parasite detection by thick blood smear (TBS) elicited robust innate responses, with 1251 differentially expressed genes compared to baseline (|log2FC|>0.6 & FDR<0.01), increased plasma cytokines and frequencies of activated DC ($CD86^+$, $PDL1^+$ & $CD40L^+$). Top upregulated genes included CXCL10, CXCL9, and CCL2, correlating with their elevated plasma concentrations. Upregulated blood transcriptional modules (BTMs) were related to interferon, DC activation, and cell cycle regulation, while downregulated BTMs were linked to NK, T and B cells, which correlated with lymphocyte cell counts (rho>0.7, p<0.01). Interestingly, transcriptional analysis revealed 'high' and'low' responders, with larger gene expression changes in high responders. BTMs associated with innate responses (DC, monocytes, platelets, interferons, inflammation, and chemokines) were upregulated in high responders. This coincided with higher cytokine concentrations and increased frequencies of activated DC. Consistently, cell deconvolution showed more activated DC and M1 macrophages. Instead, BTMs linked to adaptive responses (B & T cells, plasma cells) and NK cells were more downregulated. No significant differences were observed in pre-patent period (12.17 *vs* 12.27 days) and TBS parasite density at patency between the two groups. However, time to positive qPCR was longer in low responders (9.33 *vs* 7.73 days, p=0.02). Furthermore, high responders exhibited significantly more neutropenia and fever at patency. Innate responses to a first Pf infection in adults are highly variable and may impact parasite kinetics, clinical outcome, and whole parasite vaccine responses.

ANTI-CIRCUMSPOROZOITE PROTEIN ANTIBODIES AS MARKERS FOR MALARIA TRANSMISSION MONITORING

Linda Akuffo, Kwadwo Asamoah Kusi, Rawdat Baba-Adam, Eric Kyei-Baafour, Bright Asare, Oscar Darko

Noguchi Memorial Institute for Medical Research, Accra, Ghana

Malaria, remains a global burden, despite progress towards elimination in some endemic areas. Researchers are renewing efforts to track transmission to assess anti-malarial interventions. This correlation underscores the need for robust methods for monitoring malaria exposure and transmission. Antibodies to the *Plasmodium* antigen, circumsporozoite protein (CSP), is a promising alternative to the existing methods used for transmission intensity estimation. However, this may vary within populations and could be compromised by CSP antigen polymorphism. This study aimed to assess the use of anti-CSP antibodies as markers of recent exposure to malaria, taking antigen polymorphism into consideration. Sixty children and 120 adults from 2 regions of Ghana were sampled monthly for a year. Malaria infection status and parasite density were assessed by PCR. Enzyme-linked immunosorbent assays were used to determine anti-CSP antibody seroprevalence against the recombinant PfCSP (3D7 strain) and two conserved 24-mer peptides (NANPNANP repeats and NVDPNANP repeats) from the central repeat region of PfCSP. The *csp* genes were

amplified using Sanger sequencing and analyzed using MEGA 11 software. Parasite prevalence was 65% and 1% among children and adults respectively. Seropositivity varied significantly by month among children for anti-CSP (p-value<0.001), Anti-24 mer peptide 1 (p-value=0.001) and anti-24 mer peptide 2 (p-value=0.004). Seropositivity however did not significantly vary amongst adults. Parasite prevalence was significantly higher in children than in adults over the period, but antibody seropositivity was high in both children and adults. This study supported previous works on anti-CSP antibody method for monitoring malaria transmission. Further, these results showed that anti-CSP antibody measurement could be more useful in adults in low malaria transmission areas with undetectable levels of *Plasmodium* parasites even by PCR. Although *csp* gene is polymorphic, this did not significantly affect the levels of antibodies as measured with a standard strain for estimating malaria exposure among our study participants.

PLASMABLAST IG REPERTOIRE DYNAMICS THROUGH REPEAT *PLASMODIUM FALCIPARUM* CHALLENGES REVEAL SIGNATURES OF NEGATIVE SELECTION

Patricia Ferrer[1], Andrew Frank[1], Andrea A. Berry[2], Kirsten E. Lyke[2], Kim C. Williamson[3]

[1]Uniformed Services University of the Health Sciences & Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD, United States, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]Uniformed Services University of the Health Sciences, Bethesda, MD, United States

To understand the development of immunity against malaria, a controlled human malaria challenge (CHMI) model was used to expose malaria-naïve individuals to the same *P. falciparum* (*Pf*) strain (NF54) four times over two years. Consistent with the gradual immunity observed naturally, the time to parasite detection increased significantly (delayed patency (DP)) by the 3rd CHMI. Plasmablast Ig repertoire maturation was tracked 7 days after peak parasitemia at each CHMI. Clone copy numbers and CDR3 counts for the major clones (CDR3 >200 or clone copy >20 000) increased significantly after exposure to Pf in all participants with DP and peaked at CHMI-2 in most DP. In contrast, the participants without DP had no significant increase in clone copy number or CDR3 count until CHMI-4. In these major clones, the ratio of replacement to silent mutations (R/S) declined from baseline through the 4 CHMIs and there was a significant decrease in R/S for the 12 Ig heavy chain variable genes associated with anti-Pf immunity in DP only. Phylogenetic analysis indicated that clones with longer tree lengths (more divergence) correlated with increasing negative selection (omega). These patterns suggest that a certain level of B cell activation is needed to reduce parasite replication and DP. However, there is a limit to the maturation of specific clones, possibly because most additional replacement mutations do not improve affinity and are selected against. VENOUS BLOOD GAS ANALYSIS IN UGANDAN CHILDREN WITH SEVERE MALARIA

Michael T. Hawkes[1], Andrea L. Conroy[2], Robert O. Opoka[3], Sophie Namasopo[4], Hunter J. Wynkoop[5], Michael D. Lintner-Rivera[2], Chandy C. John[2], Kevin C. Kain[6]

[1]University of British Columbia, Vancouver, BC, Canada, [2]Indiana University, Indianapolis, IN, United States, [3]Aga Khan University, Nairobi, Kenya, Nairobi, Kenya, [4]Kabale Regional Referral Hospital, Kabale, Uganda, [5]Nationwide Children's Hospital, Columbus, OH, United States, [6]University of Toronto, Toronto, ON, Canada

Acidosis, defined as base deficit (BD) >8mmol/L, is a criterion of severe malaria (WHO guidelines 2023). If the BD is not available, a plasma bicarbonate concentration [HCO_3^-] of <15mmol/L or venous plasma lactate ≥5mmol/L can be used to define acidosis. Kussmaul respirations may also suggest acidosis. We examined the agreement between markers of acidosis and their predictive value for mortality among children with severe malaria. Venous blood gas measurements (i-STAT biochemistry analyzer, Abbott Point of Care) from children <5 with severe falciparum malaria enrolled in a past clinical trial (July 2011 to June 2013) were examined retrospectively. Inclusion criteria were: (1) <5yr of age; (2) *P. falciparum* detected by both microscopy and rapid diagnostic test; (3) met criteria for severe malaria; and (4) venous blood gas measurement recorded at admission. 124 children (median age 2yr, 44% female) were included. Acidosis (BD > 8 mmol/L) was present in 59/124 (48%), hypobicarbonatemia in 51/124 (41%), hyperlactatemia in 42/121 (35%), and Kussmaul respirations in 58/124 (47%). Base deficit was inversely correlated with [HCO_3^-] (ρ= -0.93, p<0.0001), directly correlated with lactate level (ρ=0.38, p<0.0001), and was significantly higher in patients with Kussmaul respirations (9.7 mmol/L (IQR 4.5-14) versus 5.7 mmol/L (IQR 2.9-11), p=0.0064). Using BD>8mmol/L as a reference standard, hypobicarbonatemia, hyperlactatemia, and Kussmaul respirations were 85%, 53%, and 59% sensitive, and 98%, 83%, and 65% specific for detection of acidosis, respectively. There were 11 deaths (8.9%). All 11 deaths occurred in children with acidosis (OR >3.1, p=0.00018). Hypobicarbonatemia, hyperlactatemia, and Kussmaul respirations increased the odds of death by 17-fold (95%CI 2.3 - 760, p=0.00063), 3.1-fold (95%CI 0.68 - 16, p=0.094), and 13-fold (95%CI 1.8 - 590, p=0.0029), respectively. Our findings support the current WHO definition of acidosis: BD>8mmol/L is a strong predictor of mortality in children with malaria. Other markers of metabolic acidosis (hypobicarbonatemia and Kussmaul respirations) also have prognostic value.

DYSREGULATION OF NETOSIS IN PEDIATRIC PATIENTS WITH SEVERE MALARIAL ANEMIA

Sharley A. Wasena[1], Qiuying Cheng[2], Evans Raballah[1], Shamim W. Osata[1], Ivy Hurwitz[2], Clinton O. Onyango[1], Philip D. Seidenberg[3], Christophe G. Lambert[4], Benjamin H. McMahon[5], Collins Ouma[1], Kristan A. Schneider[6], Samuel B. Anyona[7], Douglas J. Perkins[2]

[1]University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, [2]Department of Internal Medicine, Center for Global Health, University of New Mexico, Alberqueque, NM, United States, [3]Department of Emergency Medicine, School of Medicine, Alberqueque, NM, United States, [4]Department of Internal Medicine, Division of Translational Informatics, University of New Mexico, Alberqueque, NM, United States, [5]Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States, [6]Department of Applied Computer and Bio-Sciences, University of Applied Sciences Mittweida, Mittweida, Germany, [7]Department of Medical Biochemistry, School of Medicine, Maseno University, Kisumu and Siaya, Kenya

Human malaria remains among the leading global causes of childhood morbidity and mortality, accounting for 249 million cases and 608,000 deaths annually. The World Health Organization African Region accounts for the majority (95%) of fatalities of which 80% occur in children <5 years. In western Kenya, a holoendemic *Plasmodium falciparum* area, severe malarial anemia (SMA, Hb<6.0 g/dL) is the primary manifestation of severe childhood malaria. Although antimalarials are pivotal for malaria control, rising drug resistance underscores the importance of defining novel molecular targets to support drug discovery efforts. As such, we explored the entire expressed transcriptome (Illumina® NovaSeq 6000) in the peripheral blood of Kenyan children with either SMA (n=18) or non-SMA (Hb≥6.0 g/dL, n=39), excluding cases of sickle cell disease. There were 1,682 differentially expressed genes (DEGs, *padj*<0.05) in SMA relative to non-SMA: 1,403 up-regulated and 279 down-regulated. Pathway analysis using MetaCore™ (threshold: $\log_2$foldchange=0.585, *padj*<0.05) revealed that NETosis in Systemic Lupus Erythematosus (SLE) was the top disrupted pathway (*padj*=8.134E-5) in children with SMA. NETosis is a cellular process initiated by pathogen products, antibodies, immune complexes, and cytokines for the formation and release of neutrophil extracellular traps

(NETs), composed of decondensed chromatin DNA and neutrophil granule peptides/proteins (e.g., PERM, alpha-defensin, leukocyte elastase, and histones). Consistent with chromatin decondensation and formation of NETs,
children with SMA had up-regulation of PERM (+1.77), alpha-defensin (+2.20), leukocyte elastase (+1.68), histone H1 (H1-0:+1.1 and H1-2:+0.71) and H2 (H2AC6:+1.04). In addition, NETs activate the classical complement pathway by interacting with C1q which was also upregulated in children with SMA (C1QA:+1.34, C1QB:+1.33, and C1QC:+1.52). Collectively, these results identify molecular mechanisms associated with enhanced chromatin decondensation and formation of NETs as potential therapeutic targets to reduce tissue hypoxia and organ dysfunction.

Asymptomatic *Plasmodium* carriage is a major public health threat affecting both children and adults and hindering malaria eradication, yet the mechanisms that allow for asymptomatic malaria are unclear. Many LMICs are endemic for both malaria and soil-transmitted helminths (STH). Studies have confirmed that helminths secrete various proteins during infection to regulate host immune responses as a survival strategy meanwhile reducing host immune responses to other inflammatory processes. We conducted a two-part study to evaluate if STH infection drives the phenotype of asymptomatic *Plasmodium* infection. First, a one-month longitudinal study of 134 primary school children across 3 school-based study sites in Esse, Cameroon (where both malaria and STH are endemic) was performed to identify the prevalence of asymptomatic *P. falciparum* infection, factors associated with subsequent development of symptomatic malaria, and the prevalence of STH co-infection. Blood samples determined malaria status and anemia, daily temperature checks were used to monitor for symptomatic disease development, and stool samples screened for STH infection using the Kato Katz method. Due to presumed falsely low Kato Katz results, a secondary retrospective study was conducted to establish STH IgG positivity. Overall, 85.8% of children had asymptomatic *P. falciparum* infection by microscopy, 88.8% had serologic positivity for at least one STH antigen, and 76.1% had asymptomatic *P. falciparum* plus STH exposure. We found no significant difference in the proportion of children with STH exposure and asymptomatic vs. symptomatic *P. falciparum* carriage (88.7% vs 83.3%, p >0.05), or in the proportion of asymptomatic *P. falciparum* carriers who were STH-exposed vs. STH-unexposed (85.7% vs. 86.7%, p > 0.05). The quantity of reactive antibody to STH was no different in asymptomatic vs. symptomatic *P. falciparum* carriers (p>0.05), and, for asymptomatic children, there was no correlation between anti-STH antibody level and *P. falciparum* load (p > 0.05). While limitations exist, we observed no association between STH exposure and asymptomatic *P. falciparum* infection.

7272

UPREGULATION OF GENE TRANSCRIPTS FOR SEVEN CRITICAL *PLASMODIUM FALCIPARUM* GLYCOLYTIC ENZYMES IN PEDIATRIC SEVERE MALARIAL ANEMIA

Sarah Naulikha Kituyi[1], Quiying Cheng[2], Clinton Onyango[3], Ivy Hurwitz[3], Beauty Kolade[4], Philip Seidenberg[3], Christophe Lambert[3], Benjamin Mcmahon[4], Kristan Schneider[3], Ananias Escalante[5], Samuel Anyona[6], Collins Ouma[6], Douglas J. Perkins[3]

[1]University of Embu, Embu, Kenya, [2]University of New Mexico, Alberqueque, NM, United States, [3]University of New Mexico, Albuquerque, NM, United States, [4]Los Lamos National Laboratory, Los Lamos, NM, United States, [5]Temple University, Philadelphia, PA, United States, [6]Maseno University, Kisumu, Kenya

The potential of novel therapeutic targets for severe malaria infections caused by *Plasmodium falciparum* is essential. This can be achieved by harnessing components of the parasite's metabolic pathways vital for its viability and infectivity in human hosts. One such target is the glycolytic pathway responsible for energy generation for the parasite's activities. This pathway is catalyzed by enzymes that control the flow of glycolytic metabolites. Enzymes in the pathway also influence non-glycolytic processes essential for the infectivity of the parasite such as: (i) the motility of sporozoites towards the liver cells and the subsequent attachment and entry into the hepatocytes, (ii) the egress of merozoites, (iii) infection of red blood cells, and (iv) the adherence of the parasites to the endothelial vessels. To explore if genes encoding key enzymes in the glycolytic pathway of *P. falciparum* contribute to the pathogenesis of severe malaria anemia [SMA, hemoglobin (Hb)<6.0 g/dL], a major manifestation of severe malaria, we performed *P. falciparum* transcriptome profiling on the peripheral blood of pediatric malaria patients in Siaya County Referral Hospital, Kenya, stratified into two clinical groups: SMA (n=20) and non-SMA (Hb≥6.0 g/dL, n=40). Our results revealed significant upregulation (FDR-adjusted $P<0.05$) of genes encoding seven key parasitic enzymes in the glycolytic pathway in children with SMA: pyruvate kinase 2 (*PykII*, $\log_2$FoldChange=1.262), phosphoglycerate mutase (*PGM*, $\log_2$FoldChange=0.710),phosphoglycerate kinase (*PGK*, $\log_2$FoldChange=0.645), enolase (*ENO*, $\log_2$FoldChange=0.609), triosephosphate isomerase (*TIM*, $\log_2$FoldChange=0.608), phosphoglycerate mutase (no gene symbol, $\log_2$FoldChange=0.533), and 6-phosphofructokinase (*PFK9*, $\log_2$FoldChange=0.519). Harnessing key enzymes in the glycolytic pathway of *P. falciparum* presents a promising avenue for targeting severe malaria infections, as evidenced by significant upregulation of these enzymes in pediatric patients with SMA, suggesting their potential role in disease pathogenesis.

HEME AND HEMOGLOBIN SCAVENGING DEFICIENCIES IN PEDIATRIC SEVERE MALARIAL ANEMIA-- INSIGHTS FROM PLASMA PROTEOMICS

Qiuying Cheng[1], Clinton Onyango[2], Samuel B. Anyona[3], Ivy Hurwitz[1], Evans Raballah[4], Sharley A. Wasena[2], Sarah Kituyi[5], Shamim W. Osata[2], Philip D. Seidenberg[6], Collins Ouma[2], Kristan A. Schneider[1], Benjamin H. McMahon[7], Douglas J. Perkins[1]

[1]Center for Global Health, University of New Mexico, Albuquerque, NM, United States, [2]Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Kisumu, Kenya, [3]Department of Medical Biochemistry, School of Medicine, Maseno University, Kisumu, Kenya, [4]Department of Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, [5]Department of Biological Sciences, University of Embu, Embu, Kenya, [6]Department of Emergency Medicine, University of New Mexico, Albuquerque, NM, United States, [7]Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States

Severe malarial anemia (SMA: Hb<6.0 g/dL, with any density parasitemia) is the primary clinical manifestation of severe malaria and among the

leading causes of morbidity and mortality in children under five years in holoendemic *Plasmodium falciparum* transmission regions, such as Siaya County, western Kenya. *P. falciparum* infection causes hemolysis of infected and uninfected human erythrocytes, resulting in the release of heme and free hemoglobin (Hb) into peripheral circulation. These molecules act as blood toxins to exposed cells and can promote organ failure when not promptly scavenged. To define molecular signatures associated with severe disease, we utilized an aptamer-based technology (SomaScan) to quantify 6,612 circulating human proteins in plasma samples collected from children (3-36 months) with non-SMA (Hb≥6.0 g/dL, n=20) and SMA (n=20) upon enrollment (pre-treatment: day 0). The proteomics revealed that levels of 670 plasma proteins were significantly higher in SMA relative to non-SMA (P<0.05, FDR<0.25), whilst the circulating levels of 665 proteins were significantly lower in SMA vs. non-SMA (P<0.05, FDR<0.25). Of the 1,335 differentially expressed proteins (DEPs), two critical heme scavengers, hemopexin and alpha-1-microglobulin, as well as the sole Hb scavengers, haptoglobin isoforms, were all down-regulated in the SMA group: hemopexin (log_2FoldChange= -0.842, P=3.753E-4); alpha-1-microglobulin (log_2FoldChange=-0.385, P=3.660E-3); haptoglobin, mixed type (log_2FoldChange=-3.961, P=8.089E-3); and haptoglobin isoform 2 (log_2FoldChange=-3.944, P=4.372E-3). Collectively, these proteomic results demonstrate that SMA is characterized by a deficiency of scavenging capability for heme and free hemoglobin during severe malaria infections.

7274

TRANSCRIPTOMIC INSIGHTS INTO COMPLEMENT-ASSOCIATED GENE DYSREGULATION IN CHILDHOOD SEVERE MALARIAL ANEMIA

Evans Raballah[1], Sharley A. Wasena[2], Samuel B. Anyona[2], Qiuying Cheng[3], Ivy J. Hurwitz[3], Shamim W. Osata[4], Clinton O. Onyango[2], Collins Ouma[2], Philip D. Seidenberg[5], Benjamin H. McMahon[6], Christophe G. Lamber[3], Kristan A. Schneider[3], Douglas J. Perkins[3]

[1]Masinde Muliro University of Science and Technology, Kakamega, Kenya, [2]Maseno University, Kisumu, Kenya, [3]University of New Mexico, Center for Global Health, Department of Internal Medicine, Albuquerque, NM, United States, [4]University of New Mexico Global Health Programs, Siaya and Kisumu, Kisumu, Kenya, [5]University of New Mexico, Department of Emergency Medicine, Albuquerque, NM, United States, [6]Los Alamos National Laboratories, Los Alamos, NM, United States

Severe malarial anemia (SMA: Hb<6.0 g/dL) is among the leading causes of global childhood morbidity and mortality. In holoendemic *Plasmodium falciparum* transmission regions, such as western Kenya, severe malaria primarily manifests as SMA. We have previously demonstrated that genetic variations in complement components alter the longitudinal risk of SMA and mortality. To extend these findings, we examined the entire expressed transcriptome in peripheral blood samples collected from children (1-59 mos.) with non-SMA (Hb≥6.0 g/dL, n=41) and SMA (n=25). Of the 585 human complement-associated genes identified in NCBI, 566 of the genes were contained within the RNA-Seq data with 189 genes differentially expressed in children with SMA relative to non-SMA at FDR≤0.050. Of the 189 genes, 79 were up-regulated and 110 were down-regulated. Gene ontology (GO) enrichment analysis using clusterProfiler in R revealed complement activation (FDR=$8.49x10^{-22}$), humoral immune response (FDR=$1.09x10^{-21}$), and complement activation (classical pathway, FDR=$6.60x10^{-15}$) as the top-enriched biological processes. Collagen-containing extracellular matrix (FDR=$5.25x10^{-15}$), blood microparticle (FDR=$1.61x10^{-13}$), and secretory granule lumen (FDR=$1.46x10^{-12}$) were the most enriched cellular processes. Glycosaminoglycan binding (FDR=$8.02x10^{-09}$), cytokine binding (FDR=$1.62x10^{-06}$), and extracellular matrix structural constituent (FDR=$2.97x10^{-06}$) as the top associated molecular functions. Functional pathway enrichment analyses using MetaCore™ (threshold: log_2foldchange=0.585 and FDR<0.05) showed that SMA was characterized by dysregulation in Plasmin Signaling (FDR=$2.93x10^{-8}$), Classical Complement Pathway (FDR=$4.32x10^{-8}$), and C3a Signaling (FDR=$6.32x10^{-6}$) related to the immune response. Collectively, these findings illustrate that acute malaria, and particularly SMA is associated with dysregulation in several complement signaling cascades.

PLASMODIUM KNOWLESI INFECTION IS ASSOCIATED WITH ELEVATED CIRCULATING BIOMARKERS OF BRAIN INJURY AND ENDOTHELIAL ACTIVATION

Cesc Bertran Cobo[1], Elin Dumont[1], Naqib Rafieqin Noordin[2], Meng-Yee Lai[2], William Stone[1], Kevin Tetteh[1], Chris Drakeley[1], Sanjeev Krishna[3], Yee-Ling Lau[2], Samuel C. Wassmer[1]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]Universiti Malaya, Kuala Lumpur, Malaysia, [3]St George's University of London, London, United Kingdom

Introduction: Malaria remains a major public health concern with substantial morbidity and mortality worldwide. In Malaysia, the emergence of *Plasmodium knowlesi* has led to a surge in zoonotic malaria cases and deaths in recent years. Signs of cerebral involvement have been observed in a non-comatose, fatal case of severe *knowlesi* infection, but the potential impact of this malaria species on the brain remains underexplored.
To address this gap, we investigated circulating levels of brain injury, inflammation, and vascular biomarkers in a cohort of *knowlesi*-infected patients and controls.
Methods: Archived plasma samples from 19 patients with confirmed symptomatic *knowlesi* infection and 19 healthy, age-matched controls from Peninsular Malaysia were analysed. A total of 52 plasma biomarkers of brain injury, inflammation, and vascular activation were measured using Luminex and SIMOA assays. Wilcoxon tests were used to examine group differences, and biomarker profiles were explored through hierarchical clustering heatmap analysis.
Results: Bonferroni-corrected analyses revealed significantly elevated brain injury biomarker levels in *knowlesi*-infected patients, including S100B (p<0.0001), Tau (p=0.0007), UCH-L1 (p<0.0001), αSyn (p<0.0001), Park7 (p=0.0006), NRGN (p=0.0022), and TDP-43 (p=0.005). Compared to controls, levels were lower in the infected group for BDNF (p<0.0001), CaBD (p<0.0001), CNTN1 (p<0.0001), NCAM-1 (p<0.0001), GFAP (p=0.0013), and KLK6 (p=0.0126). Hierarchical clustering revealed distinct group profiles for circulating levels of brain injury and vascular activation biomarkers.
Conclusions: Our findings highlight for the first time the impact of *Plasmodium knowlesi* infection on the brain, with distinct alterations in cerebral injury and endothelial activation biomarker profiles compared to healthy controls. Further studies are warranted to investigate the pathophysiology and clinical significance of these altered surrogate markers, through both neuroimaging and long-term neurocognitive assessments.

About 80% of malaria-related deaths in the World Health Organization African region occur in children <5 years, who develop severe malarial anemia [SMA, hemoglobin (Hb)<6.0 g/dL] as the primary clinical manifestation of severe malaria. However, differential expression of *Plasmodium falciparum* genes in SMA vs. non-SMA remains largely unexplored. As such, we characterized the entire *P. falciparum* transcriptome in peripheral blood obtained from children (3-36 months) with non-SMA (Hb≥6.0 g/dL, n=40) and SMA (n=20) at enrollment. Next-generation sequencing was performed at a depth of >20 million high-quality mappable reads. Reads were mapped to a Kenyan isolate (*pf*KE01) reference genome using the HTSeq platform, revealing 3,155 *P. falciparum* mRNA transcripts. Expression levels of 566 genes were significantly ($p \leq 0.05$) altered in SMA (499 up- and 67 down-regulated). Principle component analysis revealed that the first two principal components explained 72.9% of the variance. Gene expression deconvolution analysis showed a higher proportion of trophozoites ($p=0.028$) and a lower proportion of ring stages ($p=0.008$) in SMA, but comparable proportions of schizont and gametocyte stages between SMA and non-SMA. Notably, the male gametocyte proportion was higher than the female gametocyte proportion across all malaria patients ($p=1.000E-6$). Weighted gene co-expression network analysis of the 566 differentially expressed genes identified five modules enriched in the following functional terms: molecular function-threonine-type endopeptidase activity ($p=3.780E-5$); biological process- proteasomal ubiquitin-independent protein catabolic process ($p=4.780E-6$); cellular component- proteosome complex ($p=1.710E-12$), and KEGG-proteasome ($p=6.060E-8$). This study provides the first transcriptional profile of blood-stage *P. falciparum* in children with SMA, highlighting the parasite's reliance on proteasome-mediated protein degradation pathways for survival within the host and suggesting potential targets for therapeutics.

7277

PROBING THE RELATIONSHIPS BETWEEN COAGULATION, INFLAMMATION, AND OXIDATIVE STRESS IN PLACENTAL MALARIA PATHOGENESIS

Alicer K. Andrew[1], Demba Sarr[2], Brittany N. Russ[1], Nicole Nazario-Maldonado[1], **Stephen Mwalimu**[1], Julie M. Moore[1]

[1]University of Florida, Gainesville, FL, United States, [2]University of Georgia, Athens, GA, United States

Plasmodium falciparum infection in pregnancy contributes to poor birth outcomes via adherence of infected erythrocytes in the placenta, precipitating maternal responses that induce placental damage and dysfunction. This syndrome, termed placental malaria (PM), is characterized by placental oxidative stress and dysregulated inflammatory and coagulation responses, though the extent to which these responses are molecularly linked is unclear. Preliminary data in human PM identifies correlations between key markers of these processes, but do not prove causation. To pursue this question, a mouse model was utilized. *P. chabaudi* infection in *Tnf*$^{-/-}$ and endothelial tissue factor-deficient (*F3*$^{flox/flox}$ Tie-2^{Cre}) mice and ablation of tumor necrosis factor (Tnf) and anticoagulant treatment in mice infected with the rodent-infective parasite improved pregnancy outcomes. Relative to infected C57BL/6J (B6) controls, infected *Tnf*$^{-/-}$ mouse embryos showed two to four-fold reduced expression of protease activated receptor 2 (*F2rl1*), which links activated coagulation with inflammatory responses. Tissue factor (*F3*) expression was 50% reduced, while endothelial protein C receptor (*Procr*) transcripts increased three to five-fold, supporting the notion that coagulation and inflammation are co-regulated in PM, with reduced inflammation promoting natural anticoagulant function. With anti-coagulant drug treatment of the dam, transcripts for cytokines and chemokines (*Ifng, Tnf, Il10, Il1b,* and *Ccl2*), antioxidants (*Sod1*, *Sod2*, and *Nfe2l2*) and *F3* were significantly downregulated relative to sham-treated, infected B6 mice, whereas *Procr* transcripts were elevated. These results support the assertion that inflammation, coagulation and oxidative stress are functionally linked in PM pathogenesis, and suggest that targeting of one or more of these responses therapeutically may be broadly protective by disrupting all three pathogenic processes.

7278

REGULATED CELL DEATH IN PLACENTAL MALARIA: NECROPTOSIS ASSOCIATES WITH INFECTION AND INFANT BIRTH WEIGHT

Demba Sarr[1], **Ashish Shukla**[2], Brittany N. Russ[2], Stephen Mwalimu[2], Julie M. Moore[2]

[1]University of Georgia, Athens, GA, United States, [2]University of Florida, Gainesville, FL, United States

Placental damage and dysfunction are key features of malaria infection during pregnancy and associate with poor birth outcomes. Necrotic shedding of villous trophoblast is a key feature of placental malaria (PM), but the molecular basis for this outcome has not been explored. Toward this end, primary human trophoblast (PHT), villus explants and placenta from malaria-infected women and mice were used to assess markers of necroptosis by RT-qPCR, western blot, bead-based protein complex detection, and immunostaining. Receptor interacting protein kinase 3 (RIP3) and phosphorylated mixed lineage kinase domain-like protein (pMLKL), as well as RIP1/RIP3 necrosomal complexes, all indicators of activation and execution of necroptosis, were significantly higher in human placenta with PM. RIP3 levels in infected placenta inversely correlated with infant birth weight and positively correlated with placental hemozoin load. In contrast, while *in vitro* exposure of syncytialized PHT to hemozoin induced elevated transcripts for *RIPK1* and *RIPK3*, no RIP3 or pMLKL was detected in isolated cells. Furthermore, *in vitro* treatment of PHT with activators of necroptosis (tumor necrosis factor, cycloheximide and carbobenzoxy-valyl-alanyl-aspartyl-[O-methyl]-fluoromethylketone (Z-VAD)) failed to induce this cell death pathway, instead driving trophoblast apoptosis. Only treatment conditions that included the caspase inhibitor Z-VAD, which suppresses apoptosis, were able to restore PHT viability to control levels. Thus, under the *in vitro* conditions used in this study, PHT was resistant to necroptosis, yet, *in vivo*, this cell death pathway appears to play an important role in PM pathogenesis and associated poor birth outcome. Regulation of cell death pathways in the syncytiotrophoblast requires further investigation to establish critical triggers that can precipitate placental loss of function and pregnancy compromise in PM. Current work is assessing this cell death pathway in placental tissue explants which more accurately model the native physiological and architectural context of the syncytiotrophoblast.

7279

THE RELATIONSHIP BETWEEN PLACENTAL MALARIA INFECTION, HIV, INTESTINAL PERMEABILITY, AND INFLAMMATION IN POST-PARTUM KENYAN WOMEN

Brittany N. Russ, Marie Rivera, Simon O. Owino, Julie M. Moore

University of Florida, Gainesville, FL, United States

Placental malaria, which compromises maternal health and causes poor infant health outcomes in association with *Plasmodium falciparum* infection, has long been associated with intense and damaging inflammatory responses in the maternal peripheral and placental blood. HIV infection further exacerbates these outcomes. Maternal responses to these infections lead to significant placental dysfunction, but how they impact other organ systems in pregnant women has been less well studied. The aim of this study was to determine the relationships between placental malaria (PM), HIV serostatus, markers for intestinal permeability (lipopolysaccharide (LPS), LPS-binding protein (LBP), and zonulin), and markers of inflammation (interleukin-6 (IL-6), IL-8, IL-10, Tumor Necrosis Factor (TNF), TNF receptor II (TNFRII), and interferon γ-induced protein 10 (IP-10)) in post-partum women exposed to malaria and HIV in Kenya. Clinical and diagnostic parameters (i.e., infection status, self-reported maternal health pre-partum, and infant outcomes), as well as levels of these biomarkers in the peripheral venous blood (measured by ELISA), were analyzed. LPS and zonulin levels weakly to moderately positively correlated with placental parasite load, and

zonulin was significantly elevated with PM and PM/HIV co-infection as well as self-reported recent malaria infection. LPS was elevated in women with low birth weight infants relative to normal birth weight infants, and positively correlated with markers of inflammation (TNF, IL-6, IL-8, IL-10, and IP-10). These data suggest that infection-associated inflammatory cytokine and chemokine responses coincide with induction of gut permeability in pregnant women, and may synergize to exacerbate poor maternal and infant outcomes. Future investigations to establish the causal relationships between these responses in malaria and HIV infected women could reveal potential new targets for diagnostics and therapeutic intervention.

BIOCHEMICAL AND BIOINFORMATIC CHARACTERISATION OF UNDERSTUDIED ERYTHROCYTE SURFACE EXPRESSED HYPERVARIABLE PROTEIN FAMILIES IN PLASMODIUM FALCIPARUM

Hristina Vasileva

London School of Hygiene and Tropical Medicine, London, United Kingdom

Title: BIOCHEMICAL AND BIOINFORMATIC CHARACTERISATION OF UNDERSTUDIED ERYTHROCYTE SURFACE EXPRESSED HYPERVARIABLE PROTEIN FAMILIES IN *PLASMODIUM FALCIPARUM.* **Abstract:**Malaria, is a vector borne disease, caused by infection with Plasmodium species, responsible for approximately 608 thousand deaths and 249 million cases worldwide in 2022, with 94% cases in sub-Saharan Africa, the majority caused by infection with Plasmodium falciparum (Pf). Parasite virulence is partly caused by evasion of the human host immune system during the blood stage of infection. Sequestration and cytoadherence are characteristic Pf virulence factors, enabled by parasite-derived proteins expressed on the surface of infected erythrocytes (IEs). These proteins are associated with acquired immunity to Pf and with antigenic variability also called Variant Surface Antigens (VSAs). VSAs are translocated from blood stage Pf to be expressed on the surface of the IE membrane. STEVOR is a VSA protein family encoded 40 stevor gene copies per parasite, expressing single variant per parasite. Members of the family differ mostly in their hypervariable region, which is exposed to the circulation and possesses antigenic epitopes. The variable domain is associated with P. falciparum exposure and potentially clinical outcome. Seroreactivity and recognition to the variants are age and exposure dependent, with higher reactivity in adults and higher domain recognition in individuals with clinical disease. This study demonstrates successful expression of isolated domains of STEVOR proteins as recombinant proteins, characterizes their antigenicity and expands understanding of the Pf proteome. By developing specific in-silico model, this study characterizes STEVOR variants into clusters for the selection and subsequent development of a library of variants to explore the breath of antibody responses to the library in various Sub-Saharan African populations, characterized with different malaria endemicity levels.

PRECARIOUS SECURITY CONTEXT AND ADAPTATIVE METHODS TO IMPLEMENT SEASONAL MALARIA CHEMOPREVENTION (SMC) IN BURKINA FASO

Moumouni Bonkoungou[1], Ousmane Badolo[1], Frederic Guigma[1], Francine Ouedraogo[1], Edward Kenyi[2], Andre Kone[1], Lolade Oseni[2], Sidzabda KOMPAORE[3], Martine Balima[1], Amsetou Ouiya[1], Justin Tiendrebeogo[1], Sayouba Sebgo[1], Mame Birame DIOUF[4], Irène Yaméogo Ngendakumana[4], Gladys Tetteh[2]

[1]U.S. President's Malaria Initiative, IHS Project, Ouagadougou, Burkina Faso, [2]Jhpiego, Baltimore, MD, United States, [3]Secretariat Permanent pour l 'Elimination du Paludisme (SP/Palu), Ministry of Health, Ouagadougou, Burkina Faso, [4]U.S. President's Malaria Initiative, United States Agency for International Development, Ouagadougou, Burkina Faso

Burkina Faso's Permanent Secretariat for Malaria Elimination, SP/Palu, has been organizing Seasonal Malaria Chemoprevention (SMC) campaigns since 2014 to prevent malaria illness and deaths in children under five years during the rainy season. SMC treatments are administered by community distributors (CDs) through door-to-door visits and at fixed distribution points at health facilities. The USAID-funded Integrated Health Services (IHS) project supports SMC distribution in 19 districts in 3 regions. Since 2015, the country has been contending with insecurity, leading to a surge of internally displaced persons (IDPs), many of them children. This has implemented SMC a challenge in many areas, including 16 out of 19 IHS-supported districts. In addition, during the 2023 SMC campaign, 37 of 598 health facilities in these districts were closed, and affected health and community workers relocated. To ensure that all eligible children receive treatments, the IHS project adapted its SMC interventions to facilitate the reach of eligible targets. This included introducing a "tick card" for children at IDP sites, training additional CDs, increasing the number of CD trainers, selecting an IDP to raise awareness with the public crier jointly, and verifying insecticide-treated net availability in affected districts. 16 IDP sites were encountered in IHS-supported districts during the 2023 SMC campaign. 5,957 internally displaced children were treated during cycle 0 (7 districts) and 26,944 during cycle 4 (19 districts). IDPs reached with SMC in IHS-supported districts represented 9% of IDP children who benefitted from SMC nationwide; children benefiting from SMC in HIS area represent 21% of all children treated in the country. In IDP sites, challenges encountered included difficult access to some IDP sites, inadequate communication between CDs and households, and a lack of data to estimate the number of children at IDP sites for planning and drug quantification. Coverage isn't ensured, but substantial efforts are being made to reach vulnerable and displaced populations.

7282

PERFORMANCE OF A NEW COMMUNITY HEALTH POLICY IN BENIN FOR DISTRIBUTING INSECTICIDE-TREATED NETS: EXPERIENCE OF 2023 MASS CAMPAIGN

Rock Aikpon[1], Achille Batonon[1], Cyriaque Affoukou[1], Virgile Gnanguenon[2], Catherine Dentinger[3], Daniel Impoinvil[3], Gil Padonou[4], Martin Akogbéto[4]

[1]Ministry of Health Benin/ National Malaria Control Program, Cotonou, Benin, [2]U.S. President's Malaria Initiative (PMI), U.S. Agency for International Development (USAID), Cotonou, Benin, [3]U.S. President's Malaria Initiative (PMI), U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, [4]Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

The national insecticide-treated bed net (ITN) policy in Benin is universal coverage of 1 ITN for 2 people per household. Benin recently adopted a community health policy in which paid community health workers (*Relais Communautaire*, [RC]) deliver a package of non-clinical interventions to their communities. For the 2023 campaign, RCs conducted door-to-door ITN distribution (Community-based approach [CBA]) to about 200 households (HH) as part of their routine work. We compared CBA distribution with traditional distribution (Employee-based approach [EBA]), in which employees are hired to distribute ITNs at fixed points in villages. Both approaches included training for HH enumeration, and ITN distribution using the RedRose digital platform (RCs had work smartphones, hired staff were lent smartphones). The data collected included HH location and the number of residents by age while the RedRose application generated HH ITN targets. The ITN coverage (ITNs delivered/HH ITN targets) from the six CBA and eight EBA districts was compared using a Chi-square test in R Studio. ITN coverage was significantly higher in CBA compared with EBA districts (98% [373,706/381,247] vs. 92% [436,548/473,884]; $p<0.05$) though the CBA required more distribution days than EBA (8-15 vs. 4 days, respectively). CBA HHs benefited from individual messages regarding ITN use and maintenance rather than group messaging at EBA delivery sites. CBA did not require additional labor costs for distribution as these were incorporated into RC salaries. ITN distribution coverage was higher using door-to-door CBA delivery vs traditional fixed-point EBA delivery. Additional evaluations of the two systems will help to determine future delivery modes.

EVALUATION OF SEASONAL MALARIA CHEMOPREVENTION IMPLEMENTATION IN THE UPPER EAST REGION OF NORTHERN GHANA

Emmanuel Yidana Ayamba[1], Emmanuel K. Dzotsi[2], William Dormechele[1], Nana A. Ansah[1], Oscar Bangre[1], Josephat A. Nyuzaghl[2], Sydney A. Abilba[2], Samuel K. Boakye-Boateng[2], Patrick O. Ansah[1]

[1]Navrongo Health Research Centre, Navrongo, Ghana, [2]Regional Health Directorate, Upper East, Ghana

AbstractGhana adopted the WHO-recommended Seasonal Malaria Chemoprevention (SMC) in 2016 following a pilot study as a vital strategy for malaria control. This study monitored the implementation of SMC to ensure the intervention is achieving its target.We conducted a prospective longitudinal study in four administrative districts of the Upper East Region of Ghana. Children aged between 3 and 59 months were sampled and followed up one week after each cycle of SMC dosing to complete a questionnaire. SMC status was determined through the caregiver's report and child welfare cards, if available. Caregivers were asked if the participant had been treated for malaria since the last cycle. Simple and multiple logistic regressions were employed to determine associations between SMC adherence and the independent variables, with all results interpreted at a 95 % confidence level (CI).A total of 2099 participants were enrolled in this study. This study reported an average SMC coverage of 87% (CI: 86.7-89.5) per cycle with a 2% dropout after the first cycle. SMC adherence rate remained above 82% (CI: 1.4-2.5), with malaria incidence decreasing in those who received all four doses of SMC compared to partial recipients. The main reasons reported for non-adherence were the participant not available/in school (74%), caregiver refusal (14%), and forgetfulness (5%). Significant predictors of adherence were household size (aOR=1.04, 95% CI: 1.01-1.08), sleeping under bednets (aOR=1.88, 95% CI: 1.44-2.48), and indoor residual spraying (IRS) presence (aOR= 0.83, 95% CI: 0.69-1.99). Despite achieving an average coverage of 87% per cycle, it falls short of the national target of 90%. Notable reasons for drop-outs and non-adherence were, the caregiver being unavailable
during the distribution, highlighting the need for diversified approaches in SMC campaigns to enhance coverage and adherence, and maximize intervention benefits.

LOCALIZATION IN ACTION: TRANSITIONING INDOOR RESIDUAL SPRAYING MANAGEMENT TO HOST COUNTRY GOVERNMENT IN ANKAZOABO DISTRICT, ATSIMO ANDREFANA REGION, MADAGASCAR, 2023

RAMANDIMBIARIJAONA Herizo

NMCP Madagascar, Antananarivo, Madagascar

Localization in action: Transitioning indoor residual spraying management to host country government in Ankazoabo District, Atsimo Andrefana Region, Madagascar, 2023

[1]Herizo Ramandimbiarijaona, [1]Hasina Harinjaka Ramiandrisoa, [2]Jean-Desire Rakotoson, [2]Ndombour Gning Cissé, [2]Mauricette Nambinisoa Andriamananjara, [3]Anna Bowen, [4]Laurent Kapesa, [4]Jocelyn Razafindrakoto, [4]Jemima Andriamihamina, [5]Lehimasy Emihangy, [5]Ntsolo Samuel, [1]Omega Raobela, [1]National Malaria Program, Antananarivo, Madagascar[2]PMI Evolve Project, Abt Associates, Antananarivo, Madagascar [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Antananarivo, Madagascar, [4]U.S. President's Malaria Initiative, USAID, Antananarivo, Madagascar, [5]Ministry of Public Health, Madagascar

ABSTRACT

As part of PMI's approach to promoting shifting power to local actors, PMI Evolve is committed to strengthening capacity of the national malaria program (NMP) to manage indoor residual spraying (IRS) operations while promoting gender equality, social inclusion and climate change mitigation. For the 2023 spray campaign, after a memorandum of understanding was signed between NMP and PMI Evolve to delineate the roles and responsibilities of both parties and ensure standardized procedures across different phases of IRS operations, the NMP led all stages of IRS implementation in Ankazoabo Sud district. NMP and district health services coordinated and monitored IRS implementation, trained actors, handled logistics and environmental compliance and provided trainings. PMI Evolve provided technical guidance to NMP, procured spray materials, funded expenses and supported NMP in national results dissemination. The intervention covered 20,613 structures (93.8% of structures found), and 85,385 people. With support from local, district and regional health systems, NMP successfully coordinated and planned activities, managed staffing, and social mobilizations through community meetings. Along with the district health team, NMP and PMI Evolve will prioritize IRS implementation sustainability plan and preparation for 2024.

7285

SEASONAL MALARIA CHEMOPREVENTION IN NORTHERN MOZAMBIQUE: A COST-EFFECTIVENESS ANALYSIS

Neide Canana[1], Baltazar Candrinho[2], Albertino Zunza[1], Maria Rodrigues[1], Sonia Enosse[1], Kevin Backer[3], Ivan Alejandro Pulido Tarquino[1], **Elisa Maffioli**[4]

[1]Malaria Consortium, Maputo, Mozambique, [2]Ministry of Health, Maputo, Mozambique, [3]Malaria Consortium, London, United Kingdom, [4]University of Michigan, Ann Arbor, MI, United States

Malaria is endemic in Mozambique and one of the leading causes of death in children under five years old. In 2020 the country adopted the WHO-recommended Seasonal Malaria Chemoprevention (SMC) strategy, and started delivering the intervention in 2, 4 and then all 23 districts of Nampula province by 2023. The aim of this study was to estimate the cost-effectiveness of SMC in Nampula, Mozambique. Costs were analyzed from a health care provider perspective and reported in 2023 US$. Data on resource use were collected from intervention records by the Malaria Consortium, data on the beneficiaries were collected from surveys after Cycle 4, and malaria cases and deaths averted by SMC were estimated based on prevalence data obtained from available data sources, e.g., Global Burden of Disease 2019 and the Malaria Incidence Survey 2018. Incremental cost-effectiveness ratios (ICERs) were estimated by round, for the three rounds conducted between 2020 and 2023, and sensitivity analyses were conducted to test the robustness of the ICERs. We found that the total financial cost of SMC in Mozambique was US$ 8,994,226.90 (2023) for three rounds implemented between 2020 and 2023. We estimated a cost per targeted child of $5.99; a cost per household with eligible children visited by a community distributor at $7.00; a cost per child who received day 1 SPAQ at $7.37; a cost per child who received day 1 SPAQ by community distributor adhering to DOT at $7.73; and a cost per child who received 3 full-day course SPAQ at $7.49. In addition, we estimated a cost per malaria case averted at $27.20, and a cost per malaria death averted at $3,107.97. Cost-effectiveness was higher in round three, suggesting substantial economies of scale. The ICERs were robust to a variety of alternative assumptions on benefit estimates as well as discounting rate. Finally, we found that $1,670,827.55 could have been saved if the program did not include ineligible children (60-119 months old). In line with existing evidence from other African countries, SMC is cost-effective in Mozambique: SMC is a beneficial prevention strategy to improve under-five health in the country, at a relatively low-cost.

7286

ACCEPTABILITY OF A SCREENING AND TREATMENT STRATEGY TO THE POPULATION AS PART OF STRENGTHENING THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION IN BURKINA FASO

Kadija OUEDRAOGO[1], Fadima Bocoum[2], Chantal fifi Kouevi[1], Solange Traoré[1], Elisée Kambou[1], Bérenger Kaboré[1], Toussaints Rouamba[1], Paul Sondo[1], Halidou Tinto[1]

[1]Clinical Research Unit of Nanoro, OUAGADOUGOU, Burkina Faso, [2]Institut de Recherche en Sciences de la Santé, OUAGADOUGOU, Burkina Faso

Population screening and treatment strategies are now making considerable headway in the fight against malaria. In order to improve the effectiveness of seasonal malaria chemoprevention **(**SMC), which has been recommended since 2014 for the prevention of malaria in children, the SMC-RST project has been implemented in Burkina Faso. This project consists of screening and simultaneous treatment of roommates of children under SMC coverage. This study aims at determine the social, cultural and behavioural factors that facilitate or hinder adoption and adherence to the newly added antimalarial treatment. We conducted a qualitative study of 41 roommates, 5 health care workers, 5 field workers between October 2022 to January 2023 using purposive sampling in 5 rural villages in the Health District of Nanoro. Data collection combined in-depth interviews and observations of interactions between housemates and data collectors. Interviews were conduct in local language audio recorded and transcribed. Data were coded and a thematic analysis was carried out using QSR N'vivo 12 software. Our findings reveal good acceptability of this new screening and simultaneous treatment intervention for roommates of children with SMC coverage. Indeed, participants perceive an improvement in the health of children under 5 years of age under SMC coverage through the intervention. They appreciate the fact that they can be screened and treated at home, free of charge, and that they can prevent illness or treat themselves before it gets worse. Health care workers mentioned that they received fewer consultations from children under 5 since the start of the intervention, despite the fact that this is a time of high malaria rates. Overall, the study had a positive impact on the health of children under 5 and their housemates. It demonstrated a positive perception of simultaneous screening and treatment of roommates of children under SMC coverage.

7287

LEVERAGING PERENNIAL MALARIA CHEMOPREVENTION (PMC) PILOT IMPLEMENTATION TO PAVE THE WAY FOR PMC AND MALARIA VACCINE CO-IMPLEMENTATION IN THE DEMOCRATIC REPUBLIC OF CONGO

Aline Maliwani[1], Mvuama Mazangama[2], Nono Koka[3], Packy Mukanya[1], Jicko Bondole[2], Gloire Mbaka Onya[2], Rova Ratsimandisa[2], Michael Hainsworth[4], Arantxa Roca Feltrer[5], Caterina Guinovart[6], Eric Mukomena[1], Henry Ntuku[7]

[1]National Malaria Control Program, Kinshasa, Congo, Democratic Republic of the, [2]PATH, Kinshasa, Congo, Democratic Republic of the, [3]Provincial Malaria Control Program, Kongo Centrale, Congo, Democratic Republic of the, [4]PATH, Seattle, WA, United States, [5]PATH, Maputo, Mozambique, [6]The Barcelona Institute for Global Health, Barcelona, Spain, [7]PATH, Geneva, Switzerland

The World Health Organization recommends both PMC and malaria vaccine for the prevention of Plasmodium falciparum malaria in children in areas of moderate to high malaria transmission. Although the funding sources are currently different (i.e. through the malaria program and immunization program), these two interventions are recommended to be delivered through the same EPI platform and target the same age group. Furthermore, the rollout phase involves similar steps, including the establishment of coordination mechanisms between the malaria program and EPI, the development of an optimal delivery schedule, the modification of national Health Information Management System (HIMS) tools, and the development of a community engagement plan to ensure uptake. The DRC recently introduced PMC with rollout starting in December 2023. The country has opted for a six-contact model administering Sulfadoxine-Pyrimethamine (SP) at 10 and 14 weeks of age, 6, 9, 12 and 15 months. The country has also been approved by Gavi to receive support for initial subnational malaria vaccine introduction, with a four-dose schedule at 6,7,9 and 24 months. As the service provision is integrated at the point of delivery (i.e. health facility), meaning the same healthcare provider will deliver both PMC and malaria vaccine, an approach leveraging PMC introduction to prepare for malaria vaccine rollout was taken. Hence, the coordination mechanism created to co-develop the PMC schedule was leveraged for vaccine introduction. The coordination platform includes the Malaria Program, EPI, Nutrition Program (NNP), Health Promotion and Communication Program, HMIS department, National Program to fight Cholera and Diarrheal Diseases, the National Supply Chain for Essential Drugs, and implementing partners. During PMC introduction, through an inclusive and consensual decision-making process, all normative documents and HMIS data collection and reporting tools updated to capture PMC data incorporated aspects related to malaria vaccine. These include the vaccination register, the tally sheet, the child vaccination card as well as the national DHIS2 platform.

7288

ACCEPTABILITY OF INTEGRATING NOVEL MALARIA PREVENTION TOOLS INTO ROUTINE IMMUNIZATION VISITS IN CAMEROON

Mauricio J. Kahn[1], Emmanuel Nfor[2], Mallie Froehlich[3], Kristin Banek[4], Anjali Dudhat[3], Gitanjali Alapati[3], Rahel Mbah[2], Mac DeLay[3], Patrick Kachur[5], Wilfred Mbacham[6], Jodie A. Dionne[1], Katia Bruxvoort[3]

[1]Division of Infectious Diseases, Department of Medicine, University of Alabama at Birmingham, Birmingham, AL, United States, [2]Malaria Control Program, Cameroon Baptist Convention Health Services, Bamenda, Cameroon, [3]Department of Epidemiology, School of Public Health, University of Alabama at Birmingham, Birmingham, AL, United States, [4]Institute for Global Health and Infectious Diseases, University of North Carolina, Chapel Hill, NC, United States, [5]Heilbrunn Department of Population and Family Health, Columbia University Mailman School of Public Health, New York, NY, United States, [6]Fobang Institutes for Innovations in Science and Technology, Yaounde, Cameroon

Cameroon is among the 11 countries with the highest malaria burden worldwide. In the past year, Cameroon began implementing the RTS,S/AS01 malaria vaccine and perennial malaria chemoprevention (PMC) for children <24 months of age. We conducted a 2-phase health facility cross-sectional study (Nov-Dec 2023 dry season and April-June 2024 rainy season) to examine vaccine acceptability and PMC uptake through routine immunization services at Cameroon Baptist Convention Health Services (CBCHS). We selected 7 CBCHS clinics in 5 regions in Cameroon with varying malaria prevalence. Caregivers of children presenting for immunizations were randomly selected for a brief survey. In the dry season phase, we surveyed 353 caregivers: median age 29 years (IQR 25-32), 96.6% female, 64% with at least secondary education; 84% reported the child slept under a mosquito net the night before, and 11% reported that the child had fever/malaria in the prior 2 weeks. Only 47% of caregivers knew of the malaria vaccine, and 91% said they would accept it for their child at CBCHS. However, 33% expressed concerns about the vaccine: fear of side effects (23%), uncertain about safety (9%), possible interaction with other vaccines (7%), uncertain of efficacy (7%), other (13%). 23% said ≥1 neighbor would not accept the vaccine. A higher proportion (76%) had heard of PMC ("Fansidar for infants"), and 50% reported that their child had received ≥1 dose. Few caregivers expressed concerns about PMC. In multivariable logistic regression, caregivers in the highest vs lowest wealth quartile were less likely to be willing to accept malaria vaccine (OR 0.08 [95% CI: 0.01-0.78]). Having fever/malaria in the prior 2 weeks was associated with not expressing concerns about the vaccine (OR 2.89 [1.10-7.57]). The rainy season survey and dried blood spot analyses are ongoing. Integration of malaria vaccine and PMC into routine immunization visits is acceptable to caregivers of young children attending CBCHS, although

continued efforts are needed to increase confidence in these interventions. Alternative strategies are needed to reach those who do not regularly attend routine immunization visits.

IMPACT ON PREGNANCY OUTCOMES OF INTERMITTENT PREVENTIVE TREATMENT WITH SULPHADOXINE-PYRIMETHAMINE IN URBAN AND PERI-URBAN PAPUA NEW GUINEA - A RETROSPECTIVE COHORT STUDY.

Holger Unger[1], Philip Cellich[2], Stephen J. Rogerson[3], Glen DL Mola[2]

[1]Menzies School of Health Research, Darwin, Australia, [2]Division of Obstetrics and Gynaecology, Port Moresby General Hospital, Port Moresby, Papua New Guinea, [3]University of Melbourne, Melbourne, Australia

Background Intermittent preventive treatment in pregnancy with sulphadoxine-pyrimethamine (IPTp-SP) prevents low birth weight (<2,500 g) and other adverse pregnancy outcomes through malaria and non-malarial mechanisms. Malaria transmission in Papua New Guinea (PNG) is highly heterogeneous. The impact of IPTp-SP in settings with little or no malaria transmission, such as the capital Port Moresby, is unknown.
Methods A retrospective cohort study was conducted amongst HIV-negative women with a singleton pregnancy who delivered at Port Moresby General Hospital between 18 July and 21 August 2022. The impact of IPTp-SP doses on adverse birth outcomes and anaemia was assessed using logistic and linear regression models, as appropriate.
Results Of 1,140 eligible women amongst 1,228 consecutive births, 1,110 had a live birth with a documented birth weight. A total of 156 women (13.7%) did not receive any IPTp-SP, 347 women (30.4%) received one, 333 (29.2%) received two, and 304 (26.7%) received the recommended ≥3 doses of IPTp-SP. A total of 65 of 1,110 liveborn babies (5.9%) had low birth weight and there were 34 perinatal deaths (3.0%). Anaemia (haemoglobin <100 g/L) was observed in 30.6% (243/793) of women, and 14 (1.2%) had clinical malaria in pregnancy. Compared to women receiving 0-1 dose of IPTp-SP, women receiving ≥2 doses had lower odds of LBW (adjusted odds ratio [aOR] 0.50; 95% confidence interval [CI] 0.26, 0.96), preterm birth (aOR 0.58; 95%CI 0.32, 1.04), perinatal death (aOR 0.49; 95%CI 0.18, 1.38), LBW/perinatal death (aOR 0.55; 95%CI 0.27, 1.12), and anaemia (OR 0.50; 95%CI 0.36, 0.69). Women who received 2 doses versus 0-1 had 45% lower odds of LBW (aOR 0.55, 95%CI 0.27, 1.10), and a 16% further (total 61%) reduction with ≥3 doses (aOR 0.39, 95%CI 0.14, 1.05). Birth weights for women who received 2 or ≥3 doses versus 0-1 were 81 g (95%CI -3, 166) higher, and 151 g (58, 246) higher, respectively.
Conclusions Provision of IPTp-SP in a low malaria-transmission setting in PNG appears to translate into substantial health benefits, in a dose-response manner, supporting the strengthening IPTp-SP uptake across all transmission settings in PNG.

7290

A RANDOMIZED CONTROLLED TRIAL OF DIHYDROARTEMISININE PIPERAQUINE FOR SEASONAL MALARIA CHEMOPREVENTION IN CHILDREN UNDER 10 YEARS OLD IN KOULIKORO, MALI

Mahamoudou Toure[1], Soumba Keita[1], Moussa Keita[2], Ibrahim Sanogo[1], Daouda Sanogo[1], Fousseyni Kane[1], Hamady Coulibaly[1], Mountaga Diallo[1], Bourama Traore[1], Dejeneba Dabitao[1], Sekou Amadou Traore[1], Cheick Oumar Tangara[1], Sidi Niare[3], Mariam Tall[4], Aissata Kone[5], Mahamadou H Magassa[5], Nafomon Sogoba[6], Mahamadou Diakite[1], Jeffrey G. Shaffer[7], Seydou Doumbia[1]

[1]Universty Clinical Research Center (UCRC), Bamako, Mali, [2]Malaria Research and Training Center (MRTC), Bamako, Mali, [3]Koulikoro District Health Center, Koulikoro, Mali, [4]Catholic Relief Services, Bamako, Mali, [5]National Malaria Control Program, Bamako, Mali, [6]Malaria research and Training Center, Bamako, Mali, [7]Tulane University, New Orleans, LA, United States

Seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine-amodiaquine (SP-AQ) was recommended by the Word Health Organization (WHO) in 2012 for children under five year-old living in highly seasonal malaria transmission areas. Efficient SMC implementation has been met with challenges with treatment compliance and adverse drug effects. Also, increasing resistance markers among *Plasmodium falciparum (P.f)* to both SP and AQ in these countries require more attention when scaling up SMC for malaria elimination initiatives. This study aimed to assess the effectiveness of Dihydroartemisinine-piperaquine (DHA-PQ) as an alternative to the standard regimen for SMC while extending the age limit to up to 9 years. In 2019 and 2020, six villages within the health district of Koulikoro, Mali were cluster-randomized to receive either SP-AQ or DHA-PQ. The primary outcome was malaria incidence, defined as the presence of fever plus a positive malaria rapid diagnostic test. Cross-sectional surveys were used to determine the effect of each treatment regimen on asymptomatic malaria and anemia at the start and the end of the SMC campaign in each cohort. Adverse side effects, and compliance to treatment were assessed through monthly household survey. Over 95% of children received the first dose of SMC treatment under direct observation in both study arms, and about 71.5% (SP-AQ arm) and 82.0% (DHA-PQ arm) received 3 to 4 rounds of SMC yearly. Nausea (OR: 0.37, 95% CI: 0.29–0.47]) was the most frequent SAE reported and more frequent in the SP-AQ arm. Asymptomatic *P.f* prevalence decreased by 18% (95% CI: 0.66–1.97) in the SP-AQ arm versus 26% (95% CI: 0.57–0.94) in the DHA-PQ arm. DHA-PQ was associated with reduced the risk of malaria disease over SP-AQ by 49% (incidence risk ratio [IRR]: 0.51, 95% CI: 0.46–0.55). Our findings show that both treatment regimens are highly effective among children between under 10 years-old with more advantages for DHA-PQ such as fewer side effects, and significant reduction in both asymptomatic infection carriage and incidence. The findings are relevant to countries were SMC with SP-AQ has shown high impact on malaria burden.

7291

EVALUATION OF CLOTHIANIDIN INDOOR RESIDUAL SPRAYING (IRS) AND PIPERONYL BUTOXIDE (PBO) INSECTICIDE-TREATED NET (ITN) CO-DEPLOYMENT COMPARED TO PBO ITNS ONLY USING HEALTH MANAGEMENT INFORMATION SYSTEM DATA IN SIERRA LEONE, 2017-2023

Natalie C. Galles[1], Frederick Yamba[2], Musa Sillah-Kanu[2], Kevin Opondo[3], Yemane Yihdego[4], Evelyne Alyko[3], David Schnabel[5], Rebecca S. Levine[6], Jenny Carlson Donnelly[7], Celeste Carr[8], Tony Hughes[9], Isabel Swamidoss[6], Ramlat Jose[8], Laurent Iyikirenga[3], Djenam Jacob[4], Dennis Marke[2], Ronald Carshon-Marsh[2], Samuel Juana Smith[2], Mac-Abdul Falama[2], Sarah Burnett[10]

[1]PMI Evolve Project, PATH, Seattle, WA, United States, [2]National Malaria Control Program, Freetown, Sierra Leone, [3]PMI Evolve Project, Abt Associates, Freetown, Sierra Leone, [4]PMI Evolve Project, Abt Associates, Rockville, MD, United States, [5]U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Freetown, Sierra Leone, [6]Centers for Disease Control and Prevention, Atlanta, GA, United States, [7]U.S. President's Malaria Initiative, USAID, Washington, DC, United States, [8]U.S. President's Malaria Initiative, USAID, Freetown, Sierra Leone, [9]Navy and Marine Corps Force Health Protection Command, Centers for Disease Control and Prevention Detachment, Freetown, Sierra Leone, [10]PMI Evolve Project, PATH, Washington, DC, United States

Indoor residual spraying (IRS) and pyrethroid/piperonyl-butoxide (PBO) insecticide-treated nets (ITNs) are proven malaria vector control tools; however, the impact of their combined use is not well studied. To combat increasing insecticide resistance and high malaria burden, the Sierra Leone National Malaria Control Program conducted a mass distribution of PBO ITNs between May-June 2020. Clothianidin-based (CTD) IRS was co-deployed in Bo and Bombali districts between May-June 2021 and 2022. Using an observational study design, six years of routinely reported Health Information System data (May 2017-April 2023) and 20 months of vector density data (July-April from 2020-2022) were evaluated to estimate the epidemiological and entomological impact of IRS and PBO ITN co-deployment in Bo and Bombali compared to PBO ITNs alone in two control districts, Karene and Port Loko. Negative binomial mixed effects modeling frameworks were used to independently estimate confirmed malaria case

incidence, human biting rate (HBR), and indoor resting density (IRD) over time. In both intervention groups, there were significant post-intervention declines in confirmed case incidence compared to baseline (IRS + PBO ITNs: -43.4% [95% credible interval (CI): -44.5%, -42.4%]; PBO ITNs only: -41.9% [95% CI: -43.0%, -40.8%]). However, there was no significant difference in confirmed case incidence overall between areas that received co-deployment or PBO ITNs alone (-1.5% [95% CI: -3.6%, 0.5%]). Only during the third year post-PBO ITN distribution did the co-deployment areas observe greater reductions in confirmed case incidence (2.7% [95% CI: 0.2%, 5.2%]). Co-deployment was also associated with a 10% greater reduction in HBR (IRR: 0.90, 95% CI: 0.82-0.99, p-value: 0.04) but no significant difference in IRD (IRR: 0.95, 95% CI: 0.75-1.21, p-value: 0.68). These results leveraging routine data sources could suggest that PBO ITNs may not be providing sufficient protection for their intended duration, but IRS may provide some protection.

7292

SUB-NATIONAL AND SUB-ANNUAL COVERAGE OF SEASONAL MALARIA CHEMOPREVENTION IN AFRICA 2012-2023

Adam Saddler[1], Samuel K. Oppong[1], Susan F. Rumisha[2], Alioune Camara[3], Christian Rassi[4], Chuks Nnaji[4], Paul Milligan[5], Tasmin L. Symons[1], Peter W. Gething[1], **Daniel J. Weiss**[6]

[1]Telethon Kids institute, Nedlands, Australia, [2]Ifakara Health Institute, Dar es Salaam, Tanzania, United Republic of, [3]Programme National de la Lutte contre le Paludisme, Ministère de la Santé et de l'Hygiène Publique, Conakry, Guinea, [4]Malaria Consortium, London, United Kingdom, [5]London School of Hygiene & Tropical Medicine, London, United Kingdom, [6]Curtin University, Bentley, Australia

The use of seasonal malaria chemoprevention (SMC) to prevent malaria in children has expanded rapidly since it was recommended for use by the WHO in 2012. SMC has been shown to be highly effective at reducing malaria incidence in control trials, suggesting that the rapid scale up of SMC will have important implications for the burden of malaria. To quantify this impact and adequately incorporate SMC when mapping and predicting burden, detailed information on the spatiotemporal intervention coverage of SMC will be required. SMC coverage is measured either during campaigns, where data is collected on the number of children receiving SMC drugs per distribution cycle, or in surveys where the proportion of children receiving SMC drugs is recorded. Campaign data is available for most country-years, however, coverage estimates often exceed 100%, which may indicate inaccurate estimates of target populations or that drugs were going towards non-target populations (e.g., older children). While surveys are perhaps a more robust measure of coverage, they were only conducted in a subset of administrative units and years and thus cannot provide complete Africa-wide coverage estimates. Here, we use the geographically complete campaign estimates to provide a binary (yes/no) coverage layer of where and when SMC was deployed and then estimate proportional SMC coverage from the survey results and an infilling methodology. Our results provide sub-annual and sub-national estimates and maps of SMC coverage for sub-Saharan Africa for years 2012-2023. By producing monthly results, we standardise for shifts in the timings of SMC campaigns and changes in the number of cycles distributed. Key findings of this research include (a) affirming the well documented geographical expansion of SMC and quantifying this expansion in terms of population coverage; and (b) enumerating the considerable heterogeneity in coverage levels achieved in early SMC campaigns, which became more consistent and higher by 2021.

Protection of US military personnel in regions around the world endemic with malaria currently rely on the prophylactic use of oral medications that must be taken on a daily basis. This situation is not ideal and introduces the challenge of compliance under the stress of warfare and active combat. Development in other fields (HIV, contraception, and psychiatry) suggest that long-acting injectables and implantables could be developed as a long-acting preventative, providing 3 months or longer of broad protection from malaria infection and transmission. With support from the PRMRP program of the US Department of Defense, we have designed and developed a subdermal implant, loaded with the prodrug ELQ-331, using the patented Proneura® implant technology. After iterative rounds of testing, our most advanced implant design provided steady release of the active antimalarial agent, ELQ-300, in low bloodstream concentrations that were sufficient to protect mice from multiple sporozoite challenges (10,000 sporozoites/challenge) for at least 16 weeks, which was the duration for this efficacy evaluation. Full details of our successful findings, together with long-term strategies to advance this technology for the prevention of malaria infection and transmission in humans, in soldiers and civilians alike, will be presented. Note: Material has been reviewed by the Walter Reed Army Institute of Research. There is no objection to its presentation and/or publication. The opinions or assertions contained herein are the private views of the author(s), and are not to be construed as official, or as reflecting true views of the Department of the Army or the Department of Defense. Research was conducted under an IACUC-approved animal use protocol in an AAALAC International-accredited facility with a Public Health Services Animal Welfare Assurance and in compliance with the Animal Welfare Act and other federal statutes and regulations relating to laboratory animals.

THREE YEARS OF MONITORING AND EVALUATING SEASONAL MALARIA CHEMOPREVENTION DELIVERY IN NEW LOCATIONS IN EAST AND SOUTHERN AFRICA: RESULTS AND LESSONS FROM THREE COUNTRIES

Chukwudi Nnaji[1], Salima El Haj[1], Celio Matusse[2], Sonia Enosse[2], Albertino Zunza[2], Norman Aweno[3], Abubaker Rom Ayuiel[3], Jamshed Khan[3], David Odong Salandini[4], Tonny Kyagulanyi[4], Anthony Nuwa[4], Maurice Kwizera[4], Joshua Okafor[1], Monica de Cola[1], Christian Rassi[1]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Maputo, Mozambique, [3]Malaria Consortium, Juba, South Sudan, [4]Malaria Consortium, Kampala, Uganda

The scale-up of seasonal malaria chemoprevention (SMC) in West and Central Africa has been widely considered a success story. Updated World Health Organization guidelines for malaria no longer restrict SMC to specific geographies. This provides greater flexibility which enables malaria-endemic countries to adapt chemoprevention strategies to suit local epidemiology. Since 2021, SMC has been introduced and delivered in new geographies in East and southern Africa (ESA). We present results and lessons from three years of implementing, monitoring and evaluating SMC programs using sulfadoxine-pyrimethamine plus amodiaquine(SPAQ) targeting children under five in Mozambique, South Sudan and Uganda. End-of-cycle household surveys using lot quality assurance sampling (LQAS) methods

and end-of-round surveys were conducted in the 2021-2023 rounds. Surveys were used to monitor program performance against coverage, quality, safety and community awareness, knowledge and acceptability standards. Data were analyzed to compute estimates for each performance indicator by monthly cycle and location, expressed as percentages with 95% confidence intervals (CI). SMC programs targeted a population of around 200,000 eligible children in Mozambique and Uganda in 2021, increasing to 1.6 million children in the three countries in 2023. Coverage in terms of receipt of Day 1 SPAQ by eligible children exceeded 90% in most cycles and locations, ranging from 77.2% (95% CI: 70.8-82.5) to 100.0%. Similar levels of administration of Day 1 SPAQ as directly observed therapy and receipt of the full three-day course of SPAQ were maintained. Results also indicate that SMC was generally delivered to high safety, community awareness, knowledge and acceptability standards. There were however notable within-country variations in coverage and other indicators between locations and over time. Overall, results demonstrate the feasibility and sustainability of SMC when delivered at scale in new geographies in ESA. Observed sub-national disparities in program performance have implications for instituting program improvement efforts in future SMC campaigns.

7295

FACTORS ASSOCIATED WITH MALARIA INCIDENCE AMONG CHILDREN RECEIVING SEASONAL MALARIA CHEMOPREVENTION IN NINE STATES IN NIGERIA.

Olabisi A. Ogunmola[1], Ebenezer C. Ikechukwu[1], Jennifer Chukwumerije[1], Chukwudi Nnaji[2], Chibuzo Oguoma[1], Olusola Oresanya[1]

[1]Malaria Consortium, Abuja, Nigeria, [2]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention (SMC) is an intervention used to prevent malaria among vulnerable populations, particularly children under five years of age. Understanding the factors associated with malaria incidence among SMC-eligible children is essential to optimize the impact of this intervention. This study aimed to understand the relationship between caregiver's characteristics, such as gender, education, occupation, adherence to dosing schedule, reporting of adverse reactions to SMC drugs and belief in SMC effectiveness and delivery factors; community drug distributors (CD) visit to household, are associated with malaria incidence. We extracted data from 11,880 caregivers of SMC-eligible children randomly sampled during SMC end-of-round surveys conducted in November and December 2023 across nine SMC implementing states in Nigeria. A Pearson chi-square test was used to determine the association between each independent variable and children reported with malaria. Mixed-effects logistic regression was used to identify adjusted association between the independent and outcome variables. A total of 2,365 (19.91%) caregivers reported their child had a fever in the past month, of which 1,539 (53.6%) received a diagnostic test and 1,266 (21.6%) tested positive for malaria. The odds of testing positive for malaria were lower in caregivers who adhered to dosing schedule (aOR = 0.667, 95% CI = 0.53 - 0.85 p<0.001), believed SMC is effective (aOR = 0.484, 95% CI = 0.36-0.64 p<0.001) and were employed in skilled manual work (aOR = 0.602, 95% CI =0.45-0.79 p<0.001) and sales (aOR = 0.535, 95% CI = 0.44-0.64 p<0.001). Individuals who experienced adverse reactions related to SMC drugs were almost three times more likely to be malaria positive than those who did not (aOR = 2.606, 95% CI =2.066-3.286 p<0.001). The study concludes that adherence to dosing schedule of SMC drug and caregiver's belief in SMC effectiveness are associated with reduced malaria incidence in SMC eligible children. Further research is required to better understand the causal pathway of increased malaria incidence among children reporting adverse reaction to SMC drugs.

7296

CLUSTER RANDOMIZED CONTROLLED TRIAL TO ASSESS THE SAFETY AND TOLERABILITY OF FIVE MONTHS' REPEATED DOSES OF DIHYDROARTEMISININ PIPERAQUINE AND SULFADOXINE PYRIMETHAMINE PLUS AMODIAQUINE WHEN USED FOR SEASONAL MALARIA CHEMOPREVENTION IN CHILDREN UNDER FIVE IN UGANDA.

ANTHONY NUWA[1], Chukwudi Nnaji[2], Richard K. Kajubi[1], Baker N. Kevin[2], Musa Odongo[1], David S. Odong[1], Maureen Nakirunda[1], Tonny Kyagulanyi[1], Godfrey Magumba[1], Christian Rassi[2], Katherine Theiss-Nyland[2], Jimmy Opigo[3], James K. Tibenderana[2]

[1]Malaria Consortium, Kampala, Uganda, [2]Malaria Consortium, London, United Kingdom, [3]Ministry of Health, Uganda, MOYO, Uganda

Seasonal malaria chemoprevention (SMC) with sulfadoxine pyrimethamine plus amodiaquine (SPAQ) is recommended for children at risk of severe malaria living in areas of seasonal transmission. Previous studies have demonstrated the safety of monthly SPAQ courses for up to four SMC cycles annually. However, the safety of additional cycles remains unexplored. A potential alternative SMC drug regimen is dihydroartemisinin piperaquine (DP) but there is a paucity of data on its safety when administered monthly for SMC. This study evaluated the safety and tolerability of five monthly cycles of SMC with SPAQ versus DP in children under five in Karamoja, Uganda. A three-arm open-label superiority and non-inferiority cluster-randomized controlled trial (cRCT) was conducted in 2022 as part of a hybrid effectiveness-implementation study. A total of 3,749 children were randomized to receive SMC with either SPAQ (1,698) or DP (1,667), while 384 acted as control and relied on standard malaria care over the five-month high-transmission period. Adverse events following SPAQ or DP administration were collected from caregivers during end-of-cycle surveys. A total of 115 (7.0%) children in the SPAQ arm and 168 (10.3%) in the DP arm experienced at least one adverse event following administration of the medicines over the five monthly cycles (p=0.001). Across both arms, the most reported adverse events were fever (33.1% of reported events in the SPAQ arm and 31.5% in the DP arm), vomiting (26.9% in the SPAQ arm and 23.8% in the DP arm) and headache (15.7% in the SPAQ arm and 17.9% in the DP arm). However, reports of nausea (p<0.001), vomiting (p<0.001) and skin rashes (p=0.02) were significantly higher in the DP arm than in the SPAQ arm. Adverse events occurred more frequently in the earlier cycles across both arms. Less commonly reported adverse events across both arms included abdominal pain, cough and dizziness. No serious or fatal adverse events were reported in either arm. The administration of DP and SPAQ for SMC over five cycles were found to be safe and well-tolerated among children in Karamoja, Uganda.

7297

DIRECT EVIDENCE OF FACTORS ASSOCIATED WITH SEASONAL VARIATIONS IN THE USE OF INSECTICIDE-TREATED NETS IN NIGERIA

Tarekegn A. Abeku[1], Azuka Iwegbu[2], Saliu Ogunmola[2], Oluwabukola Babalola[3], Olusola Oresanya[2], Abiola Oluwagbemiga[2]

[1]Malaria Consortium, London, United Kingdom, [2]Malaria Consortium, Abuja, Nigeria, [3]Federal University of Technology, Akure, Nigeria

Despite the substantial contribution of insecticide-treated nets (ITNs) to malaria reduction in Africa, encouraging their consistent use remains challenging. Understanding underlying factors is important for developing strategies to improve ITN use. Several studies have shown perceptions related to heat and mosquito abundance are important determinants of ITN use in populations with access, but there has been limited direct evidence linking seasonal climatic variations with ITN use. We conducted repeated household surveys, in different seasons in Ondo State of Nigeria, to investigate seasonal changes in ITN use rates and the potential determinant factors.Five household surveys were conducted, using similar study design and sample sizes, before an ITN distribution campaign in December 2021 and post-campaign in April 2022, and June, August and October 2023.

A multi-stage stratified cluster sampling design was used to select 832 households in 52 wards during each survey. Household interviews were conducted using a digital questionnaire. Satellite-driven data on rainfall estimates and temperature were analysed in relation to ITN use rates overall and among populations with access. Data on household characteristics, types of available nets, and age and gender of household members were also collected and used in the analysis. The study showed significant seasonal variations in ITN use among populations with access. Reasons for non-use of available nets included feeling hot, perception of mosquito abundance, climate, urban-rural residence, age and condition of nets, and availability of extra nets in the households. The study confirmed the crucial effects of seasonality and climatic factors, especially rainfall and temperature patterns in determining ITN use rates, with increases in the rainy season and reductions in the hot, dry season. ITN use among populations with access is determined by interactions of multiple factors that should be considered when designing behavioral change communication strategies, as well as timing of distribution campaigns, promotional messages, and surveys to evaluate outcomes of the intervention.

7298

PROMOTING THE USE OF THE INTERCEPTOR DUAL AI G2 INSECTICIDE TREATED NETS TO REDUCE MALARIA INFECTIONS THROUGH FOCUSED SOCIAL BEHAVIOR CHANGE CAMPAIGNS IN NAMAYINGO DISTRICT, UGANDA.

Rebecca Babirye, Peter Anyumiza, Collin Baluku, Flavia Kabasuga, Geoffrey Nuwamanya

1.Programme for Accessible Health Communication and Education (PACE), Kampala, Uganda

PACE, with support from BASF, is running the hang-up, keep-up campaign to promote Interceptor G2 dual Active Ingredient Insecticide Treated Nets (ITNs) against malaria in Namayingo district, Uganda. This follows the Ministry of Health's distribution of IG2 ITNs to 9.4 million households across 18 districts, via a universal net coverage campaign. A post-distribution Social and Behavioral Change (SBC) campaign in Namayingo Town Council and Buswale sub-counties aims to enhance net use to reduce malaria infections in district. A baseline assessment was conducted in to provide benchmarks against which changes in knowledge, attitude and practices (KABs) regarding net use would be measured. A cross-sectional study design employed quantitative methods of data collection. 8,238 household were targeted to participate in the baseline whether they received nets or not. We administered questionnaires to 8,195 household in 63 villages to identify KABs that impact the utilization of nets. Analysis conducted using STATA version 14. Findings revealed that 94% of households, confirmed that they had received IG2 Dual AI ITNs; while 6,158 (80%) did not hang or use the newly distributed nets one month post ITN distribution. Among those who did not use/hang up the nets, cited reasons that included concerns about the smell or irritation caused by the net 497 (32%), the perception that it was too hot 399 (26%), and the intention to hang it later (24%) among others. 85.3% were aware of the correct net hanging and usage practices and believed that ITNs were effective in protecting them against mosquito bites. SBC and monitoring of net use should be implemented during, and post universal ITN distribution campaign foster to positive knowledge, attitude and practices regarding net use for malaria prevention.

7299

CLOSING THE ACCESS-USE GAP: INVESTIGATING INFLUENCERS OF BEHAVIOR AROUND INSECTICIDE-TREATED NET USE IN NIGERIA AND UGANDA

Elisabeth G. Chestnutt[1], Kristina Londakova[2], Niamh Thompson[2], Mia Mayixuan Li[2], Zain Hussain[2], Anthony Nuwa[3], Olusola Oresanya[4], Tarekegn A. Abeku[1], Katherine Theiss-Nyland[1]

[1]Malaria Consortium, London, United Kingdom, [2]The Behavioural Insights Team, London, United Kingdom, [3]Malaria Consortium, Kampala, Uganda, [4]Malaria Consortium, Abuja, Nigeria

Over the last two decades insecticide-treated nets (ITNs) have been distributed as a method to prevent malaria and were responsible for 68% of the cases averted between 2000 and 2015. However, the consistent use of ITNs among communities is low, even in areas where access is high, which limits the impact of this intervention and poses a barrier to the control of the disease. To date information on barriers to net use have been collected as part of routine surveys which provide limited insights into the motivations that influence human behaviour. This formative phase - conducted between April and August 2024 - uses a mixed-method approach to explore factors that influence ITN use in areas of Nigeria and Uganda where access to ITNs is high and use rates are low. The findings from this formative research will be used to inform co-created interventions with communities that encourage ITN use. A pilot study will also be conducted to test the feasibility and acceptability of these interventions. This research will guide the design and deployment of appropriate behavioural change intervention strategies to improve ITN use in similar contexts across Africa. We are conducting a desk review of published literature and analysis of existing survey data to inform tools for primary data collection. Qualitive research, using purposive sampling, will then be carried out to investigate the factors identified in more depth. We will conduct focus group discussions with target communities, and local and national stakeholders are invited to participate in in-depth interviews. Direct observations will also be carried out in communities to observe the user experience with ITNs. Results will be analysed using a behavioural science lens to identify which factors can be targeted with behaviour change interventions. We present key findings on the barriers and enablers to ITN use in communities where access rates are already high. Our results provide a comparison across two countries, and offer evidence-based recommendations to enhance ITN uptake.

PREDICTORS OF COHORT RETENTION AMONG ELIGIBLE CHILDREN RECEIVING SEASONAL MALARIA CHEMOPREVENTION IN NINE STATES IN NIGERIA

Ebenezer C. Ikechukwu[1], Olabisi A. Ogunmola[1], Chukwudi Nnaji[2], Ekechi Okereke[1], Jennifer Chukwumerije[1], Chibuzo Oguoma[1], Daniel Emeto[1]

[1]Malaria Consortium, Abuja, Nigeria, [2]Malaria Consortium, London, United Kingdom

Seasonal malaria chemoprevention (SMC) with sulfadoxine/pyrimethamine plus amodiaquine (SPAQ) has shown high protective efficacy against malaria in children under five during the high transmission season. Adherence to a full three-day course of SPAQ over four or five cycles (cohort retention) is required to confer adequate protection. This study measured cohort retention and identified child, caregiver and health systems-related predictors of retention among eligible children. Data were extracted from SMC end-of-round (EoR) survey conducted between November and December 2023 in nine states in Nigeria. The EoR survey randomly sampled 11,880 primary caregivers of eligible children aged 3-59 months. Mixed effects multivariable logistic regression models were fitted to explore the child, caregiver and health systems factors associated with cohort retention. The results indicate that 82.9% (95% CI: 82.2-83.6) of children received full three-day course of SPAQ in all cycles. We observed lower odds of retention among children with history of fever (aOR: 0.82, 95% CI:0.70-0.95) or adverse drug reactions (aOR: 0.76, 95% CI: 0.64-0.92), children whose primary caregivers were not responsible for

child medical decisions (aOR:0.78, 95% CI:0.64-0.94), children whose caregiver had post-secondary education (aOR: 0.71, 95% CI:0.57-0.88). Conversely, higher odds were observed as child age increased (p<0.01), where caregivers were knowledgeable about SMC eligibility (aOR: 1.59, 95% CI:1.21-1.89), in households that were visited by lead mothers (aOR: 2.39, 95% CI:2.09-2.73), when SPAQ was administered under direction supervision by drug distributors (aOR: 1.47, 95% CI:1.21-1.80), and when drug distributors were known to caregivers (aOR: 1.59, 95% CI:1.41-1.80). Understanding the factors that influence SMC cohort retention can help programmes design appropriate interventions to improve cohort retention throughout the SMC round. Further research may be required to understand the negative association between retention and caregivers' education status.

7301

A REVISED TOOLKIT TO SUPPORT PLANNING, IMPLEMENTATION AND MONITORING OF CONTINUOUS DISTRIBUTION OF INSECTICIDE TREATED NETS

Stephen Poyer[1], Eleanore Sternberg[2], Robert Opoku[3], Ketty Ndhlovu Sichalwe[4], Prince Owusu[5], Hannah Koenker[6], Mary Kante[7], Lilia Gerberg[8], Mary Erskine[3]

[1]Tropical Health, Bristol, United Kingdom, [2]Tropical Health, Liverpool, United Kingdom, [3]International Federation of Red Cross and Red Crescent Societies, Geneva, Switzerland, [4]National Malaria Elimination Centre, Ministry of Health, Lusaka, Zambia, [5]President's Malaria Initiative (PMI) Evolve, Accra, Ghana, [6]Tropical Health, Baltimore, MD, United States, [7]Eau Claire Consulting, Eau Claire, WI, United States, [8]United States President's Malaria Initiative, USAID, Washington, DC, United States

Despite the deployment of more than 1.3 billion insecticide-treated nets (ITNs) in the past five years, ITN access and use remains below the levels observed in 2017. Approximately half of countries that distribute ITNs expect no more than an average of two years of useful life from their nets and some national malaria programmes (NMPs) have considered shifting their ITN mass campaign cycle from every three to every two years. However, recent modelling for ITN distribution strategies has shown that full scale deployment of continuous distribution (CD) can provide better ITN access for 20% fewer ITNs compared to 3-year mass campaigns, assuming ITNs have a median useful life of at least 2.5 years. Implementation experience from Ghana, Madagascar, Senegal and Tanzania at different subnational scales shows that ITN CD maintains access and is operationally feasible and cost-effective. However, widespread uptake of CD strategies (like community- and school-based distribution) has not occurred, and best practice guidance has not been systematically updated since 2017. The CD working group of the Alliance for Malaria Prevention has revised the CD Toolkit (available at www.continousdistribution.org) in 2024 to provide new step-by-step guidance, tools and editable resources necessary to support planning, implementation and monitoring of CD. New guidance on ITN quantification for CD channels is presented alongside country success stories and lessons learned. The online toolkit has been developed with NMPs and technical partners implementing and supporting CD and is designed to remove barriers to initiating CD as part of a national vector control strategy. Website and material use will be monitored during 2025, with elements adapted based on user feedback. Expanding CD offers opportunities to improve and maintain ITN access. NMPs are encouraged to align with WHO Malaria Guidelines and donor recommendations, review operational and financial data, and consider increasing CD to complement or replace ITN mass campaign distribution, using resources available through the CD Toolkit to support planning and implementation.

7302

IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON THE INCIDENCE OF MALARIA AMONG CHILDREN UNDER THE AGE OF FIVE YEARS IN LAU LOCAL GOVERNMENT AREA OF TARABA STATE, NIGERIA

Tukur Aliyu[1], Khalid Kasim[1], **Joshua Emeni**[1], Mohammed Alhassan[1], Victoria Erinle[2], Chinedu J. Chukwu[2], Uchechukwu N. Ikhimioya[2], Thomas Hall[3], Bravo Otohabru[2], Temitope Ipinmoye[4], Emmanuel Obi[4], Frank Oronsaye[4], Sonachi S. Ezeiru[4], Emmanuel D. Shekarau[5], Nnenna Ogbulafor[5], Issa B. Kawu[5], Chukwu Okoronkwo[5], Godwin Ntadom[5], James Ssekitooleko[6]

[1]Management Sciences for Health, Jalingo, Taraba State, Nigeria, [2]Management Sciences for Health, Abuja, Nigeria, [3]Management Sciences for Health, Arlington, VA, United States, [4]Catholic Relief Services, Abuja, Nigeria, [5]National Malaria Elimination Programme, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Malaria continues to pose a significant threat to public health, particularly among children under the age of five, in many parts of sub-Saharan Africa, including Nigeria. Lau Local Government Area (LGA), situated at the bank of river Benue in Taraba State, Nigeria, faces significant challenges in combating malaria due to factors such as high transmission rates, limited access to healthcare services, and socio-economic disparities. With financial support from The Global Fund to fight AIDS, TB and Malaria, Management Sciences for Health implemented Seasonal Malaria Chemoprevention (SMC) across nine LGAs within Taraba State, including Lau. This paper explores the impact of the SMC campaign on the incidence of malaria among children under the age of five in Lau LGA of Taraba State. To examine the impact of the SMC campaign on malaria incidence among children under five years old, we analyzed the malaria test positivity rates (TPR) among this age group before the initiation of SMC (January 2020 to June 2021) and during the period of SMC implementation (July 2021 to November 2023) across all supported public health facilities in the LGA. The data used for this assessment was obtained from DHIS2, and data analysis was conducted using Statistical Package for Social Sciences (SPSS). The TPR ranges from 64.82% to 83.84% prior to SMC and from 34.98% to 62.78% two months after the start of SMC. The average TPR before SMC initiation stood at 74.74%, whereas it decreased to 51.25% two months after the commencement of SMC. Analysis of variance revealed a significant difference ($p < 0.05$) in the mean TPRs before the initiation of SMC and two months thereafter. These results suggest that the SMC campaign has significantly reduced malaria incidence among children under five in Lau LGA from an average of 74.74% to 51.25%. The decrease in malaria TPR observed among children at health facilities indicates the effectiveness of SMC in preventing and controlling malaria within the target population.

7303

THE IMPACT OF THREE ADDITIONAL DOSES OF PMC ADMINISTERED THROUGH EPI SCHEDULES ON VITAMIN A SUPPLEMENT UPTAKE IN CAMEROON

Michaela Gross[1], Jonna M. Mosoff[2], Albertine Lele[3], Mercy Tah-Monunde[3], James Sinsai[3], Alba McGirr[2], Carine Nfor[3], Sham Lal[2], Roland Gosling[2], Wilfred F. Mbacham[3], Akindeh M. Nji[3], R Matthew Chico[2], Gillian Stresman[1]

[1]University of South Florida, Tampa, FL, United States, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Fobang Institutes for Innovations in Science and Technology, Yaounde, Cameroon

Vitamin A is crucial for child development and deficiency is associated with increased morbidity and mortality, particularly from infectious diseases. In Cameroon, four vitamin A doses (6-11 months: 100000 IU, 12-59 months: 200000 IU) are recommended as part of the expanded program on immunization (EPI) but attendance is typically poor, especially for the three doses in the second year of life. As part of one visit, Cameroon's national malaria programme (NMP) recommends administering sulfadoxine-pyrimethamine (SP) for perennial malaria chemoprevention (PMC) which may provide additional attendance incentive. This study evaluates the

impact on vitamin A coverage of three additional doses of SP to the PMC schedule, during EPI visits that coincide with vitamin A. Data come from a prospective cohort of children under 2 years of age in Cameroon beginning July 2023. The study took place at two sites, Soa, the intervention area with up to eight PMC doses co-implemented with four vitamin A contacts, and Mbankomo, the control with up to five PMC doses co-implemented with one vitamin A contact. Beginning May 2023, all children residing in the study areas with parental consent were enumerated, and any EPI visits recorded using their EPI book. All subsequent PMC and/or EPI visits for participants were recorded by field workers based in health facilities using an assigned ID in the EPI book or through a name look-up form. Generalized estimating equations (GEE) were used to estimate a marginal model for the effect of intervention area and time on the proportion of children who received at least one dose of vitamin A supplementation. Preliminary results from the recruitment cross-sectional survey found 10.1% (397/3921) of children under 2 years received initial vitamin A supplements as indicated by their EPI books. In terms of the first vitamin A visit only, the contact point consistent between the two sites, coverage was 10.3% and 9.6% (p>0.05) in Soa and Mbankomo, respectively. Findings from this study will provide valuable insights for policymakers and NMPs into the impact of integrating additional doses of SP into the EPI schedule on improved vitamin A uptake.

7304

DOES MOSQUITO NET USE CONTRIBUTE TO MALARIA PREVENTION: AN ANALYSIS OF LOT QUALITY ASSURANCE SURVEY AND ROUTINE HEALTH FACILITY DATA FOR CONFIRMED MALARIA CASES

Richard Ongom Opio[1], Angela Kateemu[1], Edward Mugwanya[1], Edgar Agaba[2], Kenneth Kasule[3], Ronald Kimuli[4], Amy Casella[5], Aliza Hasham[5], Benjamin Binagwa[1], Nancy Brady[5]

[1]USAID/PMI Uganda Malaria Reduction Activity; JSI, Kampala, Uganda, [2]U.S. President's Malaria Initiative, Kampala, Uganda, [3]USAID Strategic Information Technical Support Project, Kampala, Uganda, [4]Ministry of Health, National Malaria Control Program, Kampala, Uganda, [5]USAID/PMI Uganda Malaria Reduction Activity; JSI, Boston, MA, United States

Mosquito net use is generally recognized as an effective protection against malaria infection globally (WHO 2017). This abstract compares net coverage, condition, use, and malaria test positivity rates (TPR) in five high-burden regions of Uganda: Acholi, Busoga, Karamoja, Lango, and West Nile. We analyzed Lot Quality Assurance Survey (LQAS) August 2022 - September 2023 household-level data of 7,224 respondents with 5,311 observed household nets and malaria TPR from 3,420,496 fever cases and 2,066,367 confirmed malaria cases for October 2022 - September 2023 health facility level DHIS2 data extract to understand the relationship between net use and malaria. Data was analyzed for key mosquito net coverage and use indicators: Proportion of households with at least one ITN for every two people; proportion of the population that slept last night under an ITN, correlated to conditions of ITN observed and annual regional malaria TPR from routine DHIS2 data. On average, nearly 81% (5,846) of households had a net, and at least 49% (3,541) of the households had a net for every two people; 74% (5,346) of the respondents had slept under a net the night before the survey and 5,311 mosquito nets were observed with 57% (3,049) in good condition and appropriately hung over beds. Analyzed DHIS2 data showed that higher malaria TPR was found in regions with lower observed nets in good condition and appropriately hung (62% TPR compared to 40% in Acholi and 52% TPR compared to 45% in West Nile, respectively) while lower TPR was found in regions with nets in good condition and appropriately hung (47% TPR compared to 69% in Busoga, 44% TPR compared to 51% in Karamoja, 62% TPR compared to 77% in Lango, respectively). Regardless of the proportion of availability of at least one ITN for every two people, high TPR was observed in the age groups 29 days-4 years and 10-19 years and lower TPR among 0-28 days and 20+ years of both sexes. Low malaria TPR may be associated with proper net maintenance, hanging and use as observed during the survey. Ensuring people at risk of malaria infection repair damaged nets, correctly and consistently use the nets can be an effective strategy for malaria prevention.

7305

LEVERAGING BEHAVIORAL SCIENCE FOR ENHANCED MALARIA PREVENTION IN UGANDA: HOUSEHOLD ACTION AGAINST MALARIA

Aaron Musimenta[1], Dorah Taranta[1], Rukia Nakamate[2], Angela Kateemu[1], Edward Mugwanya[1], Benjamin Binagwa[1], Nancy Brady[3], Disan Ndaula[4], Amy Casella[3], Aliza Hasham[3]

[1]USAID/PMI Uganda Malaria Reduction Activity; JSI, Kampala, Uganda, [2]Ministry of Health, National Malaria Control Program, Kampala, Uganda, [3]USAID/PMI Uganda Malaria Reduction Activity; JSI, Boston, MA, United States, [4]USAID/PMI Uganda Malaria Reduction Activity; PACE, Kampala, Uganda

Malaria is the leading cause of illness and death in Uganda, despite being preventable and treatable. The PMI Uganda Malaria Reduction Activity (PMI MRA) builds community and household capacities to prevent malaria through the household action against malaria (HAAM) approach, adapted from the Ministry of Health's Mass Action Against Malaria. HAAM empowers communities to own malaria prevention at household level to achieve malaria smart home status: malaria-free for six consecutive months. Adhering to behavioural science principles—empowerment, inclusivity, community involvement, feedback loops, and collaboration—underpin HAAM success. HAAM is implemented in 12 high malaria-burden districts through health facility staff who line-list malaria cases from HMIS registers, map villages with >5 cases (high burden villages) and cluster households for all-village inclusion. Households are assessed for malaria transmission drivers using the HAAM assessment tool and action plans are co-created with household members to address them. Monthly follow up visits are conducted to monitor progress. During implementation, household malaria champions reinforce accountability and follow up malaria response plans. District/village health teams and other stakeholders are engaged to ensure community involvement. From October 2022-February 2024, 57,677 households were assessed, clustered and sensitized using the HAAM checklist. Results from HAAM assessment data show a reduction in household malaria episodes from an average of 61% to 32% from visit 1 to visits 3 or 4 in this time period. Households clearing breeding spots increased from 55% to 96%, while consistent net use among pregnant women increased from 85% to 100%. Households planting locally available mosquito repellents rose from 23% to 81%. By co-creating prevention actions with households based on locally available resources and strategies and, and clustering households for follow-up, HAAM fosters and local empowerment and community ownership for malaria prevention.

7306

CONTRIBUTION OF SOCIAL BEHAVIOR CHANGE THROUGH COMMUNITY HEALTH WORKERS AND LOCAL LEADERS IN REDUCING MALARIA INCIDENCE IN KAYONZA DISTRICT, EASTERN PROVINCE OF RWANDA

GAHIGANA Seraphina[1], Manasseh WANDERA GIHANA[1], KABATESI Irene[1], Aimable Mbituyumuremyi[2], Michee Kabera[2], Janepher TURATSINZE[1], Alice Bagwire Kashaija[3]

[1]Society for Family Health, Kigali, Rwanda, [2]Rwanda Biomedical Center, Malaria & Other Parasitic Diseases Division., Kigali, Rwanda, [3]jhpiego, Kigali, Rwanda, Kigali, Rwanda

Malaria remains a major public health problem in Rwanda and is considered among the leading cause of morbidity and mortality. The National Malaria Strategic plan objective five states that by 2024, 85% of the population at risk will have correct and consistent practices and behaviors towards malaria control interventions. In 2019, Kayonza district ranked in the top 10 with the highest malaria incidences nationwide requiring an integrated approach of malaria control. SFH in partnership with the Ministry of Health started implementation of social behavior change communication project complementing other existing interventions. Inclusive SBC intervention through different channels like community education, peer education and community outreach implemented by community health workers and local leaders at community level which yielded a significant reduction in malaria

incidence. These interventions are spearheaded by the theme "Zero Malaria Starts with Me" promoting community ownership in malaria prevention. We conducted a desk review to assess the contribution of SBC using Ministry of health data and reports from Health Management information System (HMIS) and score cards from 2019 to 2023. Data analysis showed that social behavior change complementing existing interventions has contributed to the significant reduction of malaria incidences in Kayonza district. Results show that malaria incidences reduced from 452 per 1000 population (total malaria cases =190,464) in 2019 to 12 (total malaria cases =5,277) in 2023. Social Behavior Change in Kayonza was proven to be a successful intervention towards adapting proper behaviors like use of Bed nets (LLINs), accepting Indoor Residual Spraying (IRS), early treatment seeking behavior and integrated vector control management (IVM) that yielded a substantial reduction in malaria incidences and thus contributing towards the goal of malaria elimination in Rwanda.

7307

TRENDS AND LEVELS OF MALARIA INCIDENCE DURING INDOOR RESIDUAL SPRAYING IN HOMABAY COUNTY, 2019-2023

Dr. Beatrice K. Machini[1], Dr. Kibor Keitany[1], James N. Kiarie[1], Dr. Otieno Dan James[2], Stephen Aricha[1], Dr. Joash Auka[3]

[1]National Malaria Control Program, Nairobi, Kenya, [2]World Health Organization, Nairobi, Kenya, [3]Ministry of Health, Nairobi, Kenya

Malaria in Kenya accounts for 16% of all outpatient visits. Vector control interventions are implemented according to malaria risk stratification. Homa Bay County (HBC) is in a malaria endemic zone that has implemented indoor residual spraying (IRS) from 2018-2023 to supplement long-lasting insecticide nets (LLINs), resulting in high coverage rates over the 85% recommended by WHO for community effectiveness. We describe the trends of malaria incidence using reported program data during IRS intervention. This was a cross-sectional retrospective review of data from HBC extracted from the Kenya Health Information Systems (KHIS) and National Malaria Control Program activity reports from 2019-2023. Number of all suspected malaria cases and those tested were used to calculate test positivity rate (TPR) and malaria incidence was calculated as cases per 1000 population at risk. Geospatial maps were developed in QGIS to visualize incidence patterns over time. On average the IRS coverage was 93.8% and 95.8% of population targeted were protected. While there was an initial decline in incidence from 197.3 in 2018 to 106.7 in 2020, there was a gradual increase during the IRS period, up to 359.6 in 2023. TPR increased from 21.0% in 2019 to 42.2% in 2023. Number of malaria cases detected in the community increased from 16,690 in 2021 to 80,595 in 2023. The malaria incidence risk maps showed a gradual increase of malaria transmission intensity from 2019 that covered the whole county by 2023. The initial decline in malaria incidence may be attributable to IRS intervention. Due to implementation of community case management, the number of malaria cases detected in the community increased, contributing to increased incidence despite IRS. Comparing malaria incidence over time has limitations given its dependence on data completeness and quality. Reporting in KHIS have improved over time, resulting in what appears to be increased incidence. The malaria program data demonstrate that HBC is still receptive to malaria transmission and close monitoring of malaria data and insecticide resistance are critical in the period after IRS withdrawal.

7308

ENHANCING MALARIA DIAGNOSIS, TREATMENT, AND DATA MANAGEMENT THROUGH TRAINING AND SUPERVISION OF HEALTHCARE PERSONNEL IN SIX NORTHERN PROVINCES OF ANGOLA, 2018-2023

Jose Franco Martins[1], Erin Eckert[2], Joana Martinho do Rosario[3], Teresa Nobrega[4], Anya Fedorova[5], **Benjamin Nieto-Andrade**[5]

[1]National Malaria Control Program / Angola, Luanda, Angola, [2]PSI/USA, WASHINGTON, DC, United States, [3]USAID, Luanda, Angola, [4]The Mentor Initiative / Angola, Luanda, Angola, [5]PSI/Angola, Luanda, Angola

Malaria remains a health challenge in Angola, with high incidence rates (267/1000 cases in 2023) and associated mortality. Effective diagnosis, treatment, and accurate data recording are key in malaria control efforts. Since 2018, a comprehensive training and supervision program was implemented targeting health workers (HWs) in 6 hyper-endemic provinces in Angola, with support from PMI. The program emphasized parasitological confirmation over clinical diagnosis, adhering to standardized treatment protocols, and improved data recording practices. In total 11,704 HWs were trained in-person or via the KASSAI online platform on rapid malaria diagnostics, 9,032 HWs were supervised on malaria diagnostics and 1,021 data verification visits to health units (HUs) were conducted. To assess the impact of this program, we used routine surveillance data from 2018 to 2023 and compared malaria diagnostic practices against 4 non-PMI provinces with high malaria burden. Results shows the percentage of clinically diagnosed cases declined from 16% to 2% in 6-PMI focus provinces from 2018 to 2023, as compared to no change (28%) in 4 non-PMI-focus provinces. Malaria incidence rates increased across all PMI-focus provinces: 207/1000 in 2018 and 467/1000 in 2023, likely due to improved case detection rather than a surge in actual cases, indicative of enhanced diagnostic practices, increased reporting rates (70.0% in 2018 and 92.0% in 2023) and improved data quality (quality scores rose from 84.3% in 2021 to 91.5% in 2023). The case fatality rate decreased from 0.28% in 2018 to 0.08% in 2023, suggesting improved treatment outcomes. The use of diagnostic tests over clinical diagnosis signifies a shift towards evidence-based practices, while improved data recording enhances the reliability of surveillance data for decision-making. The use of online platforms like KASSAI enhanced the scalability and accessibility of training initiatives. These findings underscore the importance of continuous training via multiple platforms and of target supervisions, in strengthening healthcare systems and combating malaria in resource-limited settings like Angola.

7309

BUILDING A LOCAL INSTITUTION WITH GLOBAL REACH: INVESTING IN AFRICA UNIVERSITY FOR ENTOMOLOGICAL SURVEILLANCE TO FIGHT MALARIA IN ZIMBABWE

Sungano Mharakurwa[1], Juliet Sithole[1], Jeanette Dadzie[1], Aramu Makuwaza[1], Nobert Mudare[1], Ottias Tapfumanei[2], Andrew Tangwena[2], Wilson Chauke[2], Patience Dhliwayo[2], Busisani Dube[3], Regis Magauzi[3], Jesicca Kafuko[3], Erik J. Reaves[4]

[1]Africa University, Mutare, Zimbabwe, [2]National Malaria Control Programme, Ministry of Health and Child Care, Harare, Zimbabwe, [3]U.S. President's Malaria Initiative, USAID, Harare, Zimbabwe, [4]U.S. President's Malaria Initiative, U.S. Centres for Disease Control, Harare, Zimbabwe

Localization is a commitment to shift program ownership and leadership to local institutions with the capability and credibility to drive positive change in their own countries and communities. We describe our multi-year journey to strengthen capacity to achieve rigorous entomological surveillance through Africa University in Zimbabwe. In 2017, the U.S. President's Malaria Initiative (PMI) began a stepwise, iterative process with Africa University, the National Malaria Program (NMP), and key partners to design activities, set performance milestones, and collaborate during implementation and monitoring. The key prerequisite was demonstrable success in conducting entomological surveillance as a sub-awardee under a global contract. In 2021, PMI awarded Africa University a three-year performance-based, fixed-amount cooperative agreement (total $1,650,000 USD). Concurrent

capacity strengthening included construction of an insectary and provision of equipment to the existing molecular laboratory. Existing and new cadres of field and laboratory staff received training. Entomological samples analyzed annually averaged 1,827 (range: 858-3,407) and increased to 8,872 post-localization (range: 6,453-11,291). Live reference colony mosquitoes supplied annually to the Health Ministry increased from a mean of 20,665 to 47,525. Direct upload of entomological data into the national database was established for program decision-making. Africa University also became a member of the Malaria Vector Control Subcommittee which provides technical support to NMP. Cost savings and capacity have permitted the geographical expansion of entomological and insecticide resistance monitoring. Building off this investment, Africa University has established a new malaria institute and entomological center of excellence with a new applied science curriculum for faculty and graduate student research, and student internships. Localization with Africa University is a model for improved local ownership and performance, cost savings, public-private partnership, impact, and sustainability of PMI investment.

7310

USING MALARIA ROUTINE DATA QUALITY AUDITS TO IMPROVE MALARIA DATA QUALITY IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Bruno Kapinga[1], Yves Ilunga[1], Erick Tshikamba[2], Yibayiri Osee Sanogo[3], Hyacinthe Kaseya[4], Packy Mbayo[4], Eric Mukomena[4]

[1]RTI International, Research Triangle Park, NC, United States, [2]U.S. President's Malaria Initiative, USAID, Kinshasa, Congo, Democratic Republic of the, [3]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Kinshasa, Congo, Democratic Republic of the, [4]National Malaria Control Program (NMCP), Ministry of Health, Kinshasa, Congo, Democratic Republic of the

In the Democratic Republic of the Congo, malaria data are collected in DHIS2, the national platform for the collection and analysis of health information data. Despite continuous efforts by the National Malaria Control Program (NMCP) and its partners, data quality issues persist. To better understand root causes of this poor data quality, we conducted malaria routine data quality audits (mRDQA) in 61 health facilities in Haut Katanga, Kasai Central, Kasai Oriental, South Kivu, and Tanganyika provinces in 2023. Sites were selected based on accessibility and historically low performance on data quality metrics. The mRDQA is an open-source digital tool accompanied by a District Health Information System 2 (DHIS2) package used to collect information on data quality for routine malaria reporting from health facilities as part of routine supervision. mRDQA results revealed that 84 percent of sites had complete data in their reports, 66 percent did not use the standard national registers, and 67 percent did not have congruent data between the primary source documents and aggregate monthly reports for the period audited. We found that only 11 percent of health facility providers had received training on data collection and analysis in the past two years, and 77 percent of providers had poor understanding of malaria data elements and indicators used in DHIS2. Based on the mRDQA results, NMCP and partners identified and corrected 6,031 instances where cases were misclassified as malaria deaths and supported more than 278 providers in data analysis. The mRDQA revealed that inaccurate compilation from source documents, use of non-standard data collection tools, and lack of training contributed to observed data quality issues. Future efforts should focus on providing standard data collection tools to all 179 supported health zones, organizing targeted training in malaria surveillance, monitoring, and evaluation to improve data quality for informed decision making.

7311

INSECTICIDE RESISTANCE DATA TO INFORM INTERVENTION SELECTION AND TARGETING IN UGANDA

Medard Rukaari[1], Jimmy Opigo[1], Munashe Madinga[2], Lucia Fernandez[3], Sylvia Nanfuka Kirumira[4], Juliet Nakiganda[4], Natalie Priestley[4], Fredrick Luwaga[4], Lorraine Kabunga[4]

[1]National Malaria Control Division, Kampala, Uganda, [2]Clinton Health Access Initiative, Abuja, Nigeria, [3]Clinton Health Access Initiative, Panama City, Panama, [4]Clinton Health Access Initiative, Kampala, Uganda

Uganda represents 5.1% of the global malaria burden as per the World Malaria Report (2023). Long Lasting Insecticide Nets (LLINs) and indoor residual spraying (IRS) are core interventions utilized to disrupt malaria transmission and reduce illness in at-risk populations. Although existing strategies led to a decline in incidence by 48% between 2000 and 2015, incidence has plateaued to between 200 to 300 cases per 1,000 population alongside growing resistance to insecticides used in vector control interventions. Routine entomological surveillance is implemented in Uganda and includes insecticide testing for the presence, intensity, and mechanism of resistance to the common insecticide classes used for LLINs and IRS. Despite growing resistance to insecticides data collected at sentinel sites is underutilized. Understanding where resistance has developed helps the National Malaria Control Division (NMCD) to optimize procurement and distribute more effective nets where they will have most impact. To improve data-driven decision making, CHAI (Clinton Health Access Initiative) supports NMCD to collate, analyze, and interpret insecticide resistance data to tailor vector control interventions. The 2017 analysis identified increasing resistance to pyrethroids and was used to advocate for procurement of 25% Piperonyl-butoxide (PBO) nets for the 2017/2018 mass LLIN campaign. Analysis of 2021 data showed in 7/11 sites that submitted data, PBO did not restore susceptibility to pyrethroids. In 2022 data, 14/17 sentinel sites across the country had confirmed resistance to pyrethroids. These analyses informed a shift in procurement toward more dual active ingredient (AI) nets in the 2023 mass campaign from 0-19%, though due to cost implications most nets were PBO (71%) and the remaining 10% pyrethroid-only. Annual analysis and advocacy informed the latest global fund application where the country requested to increase the proportion of dual AI nets procured to 50% due to growing resistance. Routine use of entomological surveillance data is vital to ensure that resources are used to procure and deploy the most effective vector control tools.

7312

DECADAL TRENDS IN UNDER-5 MALARIA MORTALITY; INSIGHTS FROM AN ENDEMIC HDSS SITE IN RURAL WESTERN KENYA

PETER SIFUNA, Michal Mbinji, Doris Njoroge, Walter Otieno

WRAIR AFRICA, KISUMU, Kenya

Peter M. Sifuna,[1,2*] **Michal Mbinji**[1,2]**, Doris Njoroge**[1,2] **and Walter Otieno**[1,21]**Kenya Medical Research Institute, Kisumu, Kenya;** [2]**U.S. Army Medical Research Directorate—Africa, Kisumu, KenyaBackground:** The burden of malaria disproportionately affects children under the age of five, who are especially vulnerable to severe complications and fatalities, particularly in regions where malaria is endemic. **Objectives:** To describe trends in under 5 mortality attributable to malaria in an endemic zone. **Methods:** The analyses are based on the entire series of 11,595 deaths (among all ages) registered in the Kombewa HDSS from 2013 and 2023. The deaths were followed up with a standardized Verbal Autopsy (VA) interview by specially trained lay interviewers to record events surrounding death. VA interviews were conducted using the modified 2007 then the 2012 standardized WHO questionnaires recommended by INDEPTH for deaths occurring in the HDSS. Assignment of causes of death was made using the InterVA-4 model version 4.02. Cox regression model adjusted for sex, was built to evaluate the influence of age on mortality. **Results:** Malaria emerged as the second leading cause of death across all age groups and the primary cause of death among children under the age of five within the HDSS population. Out of 7,858 deaths with assigned

causes, 878 were attributed to malaria (10.6%). Malaria mortality rates showed a decline from 180 deaths per 100,000 population in 2013 to 42 deaths per 100,000 population by the conclusion of 2023. Peaks in malaria mortality were observed in 2014 (337 per 100,000) and 2017 (203 per 100,000 population).

Conclusion: The real-world effectiveness of the various malaria interventions, as well as its impact on under-5 mortality in endemic settings, remains to be fully understood. As these interventions are rolled out in regions where malaria burden is high, it is essential to monitor its performance in reducing malaria-related deaths among children under five years old.

7313

NAVIGATING VILLAGE BOUNDARIES: A COMPARATIVE EXPLORATION OF THREE MAPPING TECHNIQUES

Wycliffe Odongo[1], Daniel McDermott[2], Kizito Obiet[3], Brian Seda[3], Oliver Towett[3], Frank Aduwo[3], Simoon Kariuki[3], Julie Gutman[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Liverpool School of Tropical Medicine, London, United Kingdom, [3]Kenya Medical Research Institute, Kisumu, Kenya

Clear, well-defined village boundaries are vital for community-based intervention trials, vector control studies and malaria surveillance. They facilitate spatial analysis, capturing population denominators for more precise monitoring of infection transmission dynamics. Existing boundary mapping tools may not capture variations in land use or building characteristics (commercial vs residential). We examine three distinct techniques for mapping village-level spatial boundaries: i) village walk-around - traversing the entire village perimeter with a GPS receiver; ii) structure mapping- identifying and recording GPS coordinates for all physical structures in a village; and iii) centroid mapping - using a local expert to map perceived “centers” of the village and utilizing geospatial techniques to calculate centroids and Voronoi polygons to generate village boundaries. We evaluated practicality (ease of use, flexibility, precision, and scalability) and cost-effectiveness (operational cost analysis, time efficiency in data collection and processing) in various operational contexts, providing a detailed comparison for diverse field settings. Each technique presents unique advantages, challenges, and uncertainties, with practicality varying based on mapping objectives and study area characteristics. Structure mapping generates a fine-grained resolution dataset but is labor-intensive and at $112 per village is 5.3 times costlier than walk-around and centroid techniques. Boundary walk-around can be done relatively quickly (2 villages per day), but precision relies heavily on local area knowledge. Centroid mapping is an easy to deploy technique but may be limited by geographical orientation and estimation skills of local experts. Terrain complexity, population density, budget, and data processing timelines are key considerations in technique selection. Our findings offer valuable insights into technical aspects of village-level boundary mapping and provide a framework for selecting the most appropriate mapping method, optimizing spatial data collection and use.

7314

ASSESSING THE TRENDS AND CONCORDANCE OF MALARIA PREVALENCE BETWEEN PREGNANT WOMEN ATTENDING ANTENATAL CLINICS AND ASYMPTOMATIC INDIVIDUALS IN THREE REGIONS OF MAINLAND TANZANIA

Angelina Julius[1], Daniel Petro[2], Daniel challe[1], Salehe Mandai[1], Gervas Alexander[1], Rashid Madebe[1], Seth Misago[1], Dativa Pereus[3], Filbert Francis[4], Catherine Bakari[1], Rule Budodo[1], Ramadhan Moshi[1], Ruth Mbwambo[1], Daniel Mbwambo[5], Ntuli Kapologwe[6], Sijenunu Aarlon[5], Celine Mandara[1], Deus Ishengoma[1]

[1]National institute for medical research, DAR ES SALAAM, Tanzania, United Republic of, [2]University of Dar es Salaam, DAR ES SALAAM, Tanzania, United Republic of, [3]Muhimbili University of health and allied sciences, DAR ES SALAAM, Tanzania, United Republic of, [4]National institute for medical research Tanga, Tanga research center, Tanga, Tanzania, United Republic of, [5]National Malaria Control Programme, Dodoma, Tanzania;, DAR ES SALAAM, Tanzania, United Republic of, [6]Directorate of Preventive Services, Ministry of Health, Dodoma, Tanzania;, Dodoma, Tanzania, United Republic of

Tracking the burden and transmission of malaria using reliable data is crucial for designing and implementing effective control strategies and accurately monitoring the impacts of interventions and progress towards the elimination targets. Surveillance of malaria in Tanzania is based on different types of data including those obtained from screening of pregnant women at their first antenatal care clinic (ANC) visits since 2014. ANC malaria prevalence is highly correlated to prevalence in under-fives but the correlation with other age groups has not been established. This study assessed the trends and concordance of malaria prevalence between asymptomatic individuals of all age groups from community cross-sectional surveys (CSS) and pregnant women attending ANC clinics in three regions of Kigoma, Ruvuma and Tanga in Mainland Tanzania from 2021 to 2023. In both CSS and ANC clinics (from 2021 to 2023), testing for malaria was done using malaria rapid diagnostic tests (RDTs) and covered 8,096 asymptomatic individuals in CSS and 819,103 women. Malaria prevalence in CSS was 32.7% (95% confidence interval (CI), 31.7-33.7) in 2021, 36.8% (95% CI, 35.8-37.9) in 2022 and 30.5% (95% CI, 29.5-31.5-32.7) in 2023. The prevalence in pregnant women was 8.63% in 2021, 7.30% in 2022, and 7.93% in 2023 with higher prevalence among women aged <20 years (12.26%) compared to older women (7.14%). In both CSS and ANC, there was a significant positive correlation between malaria prevalence in CSS and ANC (r=0.719, P=0.03). The strongest positive correlation was among children <5 years and pregnant women aged <20 years (r=0.84,p=0.005); and school children aged 5-15 years and pregnant women aged >20 years (r=0.85, p=0.018). Malaria prevalence in pregnant women provided a close match to both under-fives and school aged children. The findings support previous studies and suggest that ANC data can be used as a sentinel surveillance group to monitor the trends of malaria prevalence in these groups rather than surveys that focus on presence or absence of asymptomatic infections in time points.

7315

TRANSFERRING CAMPAIGN DIGITIZATION EXPERTISE TO NATIONAL ENTITIES AND STRENGTHENING MALARIA CONTROL ACTIVITIES IN BENIN

Cyriaque Afoukou[1], Achille Batonon[1], **Dossou-Yovo Sebastiano**[1], Bocar Anne[2], Madi Ahle[3], Richard Dossou-Yovo[3], Djawad Ramanou[3], Didier Agossadou[3], Bradley Didier[2], Macoumba Toure[2], Kevin Njiru[2], Olajumoke Adekeye[3], Lundi-Anne Omam[3]

[1]Ministry of Health, Cotonou, Benin, [2]Clinton Health Access Initiative, Dakar, Senegal, [3]Clinton Health Access Initiative, Cotonou, Benin

In 2022 malaria incidence was 21,7% among general population and 43,1% among under five children, in Benin. As the country is dedicated to achieving malaria elimination by 2030, it’s important to leverage on digital transformation to reach the target. Since 2019, the Ministry of Health has initiated campaign digitization initiatives with the technical support of Clinton Health Access Initiative. To ensure that the investments made in digitizing campaigns in Benin are sustainable, the Clinton Health Access Initiative, World Health Organization worked with the Ministry and other partners to expand and integrate the key components of campaign activities into disease control programs, while building capacities to lead digitization in the long term. The process of transferring the expertise on digitizing campaigns in Benin starts with strengthening and consolidating governance initiatives of the digitization campaign, led by the Information Systems Direction, followed by ensuring that the tool selection and deployment process leads to the adoption of suitable platforms and software addressing country specific needs, then, progressively improving digitization and integration of public health campaigns, and finally determine the sustainable ways to capacitate the government for the improvement of campaign operations. In result, leadership and coordination mechanisms were established, with steering committee that meets routinely to agree on the implementation plan for Integrated Campaigns Digitization across all Ministry of Health programs, departments and partners. The Information Systems Direction supported the malaria program to run nets distribution campaign and

Seasonal Malaria Chemoprevention campaign, engaged with technical and implementing partners to build a comprehensive platform to visualize, use and share the campaign data across programs, engaged steering committee and technical committee on design and requirements for review of existing tools and elaboration of new tools. Strengthening and transferring expertise to national entities ensure campaigns autonomous implementation by national stakeholders.

7316

UNDERSTANDING DHIS2 DATA LIMITATIONS FOR MALARIA BURDEN ESTIMATION: A COMPARISON WITH GOLD STANDARD MEASUREMENTS FROM A COHORT STUDY IN ZAMBIA

Andrew Andrada[1], Thomas P. Eisele[1], Chama Chishya[2], John Chulu[2], Handrinah Banda[2], Chanda Chitoshi[2], Annie Arnzen[3], Erica Orange[3], Busiku Hamainza[4], Kafula Silumbe[5], Megan Littrell[6], Ruth Ashton[1]

[1]Tulane, New Orleans, LA, United States, [2]PATH, Kaoma, Zambia, [3]PATH, Seattle, WA, United States, [4]Zambia National Malaria Elimination Centre, Lusaka, Zambia, [5]PATH, Lusaka, Zambia, [6]PATH, Washington DC, DC, United States

To achieve public health goals and effectively respond to epidemics, robust health management information systems are indispensable. Platforms such as DHIS2, an open-source system, offer broad geographic coverage and timely disease incidence data, which can be helpful for malaria programming and intervention targeting. However, DHIS2 data inherently have limitations and may not provide a true estimate of community malaria incidence. Factors that contribute to these limitations include treatment-seeking behaviors, case management practices, and data quality concerns. This study aims to assess the differences in malaria incidence rates between passively-detected DHIS2 data and a gold standard measurement method, involving a prospective cohort with active case detection from a trial conducted in Western Province, Zambia for evaluating attractive targeted sugar baits (ATSB) from 2021 to 2023. Specifically focusing on children aged 12-59 months from the ATSB cohort that were cleared of parasites at the start of the malaria season and followed up monthly for 6 months to capture malaria incidence cases. These cases will be compared to the malaria incidence trends from matching health facility catchment areas using line plots. Concordance between the two estimates will be assessed via z-score scatter plots and Bland-Altman diagrams. Associations between health facility characteristics, patient preferences, and differences in estimates will be assessed through linear regression. Finally, Poisson regressions will be used to model the relationship between the outcome of monthly malaria incidence with both estimates, incorporating health facility characteristics and patient preferences. Examining the disparities between DHIS2 data and a gold standard measurement, and assessing the effects of contributing factors, may provide valuable insights into the limitations of DHIS2 estimates, aiding in their interpretation and informing their use in malaria programming efforts.

7317

CREATING COMMUNITY RESOURCES TO MAKE MALARIA GENOMIC DATA ANALYSIS MORE ACCESSIBLE BY EVALUATING, IMPROVING, AND HARMONIZING SOFTWARE TOOLS

Shazia Ruybal-Pésantez[1], Aimee Taylor[2], Alfred Simkin[3], Jason Hendry[4], Jody Phelan[5], Jorge Amaya-Romero[6], Karamoko Niare[7], Kathryn Murie[8], Kirsty McCann[9], Maxwell Murphy[8], Mouhamadou Fadel Diop[10], Nicholas Hathaway[11], Nicholas Brazeau[12], Sophie Berube[13], Stephen Schaffner[14], Bryan Greenhouse[8], Amy Wesolowski[13], Robert Verity[1]

[1]Imperial College London, London, United Kingdom, [2]Institut Pasteur, Paris, France, [3]Brown University, Providence, RI, United States, [4]Max Planck Institute, Berlin, Germany, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Harvard University, Cambridge, MA, United States, [7]Brown University, Providenc, RI, United States, [8]University of California San Francisco, San Francisco, CA, United States, [9]Deakin University, Geelong, Australia, [10]MRC Unit The Gambia, The Gambia, Gambia, [11]University of Massachusetts Chan Medical School, Boston, MA, United States, [12]Duke University, Durham, NC, United States, [13]Johns Hopkins University, Baltimore, MD, United States, [14]Broad Institute, Boston, MA, United States

Major advances in *Plasmodium* sequencing approaches, pipelines, and data analysis tools have provided valuable insights from parasite genomic data on malaria epidemiology. However, translating genetic data into actionable information for NMCPs is still challenging. Important barriers still limit integration of these advances into a seamless data analysis ecosystem that produces standardized, interpretable results for use by NMCPs. The PlasmoGenEpi network convened 18 subject matter experts to landscape available tools, evaluate software standards, improve documentation, and evaluate next steps in the context of key use cases at the: **R**eproducibility, **A**ccessibility, **D**ocumentation, and **I**nteroperability **S**tandards **H**ackathon (RADISH23). We defined eight use cases for Plasmodium genetic data informing malaria surveillance, based on data analysis and functionality requirements. For each use case, we mapped out workflows with respect to information flow through each analysis functionality. In combination with the landscaping of tools and their functionalities, each step of the workflow can be mapped flexibly to available tools and can be used to identify gaps where new software is needed. These resources are available on **PGEforge** (mrc-ide.github.io/PGEforge), a community resource built during RADISH23. We identified 40 Plasmodium genomic analysis tools, of which 17 were prioritized for resource development. PGEforge contains the tool landscaping, software standard guidelines, and fully reproducible tutorials showing example usage of each tool using canonical target and whole genome sequencing datasets (empirical and simulated). Installation of R-based tools is simplified by our implementation of a centralized "R-universe" package repository. PGEforge now serves as a central, open repository for current and future resources for malaria genetic data and analysis workflows, greatly improving accessibility. Ongoing and future work will focus on rigorous benchmarking of tools and modular workflows to tackle the more ambitious goal of developing best practices in malaria genomic surveillance.

7318

USING ROUTINE SURVEILLANCE DATA TO ASSESS ADHERENCE TO MALARIA TREATMENT GUIDELINES IN THE COUNTY REFERRAL HOSPITALS IN KENYA

Robert M. Mwaganu[1], Fredrick O. Odhiambo[2], Regina J. Kandie[1], Emma Nyandigisi[1], Beatrice K. Machini[1]

[1]National Malaria Control Program, Ministry of Health, Nairobi, Kenya, [2]National Public Health Institute, Nairobi, Kenya

The WHO recommends early diagnosis and prompt, effective treatment of malaria by observing appropriate weight-based dosing and rational use of antimalarial agents to reduce the spread of drug resistance. Kenyan malaria treatment guidelines recommend the appropriate dosage of Artemether Lumefantrine (AL) as the initial line of treatment for test-positive uncomplicated malaria. Cases are entered into registers; monthly summaries are uploaded to the Kenya Health Information System (KHIS). We assessed the adherence to the guidelines in Kenya's 47 County Referral Hospitals (CRHs) during the biannual commodity review meetings in November 2023. Suspected malaria cases are tested and recorded in a laboratory register (MOH 706); this information is replicated in the commodity summary report (MOH 743), which contains a summary of malaria tests, AL dispensed, and patients by weight category. A standard template was shared with the 47 counties to collect aggregated data from KHIS for Sept 2023, the most recent reporting month. Analysis of the total no. of patients who tested positive in both reporting tools, the total no. of patients treated with AL compared to the total no. of patients who tested positive in MOH 706 and MOH 743 for all CRHs. The conversion of doses dispensed to the number of tablets that should have been dispensed for the reported total no. of patients by weight category to cater for substitutions of AL packs. A total of 7,176 patients were treated with AL, yet only 3,080 (43%) tested positive for malaria, translating to overtreatment of

4,096 (57%) patients. A comparison of MOH 743 with MOH 706 (source document for laboratory test data), revealed over-reporting by 24% on the number of patients who tested positive. Only 580 (8%) of the total patients treated with AL were tested and treated correctly, with 11 CRHs (23%) giving correct dosing to positive patients. Data quality audits should be carried out to address data discrepancies, and data review meetings to be sustained for peer learning. Capacity building of health workers is also critical for rational drug use and inventory management.

7319

ADAPTING MALARIA INDICATOR SURVEYS TO INVESTIGATE TREATMENT ADHERENCE: A PILOT STUDY ON BIOKO ISLAND, EQUATORIAL GUINEA

David S. Galick[1], Olivier Tresor Donfack[1], Teresa Ayingono Ondo Mfumu[1], Cristina Ngui Otogo Onvogo[1], Teobaldo Babo Dougan[1], Monica Idelvina[1], Godino Esono Nguema[1], Charity Okoro Eribo[1], Maria Mirella Buila Euka[1], Kate Martin[2], Wonder P. Phiri[1], Carlos A. Guerra[2], Guillermo A. García[2]

[1]MCD Global Health, Malabo, Equatorial Guinea, [2]MCD Global Health, Silver Spring, MD, United States

Adherence to antimalarial treatment regimens is an important aspect of understanding and improving the impact of malaria case management. However, both adherence to artemisinin combination therapies (ACT) and the factors driving it vary widely. While many other evaluation activities have been conducted on Bioko Island, until now adherence to antimalarial treatments, and in particular ACTs has not been evaluated. The implementation of a malaria indicator survey (MIS) conducted on Bioko in 2023 was leveraged to evaluate adherence to ACTs provided to individuals testing positive following the survey. A follow-up team visited the targeted households, physically observed treatment blisters where possible, and provided messaging to household members on the importance of adhering to the treatment guidelines to household members. The team used survey data from the targeted households to make messaging as relevant to the household's particular context as possible. Overall ACT adherence on Bioko Island was low, around 50%, and this varied demographically and geographically. Some of the highest transmission areas had exceptionally low adherence, but no systematic relationship between proper adherence and *P. falciparum* prevalence was detected. Estimates of adherence from follow-up visits were much lower than survey-based estimates in the same households (52.5% versus 87.1%), suggesting that lack of proper adherence may be a much larger issue on Bioko Island than previously thought. Anecdotally, the data-driven communication approach taken in this study was more effective in achieving desired behaviors than previous approaches focused on delivering a core set of messages to as many people as possible. The large discrepancy between adherence as measured in this study and survey-based estimates on Bioko Island suggests a health facility-based study to quantify adherence among the population receiving treatment for symptomatic malaria may be necessary.

7320

MALARIA OUTBREAK INVESTIGATION IN THE ARID NORTHERN WAJIR COUNTY, KENYA, DEC 2023-FEB 2024

Diana Rose Wangari Mwaura[1], Megumi Itoh[2], Brian Sigu[1], Elizabeth N. Kileku[1], Rose Ajambo[3], Ahmed Abade[1], Beatrice Machini[4], James Kiarie[4], James Sang[4], Jane Githuku[5], Maurice Owiny[1]

[1]Kenya Field Epidemiology and Laboratory Training Program (FELTP), Nairobi, Kenya, [2]United States President's Malaria Initiative, United States Centers for Disease Control and Prevention, Nairobi, Kenya, [3]Wajir County Health Department, Ministry of Health, Kenya, Wajir, Kenya, [4]National Malaria Control Program, Ministry of Health, Nairobi, Kenya, [5]Country Health Information Systems and Data Use, Nairobi, Kenya

From Jan–Feb 2024, Wajir County reported 373 malaria cases, compared to an expected <10 cases, in what is considered a low transmission zone. Rainfall in Oct–Nov 2023 (2992mm) was significantly more than the same period in 2022 (110mm). We investigated the outbreak to ascertain the case characteristics and implement intervention measures. We reviewed data from Dec 2023–Feb 2024 in registers from health facilities that reported confirmed malaria cases higher than the sum of the median and 3rd quartile of cases reported in the past 5 years. We conducted a data quality audit (DQA) by comparing data in the registers against data in the Kenya Health Information System (KHIS). Key informant interviews were conducted with questionnaires to assess epidemic preparedness in coordination structures, surveillance, emergency commodities, and field response. Environmental risk factors were assessed in villages with the most cases and we evaluated community knowledge, attitudes, and practices on malaria. Frequencies and proportions were calculated for quantitative variables and qualitative data were analyzed thematically. Of the 710 positive cases investigated, 471 (66.3%) were male and 587 (82.7%) were ≥ 5 years of age. Most cases 499 (70.3%) were from Jan 2024, 2 months after the peak rainfall. There were 20 (2.8%) *P. vivax* cases, 57 (8.0%) severe malaria cases, and 4 deaths (CFR 0.6%). The county lacked epidemic preparedness and response coordination structures, and adequate stocks of key diagnostic and treatment commodities. Mosquito breeding sites were identified, and the community was aware of malaria treatment, prevention, and risk factors. DQA found only one-third of the suspected malaria cases were reported in KHIS. After the increased rainfall from Oct–Nov 2023, Wajir saw a >30-fold increase in malaria. Challenges included commodity stockouts, presence of *P. vivax* (new for the area), and lack of a coordinated county response. Strengthening diagnostic and treatment capacity, and improving data quality for surveillance to guide intervention strategies are key to minimizing morbidity and mortality in future malaria outbreaks.

7321

QUALITY OF MALARIA SERVICE DELIVERY BY HEALTH CARE WORKERS FOR PATIENTS PRESENTING WITH FEBRILE ILLNESS IN HEALTH FACILITIES IN SOUTHEASTERN TANZANIA, 2023

Stella Makwaruzi[1], Michael Gulaka[1], Saidi Mgata[1], Geofrey Makenga[1], Marguerite M. Clougherty[2], Albert Ikonje[3], Chonge Kitojo[3], Sarah-Blythe Ballard[4], Naomi Serbantez[3], Sigsibert Mkude[1], Abdallah Lusasi[5], Samwel Lazaro[5]

[1]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [2]Population Services International (PSI), Washington DC, WA, United States, [3]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [4]U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, Tanzania, United Republic of, [5]National Malaria Control Programme, Ministry of Health, Dodoma, Tanzania, United Republic of

High quality clinical management improves patient outcomes. Clinical management of febrile patients depends on the skills of health care workers (HCWs). To assess and improve malaria service delivery quality by HCWs in Tanzania, we supported the National Malaria Control Program to assess services via the Malaria Services and Data Quality Improvement (MSDQI) platform and conduct supportive supervision (SS). Using standard MSDQI checklists that generate composite competency scores in the areas of clinical history taking, physical examination, malaria testing, malaria diagnosis, malaria treatment, and provider counseling, we analyzed clinical observation data from 1,822 febrile patient visits collected from 590 health facilities in the high-burden southeastern PMI coverage regions of Lindi, Mtwara, Ruvuma, and Pwani from January to June 2023. If reporting data were complete for a given competency area, then the competency score for that area was analyzed descriptively, with the national competency standard defined as a score of >=75% ("good"). During 1,822 reported febrile patient visits, HCWs met area-specific national competency standards for 370/923 (40%) clinical histories, 717/1622 (44%) physical examinations, 1534/1615 (95%) malaria testing, 1596/1607 (99%) malaria diagnosis, 1522/1570 (97%) malaria treatment, and 1080/1790 (60%) counseling. HCWs met overall competency standards for all six categories in 948/1822 (52%) of visits. Despite high proportions of HCWs meeting competency standards for malaria testing, diagnosis, and treatment, we found that provider history taking, physical examination, and counseling contributed to degradation

of the overall quality of service delivery. Facility-based service delivery in southeastern Tanzania could be improved by identifying and intervening on factors contributing to weakness in these areas.

7322

OPERATIONAL FACTORS INFLUENCING TIMELY MALARIA CASE REPORTING BY PRIVATE HEALTH FACILITIES IN URBAN DISTRICT, UNGUJA ZONE, ZANZIBAR

Mwatima S. Ali[1], Shija J. Shija[1], Mohamed Ali Haji[1], Geofrey Makenga[2], Humphrey Mkali[2], Marguerite M. Clougherty[3], Naomi Serbantez[4], Wahida Shirazi[1], Happiness P. Saronga[5], Phares G. Mujinja[5]

[1]Zanzibar Malaria Elimination Program, Ministry of Health, Zanzibar, Tanzania, United Republic of, [2]Population Services International (PSI), Dar es Salaam, Tanzania, United Republic of, [3]Population Services International (PSI), Washington DC, WA, United States, [4]U.S. President's Malaria Initiative, U.S. Agency for International Development, Dar es Salaam, Tanzania, United Republic of, [5]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania, United Republic of

In Zanzibar, an area targeted for elimination, delayed reporting of malaria cases remains a challenge. Healthcare providers in public and private facilities are required to report malaria cases through the Malaria Case Notification system within 24 hours of diagnosis using a mobile reporting application. In 2021, reporting timeliness was 72.7%, and District Malaria Surveillance Officers observed private health facilities had lower malaria reporting timeliness. A cross-sectional explorative study using a phenomenological qualitative approach was conducted to examine operational factors impacting timeliness of case reporting among private health facilities in Urban Districts of Unguja. Sixteen study participants were selected using purposive sampling due to their reporting responsibilities. In-depth Key Informant Interviews were conducted using semi-structured guides, and thematic data analysis was performed using NVIVO software version 12. Of healthcare workers who participated in the study, 94% (15/16) demonstrated awareness of the reporting process and all (100%) received training on timely reporting. All participants also (100%) reported communicating with other staff at their facilities about reporting responsibilities, despite some challenges including effective communication, workloads, and lack of collaboration within facilities. Furthermore, 56% of healthcare workers reported receiving incentives including meeting allowance and best-performing rewards for timely reporting, which they found motivating. All respondents acknowledged operational resources like smartphone and internet bundles also played a role in reporting timeliness. The findings suggest that incentives, effective communication, and availability of resources can influence reporting timeliness for malaria cases from private healthcare facilities. Strategies to address communication challenges and ensure adequate provision of operational resources might be further assessed to enhance timely reporting of malaria cases, ultimately contributing to improved malaria surveillance and control efforts in Zanzibar

7323

RETROSPECTIVE ANALYSIS OF MALARIA INCIDENCE IN GUINEA 2018 TO 2022

Abdourahamane Diallo[1], Oumar Billa[2], Nouman Diakité[1], Ousmane Diallo[3], Mohamed Saran Condé[4], Lazare Loua[1], Mohamed Dioubate[1], Mohamed Binne Camara[1], Galatas Beatriz[5], Jaline Gerardin[6], Alioune Camara[1]

[1]National Program for Malaria Control, Conakry, Guinea, [2]Northwestern University,, Guinea, Chicago, IL, United States, [3]Northwestern University,, Chicago, IL, United States, [4]Catholic Relief Services, Conakry, Guinea, [5]Global Malaria Program, Geneva, Switzerland, [6]Northwestern University, Chicago, IL, United States

The objective of this study was to analyze the trend in malaria incidence in Guinea at the level of health districts and identify factors associated with high or low incidence. We used malaria surveillance data from 2018 to 2022, along with demographic data and results from national surveys (DHS 2018 and MIS 2021). The analytical methods included estimation of adjusted malaria incidences, time series decomposition, and the Mann-Kendall test ($p < 5\%$). We also employed Sen's slope to determine the direction and quantify the intensity of the trend, as well as multivariable analysis to identify factors associated with increased incidence. The results showed that nationally, between 2018 and 2022, the annual crude incidence increased by 36.7%, and adjusted incidence (completeness + testing) increased by 34.4%, with a variation rate ranging from 0 to 27% depending on the health district (HD) and year. In total, 27 out of 33 districts exhibited a significant upward trend (coef: 20 to 60%), 1 district (Siguiri) showed a significant downward trend (coef: -20 to -40%), and in 5 districts, the incidence trend was not significant. Multivariable analysis identified factors related to intervention and the healthcare system associated with high or low incidence in the districts. In summary, this study highlights a significant increase in malaria incidence in Guinea between 2018 and 2022, with notable variations among districts. The results suggest particular concern for the 27 districts showing an upward trend, and the identified factors associated with this increase provide factual insights to guide malaria control efforts in Guinea.

7324

COST-UNIT ANALYSIS OF VECTORCAM: A NOVEL COMMUNITY-BASED AI TOOL FOR VECTOR SURVEILLANCE TO IDENTIFY MOSQUITOES' SPECIES IN RURAL UGANDA

Marina Rincon Torroella, Bryan Patenaude, Sunny Patel, April Zambelli-Weiner, Soumyadipta Acharya

Johns Hopkins University, Baltimore, MD, United States

Introduction: Advancements in digital tools have revolutionized mosquito surveillance for malaria control. VectorCam, is a novel tool that utilizes computer vision algorithms enabling low-cost, user-friendly mosquito identification at the village level. This study conducted collaboratively by the Johns Hopkins University, Makerere University, and the Ugandan Ministry of Health, aims to evaluate the cost per unit using VectorCam compared to traditional surveillance methods. **Methods:** In the randomized control trial in Uganda the village health team members (VHTs) in each arm collected mosquitoes using standard methods CDC light traps and pyrethrum spray catch from community households. Vector Control Officers in the control group, use microscopes and paper-based systems to morphological identify mosquitoes whereas in the study group, the VHTs employ the VectorCam app. Data in the control arm is manually transferred to the Ministry of Health's DHIS2 platform, whereas the study group's data is directly transferred via the app. **Preliminary Results:** Preliminary findings demonstrate VectorCam's ability to analyze a substantial volume of mosquitoes. Since September 2023, over 52,000 mosquitoes were imaged and analyzed, with 20.5k identified as *Anopheles* mosquitoes, of which 88% were female *Anopheles*. VectorCam's cost per mosquito analyzed was $0.50 per female *Anophelines* compared to the control arm of $0.64 per female *Anophelines*. **Conclusion:** Although both arms demonstrate an economy of scale the study arm maintains a consistently lower cost per unit. These findings highlight that in a country where scalability of their surveillance system is a priority, VectorCam could offer a financially advantageous alternative in high-volume settings than paper-based surveillance systems. VectorCam emerges as a robust tool for vector surveillance enhancing data collection and analysis, providing valuable insights for targeted interventions at the community level. This study highlights the importance of innovative digital solutions in advancing global health initiatives, particularly in resource-limited settings.

7325

ASSESSING THE FEASIBILITY OF IDENTIFYING AND VALIDATING SEROLOGICAL MARKERS OF RECENT LOW DENSITY *PLASMODIUM FALCIPARUM* INFECTIONS IN A PRE-ELIMINATION SETTING

Jessica Schue[1], Nora Pisanic[1], Delis Mattei-Lopez[1], Tamaki Kobayashi[1], Japhet Matoba[2], Michael Musonda[2], Ben Katowa[2], Harry Hamapumbu[1], Edgar Simulundu[2], Douglas E. Norris[1], Christopher D. Heaney[1], Amy Wesolowski[1], William J. Moss[1], **Sophie Berube**[1]

[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, [2]Macha Research Trust, Choma District, Zambia

Serological markers of recent malaria infection are promising tools to measure malaria epidemiology. Previous work has identified serological markers of recent infection in moderate transmission settings; however, the generalizability of these findings to pre-elimination settings, where low parasite density infections elicit low antibody responses, remains unclear. Using a multiplex bead assay (MBA), we measured IgG responses to 19 *Plasmodium falciparum* antigens within a longitudinal cohort in Southern Province, Zambia. Monthly samples collected between October 2018 and September 2020 were tested for *P. falciparum* using ultrasensitive qPCR and quarterly samples with the MBA. The MBA was run on 1940 samples from 277 individuals, 59 of whom had at least one qPCR positive event with parasite density below 100 parasites per microliter. We found no differences in antibody responses to any antigens comparing participants with a qPCR positive event to those without, nor between pre- and post-qPCR positive events, demonstrating the limited feasibility of identifying markers of recent low-density infections. Using multilevel linear regression models, between person variability explained 63% to 86% of overall variability in antibody responses. Furthermore, while antibody responses of participants with no qPCR positive events overlapped with responses of serum from U.S. samples, the variability among serially negative participants was at least twice that of U.S. serum across all antigens suggesting that U.S. control serum fails to adequately capture the full range of antibody responses of negative serum from malaria endemic regions. Antibody responses of 56 participants showed variability in responses greater than 10 times the median within-host variability, this was not associated with age, sex, or infection. A timeseries analysis of antibody responses showed autocorrelation between -0.2 and 0.2 for all timepoints, suggesting random variation. These findings highlight the potential importance of incorporating longitudinal controls from malaria endemic areas, particularly in settings where biomarkers produce low signal.

7326

IMPACT OF ROUTINE DATA QUALITY AUDITS (RDQA) IN IMPROVING DATA QUALITY AND MALARIA MANAGEMENT STANDARDS IN HEALTH FACILITIES IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

Jicko Bondole[1], Aline Nkulu[1], Jimmy Anzolo[1], Rova Ratsimandisa[1], Michael Hainsworth[2], Arantxa Roca Feltrer[3], Hyacinthe Kaseya[4], Alain Bokota[4], Ghislain Kikunda[4], Andre Kaseba[4], Eric Mukomena[4]

[1]PATH, Kinshasa, Congo, Democratic Republic of the, [2]PATH, Seattle, WA, United States, [3]PATH, Maputo, Mozambique, [4]National Malaria Control Program, Kinshasa, Congo, Democratic Republic of the

The fight against malaria requires the production of quality data to monitor disease trends and enable evidence-based decision-making. An assessment of the DRC malaria surveillance system conducted in 2021-22 revealed significant inaccurate reporting of malaria data, with only about 20% accuracy. The NMCP, with support from PATH, has developed and piloted a decentralized approach to implementing Routine Data Quality Audits (RDQAs) in 36 health facilities in 4 health zones in Haut-Katanga Province. The approach favors ownership and accountability by the peripheral level of the health system around data quality. Health teams were trained on the RDQA approach, malaria data quality assurance procedures, and management of malaria interventions and indicators. During the pilot phase (June 2023-March 2024), purposive sampling was used for the selection of RDQA sites (n=36) for logistical reasons. The following indicators were included in the RDQA: outpatient consultation, suspected malaria, RDT performed, positive RDT, confirmed uncomplicated malaria, uncomplicated malaria treated according to national policy, confirmed severe malaria, and severe malaria treatment. Two RDQA rounds were carried out in each health facility in June 2023 and November 2023. During each visit, malaria data checks were carried out to compare data between registers, monthly HMIS reports, and data reported in DHIS2. During field visits, health workers were interviewed about malaria case management and a qualitative assessment of the data management system was conducted. Several data quality attributes were analyzed, including the average accuracy of all data elements for each round. The overall improvement in mean data accuracy from round 1 (30%) to round 2 (56%) was statistically significant ($p<0.0001$) by paired T-test. Given the promising results seen during the pilot phase, the NMCP is planning a national harmonization of RDQA approaches and developing RDQA malaria implementation manuals and training materials. Current efforts are focused on harmonizing and digitizing the RDQA tool in the country to facilitate further expansion beyond the pilot area.

7327

DESCRIPTION OF FACTORS ASSOCIATED WITH MALARIA PREVALENCE IN TWO TRANSMISSION SETTINGS IN SIAYA COUNTY, WESTERN KENYA (2022-2024)

Oliver Towett[1], Victoria Seffren[2], Alice Kamau[3], Brian Seda[1], Daniel McDermott[3], Caroline Ogwang[1], Kizito Obiet[1], Julia Janssen[2], Maia Lesosky[4], Wycliffe Odongo[2], Julie R. Gutman[2], Jonathan Schultz[2], Simon Kariuki[1], Aaron M. Samuels[2], Feiko ter Kuile[3], Sarah G. Staedke[3]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Malaria Branch, Division of Parasitic Diseases and Malaria, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Imperial College London, London, United Kingdom

Malaria remains a public health challenge in western Kenya, with persistent transmission despite ongoing prevention and control efforts. Understanding the prevalence and associated factors among malaria cases is crucial for effective control. A continuous malaria indicator survey was conducted from April 2022 to March 2024 in Rarieda and Alego Usonga sub-counties, Siaya County, western Kenya. A total of 1,960 compounds were randomly selected from sub-county censuses to be surveyed. Demographic information, temperature, history of fever, and insecticide-treated net (ITN) use, were collected from consenting persons of all ages, and a malaria rapid diagnostic test (RDT) was administered. Correlates of malaria infection, including age, current fever, fever in the past 2 weeks, and ITN use were assessed using Poisson generalized linear regression models stratified by sub-county. In total, 7,490 (3,738 in Alego Usonga and 3,752 in Rarieda) individuals were included (1,008 (13.5%): <5yrs, 2,223 (29.7%): 5-14yrs and 4,259 (56.9%): 15+ yrs old). Malaria prevalence was 39.2% [95% CI: 38.1-40.3] with a higher prevalence in Alego Usonga (54.4% [95% CI: 52.7-56.0]) vs. Rarieda (24.1% [95% CI: 22.7-25.5]). Most cases were afebrile at the time of testing (99.6% [95% CI: 97.3% - 100%); 3.4% [95% CI: 3.0-3.8] reported fever in the past 2 weeks. Most (81.6%, 95% CI: 80.7-82.5) reported ITN use the night prior. Compared to those <5yrs, those 5-14yrs had higher risk (aPR: 1.31 [95% CI: 1.15 - 1.50] in Alego Usonga and 1.67 [95% CI: 1.37 - 2.06] in Rarieda) while those >15 had lower risk (aPR= 0.68 [95% CI: 0.60 - 0.78] in Alego Usonga and 0.71 [95% CI: 0.58 - 0.88] in Rarieda). Self-reported fever in the past 2 weeks was associated with an increased malaria risk (aPR: 1.51 [95% CI: 1.20 - 1.87] in Alego Usonga and 2.64 [95% CI: 2.09 - 3.28] in Rarieda). The findings highlight that children ages 5-14yrs remain a key risk group for malaria, emphasizing the need for additional tools and strategies to control transmission particularly targeting this key risk group. Given the high ITN use, factors including ITN quality, use duration, and time of entry and exit will be explored.

7328

IMPORTANCE OF A STRONG LOGISTIC MANAGEMENT INFORMATION SYSTEM TO REDUCE MALARIA COMMODITY LOSSES IN MADAGASCAR

Solofo Razakamiadana[1], Yvette Razafimaharo[2], Jemima Andriamihamina[1], Jocelyn Razafindrakoto[1], Anna Bowen[1]

[1]US President's Malaria Initiative, Antananarivo, Madagascar, [2]National malaria program, Antananarivo, Madagascar

Between 2009 and 2020, Madagascar used a locally-designed, centrally-managed software called CHANNEL to facilitate the management of health sector commodities. Its specific purpose was to track stock levels and the movement of commodities between district pharmacies and health facilities with the aim of optimizing stock levels of essential commodities at both levels. In 2021, the Ministry of Health abandoned CHANNEL because it was inaccessible online and computer viruses destroyed the database behind the software. Since 2022, while awaiting the acquisition of new software for its logistics management system, which has been delayed, Madagascar has been using an ad hoc offline tracking platform centrally and peripheral health facilities continued reporting limited monthly stock data to DHIS2. Since 2009, the US President's Malaria Initiative has supported the Ministry of Health through an implementing partner to improve commodity management in all 115 districts. We assessed overall loss of malaria commodities through expiration, loss, or damage using data from DHIS2, comparing losses in 2022 and 2023 to those in 2021. Expiration, loss, or damage of 34,431 courses of Madagascar's first-line artemisinin-based combination therapy (ACT) and 49,715 malaria rapid diagnostic tests (mRDTs) was reported nationally in 2021. In 2022 and 2023, the number of ACTs that expired or were lost or damaged increased, respectively, to 142,925 courses (+315%) and 189,607 (+450%) courses. The number of expired, lost, or damaged mRDTs also increased in 2022 (198,471 mRDTs [+299%]) and 2023 (226,068 mRDTs [+354%]). The total procurement cost of these losses is equivalent to $24,730 in 2021, $90,532 in 2022, and $130,225 in 2023. In the absence of a supply chain management platform that integrates supply and demand data at all levels, Madagascar has experienced increased commodity loss. A supply chain system that tracks commodity movement, is accessible at all levels, and integrates supply- and demand-side data, and resources to redeploy excess stock, are crucial to improve the use of commodities in the context of limited resources and heterogenous transmission.

7329

MOLECULAR SURVEILLANCE OF MALARIA IN ENDEMIC REGIONS IN UGANDA REVEALS HIGH GENETIC DIVERSITY OF *PLASMODIUM FALCIPARUM* AND CORRELATION WITH TRANSMISSION INTENSITY

Shahiid Kiyaga[1], Thomas Katairo[1], Monica Mbabazi[1], Diana Kisakye[1], Bienvenu Nsengimaana[1], Stephen Tukwasibwe[1], Francis Ddumba[1], Victor Asua[1], David P. Kateete[2], Joyce N. Nabende[2], Samuel L. Nsobya[1], Moses R. Kamya[1], Isaac Ssewanyana[1], Andres Aranda-Diaz[3], Philip J. Rosenthal[3], Mellisa Conrad[3], Bryan Greenhouse[3], Jessica Briggs[3]

[1]Infectious Diseases Research Collaboration, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]Division of HIV, Infectious Diseases and Global Medicine, Department of Medicine, University of California San Francisco, San Francisco, CA, United States

Despite significant progress in genetic research enhancing our understanding of malaria, integrating these findings into practical strategies, especially concerning malaria transmission, remains underexplored. Although malaria epidemiology and parasite population genetics have developed distinct viewpoints, this study merges these perspectives. We explore the genetic diversity of P. falciparum and its link to transmission intensity using initial data from Uganda's first extensive molecular surveillance campaign in malaria-endemic areas. Our objective is to analyze the variability in transmission intensity across high endemic regions of Uganda, utilizing P. falciparum specific genomic data and epidemiological measures. We examined 2400 dried blood spot samples from symptomatic cases across 24 health facilities, averaging 100 samples per site. We calculated malaria incidence as cases per 1000 person-years over the three months before sample collection. The facilities represent varying transmission levels: high (over 500 cases per 1000 person-years in 9 centers), moderate (250-500 cases, 6 centers), and low (1-250 cases, 9 centers). We employed the MAD4HatTeR technique targeting 165 microhaplotypes and used MOIRE to assess infection complexity and within-host parasite relatedness. Early results showed a high average complexity of infection at 3.19, with significant within-host relatedness averaging 0.65. Interestingly, complexity decreased with patient age and increased with higher transmission levels, suggesting a link between transmission intensity and genetic diversity. These findings indicate potential superinfection and cotransmission rates, with ongoing analysis focused on identifying genetic indicators most predictive of local transmission intensities.

THE INTEGRAL ROLE OF GIS IN THE SEASONAL MALARIA CHEMOPREVENTION CAMPAIGN TO IMPROVE MONITORING_A CASE STUDY OF TARABA STATE, NORTHEAST, NIGERIA

Chinedu J. Chukwu[1], **Jerry Agulehi**[1], Isaac Adejo[1], Dozie Ezechukwu[1], Victoria C. Erinle[1], Thomas A. Hall[2], Sonachi S. Ezeiru[3], Frank Oronsaye[3], Emmanuel U. Obi[3], Chukwu Okoronkwo[4], Godwin N. Ntadom[4], James Ssekitooleko[5]

[1]Management Sciences for Health, Abuja, Nigeria, [2]Management Sciences for Health, Arlington, VA, United States, [3]Catholic Relief Services, Abuja, Nigeria, [4]National Malaria Elimination Program, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

Malaria in Nigeria is a persistent issue that requires strategic interventions. Mass Drug Administration (MDA) is crucial, especially in Taraba State, with a population of over 3.2 million. Seasonal Malaria Chemoprevention campaigns are key to malaria control. The Management Sciences for Health Global Fund Malaria has integrated geographical information systems (GIS) into MDA campaigns for better planning, implementation, and assessment. The study investigates the use of the Geographic Information System (GIS) in Taraba State's 2023 Seasonal Malaria Chemoprevention Campaign, to address inadequate supervision by monitors during mass drug distribution, focusing on intervention efficacy tracking, coverage examination, and monitoring at various levels. The SMC campaign used GIS technology to map and analyze key activities, including medicine delivery locations, demographic analysis, and malaria-prone regions. Geocoordinates were collected using platforms like Redrose and Kobocollect and placed on GIS platforms with basemaps from Google Maps and Google Satellite. SMC supervisors used handheld devices to take geo-coordinates at CDD drug administration sites. The GIS-based SMC campaign monitoring identified high-risk zones, streamlined logistics, evaluated campaign coverage, determined mass mop-up locations, and improved communication tactics. Monitoring of SMC supervisors' coverage. Real-time monitoring enabled aggressive responses to new challenges from 2021 to 2023, the supervisory coverage across supported wards increased from 60 to 90, resulting in a 65% to 89% increase. The 2023 Seasonal Malaria Chemoprevention campaign in Taraba State utilized GIS for targeted actions, logistics, and understanding of campaign dynamics. This demonstrates the potential of GIS in improving supervisors' coverage and visibility at sites, mass drug administration exercises, and providing crucial information for Nigeria's future malaria elimination plans. Consistent integration of GIS into MDA microplanning is recommended for long-term success.

7331

EXTENDED INTERVAL REGIMEN OF PREQUALIFIED MALARIA VACCINE R21 ADJUVANTED WITH 3M052 ELICITS HIGH AVIDITY ANTI-CIRCUMSPOROZOITE PROTEIN ANTIBODIES IN NON-HUMAN PRIMATES

Kan Li[1], Prabhu S. Arunachalam[2], Matthew O. Herbst[1], Gillian Q. Horn[1], Milite Abraha[1], Siam Shabbir[1], Rachel L. Spreng[1], Adrian V.S. Hill[3], Sheetij Dutta[4], S. Moses Dennison[1], Bali Pulendran[2], Georgia D. Tomaras[1]

[1]Duke University, Durham, NC, United States, [2]Stanford University, Stanford, CA, United States, [3]University of Oxford, Oxford, United Kingdom, [4]Walter Reed Army Institute of Research, Silver Spring, MD, United States

R21 is a WHO prequalified malaria vaccine targeting the pre-erythrocytic stage of *Plasmodium falciparum* (*Pf*) life cycle, exhibiting 74-77% efficacy in clinical trials in malaria endemic regions. By quantifying the binding kinetics of sera from multi-dose R21 immunized rhesus macaques to antigens (Ags) that include a recombinant *Pf* circumsporozoite protein (CSP), NANP6 (represent *CSP* central repeat region) and PF16 (represent *CSP* C-terminal region) measured using biolayer interferometry, we investigated whether varying adjuvants (3M052, GLA-LSQ or Matrix-M), immunization routes (subcutaneous (SC) or intramuscular (IM)) and/or vaccine schedules (standard regimen (weeks 0, 4, 8, and 62; SR) or extended interval regimen (weeks 0, 8, 23, and 72; ER)) influence R21-induced CSP targeting antibody (Ab) response and avidity. Among all combinations, IM groups with 3M052 or Matrix-M showed the highest Ab responses for CSP and NANP6 at post 3rd vaccination (PD3). Compared to Matrix-M IM-SR, the 3M052 IM-SR group showed comparable CSP and NANP6 responses but lower trending PF16 response, with the trend continuing at post 4th vaccination (PD4). Compared to 3M052 IM-SR, the 3M052 IM-ER group elicited >3 fold higher PF16 response but lower NANP6 response at PD3 and PD4 as well as showed 2.8-12.3 fold more retention of high Ab responses between PD3 and PD4 for CSP and PF16. Our avidity quantification further dissected the dissociation time course of Ag-sera interaction into components of different dissociation rates using Polyclonal Antibody Avidity Resolution Tool (PAART). Compared to 3M052-IM-SR, the 3M052-IM-ER group showed improved Ag occupancy by high avidity Abs at PD4 with 3 fold higher avidity over PD3 for NANP-targeting antibodies (binding to NANP6), despite low response at PD4. Additionally, for high responders in all 3M052 groups, high avidity Abs maintained >90% Ag occupancy between PD3 and PD4 despite decreasing Ab response. These results suggest that adjuvanting with 3M052 with an extended interval dosing schedule could increase the abundance and quality of R21-induced anti-CSP Abs and potentially improve Ab-mediated protection.

7332

IMPACT OF RTS,S MALARIA VACCINE ON *PLASMODIUM FALCIPARUM* INFECTION IN SCHOOL-AGED CHILDREN: INTERIM RESULTS FROM INDIVIDUALLY RANDOMIZED CLINICAL TRIAL IN MALAWI

Christopher C. Stanley[1], Tabither Kaunda[1], Harrisson Msuku[1], Alfred Matengeni[1], Karl B. Seydel[2], Lauren M. Cohee[3], Terrie Taylor[2], Clarissa Valim[4], Don P. Mathanga[1]

[1]Malaria Alert Centre, Kamuzu University of Health Sciences, Blantyre, Malawi, Blantyre, Malawi, [2]College of Osteopathic Medicine, Michigan State University, Michigan, MI, United States, [3]Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [4]Department of Global Health, Boston University School of Public Health, Boston, MA, United States

The burden of *Plasmodium falciparum (Pf)* malaria, including malaria-related anemia, is shifting towards school-aged children (SAC), who often have limited access to malaria interventions such as long-lasting insecticidal nets and prompt diagnosis and treatment. The RTS,S/AS01 malaria vaccine, the first vaccine recommended for under-five children in 2021, could potentially reduce the burden of clinical malaria in SAC. However, the effect of RTS,S/AS01 on SAC has never been assessed. As part of the first, individually randomized clinical trial assessing efficacy of RTS,S/AS01 in SAC, we evaluated the impact of the vaccine on *Pf* infection in children aged 6-15 years attending 5 primary schools in rural southern Malawi. This report is based on 3,884 children with median age 10 years (interquartile range [IQR] = 8-12 years), who were randomized to one of 4 intervention arms: 1) RTS,S/AS01 alone (963 children), 2) RTS,S/AS01 + parasite clearance with artemether-lumefantrine (AL) at enrollment (970 children), 3) parasite clearance with AL at enrollment alone (978 children), and 4) control receiving only Vitamin A (Vit A) (973 children). Participants were followed for detection of clinical malaria through a surveillance system at school clinics to which they reported whenever they felt symptoms. Malaria diagnosis was confirmed through microscopy (primary) and malaria rapid diagnostic test (mRDT). At this point, all participants in the 4 arms have received the 1st dose of the assigned intervention; 88% of participants in the two RTS,S/AS01 arms have received 2 doses and 82% all three doses of the vaccine. In 10 months of follow-up to date, median time to first mRDT positive malaria episode was 4 months (IQR: 2-6 months), with disease-free survival rates of 46% (95% CI: 42%-50%) overall, and 46% (95% CI: 37%-55%) RTS,S/AS01, 52% (95% CI: 42%-61%) RTS,S/AS01+AL; 48% (95% CI: 41%-55%) AL and 42% (95% CI: 36%-49%) Vit A. Thus far, neither of the RTS,S/AS01 arms show reduced time to *Pf* infection by mRDT. Results of an additional 7 months of exposure, and test results using both mRDT and microscopy, will be available from October 2024.

7333

ACCELERATED STABILITY STUDY OF CGMP DRUG PRODUCT INTERMEDIATE PVS230D1-EPA CONJUGATE

Daming Zhu, Holly McClellan, Weili Dai, Brendon Carnell, Karine Reiter, Nicholas J. MacDonald, Kelly M. Rausch, David L. Narum, Patrick E. Duffy

Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, MD, United States

Pvs230 is a promising *Plasmodium vivax* malaria transmission-blocking vaccine (TBV) candidate antigen. Pvs230 is expressed by gametocytes in the human host and displayed on the surface of gametes in the mosquito host. Antibodies generated against Pvs230 disrupt parasite development in the mosquito. To increase the immunogenicity of a *Pichia pastoris*-expressed domain 1 of Pvs230, recombinant Pvs230D1M was conjugated to the recombinant, non-toxic *Pseudomonas aeruginosa* ExoProtein A (rEPA), a carrier protein, in conformance with current good manufacturing practices (cGMP). To assess the stability of this conjugated vaccine candidate during storage, transportation and administration, an accelerated stability study was performed. The non-formulated cGMP Drug Product Intermediate, a 200 µg/mL Pvs230D1-EPA conjugate, was stored at -80ºC, -20ºC, 4ºC, 25ºC and 40ºC, and sampling was conducted at Days 0, 1, 3 and 7 for testing. The stability of the vaccine candidate was evaluated by appearance; pH; protein content by UV (A_{280}); SDS-PAGE with silver staining; Western blot with a transmission-blocking anti-Pvs230D1 monoclonal antibody 1H3, and an anti-exotoxin A polyclonal antibody; RP-UPLC; and size exclusion chromatography with multi-angle light scattering (SEC-MALS). Our results showed that the Pvs230D1-EPA conjugate is stable for at least 7 days after storage at 4°C and 25ºC. Storage at 40ºC showed a significant time-dependent decrease (Δ~15%, $p<0.05$) in molar mass of the conjugate when evaluated by SEC-MALS, although it is unknown whether this change impacts potency. Some changes by Western blot were observed including lower molecular weight bands when probed by both mAb 1H3 and the anti-exotoxin A polyclonal antibody after storage for 3 days at 40ºC. Storage at -20ºC showed a trend toward an increase in molar mass, suggesting minor aggregation after 1 day. These results indicate the Pvs230D1-EPA DPI maintains good stability characteristics when stored at various temperatures. More stability studies are warranted to better understand the implications of the observed changes and impact on vaccine efficacy in future formulations.

7334

DEVELOPMENT OF VACCINE CANDIDATES AGAINST PLACENTAL MALARIA USING PEPTIDE-DECORATED ANTIGENIC LIPOSOMES

Payton LeBlanc

University of Alberta, Edmonton, AB, Canada

The WHO reported over 13 million pregnancies exposed to malaria infection in 2021, endangering both the mother and fetus. *Plasmodium falciparum* causes placental malaria by infecting red blood cells that accumulate in the intervillous space and bind to the syncytiotrophoblast of the placenta. Infected cells express the parasite virulence factor VAR2CSA that binds to chondroitin sulfate A (CSA) chains on proteoglycans in the placenta. The sequestration of infected red blood cells (iRBC) is associated with low birth weight, pre-term birth and fetal growth restriction. A vaccine against VAR2CSA is highly desirable to prevent these birth outcomes. In pre-clinical studies, we identified two peptides that mapped to conserved epitopes on VAR2CSA, P6 (in DBL3X) and P10 (in DBL4ε), and induced antibodies that prevented binding of iRBCs to CSA *in vitro.* We hypothesize P6 and P10 can be combined into a liposome-based multivalent peptide vaccine to induce synergistic inhibitory antibodies against VAR2CSA. Strain promoted azide-alkyne cycloaddition chemistry was employed to conjugate the peptides to a lipid linker prior to preparation of the liposomes via thin film hydration. We prepared single and multi-epitope liposomes with encapsulated ovalbumin to enhance the immunogenicity of the liposomes. The lipophilic adjuvant monophosphoryl lipid A was incorporated into the formulation as it is a TLR4 agonist and implicated in T cell activation. The resulting peptide-decorated liposomes were 189.8 nm (± 46.8) in size with a polydispersity index ranging from 0.2-0.4. Conjugation of both peptides to the liposomes was confirmed by ELISA. C57BL/6 mice were immunized subcutaneously with the antigenic liposomes and the sera will be tested for recognition of iRBCs infected with parasite strains expressing different alleles of VAR2CSA in an inhibition-based assay. Overall, our goal is to develop immunogenic liposomes against placental malaria to contribute to the urgent need for effective malaria vaccines.

7335

SAFETY AND REACTOGENICITY OF THE MALARIA VACCINE CANDIDATE ANAPN1 IN HEALTHY ADULTS IN GABON: PRELIMINARY DATA OF A RANDOMIZED, CONTROLLED, PHASE1 DOSE-ESCALATION CLINICAL TRIAL

Jeannot Frejus Zinsou[1], Grace Cherile Ongouta[1], Jean Ronald Edoa[1], Elsy Dansou[1], Latifeh Dahmash[2], Bayode Romeo Adegbite[1], Benjamin Akim Mordmueller[3], Rhoel Ramos Dinglasan[2], Ayola Akim Adegnika[1]

[1]CERMEL, Lambarene, Gabon, [2]University of Florida, Gainesville, FL, United States, [3]Radboud University Medical Center, Nijmegen, Netherlands

Malaria remains a major global public health issue in endemic regions. In preclinical studies, the recombinant AnAPN1 vaccine candidate has shown promising activity. Here, we assessed the safety, tolerability, and reactogenicity of three doses of the AnAPN1 vaccine, formulated with and without the GLA-LSQ (glucopyranosyl lipid containing QS21/saponin) adjuvant, administered to healthy adults. A randomized, double-blind, controlled, dose-escalation phase1 clinical trial was conducted in Lambaréné, Gabon among 33 healthy male and female volunteers aged 18-45 years. Participants were randomly assigned to one of 3 ascending dose groups. In each cohort, 9 participants received AnAPN1 with GLA-LSQ and 2 received the vaccine without adjuvant. The 20µg, 50µg, and 100µg vaccine doses were administered intramuscularly at days 0, 28, and 56-day in the first, second, and third cohorts, respectively. The vaccine's safety and reactogenicity were evaluated by means of close participant monitoring for any adverse effects occurring during and after vaccinations. The trial is registered with ClinicalTrial.gov, NCT05905432 and is still ongoing. Between October and December 2023, 55 participants were screened, of whom 33 eligible participants were recruited and allocated to either the 20µg, 50 µg, or 100µg dose in 3 sequential cohorts of 11 individuals each. The median age of enrolled participants is 27 years (range: 18-43 years). At the time of this analysis, participants in cohort 1 (n=10), cohort 2 (n=10) and cohort 3 (n=11) received the complete 3-dose vaccination schedule. The most frequently solicited local adverse events were mild to moderate injection site pain, representing 92% (44/48) of local events, and mild headache 36% (29/81) and nausea 19% (15/81) at a systemic level. There were no vaccine related serious adverse events reported. Overall, these preliminary results suggest that the administration of the AnAPN1 malaria candidate vaccine is safe and well tolerated in healthy Gabonese adults. Subsequent immunogenicity studies will determine whether it induces adequate IgG responses to justify a future phase2 clinical trial.

7336

CAREGIVER PERCEPTION AND ACCEPTABILITY OF THE MALARIA VACCINE RTS,S PRIOR TO INTRODUCTION IN THE FAR NORTH REGION OF CAMEROON

Innocent M. Ali[1], Arsène Dombou Zeufack[1], Nelris M. Kongor[1], Voundi J. Voundi[2], Jean Pierre Kidwang[2], Dominique Bomba[2], Abas Muliom[3], Dorothy F. Achu[4], Jean-Louis A. Ndiaye[5], Joel Ateba[2]

[1]University of Dschang, Dschang, Cameroon, [2]National Malaria Control Program, Yaounde, Cameroon, [3]PSI Cameroon, Yaounde, Cameroon, [4]WHO AFRO, Brazzaville, Congo, Republic of the, [5]University of Thiès, Thiès, Senegal

Malaria is a recurrent public health challenge that requires a combination of strategies to address it in view of elimination. Currently, the malaria vaccine RTS,S vaccine is being introduced in several African malaria endemic countries while in Cameroon, the vaccine was introduced in January 2024. In view of interventions to evaluate the effectiveness of the RTS,S vaccine in Cameroon, pre-introduction caregiver perceptions and acceptability of the malaria vaccine was investigated in the Far North region, which poses the greatest risk of malaria related morbidity and mortality among under 5 children in Cameroon. A household survey was conducted in December 2024 involving 1240 parents/guardians in 4 randomly selected semi-urban and rural health areas of the Maroua 3 health district in the Far North region of Cameroon. The acceptability was explored. Quantitative data was analysed using regression analysis and qualitative data in Atla.ti using both inductive and deductive approaches. Among the 1203 participants, 79.3% were aged between 20 and 40 years and 71.1% had at most primary education. About 1 in 4 respondents were aware of the malaria vaccine Overall, 95.4% of caregivers interviewed were willing to accept the malaria vaccine if available. Confidence of vaccine efficacy,[5,78(aOR:1,27 ; 26,39), p=0.023], or were not concerned[aOR:3,75(1,09 ; 12,88)]. Believe in vaccine presenting low risk of serious reactions, independently affected acceptability. Community health workers were generally favorable to a combination of routine delivery through EPI and campaign style to implementation of the malaria vaccine given the high seasonality of malaria and experience with SMC. Overall, caregivers and community health workers expressed positive perception of the efficacy, health benefits and reduced out of pocket costs due to malaria infection of the RTS,S vaccine. Concerns on serious adverse reactions were expressed by <5% of respondents. Caregivers preferred vaccines delivered at home and community health care workers advocated for a hybrid approach to malaria vaccine delivery given their experience with other vaccines and SMC.

7337

EFFECTIVENESS AND IMPACT OF THE RTS,S/AS01$_E$ MALARIA VACCINE ONE YEAR AFTER THE PRIMARY VACCINATION IN REAL-LIFE SETTINGS IN THREE SUB-SAHARAN AFRICAN COUNTRIES: INTERIM RESULTS

Valerie Haine[1], *RTS,S Epidemiology EPI-MAL-003 study group*[2]

[1]GSK, Wavre, Belgium

In the framework of the WHO-coordinated Malaria Vaccine Implementation Programme (MVIP), the RTS,S/AS01$_E$ malaria vaccine was introduced in selected areas in Ghana, Kenya and Malawi through routine national immunization programs. Within selected MVIP areas, a prospective cohort

disease surveillance study (EPI-MAL-003, NCT03855995) is conducted to assess safety, effectiveness and impact of the RTS,S/AS01$_E$ vaccine in children under 5 years old. Children were followed up through home visits and continuous monitoring of outpatient visits and hospitalizations in selected sites where the vaccine was introduced (exposed clusters) and comparator sites where the vaccine was not initially introduced (unexposed clusters). Vaccine effectiveness and impact were assessed on the incidence of malaria, hospitalizations, anemia and mortality. Results (crude estimates) up to one year after the 3-dose primary vaccination are presented here. This interim analysis (study period: 2019-2023) included 44,912 children uniformly distributed between exposed and unexposed clusters. In the exposed clusters, the primary RTS,S/AS01$_E$ vaccination coverage was 85%. Incidence rate (IR, 95% confidence interval [CI]) per 100,000 person-years (PY) of severe malaria was 252.9 (182.3-341.9) in vaccinated vs 591.3 (489.9-707.6) in unvaccinated children (vaccine impact: 57%). IR (95% CI) per 100,000 PY of all-cause hospitalization was 8,713.0 (8,269.8-9,173.8) in vaccinated vs 10,644.3 (10,198.3-11,104.8) in unvaccinated children (vaccine impact: 18%). IR (95% CI) per 100,000 PY of malaria-attributed hospitalization was 2,342.3 (2,115.3-2,587.1) in vaccinated vs 3,513.3 (3,259.1-3,782.1) in unvaccinated children (vaccine impact: 33%). No vaccine impact was observed on anemia cases at hospital entry. Vaccine impact on all-cause mortality was 17% but did not reach statistical significance (IR ratio: 0.83 [95% CI: 0.64-1.08], p=0.162). The RTS,S/AS01$_E$ vaccine showed positive impact in reducing severe malaria, malaria-attributed hospitalization and all-cause hospitalization over one year after the primary vaccination in real-life settings.

CHARACTERIZING HUMAN MONOCLONAL ANTIBODIES INDUCED BY VACCINES AGAINST PLASMODIUM VIVAX DUFFY-BINDING PROTEIN

Mimi M. Hou[1], Martino Bardelli[1], Doris Quinkert[1], Cassandra A. Rigby[1], Carolyn M. Nielsen[1], Robert W. Moon[2], Kirsty McHugh[1], Angela M. Minassian[1], Simon J. Draper[1]

[1]University of Oxford, Oxford, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom

There are no licensed vaccines against *Plasmodium vivax*, the second most common cause of malaria in humans. Vaccine candidates targeting *P. vivax* Duffy-binding protein region II (PvDBPII), an antigen expressed during the blood-stage of the parasite life cycle, have recently been tested for efficacy in controlled human malaria infection trials in adults. These showed that delayed boosting with a protein-in-adjuvant vaccine partially inhibited parasite growth and that the level of *in vivo* growth inhibition correlated with antibody responses. However, the mechanism(s) of antibody-mediated parasite growth inhibition are not well defined. To determine the breadth of antibody responses that humans generate in response to PvDBPII-based vaccines and the mechanisms of protective antibody responses, we have isolated a large panel of over 150 IgG monoclonal antibodies (mAb) from humans vaccinated against PvDBPII. Anti-PvDBPII specific single cell sorted B cells were isolated from blood and recombinant mAbs were expressed in mammalian cells. The antibody variable gene sequences were analysed using IMGT V-quest. ELISA and high throughput surface plasmon resonance are being used to determine binding characteristics of each mAb and to identify mAb communities of with competitive epitope binding interactions. The functional activity of mAbs was assessed with an *in vitro* parasite growth inhibition activity (GIA) assay using transgenic *P. knowlesi* expressing PvDBP, which showed that the majority of mAbs are GIA positive over a range of potency. Data from this large panel of anti-PvDBPII mAb will be used to define characteristics that determine the functional potency of mAb across different epitopes within PvDBPII. This will help guide the rational redesign of new PvDBPII-based vaccines to improve on efficacy as well as development of prophylactic mAb against blood-stage *P. vivax*.

7339

COMPARATIVE STUDY OF ANTIBODY EFFECTOR FUNCTIONS IN UK INDIVIDUALS AFTER VACCINATION EITHER WITH RTS,S AS01$_B$ OR R21 MATRIX-M ENROLLED INTO CONTROLLED HUMAN MALARIA INFECTION STUDIES

Olivia Muñoz[1], Samuel Provstgaard-Morys[1], Ben Hollingdale[1], Adriana Tomic[2], Katie Ewer[1], Adrian V S Hill[1], Lisa Stockdale[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Hariri Institute for Computing, Boston University, MA, United States

In 2022, malaria remained a leading cause of death in Sub-Saharan Africa, with more than 249 million cases and 608,000 deaths, *Plasmodium falciparum* (*Pf*) being the most widespread and deadly form of the parasite. Highly efficacious vaccines are valuable additions to core interventions to reduce malaria incidence and mortality. Recently, two pre-erythrocytic malaria vaccines based on a *Pf* antigen circumsporozoite protein (CSP), RTS,S/AS01$_B$, and R21/Matrix-M, have been licensed for the prevention of malaria in children. Vaccine-induced IgG antibodies against the central NANP repeat region of the CSP are known as the main driver of protection. The identification of the mechanism by which vaccine-induced antibodies provide protection at the individual level after CSP-based vaccines is still needed to facilitate rapid clinical development of new vaccine candidates. In this study, we performed a comprehensive antibody profiling using serum of UK adults enrolled in Controlled Human Malaria Infection studies and vaccinated either with RTS,S (N=24) or R21 (N=33), to provide information regarding the quantitative and qualitative functions of vaccine-induced antibodies associated with protection. Associations with protection were assessed for the two vaccines at the time of challenge (one month after three doses of vaccines). For RTS,S vaccinees, we observed higher FcγRIIIa binding (*P*=0.03) in protected compared with unprotected participants. For R21 vaccinees, we observed increased ability of antibodies to inhibit sporozoite invasion (*P*=0.04) in protected compared with unprotected participants. For both vaccines, complement deposition was higher in protected participants (RTS,S *p*=0.02; R21 *p*=0.04). In conclusion, antibody characterisation after vaccination at the time of challenge highlighted different functional humoral immune profiles between protected and non-protected participants across RTS,S and R21 vaccines. These findings may help to assess vaccine immunogenicity of new CSP-based vaccine candidates.

7340

SAFETY AND IMMUNOGENICITY OF THE MALARIA VACCINE R21/MATRIX-M™IN UGANDAN CHILDREN LIVING WITH HIV

Fernando Ramos Lopez[1], Gloria Lubega[2], Lisa Stockdale[1], Meera Madhavan[1], Michael Mubiru[2], Joseph Lutaakome[2], Emma Beaumont[3], Mehreen Datoo[1], Katerina Rapi[1], Amelia Bajer[1], Sophie Weston[1], Alison Lawrie[1], Jack Quaddy[1], Mary Nyantaro[2], Prasad S Kulkarni[4], Sandesh Bharati[4], Eugene Ruzagire[2], Adrian V.S. Hill[1]

[1]The Jenner Institute, University of Oxford, Oxford, United Kingdom, [2]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Serum Institute of India Private Ltd, Pune, India

Malaria remains one of the main causes of mortality in children in Sub-Saharan Africa. Despite the initial success of preventive programmes, progress in reducing malaria incidence has stalled in recent years. A safe and highly effective vaccine is paramount to reduce malaria incidence in this population and to progress towards eradication. R21/Matrix-M™ malaria vaccine has been shown to be safe and highly effective in a phase 3 trial (73% vaccine efficacy [95% CI 70 to 76] to first malaria episode within 12 months) which resulted in the WHO recommendation in October 2023 and pre-qualification in December 2023. In sub-Saharan Africa, the areas most affected by malaria overlap substantially with the areas most affected by HIV. For successful deployment of R21/Matrix-M™, it is necessary to assess the safety and immunogenicity of R21/Matrix-M

in this vulnerable population. Although children living with HIV may have been enrolled in the R21/Matrix-M™ phase 3 trial as HIV-infection itself was not an exclusion criterion, this is the first trial to specifically assess the safety and immunogenicity of the R21/Matrix-M™ in this population. 100 HIV positive and 20 HIV negative children, aged 5-36 months, were recruited and received 3 doses of R21/Matrix-M™. We collected safety data for solicited adverse events for 7 days after each vaccination and unsolicited adverse events for 30 days after each vaccination. Serious adverse events are collected for the duration of the trial. Blood samples to assess immunogenicity were taken before enrolment, before administration of the third dose, and one, 6 and 12 months after the third dose and results will be presented in the meeting. R21/Matrix-M™ was well tolerated, and the adverse events observed were similar to the adverse events observed in previous R21/Matrix-M™ trial in children. Most of the solicited and unsolicited adverse events were mild or moderate, and short- lived. There were no observed trends in unsolicited adverse events. There were no serious adverse events assessed as related to the vaccine. These data support the safety of R21/Matrix-M™ in children living with HIV.

7341

A NOVEL *EX VIVO* ASSAY TO EVALUATE FUNCTIONAL EFFECTIVENESS OF *PLASMODIUM VIVAX* TRANSMISSION BLOCKING VACCINE USING PVS25 TRANSGENIC *P. BERGHEI*

Yi Cao, Clifford Hayashi, Nirbhay Kumar

Department of Global Health, Milken Institute School of Public Health, George Washington University, Washington DC, DC, United States

Plasmodium falciparum and *P. vivax* account for >90% global malaria burden. Transmission intervention strategies encompassing transmission-blocking vaccines (TBV) and drugs represent ideal public health tools to eliminate malaria at the population level. The availability of mature *P. falciparum* gametocytes through *in vitro* culture has facilitated development of a standard membrane feeding assay (SMFA) to assess efficacy of transmission interventions against *P. falciparum*. The lack of *in vitro* culture for *P. vivax* has significantly hampered similar progress on *P. vivax* and limited studies have been possible using blood from infected patients in endemic areas. The ethical and logistical limitations of on-time access to blood from patients have impeded the development of *P. vivax* TBVs. Transgenic murine malaria parasites (*P. berghei*) engineered to express TBV candidates of *P. vivax* offer a promising alternative for evaluation of *P. vivax* TBVs through *in vivo* studies in mice and *ex vivo* membrane feeding assay (MFA). In this study, we describe the development of transmission-competent transgenic *P. berghei* parasites expressing Pvs25 (TgPbvs25), and the optimization of parameters to establish a robust *ex vivo* MFA using TgPbvs25. We validated the reliability and applicability of this MFA for evaluating transmission-reducing activity (TRA) using two transmission-blocking mAbs targeting Pvs25. Furthermore, TRA of IgG from sera of mice immunized a Pvs25 DNA vaccine was demonstrated in *ex vivo* MFA using TgPbvs25, and the results were comparable to those tested in direct membrane feeding assay (DMFA) using *P. vivax*-infected patient blood in the field. This novel assay is expected to expedite Pvs25-based TBV development without dependence on blood from *P. vivax*-infected patients in endemic areas for evaluation. Additionally, the *ex vivo* MFA approach developed can be widely employed for various transgenic *P. berghei* parasites expressing different TBV antigens from both *P. vivax* and *P. falciparum*.

7342

MALARIA VACCINE INTRODUCTION REDUCED CLINICAL MALARIA IN KENYA: TIME-SERIES ANALYSIS OF ROUTINE HEALTH FACILITY SURVEILLANCE DATA (2020-2022)

John A. Painter[1], Erika A. Wallender[2], Andrew Hill[3], Mary Hamel[4], Rafiq Okine[5], Eliane Furrer[5], Rose Jalang'o[6], Nelli Westercamp[7]

[1]U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Atlanta, GA, GA, United States, [2]Epidemic Intelligence Service, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [3]U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]Department of Immunization, Vaccines & Biologicals (IVB), World Health Organization, Geneva, Switzerland, [5]World Health Organization, Geneva, Switzerland, [6]Ministry of Health, Nairobi, Kenya, [7]Malaria Branch, Division of Parasitic Diseases and Malaria, US Centers for Disease Control and Prevention, Atlanta, GA, GA, United States

Following the introduction of RTS,S/AS01 (RTS,S) through the Malaria Vaccine Implementation Programme (MVIP) in Kenya, we examined monthly routine malaria surveillance data from the Kenya Health Management Information System (KHIS) to assess the impact of RTS,S on outpatient malaria cases in children <5 years of age. Due to KHIS data aggregation at <5 and ≥5 years, the proportion of vaccine age-eligible children (RTS,S doses at 6, 7, 9, and 24 months) among <5y was initially small but increased over time. The monthly number of confirmed malaria cases reported to KHIS from outpatient facilities and community health workers was included from 23 vaccinating and 23 comparator sub-counties. Analysis was restricted to facilities reporting at least 11 months each year from January 2015 through December 2022 (139 vaccinating; 141 comparator). We estimated the case reduction as the difference between monthly reported cases <5y and forecasted cases <5y (January 2020-December 2022). Forecasts were based on time-series models of pre-vaccination data (January 2015-December 2019). To account for factors unrelated to MVIP, such as decreased clinic attendance during the COVID-19 pandemic, IRS, and bednet distributions, the analyses included a covariate for malaria cases ≥5y, as well as adjustment for trends in comparator areas. The annual percent reduction in <5y cases in vaccinating facilities was 15% in year 1, 17% in year 2, 24% in year 3, and 18.4% across 3 years. Attributing the reduction of clinical malaria to RTS,S was supported by evidence that the impact was greatest (32.9% overall) when excluding 31 (22%) comparator facilities whose population may have received vaccine due to their proximity to a vaccinating facility (<5km). Routine health facility data may be an effective source for estimating vaccine impact following broad scale-up, but has several important limitations such as age aggregation to initially include vaccine ineligible children, assumptions about vaccination status based on population-level coverage, availability of data from comparable non-vaccinating facilities, incomplete reporting, and impact of non-vaccine factors.

7343

IMMATURE DENDRITIC CELL TARGETING MRNA VACCINE ENHANCES PROTECTION FROM *PLASMODIUM* LIVER STAGE INFECTION BY ENHANCING T CELL RESPONSES AND ANTIBODY TITERS AGAINST CSP REPEAT REGIONS

Sean Yanik, Varsha Venkatesh, James Gordy, Richard Markham, Prakash Srinivasan

Johns Hopkins, Baltimore, MD, United States

In 2021, there were 247 million clinical cases and 619,000 deaths from malaria. RTS, S, the first and only WHO approved vaccine for malaria, targets the pre-erythrocytic stage antigen circumsporozoite protein (CSP) and provides only limited efficacy, reducing clinical malaria by a modest 30%. For RTS, S and other pre-erythrocytic stage targeting vaccines, the ability to produce a robust immune response, eliciting high antibody titers and engaging a strong T cell are the primary obstacles to achieving vaccine-induced protection. Here, we describe the creation of a novel CSP mRNA, chemokine fusion vaccine, designed to overcome these challenges. Vaccination with mRNA expressing full-length CSP fused to macrophage inflammatory protein 3 alpha (MIP3α), provided significantly greater protection against sporozoite challenge than vaccination with mRNA expressing full-length CSP alone. The CSP-MIP3α fusion vaccine enhanced antibody titers against highly neutralizing NANP repeat epitopes and stimulated both CD4+ and CD8+ T cell responses. Protection from sporozoite challenge correlated significantly with titers against NANP repeats and T cell stimulation, particularly CD4+ T cytokine responses.

THE PVRBP2B-TFR1 INTERACTION IS NOT ESSENTIAL FOR RETICULOCYTES INVASION BY *PLASMODIUM VIVAX* ISOLATES FROM CAMBODIA

Lionel B. Feufack[1], Lea Baldor[1], Camille Roesch[1], Baura TAT[1], Agnes Orban[1], Dynang Seng[1], Leonore Carias[2], Christopher L. King[2], Alice SM Ong[3], Bruce Russel[3], François Nosten[4], Haitong Mao[5], Laurent Renia[6], Eugenia Lo[7], Benoit Witkowski[1], Jean Popovici[1]

*[1]Institut Pasteur of Cambodia, Phnom Penh, Cambodia, [2]Center for Global Health and Diseases, Case Western Reserve University, School of Medicine, Cleveland, OH, United States, [3]Department of Microbiology and Immunology, University of Otago, Dunedin, New Zealand, [4]Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot,, Thailand, [5]Lee Kong Chian School of Medicine, Nanyang Technology University, Singapore, [6]A*STAR ID Labs, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore, [7]Department of Microbiology and Immunology,Drexel University, College of Medicine, Philadelphia, PA, United States*

Reticulocyte invasion by *Plasmodium vivax* (Pv) involves different receptor-ligand interactions. For decades, only the Duffy Binding Protein (DBP) was known to be critical for this process. Recently, the Reticulocyte Binding Protein 2b (RBP2b) has been described as an essential ligand for Pv invasion by binding the transferrin receptor 1 (TfR1) on the surface of reticulocytes. Anti-RBP2b mouse monoclonal and rabbit polyclonal antibodies (Abs) were shown to inhibit RBP2b-TfR1 binding as well as the invasion of a few clinical Pv isolates from Thailand and Brazil. Human monoclonal anti-RBP2b Abs have been isolated, epitopes determined, and shown to block the binding of rRBP2b to reticulates *in vitro*. However, their capacity to neutralize Pv invasion has not been evaluated. Here, we aim to determine if these same mouse, rabbit and human anti-RBP2b Abs can inhibit invasion of Pv isolates collected in Cambodia. Using a robust in vitro flow cytometry-based assay allowing unambiguous reticulocyte invasion scoring and a total of 49 different Pv clinical isolates, we show that none of the mouse monoclonal, rabbit polyclonal and human monoclonal Abs inhibit invasion even at high concentration (500 µg/ml), despite anti-DBP inhibited by nearly 60% invasion of Pv. The anti-TfR1 OKT9 Abs that inhibits the RBP2b-TfR1 binding does not inhibit Pv invasion either. Combinations at high concentrations of human monoclonal Abs targeting different RBP2b epitopes do not inhibit invasion. Combinations of anti-RBP2b with anti-DBP do not enhance invasion inhibition caused by anti-DBP Abs alone. We also show that invasion of Cambodian Pv is trypsin-resistant while TfR1 is trypsin-sensitive and we demonstrate that TfR1 is not recycled following trypsin treatment. We determined the RBP2b sequence of all isolates used in the invasion assays and analyzed polymorphism within epitopes recognized by anti-RBP2b Abs. We show that polymorphism does not explain the absence of neutralization. In addition, rabbit anti-RBP2b polyclonal Abs recognized all four isolates tested in IFA. Thus, RBP2b is not be essential for Pv isolates from Cambodia to invade reticulocytes.

7345

THE EFFECTS OF VACCINE ADJUVANTS & MAJOR HISTOCOMPATIBILITY COMPLEX (MHC) ON THE IMMUNOGENICITY OF A SUBDOMINANT EPITOPE IN *PLASMODIUM VIVAX* DUFFY BINDING PROTEIN

Mohammad Rafiul Hoque[1], Daniel Ferrer Vinals[1], Simranjit Grewal[1], Catherine Mitran[1], John Klassen[1], Michael Hawkes[2], Stephanie K. Yanow[1]

[1]University of Alberta, Edmonton, AB, Canada, [2]University of British Columbia, Vancouver, BC, Canada

We are developing a vaccine that targets a specific epitope within the *Plasmodium vivax* protein PvDBP. The challenge is that this epitope (in subdomain-1, or SD1) is subdominant & not immunogenic within the recombinant protein. We hypothesized that mutations in other regions of PvDBP (subdomains 2 and 3) may alter the immunodominance hierarchy to expose this epitope. To test this, we expressed various PvDBP mutants, measured their affinity toward a mouse monoclonal antibody (3D10 mAb) specific to SD1, & measured their immunogenicity in mice. Recombinant wild-type PvDBP (Sal1 allele) & four mutants (DEKnull, DEKnull-2, DEKnull-3, DEKnull-4) were expressed in *E. coli*, purified & refolded. The affinity of the 3D10 mAb against each recombinant protein was measured by mass photometry. BALB/c and C57BL/6 mice were immunized with Sal1 & the mutant proteins alone or with Titermax, GLA-SE, or Alum as adjuvants. Immunogenicity was determined by enzyme-linked immunosorbent assay (ELISA) against a synthetic SD1 peptide. Among the five proteins, the 3D10 mAb had the highest affinity for DEKnull-4. When comparing the IgG titers specific to SD1, vast differences were observed depending on the immunogen, strain of mouse and the choice of adjuvant. SD1 remained subdominant in BALB/c mice immunized with Sal1 without adjuvant or with Titermax, but was strongly immunogenic when adjuvanted with GLA-SE and Alum. The immunogenicity of SD1 was increased further when DEKnull-4 was adjuvanted with GLA-SE or Alum. Conversely, anti-SD1 IgG responses were significantly masked in C57BL/6 mice under similar immunization conditions, indicating an important contribution of the Major Histocompatibility complex (MHCII) to SD1 immunogenicity. Supporting this, immunization of B10.D2 congenic mice (BALB/c MHCII on a C57BL/6 genetic background) with either Sal1 or DEKnull-4 adjuvanted with Alum fully restored the immunogenicity of SD1. These results demonstrate that the antigen structure, the choice of adjuvant, & most significantly, MHC restriction, drive epitope-specific immunogenicity following vaccination with subunit vaccines.

7346

VACCINE DESIGNS TO ELICIT PROTECTIVE ANTIBODIES AGAINST *PLASMODIUM FALCIPARUM* CSP

Mohammad Naghizadeh[1], Yevel Flores-Garcia[2], Sayit Mahmut Erdogan[1], Gregory M. Martin[3], Fabien Cannac[3], Nis Borbye-Lorenzen[4], Randall S. MacGil[5], Emily Locke[5], C. Richter King[5], Ashley Birkett[5], Lorraine A Soisson[6], Robin Miller[7], Kristin Skogstrand[4], Adam F. Sander[1], Morten Agertoug Nielsen[1], Ian Wilson[3], Andrew B. Ward[3], Fidel Zavala[8], **Michael Theisen**[4]

[1]Copenhagen University, Copenhagen N, Denmark, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, [3]The Scripps Research Institute, San Diego, CA, United States, [4]Statens Serum Institut (SSI), Copenhagen N, Denmark, [5]PATH Nonprofit, Seattle, WA, United States, [6]United States Agency for International Development (USAID), Washington, D.C, WA, United States, [7]United States Agency for International Development (USAID) | USAID, Washington, D.C., WA, United States, [8]Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

Vaccines and monoclonal antibodies (mAbs) that target the *P. falciparum* 3D7 circumsporozoite protein (CSP) have proven effective in blocking infection in humans but extending the length of protection likely requires improving immunogenicity and durability of CSP-based immunogens. CSP contains a central repeat region composed of 38 NANP tetramers and a minor repeat region composed of three alternating NVDP and NANP tetramers. The junctional region is located immediately upstream and is also a target of humoral immunity. Based on knowledge gained from structures of mAbs bound to these regions and with the goal of understanding and improving protection against infection, eight immunogens (IMV1-8) targeting the major and minor repeats and junctional peptide region have been designed and produced. Structural data have demonstrated that IMV1-8 display the proper structure and the anticipated antibody valency on the repeat regions. To promote immunogenicity, the purified recombinant immunogens were bound to the capsid virus-like particle (cVLP) AP205 using a split-protein conjugation system to generate stable isopeptide bound antigen-cVLP complexes. Groups (n=6) of female C57BL/6N mice were immunized three times at 3-week intervals with equimolar amounts (180 pmol) of cVLP-IMV1-8, using AddaVax as an extrinsic adjuvant. The calculated geometric mean titers, using 2A10 mAb as a reference, indicated immunogenicity was proportional to the length of the immunogen. To test infection blocking efficacy in vivo, immune sera against the different constructs were injected intravenously (IV) into mice, which were challenged IV with 2,000 tg*Pb-Pf*CSP sporozoites. Significant inhibitions were observed

for cVLP-IMV2 and cVLP-IMV8 at levels comparable to those induced by anti-RTS,S antisera. Thus, constructs presenting either the major (cVLP-IMV2) or the minor (cVLP-IMV8) repeats performed similarly to RTS,S/AS01 in producing infection blocking antibody responses in this mouse model. Whether such antibody responses might act in synergy is being investigated.

7347

AMA1-SPECIFIC HUMAN MONOCLONAL ANTIBODIES INHIBIT *PLASMODIUM VIVAX* PRE-ERYTHROCYTIC AND BLOOD STAGE INFECTION

Anna C. Winnicki[1], Melanie H. Dietrich[2], Lee M. Yeoh[3], Lenore L. Carias[1], Wanlapa Roobsoong[4], Chiara L. Drago[3], Alyssa N. Malachin[1], Karli R. Redinger[1], Lionel Brice Feufack-Donfack[5], Payton Kirtley[6], Maya Aleshnick[6], Lea Baldor[5], Nicolai C. Jung[2], Olivia S. McLaine[1], Yelenna Skomorovska-Prokvolit[1], Agnes Orban[5], D. [1]Case Western Reserve University, Cleveland, OH, United States, [2]Walter and Eliza Hall Institute, Melbourne, Australia, [3]Burnet Institute, Melbourne, Australia, [4]Mahidol University, Bangkok, Thailand, [5]Institut Pasteur du Cambodge, Phnom Penh, Cambodia, [6]Vaccine & Gene Therapy Institute, Oregon Health & Science University, Hillsboro, OR, United States, [7]Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, OH, United States

One-third of the human population is at risk of contracting *Plasmodium vivax* (Pv). Developing novel Pv-specific therapeutic options such as monoclonal antibodies is vital to decreasing the worldwide burden of Pv. Apical Membrane Antigen 1 (AMA1) is an essential invasion protein that when expressed binds to Rhoptry Neck Protein 2 (RON2), an interaction utilized by sporozoites and merozoites during host cell invasion. PBMCs from a Pv-exposed individual were screened for AMA1-RON2 blocking antibodies using a competition ELISA. 12 PvAMA1-specific human monoclonal antibodies (humAbs) were produced and their functional characteristics were analyzed. One humAb, 826827, blocks invasion of human reticulocytes using Pv clinical isolates *in vitro* (IC_{50}= 48 µg/mL). 826827 also inhibited sporozoite invasion of a human hepatocyte cell line and primary human hepatocytes (IC_{50} = 0.3 - 3.7 µg/mL). The crystal structure of recombinant PvAMA1 with the antigen-binding fragment of 826827 shows that 826827 partially occupies the highly conserved hydrophobic groove in PvAMA1 that binds its known receptor, PvRON2. Competition ELISAs confirm that 826827 competes with a PvRON2 peptide for PvAMA1 binding with a higher affinity, accounting for its potency. *In vivo* testing using a liver-humanized mouse model that supports Pv liver stage infection showed a log-fold reduction in parasite burden in the liver with 826827 compared to mice treated with an isotype control antibody (Mann-Whitney, P = 0.0143). 826827 binds to highly conserved residues on PvAMA1, explaining the observed strain-transcending properties. To our knowledge, 826827 is the first humAb reported specific to PvAMA1 and is one of the first antibodies to show potent inhibition against blood stages and pre-erythrocytic stages.

7348

DESIGN AND EVALUATION OF CHIMERIC *PLASMODIUM FALCIPARUM* CIRCUMSPOROZOITE PROTEIN-BASED MALARIA VACCINES

William H. Stump, Hayley J. Klingenberg, Amy C. Ott, Donna M. Gonzales, **James M. Burns Jr**

Drexel University College of Medicine, Philadelphia, PA, United States

Efficacy data on two malaria vaccines, RTS,S and R21, targeting *Plasmodium falciparum* circumsporozoite protein (*Pf*CSP), are encouraging. Efficacy may be improved by induction of additional antibodies to neutralizing epitopes outside of the central immunodominant repeat domain of *Pf*CSP. We designed four r*Pf*CSP-based vaccines in an effort to improve the diversity of the antibody response. We also evaluated *P. falciparum* merozoite surface protein 8 (*Pf*MSP8) as a malaria-specific carrier protein as an alternative to hepatitis B surface antigen. We measured the magnitude, specificity, subclass, avidity, durability, and efficacy of vaccine-induced antibodies in outbred CD1 mice. In comparison to N-terminal or C-terminal focused constructs, immunization with near full-length vaccines, r*Pf*CSP (#1) or the chimeric r*Pf*CSP/8 (#2), markedly increased the breadth of B cell epitopes recognized covering the N-terminal domain, junctional region, and central repeat. Both r*Pf*CSP (#1) and r*Pf*CSP/8 (#2) also elicited a high proportion of antibodies to conformation-dependent epitopes in the C-terminus of *Pf*CSP. Fusion of *Pf*CSP to *Pf*MSP8 shifted the specificity of the T cell response away from *Pf*CSP toward *Pf*MSP8 epitopes. Challenge studies with transgenic *Plasmodium yoelii* sporozoites expressing *Pf*CSP demonstrated high and consistent sterile protection following r*Pf*CSP/8 (#2) immunization. Noteworthy, antibodies to conformational C-terminal epitopes were not required for protection. These results indicate that inclusion of the N-terminal domain of *Pf*CSP can drive responses to protective, repeat, and non-repeat B cell epitopes and that *Pf*MSP8 is an effective carrier for induction of high titer, durable anti-*Pf*CSP antibodies.

ASEPTIC, PURIFIED, VIALED *PLASMODIUM VIVAX* SPOROZOITES FOR CONTROLLED HUMAN MALARIA INFECTION

Sumana Chakravarty, Natasha KC, Urvashi Rai, Asha Patil, Yonas Abebe, B. Kim Lee Sim, Stephen L. Hoffman

Sanaria Inc., Rockville, MD, United States

Malaria caused by *Plasmodium vivax* (Pv) is 2nd to *P. falciparum* (Pf) in incidence and impact. Unlike Pf, chemoprophylactic measures against Pv do not prevent relapses due to re-activation of persistent liver-stage sleeping forms of the parasites called hypnozoites. Primaquine and tafenoquine are the only licensed drugs that target Pv hypnozoites, but cause life threatening acute hemolytic anemia in patients with G6PD deficiency. Drug and vaccine development are hampered by inability to propagate blood stages of Pv parasites *in vitro* and mosquitoes for controlled human malaria infection (CHMI) can only be generated with Pv-infected blood from patients. We produced Pv sporozoites (SPZ) of the Chesson strain by feeding infected blood from specific pathogen free (SPF) *Saimiri boliviensis* (Sb) monkeys to aseptic *Anopheles stephensi* mosquitoes and these PvSPZ were highly infectious to FRG mice with humanized livers and produced hynozoites. We then manufactured in compliance with GMPs 1) a master cell bank of Pv (Chesson) asexual RBC stage parasites in the blood of SPF Sb, 2) small lots of aseptic PvSPZ with all in-process samples of aseptic eggs, pupae, blood meals and adult mosquitoes, and the final product testing negative for microbial growth using U.S. Pharmacopeia USP<71> tests for sterility, and 3) One lot of aseptic, purified, vialed cryopreserved PvSPZ, Sanaria® PvSPZ Challenge (Chesson) that is aseptic, pure, and potent. Our pre-IND package to the FDA including our chemistry, manufacturing, and controls, quality control (QC) assays, and a proposal for a clinical trial, received positive feedback and recommendations. PfSPZ Challenge has revolutionized CHMI studies for Pf malaria. We expect PvSPZ Challenge will similarly provide the larger malaria community with a radically enhanced tool to assess anti-Pv interventions, as a safe quality-controlled reagent with minimal variability in potency, that is logistically simpler to administer, not subject to geographical limitations for application, compared to mosquito bite CHMI. The characteristics of the SPF Sb, aseptic mosquito infections, and GMP-produced PvSPZ will be presented.

7350

ANTIMICROBIAL RESISTANCE OF *SHIGELLA* AMONG CHILDREN UNDER FIVE YEARS WITH DIARRHEA OVER A DECADE IN THE GAMBIA

Henry Badji[1], Bri'Anna Horne[2], Erika Feutz[3], Sean R. Galagan[3], Helen Powell[2], Bubacarr E. Ceesay[1], Abdoulie K. Ceesay[1], Fatima Jallow[1], Ousman Jallow[1], Samba Juma Jallow[1], Bakary Conteh[1], Mehrab Karim[1], Usman Nurudeen Ikumapayi[1], Hannah Atlas[3], Milagritos Tapia-Sow[2], Patricia B. Pavlinac[3], Karen L. Kotloff[2], Martin Antonio[1], M. Jahangir Hossain[1], Ousman Secka[1], Sharon M. Tennant[2]

[1]Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, Maryland., Baltimore, MD, United States, [3]University of Washington, Seattle, WA, United States

Antimicrobial resistance (AMR) is a major public health concern globally, especially in low- and middle-income countries (LMICs). Resistance among the leading cause of bacterial diarrhea and dysentery, *Shigella* spp., limits antibiotic options for children vulnerable to mortality and linear growth faltering. A high burden of *Shigella* spp.-attributable diarrhea was found among African sites in the Global Enterics Multicenter Study (GEMS). We describe AMR among *Shigella* spp. from children with diarrhea enrolled in the GEMS (2007 - 2011), Vaccine Impact on Diarrhea in Africa (VIDA, 2015 - 2018) and Enterics For Global Health (EFGH) *Shigella* surveillance study (August 2022 - March 2024) in Basse, The Gambia. We enrolled children with diarrhea aged 6-35 months in the EFGH study and children with moderate to severe diarrhea (MSD) aged 0-59 months in the GEMS and VIDA studies. *Shigella* spp. isolated from stool and rectal swab samples by microbiological culture are reported. Antimicrobial resistance was assessed for 114, 214, and 99 *Shigella* spp. isolates from GEMS, VIDA and EFGH diarrhea cases, respectively. *S. flexneri* was the leading serogroup in all three studies constituting 69.0%, 67.6% and 57.3% of isolates in GEMS, VIDA and EFGH, respectively, followed by *S. sonnei* (20.7%; 18.2%; 36.9%), *S. boydii* (6.0%; 11.8%; 2.9%) and *S. dysenteriae* (4.3%; 2.3%; 1.0%). AMR in the GEMS, VIDA and EFGH studies was 93.9%, 93.0% and 97.9% to trimethoprim-sulfamethoxazole, 57.9%, 41.6% and 26.6% to ampicillin, 0.0%, 0.9% and 15.1% to nalidixic acid, 0.0%, 0.0% and 7.0% to azithromycin, 0.0%, 0.5% and 0.0% to ceftriaxone and 0.0%, 0.0% and 2.0% to ciprofloxacin, respectively. Resistance to pivmecillinam, only assessed in the EFGH study, was 10.0%. These findings suggest AMR patterns parallel drug usage, with AMR increasing in the recommended treatment for dysentery (trimethoprim-sulfamethoxazole, ciprofloxacin, azithromycin) and decreasing in ampicillin, which is no longer recommended. This emphasizes the importance and urgent need for *Shigella* vaccine introduction and implementation of strategies to prevent the further increase in AMR burden.

7351

COMPARING WHOLE CELL PSORALEN INACTIVATED SHIGELLA VACCINE VERSUS FORMALIN INACTIVATED SHIGELLA VACCINE IN MICE

Jeffrey T. Kilcup[1], Leigh Ann Sanders[1], Thomas F. Wierzba[1], Michael E. DeWitt[1], Maria Blevins[1], Kevin R. Porter[2], John W. Sanders[1]

[1]Wake Forest University School of Medicine, Winston-Salem, NC, United States, [2]Naval Medical Research Command, Boyds, MD, United States

Shigella is responsible for approximately 600,000 annual deaths worldwide, predominantly among children, yet no licensed vaccines are currently available. This study evaluates the immunogenicity of a psoralen plus ultraviolet A-inactivated (PSIV) Shigella vaccine, which may enhance immunity by better preserving protein epitopes compared to traditional methods. We utilized a mouse model to compare the immunogenicity of PSIV versus formalin-inactivated (FIV) Shigella sonnei vaccines. Four groups of five mice each received one of the following treatments: PSIV with and without a double mutant heat-labile toxin (dmLT) adjuvant, and FIV with and without the adjuvant. Vaccinations were administered on days 0 and 28. Pooled sera from days 0, 28, and 49 were tested for the presence of anti-Shigella antibodies using whole-cell enzyme-linked immunosorbent assays. We found that PSIV with adjuvant resulted in the highest total antibody titer among the pooled samples, which was 30% higher than that of FIV. The mean fold change in antibody titer between days 28 and 49 across all arms was 13.5, indicating a strong booster effect. The PSIV Shigella vaccine is qualitatively superior and statistically non-inferior to an FIV Shigella vaccine in eliciting a broad antibody response. Further research is required to evaluate specific epitope responses. Our results suggest that PSIV may be an effective approach for developing a Shigella sonnei vaccine.

ESTABLISHING CHOLERA SURVEILLANCE IN RURAL NEPAL DURING COVID-19 PANDEMIC: LESSONS LEARNED

Nimesh Poudyal[1], Pradip Mishra[2], Runa Jha[3], Joyti Acharya[3], Deepak Bajracharya[4], Rabin Chaudhary[4], Hem Raj Pandey[2], Jagadish Joshi[2], Khagendra Raj Bhatta[2], Gauri Datt Joshi[2], Ramesh Shahi[2], Ashok Mishra[1], Rakesh Yadav[1], Ishwor Sharma[1], Jae Woong Lee[1], Haeun Cho[1], Yubin Lee[1], Jung Seok Lee[1], Prerana Parajulee[1], Delmy Kyoungeun Choi[1], Derick Kimathi[1], Jacqueline Kyungah Lim[1], Chulwoo Rhee[1], Julia Lynch[1]

[1]International Vaccine Institute, Seoul, Korea, Republic of, [2]Seti Provincial Hospital, Dhangadhi, Nepal, [3]National Public Health Laboratory, Kathmandu, Nepal, [4]Group For Technical Assistance, Kathmandu, Nepal

The ongoing upsurge of Cholera cases with multiple outbreaks, alarming numbers and mortality rates is a global public health concern. The situation underscores the importance of strengthened Cholera surveillance for accurate outbreak detection and response. Cholera outbreaks have been frequently reported in Nepal since early 1800's, but the country still lacks an effective surveillance system for its detection. Assessing the need, International Vaccine Institute (IVI) with the support of Global Disease Eradication Fund (GDEF) from Korea collaborated with Sudurpaschim Provincial Government of Nepal, to establish Cholera surveillance in Kailali district of Nepal in 2019. A network of 10 sentinel sites for enrollment and rapid laboratory testing of suspected Cholera cases and refurbishment of local laboratory to serve as regional reference laboratory for Cholera culture confirmation was planned. Throughout 2019, multiple engagements between stakeholders were held and project implementation was planned from 2020 through 2023 but had to be put on hold due to declaration of Covid-19 pandemic in March 2020. Finally, a collaboration agreement was signed on March 2022 after numerous virtual/on-site meetings even during Covid pandemic. Laboratory upgradation was completed in April 2023 and sentinel sites were trained on use of common protocol for diarrheal disease surveillance. The Cholera surveillance in Kailali formally kicked-off in June 2023 with the first culture confirmed Cholera case being reported in August 2023. Here we present our experience with lessons learned from planning and implementation of the project to reporting first case of Cholera from Kailali district of Nepal during Covid-19 pandemic.

A COMPARISON OF SEROLOGIC, MOLECULAR, AND GENOMIC APPROACHES FOR SEROTYPING *SHIGELLA FLEXNERI* STRAINS ISOLATED FROM THE PERUVIAN AMAZON

Lucero Romaina Cachique[1], Katia Manzanares Villanueva[1], Francesa Schiaffino[2], Bri'Anna Horne[3], Maribel Paredes Olortegui[1], Steven Huynh[4], Pablo Peñataro Yori[5], Kerry K. Cooper[6], Craig T. Parker[4], Patricia B. Pavlinac[7], Margaret N. Kosek[5]

[1]Asosciacion Benefica Prisma, Iquitos, Peru, [2]Universidad Peruana Cayetano Heredia, Lima, Peru, [3]University of Maryland, Baltimore, MD, United States, [4]United States Department of Agriculture, Albany, CA, United

States, [5]University of Virginia, Charlottesville, VA, United States, [6]University of Arizona, Tucson, AZ, United States, [7]University of Washington, Seattle, WA, United States

Shigellosis is one of the leading causes of bacterial gastroenteritis and dysentery in children under the age of 5 living in Iquitos, Peru. *Shigella* spp., a gram-negative bacillus, is the causative agent of this disease. Consequences of Shigellosis include persistent diarrhea, intestinal protein loss and intestinal inflammation, as well as linear growth faltering. Agglutination with antisera against lipopolysaccharide O-antigen is utilized as the gold standard for serotyping *Shigella flexneri*. However, molecular serotyping methods, including a qPCR-based approach, and a genomic based approach have been developed. In this study we compare the results obtained for serotyping *Shigella flexneri* isolates using serum agglutination, genomic sequencing, and qPCR of the matched rectal swabs. *Shigella* spp. isolates were obtained from the Enterics for Global Health Shigella Surveillance Study (EFGH) conducted in Iquitos, Peru. Between August 2022 and December 2023, 86 Shigella strains were isolated from unique rectal swabs from children with medically attended diarrhea. Of these, 78 had a matched qPCR result. Of these, 54 were identified as *S. flexneri*, 22 as *S. sonnei* and 1 as *S. dysenteriae*. Of the 54 *S. flexneri*, 37 (68.5%) ha a matched serotype assigned by agglutination and qPCR (1a (n=2), 2a (n=23), 2b (n=11), 3a (n=1), and 17 (31.5%) had discordant results by agglutination and qPCR. All strains were sequenced using Illumina based methods, and both reads and contigs were analyzed using ShigaTyper and ShigaPass bioinformatic programs. So far, of the 17 discordant pairs, sequencing results are available for three strains. Two of these were classified as 4a by agglutination, were not typed by qPCR and were classified as Yv by genomic serotyping. The third was classified as 1a by agglutination and 1b by qPCR and genomic serotyping. Sequencing will be completed in August 2024, and results of the pending matched and discordant serotyping will be presented at the meeting.

7354

INTERIM SAFETY DATA FROM A PHASE 1/2A, RANDOMIZED, CONTROLLED, OBSERVER-BLIND TRIAL TO EVALUATE THE SAFETY, REACTOGENICITY AND IMMUNOGENICITY OF A TRIVALENT VACCINE AGAINST INVASIVE NONTYPHOIDAL SALMONELLOSIS (INTS) AND TYPHOID FEVER IN HEALTHY EUROPEAN AND AFRICAN ADULTS.

Yasir Shitu Isa[1], Kanchanamala Withanage[2], Priyanka D. Patel[3], Antonio Lorenzo Di Pasquale[1], Alimamy Serry-Bangura[4], Giulia Luna Cilio[4], Omar Rossi[1], Beatrice Grossi[1], Chiara Crispino[1], Rita La Gaetana[1], Ilse De Coster[2], Valentino Conti[1], Rocio Canals[1], Ashwani Kumar Arora[1], Usman Nasir Nakakana[1], Melita Gordon[3]

[1]GSK Vaccines Institute for Global Health, Siena, Italy, [2]University of Antwerp, Antwerpen, Belgium, [3]Malawi Liverpool Programme, Blantyre, Malawi, [4]GSK Vaccines Srl, Siena, Italy

Invasive nontyphoidal Salmonellosis (iNTS) and typhoid fever are major public health concerns causing a significant burden, particularly in resource-limited settings of sub-Saharan Africa. There is no licensed vaccine for iNTS, and the licensed Typhoid Conjugate Vaccines (TCVs) are not widely used in Africa. A novel trivalent iNTS-TCV vaccine, aimed at preventing both diseases, is under development by GSK Global Health Vaccines R&D (GVGH). This abstract presents interim blinded safety results from an ongoing phase 1/2a study in healthy adults. In stage 1, 50 European adults were randomized in a 2:2:1 ratio to receive either iNTS-TCV vaccine and concomitant saline in different arms, or separate iNTS-GMMA and TCV vaccines in different arms, or placebo and saline in different arms intramuscularly, on Days 1, 57 and 169. Of these, 10 subjects received low doses of the study vaccines and 40 received full doses. In stage 2, 105 African adults were randomized in a 3:3:1 ratio to receive full doses of the same vaccines or comparators. Menveo, Boostrix and Typhim Vi are administered as controls for the 1st, 2nd and 3rd doses respectively. After all administrations in European adults and at least one administration in 92/105 (87.6%) African adults, majority of the adverse events (AEs) observed are of mild to moderate intensity. Injection site pain is the most reported local solicited AE, while myalgia, fatigue and headache are the most frequent systemic solicited AEs. Severe unsolicited AEs related to vaccination were reported in 4 subjects overall. No serious AE considered related to vaccination has been reported. In conclusion, based on available data, the anticipated benefit/risk profile of the iNTS-TCV vaccine continues to be positive, with no safety concerns precluding further clinical development. First immunogenicity results are expected later in 2024 and would be presented at the congress.

7355

POLYCHROMATIC FLOW CYTOMETRY PANELS TO CHARACTERIZE ANTIGEN-SPECIFIC MEMORY B-CELLS INDUCED BY ENTEROTOXIGENIC ESCHERICHIA COLI VACCINES

Tanisha M. Robinson[1], Aaron Y. Kim[2], Jessica S. Bolton[3], Frederic M. Poly[2], Chad K. Porter[4], Elizabeth B. Norton[5], Renee M. Laird[2], Elke S. Bergmann-Leitner[1]

Enterotoxigenic *Escherichia coli* (ETEC) is one of the significant pathogens causing moderate-to-severe diarrhea in travelers. ETEC is also a leading cause of morbidity in children under 5 years of age especially in resource-poor regions. Current approaches to ETEC vaccine development predominately target the colonization factors, which are involved in ETEC adhesion, and the diarrheagenic heat labile toxin (LT). Combination of colonization factor antigens and mucosal mutant LT adjuvants (mLT or dmLT) aim to induce systemic and mucosal immune responses capable of blocking infection and neutralizing LT. Here, we report on the development of antigenic probes to enable monitoring the induction and response rates of antigen-specific memory B cells induced by vaccination with intradermally administered subunit vaccine targeting the colonization factor antigen I (CFA/I) using the mLT adjuvant. This study was technically challenging due to the nature of the ETEC antigens (CfaE, LT), which bind to intestinal epithelial cells thus potentially resulting in non-specific binding to cells rather than to the antigen-specific B cell receptors. We summarize the various strategies applied to develop a highly specific and sensitive flow cytometric panel. The presentation will provide guidance on how to approach the design of antigenic probes for B cell analysis. The completed flow cytometric panel allowed simultaneous monitoring of LT- and CfaE-specific memory B cells, their functional status, and the expression of homing receptors associated with migration to intestines.

7356

RETAINING AZITHROMYCIN SUSCEPTIBILITY IN THE FACE OF INCREASING USE IN SUB-SAHARAN AFRICA-THE ROLE OF EFFLUX PUMP INHIBITORS

Kevin M. Kariuki[1], John Ochieng Benjamin Ochieng[2], Doreen Rwigi[1], Timothy Mutuma[1], Laura Riziki[2], Lilian Ambila[2], Evans Apondi[2], Polycarp Mogeni[1], Kirkby Tickell[3], Judd Walson[4], Ferric Fang[3], Patricia Pavlinac[3]

Mass drug administration (MDA) of azithromycin is being considered to prevent child mortality in some high mortality settings. Although azithromycin resistance is uncommon in enteric bacteria in sub-Saharan Africa (SSA), resistance may rise with MDA. Azithromycin resistance in *Escherichia coli* (*E. coli*) can result from ribosomal mutations, macrolide-

modifying enzymes, or by efflux pumps expelling intracellular antibiotics. We sought to establish the minimum inhibitory concentration (MIC) of azithromycin and relative importance of efflux pumps in explaining azithromycin resistance in *E. coli* isolates cultured from children recently discharged from hospitals Western Kenya. *E. coli* was isolated from children aged 6-59 months enrolled in a randomized control trial testing post-discharge azithromycin efficacy against mortality and re-hospitalization. Azithromycin MICs were established by E-test in the presence or absence of 50µg/mL Phe-Arg-β-Naphthylamide (PAβN), an efflux pump inhibitor. *E. coli* was isolated from 1220 of 1400 enrolled children and 757 (62%) isolates were resistant to azithromycin (≥32 mg/L), with 565 (75%) having the highest MIC (≥256 mg/L). In the presence of PaβN, the prevalence of azithromycin resistance was reduced by more than half (357 [29%] isolates). MIC_{50} and MIC_{90} in the absence of PaβN were 128 mg/L and 256 mg/L respectively while in the presence of PaβN were 4 mg/L and 256 mg/L respectively. Almost 75% (908/1220) of the isolates had > 2-fold change in MIC values with PaβN, of these 300 (33%) had a 16-fold change in MIC. Azithromycin resistance in *E. coli* was common among children discharged after a non-traumatic hospital admission and highlights the importance of the potentiating effect of efflux pump inhibitors in azithromycin antibacterial activity in *E. coli*. Efflux pump inhibitors, or associated mechanisms such as increased membrane permeability, may hold promise for retaining azithromycin susceptibility in enteric bacterial infections in SSA.

7357

ESTIMATING THE COST-OF-ILLNESS RELATED TO CHOLERA IN MOZAMBIQUE AND NEPAL

Prerana Parajulee[1], Jung Seok Lee[1], Nelmo Manjate[2], Sofiao Manjo[2], Kshitij Karki[3], Rakchya Amatya[3], Bisekha Jaiswal[3], Geun Hyeog Jang[1], Jae Woong Lee[1], Haeun Cho[1], Hyoryoung Lee[1], Nimesh Poudyal[1], Yubin Lee[1], Yeonji Jeon[1], Igor Capitine[2], Liliana Dengo[2], Deepak Bajracharya[3], Daniel Chulwoo Rhee[1], Krishna Prasad Paudel[4], Jose Paulo Langa[2], SeEun Park[1], Julia Lynch[1]

[1]International Vaccine Institute, Seoul, Korea, Republic of, [2]National Institute of Health, Maputo, Mozambique, [3]Group for Technical Assistance, Kathmandu, Nepal, [4]Planning, Policy and Monitoring Division, Ministry of Health and Population, Kathmandu, Nepal

Cholera is endemic and epidemic in some developing countries. This disease not only tests a country's health systems resilience, but also has direct financial implication to patients and the country alike. Knowing the economic burden of cholera in different settings provides policymakers with appropriate evidence for development, budgeting, and implementation of the national cholera plan (NCP). We carried out a cost-of-illness (COI) study on cholera in Mozambique and Nepal. Using convenience sampling, confirmed cholera cases selected during active outbreak and endemic settings in these countries were surveyed in 2023. A structured questionnaire was used for collection of personal cost (direct medical, direct non-medical and indirect cost) associated with the disease. Healthcare provider costs were also collected. Total 204 and 119 patients were enrolled for COI survey in Mozambique and Nepal respectively. All patients in Mozambique were enrolled from inpatient ward, while 60.5% (72/119) of enrolled patients in Nepal were from emergency ward. Though patients in both countries received governmental subsidies for treatment, more people received subsidy in Mozambique (203/204; 99.5%) than Nepal (32/119; 26.9%). Compared to Mozambique (4/204; 0.019%) more participants from Nepal (19/119; 15.97%) visited pharmacy prior to seeking treatment at health facility. Average cost from patient perspective in Mozambique and Nepal was direct medical (USD0.33, and 52.42 respectively), direct non-medical (7.83, 9.30) and indirect cost (6.42, 35.92). In Mozambique, average total cost from patient perspective ranged from USD17.25 in Niassa to USD26.02 in Zambezia whereas in Nepal, for inpatient was USD153.93 and for outpatient USD47.28. There was substantial difference in cholera related COI in different settings within and between Mozambique and Nepal. If we compare these costs with the income of minimum wage workers, which is approximately USD62.5 for Mozambique and USD130 for Nepal, it becomes evident that cholera poses a considerable financial burden and also challenges in accessing affordable healthcare.

7358

SINGLE DOSE AZITHROMYCIN AMONG CHILD CONTACTS OF CHOLERA PATIENTS CAN REDUCE CHOLERA AT HOUSEHOLD LEVEL: A DOUBLE-BLINDED RANDOMIZED CONTROL TRIAL

Fahima Chowdhury[1], Afroza Akter[1], Taufiqur R. Bhuiyan[1], Imam Tauheed[1], Denise Chac[2], Damien M. Slater[3], Sowmya R. Rao[4], Ana Weil[2], Regina C. LaRocque[3], Firdausi Qadri[1], Jason B. Harris[3]

[1]icddr,b, Dhaka, Bangladesh, [2]University of Washington, Seattle, WA, United States, [3]Massachusetts General Hospital, Boston, MA, United States, [4]Boston University, Boston, MA, United States

Vibrio cholerae causes 3 million cholera cases and 100,000 deaths annually with over half of deaths in children. Children who are household (HH) contacts of cholera patients are at high risk for cholera infection and are not well protected by cholera vaccines compared to adults. Azithromycin is an effective treatment for cholera and is widely used as prophylaxis against other childhood infections. Our objective of this trial is to determine whether a single dose of azithromycin given to children aged 1-15 years who are HH contacts of cholera patients will reduce the risk of *V. cholerae* infection. We are conducting a double-blinded cluster-randomized controlled trial of single-dose azithromycin (20mg/kg) compared with the non-antibiotic placebo group. After index cases are identified at icddr,b Dhaka hospital, we enroll HH children aged 1-15 years living in or around Dhaka city within 12 hours. HH contacts are assigned to receive azithromycin or a placebo. We then collect their rectal swab samples as well as clinical data with follow-up for up to 6 months post-intervention (days 1-7, day 30, and day 180). We initiated the study on 31st October 2021 and it is ongoing. A total of 1044 diarrheal patients were screened for *V. cholerae* through 29th February 2024 and 235 were cholera-positive by RDT. 84.26% of RDT-positive cases were positive by culture. Many index patients reported prior receipt of antibiotics, and 41.48% reported taking metronidazole. We enrolled 375 HH contacts from the 235 index cases. Among the HH contacts, 135 were <5 years of age, and 240 were 5-15 years of age. 36 HH contacts (9.6%) were culture-positive for *V. cholerae* O1 and only one was symptomatic. Baseline levels of antibiotic resistance, including macrolide resistance genes, were high among all participants. We report the early-stage results of a randomized clinical trial of single-dose azithromycin to prevent cholera in children. The results of the study when unblinded will inform the clinical management of close contacts of patients with cholera and provide new data about the impact of single-dose azithromycin on short- and long-term carriage of antibiotic-resistant bacteria.

TYPHOID CONJUGATE VACCINE INTRODUCTION: DECISION-MAKING IN THE CONTEXT OF LIMITED DATA USING A BURDEN AND RISK ASSESSMENT FRAMEWORK

Lucy Breakwell Nagle[1], Yesser Sebeh[2], Zimy Wansaula[1], Katrin Sadigh[1], Henry Njuguna[1], Matthew Mikoleit[1], Musa Y. Hindiyeh[3], Jenny Walldorf[3], Carol Tevi Benissan[3], Molly Hancuh[2], Amanda Tiffany[1], Anna A. Minta[3], Adwoa D. Bentsi-Enchill[3]

[1]CDC, Atlanta, GA, United States, [2]CDC Foundation, Atlanta, GA, United States, [3]World Health Organization, Geneva, Switzerland

Since WHO recommended typhoid conjugate vaccine (TCV) introduction in 2018 for all typhoid endemic countries, only six countries have introduced TCV. National decision-making for TCV introduction is limited by lack of typhoid burden data. To address this challenge, WHO and CDC, supported by a group of experts, developed a burden and risk assessment framework to provide a standardized approach to collating, scoring, and interpreting available typhoid data in six areas: incidence, prevalence, antimicrobial resistance (AMR), outbreaks, intestinal perforations, and risk factors. The framework underwent an iterative revision process through pilots in 4 purposively selected countries. Blood culture data and *Salmonella* serotype confirmation were available from tertiary hospitals, but quality and quantity varied by country. Typhoid diagnosis was frequently based on clinical symptoms and antigenic test results. AMR data were limited by the number

of available isolates and data quality varied by country. Intestinal perforation data lacked causality and outcome information. High quality WASH data were derived from national household surveys but were generally not available sub-nationally. Data on outbreaks were consistently lacking. Data collection comprised a desk review (incidence, outbreaks, risk factors) and health facility visits (prevalence, AMR, intestinal perforations), facilitated by an electronic tool, and focused on health facilities with blood culture capacity. Data collectors needed to have laboratory and moderate data management experience. Technical support and funding were required for implementation. Data interpretation required expertise in typhoid epidemiology and laboratory diagnostic methods and was nuanced to each country. The framework can help to provide an overall inference of typhoid burden in a country, even in settings where blood culture confirmation is not routine. Results may inform national typhoid control decision-making, including TCV introduction. However, technical support for implementation and data interpretation are necessary for success.

7360

MEASURING THE EFFECTIVENESS AND IMPACT OF TYPHOID CONJUGATE VACCINE FOLLOWING NATIONAL INTRODUCTION IN MALAWI (MITIMA)

Priyanka D. Patel[1], Latif Ndeketa[1], Amanda J. Driscoll[2], Theresa Misiri[1], Felistas Mwakiseghile[1], Richard Wachepa[1], Happy Banda[1], Yuanyuan Liang[2], Marc Henrion[1], Shrimati Datta[2], Neil French[3], Kathleen M. Neuzil[2], Melita A. Gordon[1]

[1]Malawi Liverpool Wellcome Research Programme, Blantyre, Malawi, [2]Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, [3]University of Liverpool, Liverpool, United Kingdom

Typhoid conjugate vaccine (TCV) has demonstrated robust efficacy in randomized controlled trials in low- and middle-income countries, including Malawi. Liberia and Zimbabwe were the first sub-Saharan African countries to introduce TCV in April and May 2021, respectively. In May 2023, Malawi became the third African country to introduce TCV. We aim to measure TCV effectiveness and impact post-introduction in a typhoid-endemic sub-Saharan African setting and inform policy decisions across Africa. We are conducting passive blood culture surveillance for typhoid fever in Blantyre. Individuals aged 9 months to 45 years presenting with febrile illness (subjective fever for ≥72 hours, axillary temperature ≥38°C, or hospitalisation with a history of fever) have a blood culture. Vaccine effectiveness will be measured post-introduction among children age-eligible for vaccination (9 months to 15 years) using a test-negative study design. Cases are blood culture positive for *Salmonella.* Typhi (*S*. Typhi); controls are blood culture negative for *S.* Typhi. TCV impact will be assessed using an interrupted time series analysis of blood culture surveillance data collected from one-year pre-introduction and two years post-introduction. We will calculate changes in *S*. Typhi-positive blood culture incidence in vaccine-eligible and 16-45-year-old participants, using the latter as a comparator for temporal trends. TCV was introduced in Malawi from 15 May to 24 May 2023. Between 18 April 2022 and 12 Apr 2024, 240,062 participants were screened; 8537 met the febrile illness definition, 6762 were enrolled, and 6704 had blood cultures collected. The blood cultures yielded 190 *S.* Typhi and 23 *Salmonella* Typhimurium cases. Among the *S*. Typhi isolates, 94.8% were multidrug-resistant, 2.1% fluoroquinolone-resistant, and 3.1% susceptible to all or some first-line antibiotics. Blood culture surveillance before and after the TCV campaign has been consistent. The data are unadjusted for vaccine coverage or other temporal trends. Surveillance continues and will provide important data on TCV effectiveness and impact in an endemic African setting.

7361

EVALUATING THE IMPACT OF VACCINATION WITH ORAL CHOLERA VACCINE ON CHOLERA BURDEN IN HIGH TRANSMISSION AREAS OF DHAKA, BANGLADESH AN INTERRUPTED TIME SERIES ANALYSIS

Ashraful Islam Khan[1], Md Taufiqul Islam[1], Zahid Hasan Khan[1], Mohammad Ashraful Amin[1], Md Golam Firoj[1], Taufiqur Rahman Bhuiyan[1], Fahima Chowdhury[1], Farhana Khanam[1], Faisal Ahmmed[1], ASG Faruque[1], Lucy Breakwell[2], Amanda Tiffany[2], Firdausi Qadri[1]

[1]International Centre for Diarrhoeal Disease Research Bangladesh (icddr,b), Dhaka, Bangladesh, [2]Global Immunization Division, US CDC, US, CA, United States

Bangladesh, a cholera endemic country, experiences two seasonal peaks: one from April to May, another from August to September. In 2022, Dhaka experienced the largest surge in cholera-related hospitalizations in last 60 years. More than half of the came from Jatrabari, Dakshinkhan, Sabujbagh, Mohammadpur-Adabor, and Mirpur regions. In response, the government of Bangladesh requested oral cholera vaccine (OCV) from the global stockpile. A targeted, two-dose vaccination campaign was implemented in the aforementioned areas in June and August 2022. This study aims to evaluate the impact of the OCV campaign on cholera burden in vaccinated areas. A pre- and post-evaluation was conducted using routinely collected surveillance data from the icddr,b hospitals. Since 1996, every 50th patient presenting for care with acute watery diarrhea is included and a stool sample is tested for cholera by culture. The proportion of cholera cases averted in the 5 vaccinated regions was calculated. An interrupted time series analysis compared the proportion of culture cholera confirmed cases in vaccinated and non-vaccinated areas of Dhaka. In the first year of the post-OCV campaign period (September 2022-September 2023), the culture confirmed cholera positivity among hospitalized diarrheal patients from vaccinated areas decreased by 46% compared to the pre-OCV campaign period (June 2017-May 2022; except 2020). In the five high burden vaccinated areas, the hospitalization rates per year during pre- and post-OCV campaign periods were 9.1 and 6.4 per 1000 population respectively. There was no significant difference in the positivity among patients from the unvaccinated areas during the same two periods. Also the cholera positivity in the post-OCV campaign period was 51.1% lower than predicted by the model. Both the cholera positivity and hospitalization rate among vaccinated areas in Dhaka decreased following the OCV campaign. While data on other factors that may have contributed to this reduction were not collected, this evaluation provides evidence to support the impact of cholera vaccination on burden reduction in the first year following vaccination.

GENETIC DETERMINANTS OF EXTENDED-SPECTRUM BETA-LACTAMASE RESISTANCE IN *SHIGELLA* SPECIES IN KENYA

Ronald K. Kirera[1], Nancy C. Kipkemoi[1], Janet N. Ndonye[1], Erick C. Kipkirui[1], Mary C. Kirui[1], Margaret C. Koech[1], Alex Ragalo[1], Elizabeth A. Odundo[1], Kirti K. Tiwari[2]

[1]Microbiology Hub Kericho, Kenya Medical Research Institute (KEMRI)/ Walter Reed Army Institute of Research -Africa/Kenya (WRAIR-A/K)., Kericho, Kenya, [2]Walter Reed Institute of Research- Africa, Kericho, Kenya

Shigella spp have increasingly become resistant to mostly used antimicrobials, which account for over 165 million cases and 1.1 million deaths annually worldwide, significantly, due to its low infective dose and high transmission rate in areas with poor hygiene and in low income areas. The emergence of multidrug-resistant *Shigella* spp complicates the treatment and management of shigellosis which has put more strain to the already paltry resources in the developing countries. This study sought to detect the presence of Extended spectrum β-lactamases (ESBLs) resistance genes markers in *Shigella* spp. isolates from diarrheal patients in Kenya. A retrospective analysis of 515 *Shigella* spp stool specimens

initially tested for phenotypic antimicrobial susceptibility was performed using molecular PCR to detect resistance markers. Specifically, we targeted ESBL resistance gene markers, that included: TEM, SHV, OXA, OXA-48, CTX Groups 1, 2, 9, 8, and 25, CTX-M, ACC, FOX, MOX, DHA, CIT, EBC, GES, PER, VEB, IMP, VIM, and KPC. After results analysis, we found two major ESBL resistance gene markers in *Shigella* isolates; blaTEM and blaOXA in the same proportion 14% (71/515). Additionally, blaVIM was found in 1.4% (7/515) and blaIMP in 0.2% (1/515). The other gene markers were not detected from the isolates; SHV, OXA-48, CTX Groups 1, 2, 9, 8, and 25, CTX-M, ACC, FOX, MOX, DHA, CIT, EBC, GES, PER, VEB, IMP, and KPC. This study concludes that, blaTEM and blaOXA are the most commonly seen genes among the *Shigella* isolates from Kenyan patients. Further analysis using whole genome sequencing could be done to detect mutations or virulent genes that could be associated with the resistance conferred by *Shigella* isolates.

7363

MOLECULAR CHARACTERIZATION AND PHENOTYPIC ANTIMICROBIAL RESISTANCE PROFILE OF DIARRHEAGENIC *ESCHERICHIA COLI* ISOLATED FROM PATIENTS WITH ACUTE DIARRHEA VISITING KERICHO COUNTY REFERRAL HOSPITAL, KERICHO, KENYA.

Alex Oduor Ragalo, Erick Kipkirui, Mary Kirui, Ronald Kirera, Janet Ndonye, Nancy Kipkemoi, Margret Koech, Kirti Tiwari, Elizabeth Odundo

Kenya Medical Research Institute/Walter Reed Army Institute of Research-Africa, Kericho, Kenya

Diarrheal disease caused by diarrheagenic Escherichia coli (DEC) is the second leading (after pneumonia) cause of morbidity and mortalities in children under five years in low-income countries. The emergence of multi-drug resistant (MDR) variant of DEC poses a formidable challenge infection control efforts. This study aimed to determine the phenotypic antibiotic resistance profiles of DEC isolated from patients with acute diarrhea visiting Kericho County Referral Hospital between January 2022 to December 2023. A total of 149 stool samples were collected from patients presenting with symptoms of acute diarrhea over a two-year period, shipped to the Microbiology Hub Laboratory-Kericho, cultured and isolated. DEC pathotypes were identified by multiplex Polymerase Chain Reaction assays targeting nine virulence genes; *Enteroaggregative E.coli (*EAEC*_aatA,aaiC),* Enteropathogenic *E.coli (*EPEC*_eae,bfpA),* Enterotoxigenic *E.coli (*ETEC*_LT, ST),* Enterohemorrhagic *E.coli (*EHEC*_StxI,StxII)* and Enteroinvasive *E.coli (*ETEC*_ipaH).* DEC positive isolates were subjected to antimicrobial susceptibility testing using BD Phoenix Gram Negative NMIC/ID-431 panel run on the M50 identification system.15 out of 149 (10.10%) stool samples tested positive for DEC pathotypes. The most commonly isolated pathotype was EAEC 7/15 (46.67%), followed by EPEC in 5/15 (33.33%), and EIEC in 3/15 (20%). No ETEC and EHEC were detected during this period. Majority of the strains were resistant to trimethoprim/sulfamethoxazole 13/15 (86.66%), ampicillin 12/15 (80%), amoxicillin/klauvanate 6/15 (40%), cefazolin 6/15 (40%), cefuroxime 3/15 (20%), ceftriazone 3/15 (20%), imipenem 3/15 (20%), and tigercycline 3/15 (20%). 5/15 (33.33%) of the isolates were resistant to three classes of antibiotics. However, none of the isolates were resistant to amikacin, ceftolozane-tazobactam, gentamicin, piperallicin/tazobactam. Results showed that EAEC is the most frequently detected pathotype. While many of these isolates show resistance to commonly used antibiotics, there is still potential treatment options for diarrhea caused by EAEC.

7364

CAMPYLOBACTER SPP AND ANTIMICROBIAL RESISTANCE IN A DIARRHEAL CASE-CONTROL STUDY IN KENYA

Mary Kirui, Janet Ndonye, Erick Kipkirui, Ronald Kirera, Nancy Kipkemoi, Margaret Koech, Kirti K. Tiwari, Elizabeth Odundo

Kenya Medical Research Institute /Walter Reed Army Institute of Research -Africa, KERICHO, Kenya

Campylobacter is one of the most commonly isolated enteric pathogens among patients with diarrhoea worldwide and has been listed among the WHO high priority pathogens due to emergence of fluoroquinolone resistant strains. Complications associated with campylobacteriosis are rare but infection may be concurrent with recurrent colitis, Guillain-Barré Syndrome (GBS), irritable bowel disease, pancreatitis, cystitis and reactive arthritis. We describe the results of surveillance of *Campylobacter spp* in a diarrheal case control study in Kenya between January 2013 and December 2020. A total of 4,062 stool samples from cases and controls were collected and cultured to determine bacterial diarrheal pathogens, including *Campylobacter spp*. *Campylobacter spp* were identified using biochemical tests and confirmed using the MALDI-TOF Mass Spectrometry System (Bruker Daltonics, Bremen, Germany). Antimicrobial susceptibility tests were performed using E-test and interpreted according to CLSI guidelines. *Campylobacter spp* was isolated from 91 (2.2 %) stool samples. Out of the 91 *Campylobacter spp* isolated, 55 (60%; p = 0.04) were from diarrheal cases while 36 (40%) were from controls. Majority of the *Campylobacter spp* were *C. jejuni* (78/91; 86%) which were mainly isolated from cases (46/78; 59%) as compared with controls. Additionally, the *Campylobacter spp* were mainly isolated from children ≤5 years (60/1705; 66%; p <0.0001). Antimicrobial susceptibility test was done for ciprofloxacin, chloramphenicol, ampicillin, azithromycin and tetracycline and they all showed 100% susceptibility. However, 24% of the isolates were resistant to trimethoprim sulphamethoxazole. Our results show that *Campylobacter sp*p disproportionately infects children ≤5 years and emphasizes the importance of continued surveillance and monitoring of antimicrobial resistance patterns to combat antimicrobial resistance.

7365

TIMING OF CHOLERA CASES ADMISSIONS AND IMPLICATIONS FOR CASE MANAGEMENT IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Espoir Bwenge Malembaka[1], Patrick Musole Bugeme[1], Chloe Hutchins[2], Jules Jackson[1], Jaime Mufitini Saidi[3], Jean-Marie Masugamuhanya Cirhonda[4], Joël Mashauri Zigashane[4], Faraja Masembe Lulela[4], Jackie Knee[2], Andrew S. Azman[1]

[1]Johns Hopkins University, Baltimore, MD, United States, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]Division Provinciale de la Santé Publique du Sud-Kivu, Zone de Santé d'Uvira, The Democratic Republic of the Congo, Bukavu, Congo, Democratic Republic of the, [4]Oxfam DRC, Uvira, Congo, Democratic Republic of the

Clinical care for cholera is free in cholera treatment centers (CTCs) in many settings. In the DR Congo (DRC), where out-of-pocket payments significantly contribute to health facility revenues, CTCs attract few resources and attention from health care providers and managers. During night and weekend shifts, CTCs are often staffed by newly recruited or insufficiently trained nurses with limited access to pharmacy stocks including critical supplies for cholera treatment like rehydration solutions and antibiotics. We examined the drivers of night and weekend admissions in CTCs in Uvira, a cholera endemic city in eastern DRC. Between August 2021 and April 2024, 2,605 patients were admitted for cholera treatment, for whom time of admission data was available for 2,413. 40.5% of admissions were registered at night and 35.5% during weekends. There was no difference in age or sex between patients admitted during the day and night, but children < 5 years old were more likely to be admitted during weekends (OR 1.42; 95% CI: 1.11–1.83) than older individuals. Patients living closer to the CTCs were more likely to be admitted at night (OR 0.96; 95% CI: 0.92–1, distance measured in km). Those admitted at

night were more likely to be severely dehydrated (OR 1.16; CI 0.99–1.36) and were admitted for longer (≥ 2 days vs <1 day, 1.71; 1.23–2.38). The odds of seeking care within the first 24 hours of symptoms onset were 1.6 higher (95% CI 1.21–2.12) for patients admitted at night than those admitted during the day. During weekends, patients were twice as likely to be admitted at night than during the day (OR 2.06; CI 1.74–2.45). As both severe cases, for whom prompt and aggressive dehydration is crucial, and young children, for whom dehydration is more challenging, are more likely to be admitted to CTCs during night and weekend shifts, the provision of healthcare services in CTCs should be organized to ensure sufficient resources are available at all hours to improve clinical outcomes. Building CTCs in remote neighborhoods might improve access to cholera care in settings like Uvira, where public transport at night is sparse to non-existent and private pharmacies are closed.

7366

ANTIMICROBIAL RESISTANCE PATTERNS AT AN URBAN REFERRAL HOSPITAL IN BLANTYRE, MALAWI

Matthew Cappiello[1], Lindsay Lim[2], Tadala Rambiki[3], Eugene Liu[1]

[1]Loma Linda University Medical Center, Loma Linda, CA, United States, [2]University of Alabama, Birmingham, AL, United States, [3]Blantyre Adventist Hospital, Blantyre, Malawi

Antimicrobial resistance is one of the biggest new threats to global health security in Africa. Recent studies in Malawi document the emergence of carbapenemase-producing Enterobacter as well as other resistant pathogens. We obtained an antibiogram for positive blood and urine cultures from September 2021 through March 2022 at Blantyre Adventist Hospital, a 40-bed pediatric and adult hospital in southern Malawi which sees an average of 75,000 patients per year. A total of n=685 cultures were obtained, with 17.6% positive specimens. Findings were notable for 39.1% ceftriaxone resistance and 40.6% ciprofloxacin resistance in tested E. coli specimens. These findings were similar or worse in tested Klebsiella specimens (57.1% ceftriaxone and/or ciprofloxacin) and tested Proteus specimens (38.5% cefuroxime and/or 23.1% ciprofloxacin). A chi-square test of independence showed a correlation between ceftriaxone and ciprofloxacin resistance, both for all gram negatives (p=4.74E-06) as well as E. coli alone (p=1.77E-05). Of note, resistance to meropenem and/or imipenem was also seen in 14.3% of tested Klebsiella specimens and 15.4% of tested Proteus specimens. Additionally, a significant number of tested urine culture specimens displayed resistance to commonly prescribed outpatient medications, including trimethoprim (E. coli 30.9%, Klebsiella 57.1%, Proteus 38.5%) and less so nitrofurantoin (E. coli 11.6%, Klebsiella 14.3%, Proteus 53.8%). In addition, tested Staphylococcus species demonstrated significant resistance to some commonly used outpatient antibiotics (36.3% trimethoprim, 27.2% third-generation cephalosporins), less so other antibiotics (4.5% clindamycin, 9% second-generation cephalosporins). Further studies should attempt to develop a full program of antibiotic stewardship at Blantyre Adventist and other regional hospitals, assessing resistance genes, uniform identification and susceptibility testing across locations, and provider education.

7367

SPATIAL PATTERNS OF HANSEN'S DISEASE AND WASH RISK FACTORS IN MINAS GERAIS, BRAZIL

Nikki Mastrud[1], Pedro Marçal[2], Lorena Oliveira[3], Marcos Pinheiro[4], Thomas R. Ziegler[1], Jeffrey M. Collins[1], Lucia A. Fraga[4], Julie Clennon[1], Lance Waller[1], Jessica Fairley[1]

[1]Emory University, Atlanta, GA, United States, [2]Georgia Institute of Technology, Atlanta, GA, United States, [3]Universidade Vale do Rio Doce, Governador Valadares, Brazil, [4]Universidade Federal de Juiz de Fora, Governador Valadares, Brazil

The mode of transmission of *M. leprae*, the causative agent of Hansen's Disease (HD), remains uncertain due to the long incubation period of HD and the inability to culture *M. leprae* in the lab. Our research investigates the role of environmental and household-level water, sanitation, and hygiene (WaSH) factors on HD transmission. We conducted a cross-sectional study of 1,315 participants living in four municipalities of a HD-endemic area of Minas Gerais, Brazil. Data were collected on participants' *M. leprae* infection status and household WaSH factors. *M. leprae* infection was determined via antibody testing against LID-1, a recombinant *M. leprae* protein. Among the study population, the highest anti-LID-1 positivity rates were found in the municipality of Mantena (12.26%). Clustering of anti-LID-1 positivity was identified using the Kuldorff spatial scan statistic and relative risk surfaces. Due to the large areas between municipalities where data were collected, clustering was examined on both a regional scale encompassing all of the study data as well as at the municipality level. Examining the whole region, clustering of anti-LID-1 positivity was identified in the municipality of Mantena. Selected household-level WaSH factors were not significant using logistic regression controlling for residence in rural areas, suggesting other factors associated with rural residence may be driving HD transmission. To investigate this, we plan to incorporate neighbors' household WaSH characteristics and environmental characteristics including elevation and proximity to natural water source.

7368

THE IMPACTS OF THE CROSSTALK BETWEEN BACTERIAL VAGINOSIS ASSOCIATED BACTERIA AND *TRICHOMONAS VAGINALIS* ON THE PATHOGENESIS AND HOST IMMUNE RESPONSES

shufang Chiu[1], Kuo-Yang Huang[2]

[1]Graduate Institute of Medical Sciences, National Defense Medical Center, Taipei, Taiwan, [2]Graduate Institute of Pathology and Parasitology, National Defense Medical Center, Taipei, Taiwan

Bacterial vaginosis (BV) is an enigmatic polymicrobial condition characterized by a depletion of health-associated *Lactobacillus* and an overgrowth of anaerobes. Trichomoniasis, caused by *Trichomonas vaginalis*, is a common infection of the urogenital system. Notably, BV-associated bacteria (BVB) and *T. vaginalis* are linked to adverse gynecologic outcomes, including an increased risk of sexually transmitted infections and cervical cancer. In this study, we aim to investigate whether BVB act as pathobionts of *T. vaginalis* infection by altering pathogenic capabilities of the parasite, focusing on adhesion to vaginal substrates and regulation of host immune responses. We established a co-culture system to investigate the interaction of *T. vaginalis* and vaginal bacteria (*Lactobacillus crispatus, Escherichia coli, Prevotella bivia*, and *Lactobacillus iners*), forming a polymicrobial infection on ectocervical cell (Ect). The gene expression of *T. vaginalis* adhesin AP65 was significantly increased after the interaction with *P. bivia*. Upon interaction with *P. bivia*, promoting *T. vaginalis*growth,and affected the survival of Ects, causing higher cytotoxicity and upregulation of IL-6, IL-8, CXCL1, and IP-10. However, *L. crispatus* suppressed the *T. vaginalis*-induced chemokines. Additionally, the crosstalk between *T. vaginalis* and *P. bivia*activated of PI3K, ERK1/2, and MAPKpathways, enhanced the EMT event (the loss of E-cadherin and increased expression of Snail) in Ect, and promoted the pathogenic effects of the parasite. Together, this study demonstrate the impacts of the crosstalk between BVB and *T. vaginalis* on the pathogenesis and host immune responses, and BVB accompanying by *T. vaginalis* infection function as pathobionts to enhance the pathogenic capabilities of this parasite.

7369

PHYLOGENETIC AND PHENOTYPIC CHARACTERIZATION OF *BURKHOLDERIA PSEUDOMALLEI* ISOLATES FROM GHANA REVEALS A NOVEL SEQUENCE TYPE AND COMMON PHENOTYPES

Regina Z. Cer[1], Kevin L. Schully[1], Logan J. Voegtly[1], Gregory K. Rice[1], Hannah Drumm[1], Maren Fitzpatrick[1], Francisco Malagon[1], April Shea[2], F. J. Lourens Robberts[3], Paul K. A. Dartey[4], Alex Owusu-Ofori[5], Danielle V. Clark[6], Kimberly A. Bishop-Lilly[1]

[1]Naval Medical Research Command, Frederick, MD, United States, [2]National Strategic Research Institute, Omaha, NE, United States, [3]Independent Consultant, Stellenbosch, South Africa, [4]CSIR-Crops Research Institute, Kumasi, South Africa, [5]Kwame Nkrumah University

of Science and Technology, Kumasi, Ghana, [6]The Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States

We previously confirmed the presence of *Burkholderia pseudomallei* in the environment of Ghana, unmasking a new area of endemicity for this tropical pathogen. Here, we describe the genetic characteristics of isolates obtained from that environmental survey. Twenty-one isolates were subjected to whole genome sequencing and found to represent three discrete sequence types (ST), one of which was novel, and designated ST 2058. Phylogenetic analysis places this novel isolate within a *B. pseudomallei* clade that includes genomes derived from the Americas, although it is closely related to a sub-clade that includes isolates from Burkina Faso. Importantly, phenotypic characterization demonstrates common features including API20NE profiles and *B. pseudomallei* CPS to support existing diagnostics, and susceptibility to standard of care antibiotics often used in the clinical management of melioidosis. These findings add to our knowledge about the presence and distribution of *B. pseudomalle*i in Africa and represent the first published genomes out of Ghana.

7370

REAL TIME PCR-HIGH RESOLUTION MELTING ANALYSIS FOR PATHOGENIC *LEPTOSPIRA* SPP. IDENTIFICATION

Ilana T. Balassiano, Keila C.F.A Silva, Jessica A.S. Santana, Tatiane M.V. Ramos, Romulo L.S. Neris, Camila Hamond, Katia E.S. Avelar

Oswaldo Cruz Foundation, Rio de Janeiro, Brazil

Leptospirosis is an important zoonotic disease widespread worldwide. The etiological agent, *Leptospira* spp., is a highly heterogeneous bacterial genus divided into pathogenic and saprophytic species. The high resolution melting (HRM) analysis was already described as an important tool for *Leptospira* spp. typing at the species and subspecies levels. The present study aims to evaluate the performance of real time PCR-high resolution melting (qPCR-HRM) analysis, targeting the housekeeping gene *mre*A, in the identification of pathogenic species of *Leptospira* spp. isolated from human cases of leptospirosis. Eighteen reference strains belonging to five *Leptospira* pathogenic species (*L. interrogans*, *L. kirshneri*, *L. noguchii*, *L. borgpetersenii* and *L. santarosai*) and six strains isolated from Brazilian human blood cultures were initially selected for this study. Human isolates were previously identified at species level by 16S DNA sequencing. All the strains were obtained from the *Leptospira* Collection/IOC/Fiocruz. Primer pairs *mre*A-1 and *mre*A-2 were designed based on the *in silico* analysis of the core genomes of these species deposited at the GeneBank. Amplification reactions were performed with 2X Type-it HRM PCR Kit (Qiagen) using the Rotor Gene-Q (Qiagen) instrument. HRM analysis was obtained using the software Rotor Gene Q Series version 2.3.2.(Qiagen). The qPCR-HRM assay using the primer pair *mre*A-2 was able to successfully distinguish *L. interrogans, L. kirshneri* and *L. noguchii*, although with low accuracy, and improvements in our qPCR-HRM assay are still necessary. On the other hand, primer pair *mre*A-1 produced distinct melting curve profiles for *L. borgpetersenii* and *L. santarosai* (Tm 84.4 and 85.6°C, respectively). This is an important finding since *L. santarosai* was already described as one of the predominant species in many countries from Central and South America. The qPCR-HRM assay we designed could be a simple tool for species identification, especially considering the prevalence of *L. santarosai* in Brazil.

7371

MULTI-DRUG THERAPY IS REQUIRED TO EFFECTIVELY TREAT *BARTONELLA* INFECTION IN DIFFERENT ENVIRONMENTS

Emily Olsen, Monica Embers

Tulane National Primate Research Center, COVINGTON, LA, United States

Bartonella is a gram negative, facultative intracellular bacterium that manifests as different clinical syndromes collectively known as bartonellosis. The well-known diseases caused by these bacteria are cat scratch disease (*Bartonella henselae*), trench fever (*Bartonella quintana*) and Carrion's disease (*Bartonella bacilliformis*). Excluding *B. bacilliformis*, which is evolutionarily more distinct than the 30+ other species, *Bartonella* infections often result in subclinical or undiagnosed disease that is left untreated. Individuals with compromised immune systems may experience life-threatening clinical manifestations. Bartonellosis can affect cardiac, circulatory, digestive and neurological function and needs to be treated with effective antibiotics. To date, there is no standard treatment course for these infections and many doctors prescribe antibiotics based on limited case studies. It has been shown that *Bartonella* can grow extracellularly, intracellularly, and in biofilms. To determine an effective antibiotic strategy, it is important to understand *Bartonella* susceptibility in each of these growth conditions. **We hypothesize that combination antibiotic treatments are required to effectively eliminate *Bartonella quintana* and *Bartonella henselae* growth, particularly in biofilm and intracellular environments**. Our previous work has shown that *B. henselae* treatment with single antibiotics in different media, as well as in DH82 canine macrophages, was ineffective in eliminating bacteria. We plan to expand this work with different antibiotics supported by case reports, as well as double and triple combination therapy in erythrocytes and biofilms. The following antibiotics were tested: doxycycline, gentamicin, azithromycin, azlocillin, rifampin, tobramycin and clarithromycin. We found that while monotherapy may inhibit growth extracellularly, it is ineffective when used against intracellular bacteria or pre-existing biofilms. The effectiveness of combination therapy supports the notion that *Bartonella* species utilize target cells and biofilms as an antibiotic tolerance strategy.

7372

EPIDEMIOLOGY OF INVASIVE *STAPHYLOCOCCUS AUREUS* IN PATIENTS SEEN AT AN OUTPATIENT CLINIC IN THE GAMBIA

Mamadou Mballow, Henry Badji

Medical Research Council Unit The Gambia at the London School of Hygiene & Tropical Medicine, Banjul, Gambia

Staphylococcus aureus is a major cause of infection globally, particularly in low-and middle- income countries. In The Gambia, *S. aureus* is a common cause of infection in children. However, comprehensive data on the epidemiology of and antibiotic susceptibility of *S. aureus* is limited. We describe the epidemiology and antibiotic susceptibility of invasive *S. aureus* causing invasive disease in The Gambia. 134 *S. aureus i*solates obtained from clinical specimens of patients seen between 2018 and 2020 at the MRCG at LSHTM outpatient clinic in Fajara, The Gambia were analyzed. *S. aureus* strains were characterized using Multilocus Sequence Typing (MLST) and antimicrobial susceptibility was determined using the Kirby-Bauer disc diffusion method. 60.3% of strains were recovered from males while children < 2 years contributed the highest number of isolates (65.0%). 82.6% of the isolates were obtained from blood cultures. Antibiotic susceptibility to trimethoprim-sulphamethoxazole, chloramphenicol, cloxacillin and methicillin was 12.7%, 97.0%, 97.0% and 96.3% respectively. MLST identified 10 Sequence Types. Our study has provided essential information on invasive *S. aureus* strains in The Gambia. Antibiotic susceptibility patterns show that invasive *S. aureus* infections can be successfully treated with widely available antibiotics in The Gambia. Methicillin Susceptible *Staphylococcus aureus* (MSSA) strains continue to be the major cause of invasive staphylococcal infection in The Gambia. Discovery of Methicillin Resistant *Staphylococcus aureus* (MRSA) strains although in small numbers emphasizes the need for continuous surveillance and better antibiotic stewardship to avoid increase in antibiotic resistance.

7373

CLINICAL CHARACTERIZATION OF HUMAN LEPTOSPIROSIS IN A REGION OF THE COLOMBIAN CARIBBEAN

Virginia C. Rodríguez-Rodríguez[1], Ana Castro-Cordero[1], Eidy Martínez-Ibarra[1], Alfonso Calderón-Rangel[1], Piedad Agudelo-Florez[2]

[1]Universidad de Córdoba, Monteria, Colombia, [2]Universidad CES, Medellín, Colombia

Leptospirosis is the emerging and re-emerging zoonosis with the highest distribution and prevalence worldwide with important repercussions on human and animal health. A prospective longitudinal descriptive study was carried out, with non-probabilistic sampling, which included 339 patients suspected of leptospirosis during July 2017 to February 2021. The cases were confirmed by the Microagglutination Test (MAT) and Polymerase Chain Reaction (PCR). The 16S rRNA gene amplification products obtained from blood or urine samples of confirmed patients were sequenced. 67 cases of the 339 suspects were confirmed. The most frequent serogroups associated with acute cases were Sejroe, Australis and Pomona. The 16S rRNA gene sequences showed L. *interrogans* and L. *borgpetersenii* as species associated with acute cases of leptospirosis. At the time of admission, the symptoms reported by the positive patients showed that 86.6% (n=58) presented the triad of symptoms: fever, headache and myalgia. In 40.3% (n=27) of cases, the triad was accompanied by jaundice and in 17.9% (n=12) by hepatomegaly. For the operational case definition, there is a greater possibility of having leptospirosis when patients presented hepatomegaly, jaundice, conjunctival injection, triad plus jaundice and triad plus hepatomegaly with statistically significant differences. In the early stages of the disease, patients with the presence of the triad (fever, headache and myalgia) associated with conjunctival injection were more likely to suffer from the disease. This symptomatology must be taken into account for the operational case definition in the study area. Leptospirosis clinical protocols in Colombia should include not only diagnostic but also clinical algorithms that guide the timely and adequate management of the disease, whose transmission is not only occurring in rural areas as has traditionally been described, but also in the urban environment.

7374

SEROLOGICAL ASSESSMENT OF *HELICOBACTER PYLORI* INFECTION AND ITS ASSOCIATED RISK FACTORS IN ASYMPTOMATIC GHANAIAN PATIENTS, ATTENDING AGONA GOVERNMENT HOSPITAL

KOFI AGYAPONG ADDO[1], Daniel Kusi Ampofo[2], Samuel Ofori Ayetibo[1], Austine Tweneboah[3], Papa Kofi Amissah-Reynolds[1], Victor Agyei[1], Kingsley Badu[2]

[1]Akenten Appiah-Menka University of Skills Training and Entrepreneurial Development, Kumasi, Ghana, [2]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [3]Institute of Zoology, Germany, Koln, Germany

Helicobacter pylori infection poses a considerable global health challenge, exhibiting high prevalence rates in developing countries. This disease lacks a definitive treatment in Ghana and is often treated with a combination of antibiotics— posing risk of antibiotic resistance. Evidence suggests that gastric cancer risk might increase due to helminths colonizing the gastric epithelium following H. pylori-induced gastric atrophy. We carried out a cross-sectional clinical survey in Ghanaian asymptomatic patients to determine the exposure rate of *H. pylori* infection, the presence of intestinal helminthic flora, and identify related risk factors for gastro-duodenal diseases. A 2ml venous blood and 3 g stool samples were collected from 275 asymptomatic patients (mean age: 29.4 ± 9.2 years) for serological tests that detected *H. pylori* serum antibodies (human IgG) and stool antigens. A portion (1 g) of the stool samples was analyzed for intestinal helminthic flora using the formo-ether concentration technique. Structured questionnaires were utilized to collect demographic information and assess risk factors. Serum antibody testing revealed *H. pylori* exposure in 63.3% of participants, while 71.3% tested positive for *H. pylori* stool antigens. Females exhibited higher positivity rates for both tests (72.3% for stool, 65.1% for serum). More individuals (60.7%) tested positive for both *H. pylori* serum antibodies and stool antigens. Microscopic examination showed that 90.6% of the participants had no intestinal helminths. Employment status did not significantly affect *H. pylori* positivity rates (X^2=01.92; p=0.908). Logistic regression identified a long-term high-fat diet as a significant predictor of *H. pylori* occurrence (p=0.003). The high exposure and occurrence of asymptomatic *H. pylori* infection in the study area highlights the need for routine screening and early intervention to prevent the development of serious gastro-duodenal diseases. Targeted public health efforts should address modifiable risk factors like dietary habits to reduce the burden of *H. pylori*-related morbidity.

ASSESSING PROGRESS TOWARDS THE ELIMINATION OF MOTHER-TO-CHILD TRANSMISSION OF SYPHILIS IN PERU

Jazmin Qquellon, Ariana Cardenas, Andrea Castro-Caparó, Gabriel Carrasco-Escobar

Health Innovation Laboratory, Institute of Tropical Medicine "Alexander von Humboldt", Universidad Peruana Cayetano Heredia, Lima, Peru

To eliminate and control the mother-to-child transmission (MTCT) of Syphilis, the World Health Organization (WHO) recommends meeting the following targets: (1) 95% coverage of syphilis screening during pregnancy, (2) reducing the incidence of congenital syphilis in less than or equal to 0.5 cases per 1000 newborns, and (3) 90% reduction in the incidence of maternal syphilis between 2018 and 2030. We evaluated the progress in the Peruvian context at the national and department level. A retrospective epidemiological analysis was performed using national data collected by the Peruvian Ministry of Health of reported cases of congenital and maternal syphilis from 2015 to 2022. The incidence rates were calculated by dividing the number of cases over the number of live births each year by department. Syphilis screening and sociodemographic data were obtained from The Demographic and Health Survey (DHS). In addition, we described departments with higher rates of congenital and maternal syphilis and higher percentages of extreme poverty and low maternal education (primary or no education). In 2022, nationwide syphilis screening during pregnancy was 82.6% (95% CI: 80.7% - 84.5%), the congenital syphilis rate was 0.82 cases per 1000 newborns, and the maternal syphilis rate increased by 53.7% from 2018. At the department level, only one department achieved all targets; 14, either target (2), (3) or both; while 10, didn't meet any targets. Among those living in extreme poverty, the jungle region exhibited the highest rate of congenital syphilis. Additionally, for maternal syphilis, this trend extended to include the highlands. When stratified by low maternal education, the jungle showed the highest rate of congenital syphilis, whereas for maternal syphilis, the north coast of Peru stood out. This study found that none of the Syphilis MTCT targets proposed by the WHO were met in Peru in 2022. Decentralized strategies are needed to achieve the goals of syphilis screening coverage and reduction of syphilis incidence by 2030.

7376

BACTERIOLOGICAL PROFILES OF DIABETIC ULCERS IN CASES OF MAJOR LIMB AMPUTATION: INSIGHTS FROM SOLOMON ISLANDS

Dylan Bush[1], Adrian Garcia Hernandez[2], Stallone Kohia[3], Thomas Fitzpatrick[4], Rooney Jagilly[5]

[1]Brown University - Warren Alpert Medical School, Providence, RI, United States, [2]Columbia University, New York, NY, United States, [3]University of Papua New Guinea, Port Moresby, Papua New Guinea, [4]World Health Organization, Honiara, Solomon Islands, [5]Solomon Islands Ministry of Health & Medical Services, Honiara, Solomon Islands

Solomon Islands is a Pacific island country with a 19.8% estimated diabetes prevalence. Diabetic patients there face limited access to medical care leading to poor glycemic control and increased risk of diabetic ulceration. This retrospective study describes the microbiota of diabetic ulcers in cases of major limb amputation in Solomon Islands. It is the first report

of microbiological data from diabetic ulcers in the nation. Demographic, microbiological, and outcomes data was collected from the records of patients with diabetes who underwent major limb amputation in Solomon Islands between 2018-2023. Summary and univariate analysis were conducted. Among 338 adults who underwent major limb amputation during the study period, 33% (N=113) had microbiological data available for abstraction. The median age was 53 (range: 22-83) and 58% were male (N=65). A total of 20 species were identified via pus and tissue culture. The most common species were *Pseudomonas aeruginosa* (N=27, 24%), *Enterococcus* spp. (N=25, 23%), and *Klebsiella pneumoniae* (N=18, 16%). MRSA was identified in one patient. 55% (N=62) of cultures demonstrated resistance. Resistance against ampicillin (N=31), amoxycillin (N=31), gentamycin (N=21), and Trimethoprim/sulfamethoxazole (N=21) were most common. On univariate analysis, colonization with *E. coli*, *K. pneumoniae*, and *Enterococcus* spp. was significantly associated with antibiotic resistance. The relative predominance of *Pseudomonas*, *Enterococcus*, and *Klebsiella* species is consistent with prior research on the microbiota of diabetic infections. Despite limited data, cultures from this cohort were diverse, including rarer opportunistic species such as *P. agglomerans* and *P. gergoviae*. The high percentage of resistance is concerning given the limited access to next generation antibiotics in Solomon Islands. Data gaps prevented assessment of the appropriateness of antibiotic selection. Further research is needed to better understand local infection management practices, factors contributing towards resistance, and clinical outcomes from antibiotic-resistant infections in Solomon Islands.

HANSEN'S DISEASE (LEPROSY) IN THE UNITED STATES OF AMERICA: A SYSTEMATIC REVIEW

Shivani Jain[1], Will Eaton[2], Rie Yotsu[2]

[1]LSUHSC-New Orleans School of Medicine, New Orleans, LA, United States, [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States

Hansen's disease, also known as leprosy, is a chronic infectious disease that is caused by the bacteria *Mycobacterium leprae* and, more rarely, by *M. lepromatosis*. It is primarily spread through respiratory droplets from person to person but can also be transmitted zoonotically from nine-banded armadillos and some other mammals. The condition commonly affects the skin, peripheral nerves, mucous membranes, and extremities and occasionally impacts internal organs. Patients often face chronic impairments in both their physical and mental health. A systematic review of all published U.S. cases of leprosy has not been undertaken prior. This study's aim was to characterize all scientifically published case reports and case series of leprosy diagnosed in the U.S. Four databases were searched for relevant studies published in English up to 6/2/2023. A total of 133 case reports and series, from 1896 to 2023, met selection criteria. From these, 328 unique cases were identified. Median age was 43 years (range: 3.5 - 87 years). Most were male (79.9%) and White (51.5%), followed by 13.4% Asian and 10.4% Black. One-third presented to the National Hansen's Disease Program (NHDP) in Louisiana. State of residence and state of diagnosis trends aligned. A majority identified the U.S. as their country of origin and resided in regions providing NHDP resources. Prior to 1960, most cases were linked to military service abroad (86.5%); however, mode of transmission was usually unknown. A growing proportion of cases has been linked to zoonoses (22.8%) since 1980. Skin biopsy remained the dominant diagnostic modality (61.6%) through 2023, with PCR utilized more since 2000. By Ridley-Jopling classification, most cases (47.3%) were lepromatous. By WHO classification, when information was reliably available, 21.8% were multibacillary and 8.3% were paucibacillary. Multi-drug regimens have dominated treatment protocols since 1980, but other antibiotics have been increasingly used over the past decade. Studies reporting leprosy in the U.S. are limited overall. This systematic review comprehensively informs on past and present trends of leprosy in the U.S.

COXBASE GOES WIKI - HOW TO CREATE SUSTAINABILITY FOR GENOMIC Q FEVER DATA.

Vanessa Scharf[1], Silke Fischer[2], Andrea Helbich[3], Mandela Fasemore[1], Mathias Walter[4], Gilles Vergnaud[5], Thomas Dandekar[6], Konrad Förstner[1], **Dimitrios Frangoulidis**[3]

[1]ZB MED - Information Centre for Life Science, Cologne, Germany, [2]LGA, Stuttgart, Germany, [3]Bundeswehr, KdoSanDstBw VI 2, Munich, Germany, [4]Bundeswehr, InstMikroBioBw, Munich, Germany, [5]Institute for Integrative Biology of the Cell (I2BC), Paris, France, [6]Department of Bioinformatics, Biocenter, Würzburg, Germany

Q fever is a wordwide distributed zoonotic disease, caused by the Gram-negative bacterium *Coxiella burnetii*. It primarily affects livestock and animals but can also be transmitted to humans through direct contact with infected animals or contaminated animal derived materials in the environment via aerosols. CoxBase (https://coxbase.q-gaps.de/) is an online platform for epidemiological surveillance, visualization, analysis and typing of Coxiella brunetii genomic sequence and for tracking outbreak. It is maintained and closely monitored by a small team of experts from German Interdisciplinary Program "Q-GAPS - Q fever GermAn Interdisciplinary Program for reSearch" (https://q-gaps.de/). It aims to gather and display information about isolates discovered all around the world. The dataset of CoxBase provides a deep dive into epidemiological information about a bacterium and its distinctive resilience little is known about. Wikibase is a versatile open-source software platform developed by the Wikimedia Foundation. It provides the infrastructure and tools needed to create, manage, modify and query data. The best known instance is Wikidata (https://www.wikidata.org/), which host more than 1 Billion items and is maintained by a large, global community of contributors. Wikibase offers an easy to use web-interface to enter the primary structured data and can be efficiently queried via SPARQL (SPARQL Protocol And RDF Query Language.) and connected to other knowledge graphs.Here we would like to present how the genomic data of CoxBase was integrated into a dedicated Wikibase instance. The resulting resource offers all the benefits of Wikibase including an easy way to curate data collaborativly, querying it with a powerful language and connecting it with other resources. In addition we hope that this would be a model for the future to produce sustainability for genomic data - independent from research projects and their grants.

7379

ROLE OF ACRAB AND OQXAB EFFLUX PUMPS IN AMIKACIN AND CIPROFLOXACIN RESISTANCE AMONG CLINICAL ISOLATES OF KLEBSIELLA PNEUMONIAE IN LIMA, PERU

Deysi J. Aguilar-Luis[1], Wilmer Silva-Caso[1], Liliana Morales-Castillo[2], Hugo Carrillo-Ng[1], Giancarlo Pérez-Lazo[2], Miguel A. Aguilar-Luis[1], **Juana del Valle-Mendoza**[1]

[1]Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [2]Guillermo Almenara Irigoyen National Hospital-EsSalud, Lima, Peru

Klebsiella pneumoniae is the most significant pathogen and is associated with one of the highest global mortality rates, with an average pooled mortality. The WHO has designated this bacterium as a top-priority target for research on novel antimicrobials, due to its raising antibiotic resistance. We conducted is study to determine the prevalence of the AcrAB and OqxAB efflux pumps in clinical isolates *K. pneumoniae* and their role in amikacin and ciprofloxacin resistance. The clinical samples identified as *Klebsiella pneumoniae* collected from in patients hospitalized from Lima, Peru. Antimicrobial susceptibility testing was conducted using the microdilution method. The susceptibility to antibiotics was evaluated in the presence and absence of the inhibitor CCCP and PaβN efflux pumps. Efflux pump resistance genes AcrA, AcrB, OqxA, and OqxB were amplified using the polymerase chain reaction amplification technique. We found that 100% of the isolates of *K. pneumoniae* were resistant to amoxicillin-clavulanic acid, cefotaxime, ceftazidime, cefuroxime, ertapenem, gentamicin, imipenem, meropenem and tobramycin. The 93.75% were

resistant to ciprofloxacin and piperacillin/tazobactam; 87.5% were resistant to trimethoprim/sulfamethoxazole; 56.25% were resistant to fosfomycin; 25% were resistant to levofloxacin and 18.75% to amikacin. The exposure to the PaβN inhibitor, an increase in susceptibility was observed in clinically resistant strains to amikacin, and strains resistant to ciprofloxacin show susceptible with both inhibitors. In the case of CCCP addition to ciprofloxacin, 18.75% exhibited a fourfold decrease and 56.25% displayed a threefold decrease in MIC, with 25% remaining unchanged. The prevalence of resistance genes show AcrA gene was detected in 43.75% isolates, the AcrB gene in 56.25%, OqxA in 31.25%, and OqxB in 25.00%. In conclusion, our findings suggest that efflux pumps are major mechanisms for ciprofloxacin and amikacin resistance in *K. pneumoniae*, with the AcrAB and OqxAB systems being significant contributors to this resistance

PREVENTION AND CONTROL OF HYDATID CYST: STRATEGIES, CHALLENGES, AND FUTURE DIRECTIONS

Haji Negawo Munaso

Arsi university, 10 kebele, Ethiopia

Background: Hydatid cyst, caused by the larval stage of Echinococcus tapeworms, is a significant public health concern worldwide but mainly in Africa. Understanding the strategies, challenges, and future directions in hydatid cyst prevention is essential for developing effective interventions and promoting global health.Objective: This abstract aims to provide an overview of the current strategies employed for the prevention and control of hydatid cyst, highlight the challenges faced in implementing these measures, and discuss potential future directions for improved prevention strategies.Methods: A review of the literature was conducted by searching electronic databases including PubMed, Scopus, and Embase. Relevant articles published between 1960 and 2021, including research studies, reviews, and public health reports, were analyzed and synthesized to provide a comprehensive overview.Results: Various prevention strategies have been implemented to combat hydatid cyst, including public health education, surveillance and control programs, veterinary interventions, and improved sanitation and hygiene practices. Future directions for hydatid cyst prevention include the development of novel diagnostic tools, vaccines, and targeted interventions, as well as strengthening collaboration between human and veterinary health sectors.Conclusion: Prevention and control of hydatid cyst necessitate a multi-faceted, integrated approach that addresses the complex interplay between human, animal, and environmental factors. Collaboration between researchers, policymakers, healthcare professionals, and communities is crucial to achieving sustainable prevention and control efforts.Keywords: hydatid cyst, echinococcosis, prevention, control, interventions, strategies, challenges, future directions.

CLINICAL MANAGEMENT AND RECURRENCE OF HUMAN CYSTIC ECHINOCOCCOSIS IN A SECONDARY HEALTHCARE CENTER OF A HIGHLY ENDEMIC AREA IN THE ANDES OF CUSCO, PERU

Roberto Pineda-Reyes[1], Thomas Junghanss[2], Jakob Zinsstag[1], Paola Vergaray[3], Maria L. Morales[4], Bolor Bold[5], Ruben Bascope[6], Miguel M. Cabada[7]

[1]Department of Epidemiology and Public Health, Swiss Tropical and Public Health Institute/associated to University of Basel, Allschwil, Switzerland, [2]Section of Clinical Tropical Medicine, Heidelberg University Hospital, Heidelberg, Germany, [3]Department of Surgery, Alfredo Callo Rodriguez Hospital - Sicuani, Sicuani, Peru, [4]Cusco Branch – Alexander von Humboldt Tropical Medicine Institute, Universidad Peruana Cayetano Heredia, Cusco, Peru, [5]National Center for Zoonotic Diseases, Ulaanbaatar, Mongolia, [6]Regional Zoonotic Diseases Strategy, Cusco, Peru, [7]Division of Infectious Diseases, University of Texas Medical Branch, Galveston, TX, United States

Cystic echinococcosis (CE) management in low- and middle-income countries remains a challenge due to advanced disease at presentation, limited resources and lack of standardization of care. Surgical outcomes including recurrence rates are unknown. Up to 45% CE patients in tertiary hospitals of Cusco City are referred from the Sicuani District. We reviewed medical records of 115 patients with CE admitted to a secondary care hospital in Sicuani from January 2010 to December 2019. The median age was 25 years (IQR, 16-46) and 60.5% were female. Fifty-six patients (48.7%) were referred from primary care centers. Liver cysts were diagnosed in 106 patients (92.2%), lung cysts in 5 (4.3%), and combined liver/lung cysts in 4 (3.5%). The median duration of symptoms was 21 days (IQR, 3-89 days). The median length of stay was 7 days (IQR, 5-10). Pre-surgical complications were documented in 46 cases (40%). One hundred seven patients (93%) had an ultrasound, identifying 134 liver cysts. The median largest liver cyst diameter was 13 cm (IQR, 9.2-15.2). Eighty-four patients (62.7%) had single cysts, 19 had two cysts, and 12 patients had 3 cysts. Eighty-one cysts (58.3%) were staged: 28 (34.6%) were Gharbi I, 31 (38.3%) Gharbi II, 17 (21%) Gharbi III, and 5 (6.2%) Gharbi IV. Of the 102 (88.7%) surgically treated patients, 57 (55.9%) received albendazole (ABZ) after surgery, 27 (26.5%) before and after surgery, 7 (6.9%) did not received it, 6 (5.9%) before surgery, and in 5 the timing was not specified. Anti-spillage measures were documented in 11 (9.6%) patients. Fourteen out of 110 (12.7%) were readmitted to the hospital, 8 for cyst recurrence (new cyst, same site), 4 for complications, 3 for elective two-stage treatment, and 1 for a new cyst (different site). Considering past medical history, readmissions, and follow-up, the recurrence rate was 16/115 (13.9%). The patients admitted to this secondary care hospital in a highly CE endemic area presented advanced disease and complications. Surgery was the main stage-specific treatment implemented. The high recurrence rate created a burden that could be effectively reduced with spillage prevention and peri-operative ABZ.

7382

SUBARACHNOID NEUROCYSTICERCOSIS: CLINICAL, SEROLOGICAL AND NEUROIMAGING EVOLUTION AFTER ANTIPARASITIC TREATMENT

Carolina Guzman[1], JAVIER BUSTOS PALOMINO[1], Herbert Saavedra[2], Isidro Gonzales[2], Hector Garcia[1]

[1]Center for Global Health, Universidad Peruana Cayetano Heredia, Lima-Peru, lima, Peru, [2]Cysticercosis Unit, National Institute of Neurological Sciences, Lima-Peru, lima, Peru

Neurocysticercosis (NCC) presenting in the subarachnoid space, represents the most aggressive form of the disease. The cysts' growth within this space tends to be uncontrolled and diffuse, often resulting in mass effects and triggering immune responses in surrounding tissues, that may lead to arachnoiditis or even vasculitis. Data on the efficacy of antiparasitic treatment in subarachnoid NCC remain scarce, leaving healthcare providers and patients without clear guidance on therapeutic outcomes. This cross-sectional study assessed the clinical, serological, and imaging evolution of 80 individuals with a history of subarachnoid NCC who received antiparasitic treatment at least two years before. Seventeen participants (23.6%) continued presenting subarachnoid NCC lesions. From these, 15 (82.35 %) had positive levels of circulating parasite antigen, most of them at high levels (11/15, 73.3%, with rations above 20, and 4 (26.6%) with ratios between 1-3). All cases continued having positive antibody responses on EITB (western blot), with 11 reacting to all 7 diagnostic bands. Univariate analysis showed that individuals with high antigen levels had 43.1 times the OR compared to those who have a negative antigen ratio, individuals with 60 years more have 6.75 the OR of having lesions compared to those age less than 45 years (CI 95% 1.33-34.26, p=0.02), patients with continuous crisis have 3.9 (CI 95% 1.03-15.03, p=0.04) times the OR compared to those who did not have seizure activity per every increase in one reactive antibody band on EITB the OR of having lesions increases by a factor of 2.9 (CI 95% 1.7-4.9, p<0.001). Multivariate analysis showed strong evidence that those who have high antigen ratio have 39.9 times the OR of having lesions compared to those who have a negative result p=0.017, when adjusted by sex, age, clinical symptoms (headache and seizures) and WB. Incomplete cure of subarachnoid NCC occurs in a sizable proportion of

patients, and serological results (in particular very high antigen levels) are strong predictors of treatment failure.

Keywords: subarachnoid, neurocysticercosis, evolution, recurrence

7383

EXPERIMENTAL INFECTIONS DEMONSTRATE CONCOMITANT IMMUNITY AGAINST *TAENIA SOLIUM* IN PIGS: QUANTIFYING THE IMPACTS OF AGE AND PRIOR INFECTIONS ON THE NUMBER OF CYSTS

Eloy Gonzales-Gustavson[1], Gabrielle Bonnet[2], Francesco Pizzitutti[3], Miguel Muro[4], Mayra Elizalde[4], Claudio Muro[4], Ricardo Gamboa[4], Gianfranco Arroyo[4], Sarah Gabriël[5], Hector H. Garcia[4], Seth E. O'Neal[6]

[1]Universidad Nacional Mayor de San Marcos, Lima, Peru, [2]Centre for the Mathematical Modeling of Infectious Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Geography Institute, Universidad San Francisco de Quito, Quito, Ecuador, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Department of Veterinary Public Health and Food Safety, Ghent University, Ghent, Belgium, [6]School of Public Health, Oregon Health & Science University and Portland State, Portland, OR, United States

Taenia solium is a major cause of epilepsy in low- and middle-income countries. Important efforts have been made to control and eliminate this parasite but, due to the high costs of large-scale field testing, it is difficult to experimentally validate the optimal strategy. Mathematical models are therefore also used to help design cost-effective strategies, but knowledge gaps around the existence and extent of pig immunity hamper the representation of transmission in endemic settings. In this study, we show that pig immunity constrains cyst development, and we quantify this effect. In a first experiment focusing on the impact of age, six groups of pigs (48 pigs in total) between 4 and 22 weeks old were infected with 20,000 eggs each. In a second experiment focusing on the impact of prior infections, 80 pigs were either infected with 100, 1,000, 5,000 or 20,000 eggs at 4 weeks old and reinfected after 12 weeks with 5,000 or 20,000 eggs, or infected only once, at the time of the first or second infection. To decrease the variability in results, pigs were infected in individual pens with eggs coming from a pool of up to 10 tapeworms with more than 75% of activated oncospheres. The first experiment showed that the ratio of viable cysts to eggs ingested first increased with age at infection, up to approximately 10-16 weeks old, then declined drastically in older pigs (KW test p=0.008). The second experiment showed that first exposure with as few as 100 eggs, almost entirely prevents the development of more cysts at reinfection, even with high re-exposure doses, with no statistical differences between infected and reinfected pigs. Despite extensive efforts to control for variability in infective doses, the number of cysts varied a lot between individual pigs within each group. In conclusion, age at infection and prior exposure affect cyst development in pigs. These factors may explain why low number of cysts are routinely found in endemic regions, usually fewer than 10 per animal, despite high transmission levels. The parameters we have obtained will be incorporated into simulation models to replicate the distribution of cysts found in pigs from endemic settings.

7384

ECHINOCOCCOSIS: ASSESSING SURVEILLANCE NEEDS FOR AN EMERGING INFECTIOUS DISEASE IN THE UNITED STATES

Elizabeth M. Wendt[1], Hanna Oltean[2], Bonny Mayes[3], Natalie Kwit[4], Tracy Woodall[5], Anne Straily[1], Mary L. Kamb[1]

[1]Centers for Disease Control and Prevention, Atlanta, GA, United States, [2]Washington Department of Healh, Olympia, WA, United States, [3]Texas Department of State Health Services, Austin, TX, United States, [4]Vermont Department of Health, Burlington, VT, United States, [5]Virginia Department of Health, Richmond, VA, United States

Echinococcosis is caused by several species of zoonotic tapeworms and affects dogs and wild canids worldwide; sheep, cervids, and rodents are intermediate hosts. Two main species, *E. granulosus* and *E. multilocularis,* affect humans, who are accidental hosts. Infection causes enlarging lesions in multiple organs; rupture of cystic lesions can lead to anaphylaxis and death. During 1980-2010, no locally acquired human cases were described, but since 2010, nine such human cases have been identified in three states, along with infections in wild canids and domestic dogs. Recently, echinococcosis consultations to CDC increased from 32 in 2022 to 61 in 2023. Echinococcosis is not nationally notifiable and is reportable in only two states: Texas and Washington. Key stakeholders were identified from states where echinococcosis is reportable (n=2) and states with locally acquired human or animal cases (n=6). Stakeholders were interviewed during September-December 2023 using a semi-structured questionnaire and participated in group discussions. Responses were analyzed for thematic patterns around surveillance. The most common themes were desire for multi-state collaboration (n=8), interest in improving surveillance (n=7), and need for a One Health approach (n=6). No states had outreach materials, although the need was recognized (n=4). Surveillance in states where echinococcosis is reportable began in 2016 (Texas) and 2023 (Washington). Clinical criteria differ between these case definitions, and one state noted difficulty applying the criteria. Given the limited number of cases in any state, the need for a coordinated approach was identified. Subsequently, two multi-state working groups were established to develop a standardized case definition and outreach materials for pet owners, hunters, farmers, veterinarians, and public health professionals. Because this emerging disease is rare, aggregating standardized human case data at CDC would help stakeholders understand the risk for transmission in the US and develop prevention strategies. Further, outreach materials would raise awareness around reporting potential cases.

7385

POVERTY LEVELS ASSOCIATED WITH THE PREVALENCE OF LIVER CYSTIC ECHINOCOCCOSIS IN A PERUVIAN RURAL COMMUNITY

Oswaldo G.E. Espinoza-Hurtado[1], Raul Enriquez[1], Luis Gomez-Puerta[2], Adriano Casulli[3], Hector H. Garcia[4], Saul J. Santivanez[1]

[1]Universidad Continental, Huancayo, Peru, [2]Department of Animal and Public Health, School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]WHO Collaborating Centre for the Epidemiology, Detection and Control of Cystic and Alveolar Echinococcosis. Department of Infectious Diseases, Istituto Superiore di Sanità, Rome, Italy, [4]Center for Global Health, Universidad Peruana Cayetano Heredia, Lima, Peru

Human cystic echinococcosis (CE) is a zoonotic parasitic disease categorized among the most neglected diseases. It detrimentally impacts the economy and the quality of life of affected individuals. While associations with poverty-related factors have been observed, these relationships have not been thoroughly assessed using appropriate methods. The current study aims to determine the influence of poverty on the prevalence of CE within the livestock-rearing community of Canchayllo, Peru. For this analysis, a secondary examination was conducted on a convenience sample of 138 individuals selected from a dataset of 232 subjects. The selection criteria included only those who responded to the survey designed to measure the Wealth Index. A generalized binomial regression model with a log link function was used to evaluate the association between the presence of liver CE and levels of poverty. Poverty was classified into two categories: high poverty (1st and 2nd wealth index quintiles) and non-high poverty (3rd to 5th wealth index quintiles). The analysis adjusted for screening coverage and other covariates. The findings indicate a liver CE prevalence of 13.04% (95%CI: 7.42 - 18.66) and a prevalence ratio (PR) of 2.35 (95%CI: 1.17 - 4.73, p=0.016) between groups with high levels of poverty compared to those with non-high levels of poverty, after adjusting for sex, gender, and screening coverage. Some variables like sheep raising were excluded from the model due to multicollinearity with the wealth Index. The results demonstrated a significant correlation between the level of poverty and the prevalence of liver cystic echinococcosis, thereby confirming the influence of poverty on the development of the disease.

7386

ALVEOLAR ECHINOCOCCOSIS: NOT JUST IN ENDEMIC COUNTRIES

Raffaella Lissandrin[1], Ambra Vola[2], Gianluca D'Alessandro[3], Sofia Frattola[3], Chiara Stocchero[4], Enrico Brunetti[5]

[1]Foundation IRCCS Policlinico San Matteo, WHO Collaborating Centre for Clinical management of Cystic Echinococcosis, Pavia, Italy, [2]Microbiology and Virology Unit, Foundation IRCCS Policlinico San Matteo, Pavia, Italy, [3]University of Pavia, Pavia, Italy, [4]Department of Clinical, Surgical Diagnostic and Pediatric Sciences, University of Pavia, Pavia, Italy, [5]Department of Clinical, Surgical Diagnostic and Pediatric Sciences, University of Pavia; Foundation IRCCS Policlinico San Matteo, WHO Collaborating Centre for Clinical management of Cystic Echinococcosis, Pavia, Italy

Alveolar echinococcosis (AE) is a zoonosis caused by the larval form of *Echinococcus multilocularis*, a cestode endemic in Asia, especially China, Turkey and north-eastern European countries. *E. multilocularis* has a sylvatic life cycle, where foxes act as definitive hosts and rodents as intermediated hosts. When the intermediate host ingests eggs of *E. multilocularis* excreted by the definitive host with feces, the larval stage can develop. Humans are accidental intermediate hosts, after ingesting contaminated foods. Until 2023, no cases of AE had ever been reported in Italy, and the first case was reported in February 2024. Here we report a second case of AE diagnosed in Italy. A 87-year-old Swiss woman living in Italy, was seen in a Hospital in northern Italy for a painful epigastric mass ,not dissociable from the gastric wall, pancreas and liver, with peripheral contrast enhancement at CT scan. An esophagogastroduodenoscopy excluded the gastric origin of the mass. The patient was diagnosed with liver neoplasm of unknown origin. Chemotherapy was excluded due to her age and performance status. No biopsy was performed. However, serology for CE returned positive and she was referred to our center. Ultrasound showed a roundish inhomogeneous mass 11 x 7 x 12 cm in diameter, with ill-defined margins, anechoic central areas, calcifications and small cystic images within. While this appearance was not consistent with CE, the Swiss nationality of the patient prompted us to inquire about contact with foxes in her home country, which she reported. AE was therefore suspected and confirmed by serology. The patient was referred to a center for AE in Switzerland where she was staged as P4 N0-1 M1 for the presence of metastatic lesions in the lung. Albendazole at 100 mg/die was started for the presence of biliary tree compression, with of resolution of epigastric pain after few weeks . She is clinically stable and asymptomatic at the time of this writing. AE is a rare but potentially fatal parasitic disease if not diagnosed and left untreated and should be included in the differential of neoplastic lesions in selected cases also in non-endemic areas.

Surgery is the established therapy for thoracic echinococcal cysts, but there is no consensus about the optimal surgical method. Options include lobectomy, segmentectomy, or cystostomy with closure of bronchial openings and capitonnage. The choice depends on several factors such as cyst integrity, quantity, location in the lung, associated lung tissue damage, and costs. Each surgical approach carries its own disadvantages and potential benefits, and a careful assessment of the individual patient's condition and the medical team's expertise is crucial. We report our experience with surgical techniques and costs in the treatment of thoracic echinococcosis (TE). We reviewed hospitalization expenses and surgical techniques used in the treatment of 11 patients with TE admitted to the Thoracic Surgery Ward at 'Santi Antonio e Biagio e Cesare Arrigo' Hospital in Alessandria, Italy from May 2023 to March 2024. The total expenditure for a single hospitalization, encompassing both hospital stay and surgical intervention, ranged from €7754.387 to €19160.987. Cystostomy with closure of bronchial openings and capitonnage was the primary surgical approach. Our data indicate that a more conservative approach, such as cystostomy, yields superior surgical outcomes, consistent with the literature. Despite incurring slightly higher costs than with lobectomy, the benefits offered by cystostomy outweigh this marginal expense difference. Given the relatively similar costs between the two procedures, opting for the more conservative surgery appears to be a prudent and therefore best choice.

FORMALIN INJECTION LEADING TO CHEMICAL CHOLANGITIS IN SURGERY FOR ECHINOCOCCAL CYST: A CASE REPORT

Sofia Frattola[1], Gianluca D'Alessandro[1], Andrea Lombardi[2], Chiara Stocchero[1], Tommaso Manciulli[3], Raffaella Lissandrin[1], Francesca Donato[2], Clara Dibenedetto[4], Marcello Maestri[1], Enrico Brunetti[1]

[1]San Matteo Hospital Foundation, Pavia, Italy, [2]IRCCS Ca' Granda – Ospedale Maggiore Policlinico, Milano, Italy, [3]University of Florence, Firenze, Italy, [4]IRCCS Ca' Granda – Ospedale Maggiore Policlinico, Milano, Italy, Milano, Italy

Cystic echinococcosis (CE) is a debilitating chronic infection predominantly affecting the liver and lungs. Various surgical options, including conservative (endocystectomy) and radical approaches (pericystectomy or segmentectomy), are employed in treatment. However, the intracystic administration of scolicidal agents is contraindicated in cases where connections to the biliary system are present, due to the risk of chemical cholangitis, a severe and feared complication.In this report, we present a case involving an Italian patient who, in 1993, underwent surgical resection of a hepatic CE cyst. The procedure involved the injection of formalin into the cyst cavity, followed by aspiration of its contents and pericystectomy. This outdated method led to the development of chemical cholangitis and multiple biliary strictures, necessitating the placement of several stents over time. The patient's condition progressively deteriorated, culminating in a liver transplant in 2016. Complications from this procedure included embolization of a hepatic artery pseudoaneurysm, ultimately necessitating a second transplant shortly thereafter.While no consensus exists on the optimal surgical technique for treating liver CE—owing to variables such as cyst stage, size, segmental location, and presence of complications—adhering to fundamental safety principles is imperative to prevent dire outcomes.

7389

A RARE CASE OF NEUROCYSTICERCOSIS WITH THE NORTHERN HEMISPHERE TAPEWORM *TAENIA CRASSICEPS*

Britta Koelking

University Hospital Heidelberg, Germany, Heidelberg, Germany

Neurocysticercosis occurs mainly in South America and Sub-Saharan Africa and is usually caused by larvae of *Taenia solium*. In Europe neurocysticercosis is not a common differential diagnosis for intracerebral lesions. In rare cases *Taenia crassiceps*, a tape worm, that is endemic in the northern hemisphere can cause neurocysticercosis. We present a case of *Taenia crassiceps* neurocysticercosis in a 72-year-old immunocompetent male.The patient presented in the emergency room with symptoms, that were suspected to be a stroke. There was no relevant medical history, especially no immunosuppression. A CT scan showed a cerebral lesion with atypical haemorrhage. Neurological symptoms resolved without intervention, hence a follow-up cerebral MRI scan of the lesion was performed after three months. This showed increasing perifocal oedema so that surgery was indicated. Macroscopically it appeared as a lesion with a rough shell and a fluid core. Histopathology showed no malignancy but the remnants of a cystic lesion with signs of chronic inflammation and small calcified bodies. A detailed travel and exposure history made the diagnosis of a parasitic disease highly likely. Neurocysticercosis seemed a potential differential diagnosis, however neither MRI nor histopathological findings were typical. Serology for cysticercosis was negative. A biopsy specimen was sent for a specific cestode PCR. The result showed DNA of the tapeworm species *Taenia crassiceps*. Given the paucity of published clinical case reports, therapy with praziquantel and albendazole was started, prednisolone was added. Therapy was well tolerated. *Taenia crassiceps* tapeworm infections have been described rarely in humans. Diagnosis is difficult on the basis of MRI-imaging and histopathological findings and needs high index of suspicion. Specific serological testing is not available; hence we are depending on molecular diagnostics. An immuncompromised host is not a precondition for infection. Reasons for the increasing number in infections as well as therapy can be discussed and need further investigation.

7390

PYROPTOSIS CELL DEATH IN RAT BRAIN TISSUE WITH NEUROCYSTICERCOSIS

Maria Milagros Dueñas-Mendoza[1], Lizbeth C. Fustamante-Fernandez[1], Ayme Y. Huaman-Navarro[1], Danitza G. Dávila-Villacorta[1], Cesar Gavidia[2], Robert Gilman[3], Manuela R. Verástegui[1], Cysticercosis Working Group in Peru[1]

[1]Infectious Diseases Laboratory Research-LID and Faculty of Science and Philosophy, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Baltimore, MD, United States

Neurocysticercosis (NCC) is a parasitic disease affecting the central nervous system (CNS), whose infectious agent is the larval form of the parasite *Taenia solium*. The pathology of the disease is not fully understood, as it is a chronic disease affecting humans. Clinical manifestations include headache, dizziness, seizures and memory loss or cognitive deficits. During treatment, the clinical manifestations are exacerbated by the death or degeneration of the parasite. The clinical picture of NCC resembles other neurodegenerative diseases such as Alzheimer's, Parkinson's and multiple sclerosis, clinical manifestations that are associated with pyroptosis processes. Pyroptosis is a type of programmed cell death that plays a protective role against infections, but excessive pyroptosis can cause neuronal damage and be detrimental to normal cells and tissues. Therefore, in this research we determined whether the larval stage of *T. solium* causes pyroptosis cell death in the central nervous system in an animal model of NCC. Brain tissues from rats with NCC, untreated and treated with antiparasitic drugs, and a control group of brain tissues from non-infected rats were used. Immunoreactivity in tissues around the cyst was determined by immunohistochemistry for markers associated with programmed cell death: NLRP3 inflammasome, Caspase-1 (Casp1), Gasdermin D (GSDMD) and IL-1β. The immunoreactivity to GSDMD was elevated in all NCC-infected tissues, being statistically significant compared to brain tissues from non-infected rats. While immuoreactivity to NLRP3, Casp1, GSDMD and IL-1β markers was elevated in 30% of infected brain tissues, being the pattern of immuoreactivity different from the control. Our data suggest that there is pyroptosis-programmed cell death due to immuoreactivity to GSDMD in rat brain tissues with NCC.

A ONE HEALTH SYSTEMATIC REVIEW OF ECHINOCOCCAL INFECTIONS IN CANADA

Katrina Di Bacco[1], Marine Hubert[1], Olivier Mukuku[1], Cédric Yansouni[2], Hélène Carabin[1]

[1]Université de Montréal, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada

Echinococcus canadensis and *multilocularis* are parasitic agents transmitted among animals, occasionally infecting humans. Despite being classified as neglected tropical diseases, echinococcal infections are believed to be emerging within the ranges of their wild definitive hosts across Canada. This study aims to consolidate and systematically review estimates of parasitic zoonoses frequency available in Canada. Considering that these parasites infect various host species and involve stages in the soil, an integrated One Health approach is imperative for obtaining an accurate epidemiological overview. A systematic review on the frequency of *E. canadensis* and *E. multilocularis* in humans, animals, and soil in Canada is currently underway following the PRISMA guidelines. We have developed a search query encompassing the names of the two parasites, the diseases they cause, and the Canadian provinces and territories. Three databases were searched for relevant articles. Subsequently, articles were imported into Covidence© software for assessment by two independent reviewers in two phases (title and abstract screening, followed by full-text review) following predetermined inclusion and exclusion criteria. These articles will undergo evaluation using modified JBI quality assessment checklists tailored for One Health studies. Data will be extracted on general study characteristics, population demographics, study design, diagnostic tests, and estimates for the outcome variable (prevalence, incidence, count). A total of 1152 unique articles were identified spanning from 1962 to 2023, of which 965 were deemed irrelevant after screening titles and abstracts. The remaining 187 articles are currently undergoing full-text review. This presentation will demonstrate the geographic distribution of the selected articles, the number of case reports for each host group, and where possible, the frequency trends over time for each host group. Additionally, the limitations of the existing JBI tools in addressing frequency measures concerning domestic and wild animals and the environment will be highlighted.

7392

COMPARISON OF THE DIAGNOSTIC ACCURACY OF LIVER ULTRASONOGRAPHY AND COMPUTED TOMOGRAPHY FOR CYSTIC ECHINOCOCCOSIS IN A NATURALLY INFECTED SHEEP MODEL

Saul J. Santivanez[1], Raul Enriquez[1], Percy Soto-Becerra[1], Andreas Neumayr[2], Cesar Gavidia[3], Oswaldo G.E. Espinoza-Hurtado[1], Hector H. Garcia[4]

[1]Universidad Continental, Huancayo, Peru, [2]Swiss Tropical and Public Health Institute, Basel, Switzerland, [3]Facultad de Medicina Veterinaria, Universidad Nacional Mayor de San Marcos, Lima, Peru, [4]Center for Global Health, Universidad Peruana Cayetano Heredia, Lima, Peru

Cystic echinococcosis (CE) is a major zoonotic disease in Peru's central highlands, where controlling this disease in animals requires significant interventions. Imaging methods are favored over serological tests for diagnosing CE due to the latter's cross-reactivity with other parasites. To evaluate the diagnostic accuracy of liver ultrasonography (US) and

computed tomography (CT) for detecting cystic lesions in sheep, using necropsy as the gold standard. We assessed the sensitivity and specificity of US and CT in sheep over four years old from an endemic area. Diagnostic criteria for US positivity were defined as any suspicious lesion, lesions ≥20 mm regardless of WHO stage, lesions in early stages (CE1, CE2, CE3) irrespective of size, and lesions ≥20 mm in stages CE1, CE2, and CE3. Necropsy data served as the basis for sensitivity and specificity estimates. Necropsy showed a CE prevalence of 82.3% (79/96). US sensitivity ranged from 18.4% to 84.6%, with specificity from 62.2% to 100%. CT sensitivity was between 26.5% and 92.3%, and specificity ranged from 35.6% to 100%. Concordance between US and CT varied from 41.4% to 89.7%, indicating significant variations depending on diagnostic criteria listed above. This study highlights the variability in the sensitivity and specificity of US and CT depending on the applied criteria. The results underscore the importance of non-invasive imaging in diagnosing CE in sheep and suggest potential applicability in human diagnostics

7393

STUDY OF THE PREVALENCE OF CYSTIC ECHINOCOCCOSIS IN LIVESTOCK COMMUNITIES OF CUSCO, PERU

Jorge Hurtado-Alegre, Oswaldo G.E. Espinoza-Hurtado, Raul Enriquez, Natalia Valverde-Espinoza, Dan Cajacuri-Solis, **Saul J. Santivanez**

Universidad Continental, Huancayo, Peru

Cystic echinococcosis (CE) poses a significant public health challenge worldwide, particularly in regions where livestock is a major economic activity and human-animal interaction is frequent, such as in Peru. The liver and lungs are the most commonly affected organs, with a previous studies performed in Peru indicating a prevalence ratio of 3:1. This study aimed to analyze the prevalence of liver CE in three endemic communities in the southern highlands of Cusco, Peru—Acopia, Combapata, and Pomacanchi—and to examine the spatial distribution of cases within these communities. We conducted an abdominal ultrasound survey across the three communities, enrolling a total of 811 participants. Epidemiological and clinical data were also collected to identify relevant risk factors. Ultrasound evaluationindicated prevalence levels of 3.4% (95% CI: 0.1% - 6.8%), 7.9% (95% CI: 4.1% - 11.7%), and 6.5% (95% CI: 4.4% - 8.7%) in Acopia, Combapata, and Pomacanchi, respectively. Geospatial analysis revealed that the spatial risk of liver CE was primarily concentrated on the peripheries of each community, where informal slaughter practices are common. The study highlights the ongoing challenge of CE in endemic regions and underscores the importance of spatial analysis in understanding the distribution of health risks. Addressing informal slaughter practices may be key to reducing the prevalence of CE in these communities.

7394

IMMUNOHISTOCHEMICAL IDENTIFICATION AND SPATIAL DISTRIBUTION OF TWO ANTIGENS IN CEREBRAL PORCINE NEUROCYSTICERCOSIS

Luz M. Toribio Salazar, Lizziee Tello, Javier A. Bustos, Manuela Verastegui, Hector Garcia

UNIVERSIDAD PERUANA CAYETANO HEREDIA, Lima, Peru

Neurocysticercosis (NCC), invasion of the central nervous system by *Taenia solium*, stands as the predominant cause of acquired epilepsy worldwide. In viable phase, cyst actively produces/releases sets of antigens that stimulate a host immunological response and can induce inflammation. However, the antigen distribution across cyst stages (viable, degenerating, and calcified) is unknown. Using anti-*T.solium* monoclonal antibodies (moabs), targeting total cyst, vesicular fluid and excretory/secretory (E/S) antigens, we explored its localization in brain tissue samples of treated naturally infected-NCC pigs in different cyst stages. We selected two clones of moabs for each antigen type based in our western blots results against well-defined recombinant antigens related to anchoring, scaffold formation, and secretion (rGP50, rT24H and sTsRS2-sTs14/18, respectively). Moabs against total cysts principally targeted rGP50, rT24H and sTsRS2, while the others recognized sTs14/18 and sTsRS2. Four moab-based immunohistochemistry techniques (IHC), two against anchoring antigens (TsW5/TsW8) and two against E/S (TsV3/TsE1) were standardized and tested with viable, degenerating, and calcified cysts from 17 pigs. IHC results determined two distinct antigen patterns: moabs TsW5/TsW8, directed against total cysts were detected in the cyst walls, vesicular fluid, and the spiral canal in viable cysts, while TsV3/TsE1, directed against E/S, in cyst walls and vesicular fluid only. Both were detected in the surrounding tissue. In calcified cysts TsW5/TsW8 recognized antigens within the cyst, while TsV3/TsE1 stained antigens in the surrounding parenchyma (500µM). Residual antigens were detected until 12-months after antiparasitic treatment with a gradual decrease in immunoreactivity percentage (4-months:30.8%, 8-months:7.5%, 12-months:1.8%). These findings demonstrate the dynamic nature of antigen distribution. The presence of antigen in the tissue, even in calcified lesions, suggests an antigen diffusion mechanism from parasite E/S to brain cells that can potentially cause structural alterations.

7395

EVALUATION OF DAMAGE IN AXONAL TRANSPORT THROUGH THE IMMUNOREACTIVITY OF THE MOTOR PROTEINS KINESIN AND DYNEIN IN BRAIN TISSUE OF RATS WITH NEUROCYSTICERCOSIS

Ayme Yadine Huaman Navarro[1], Lizbeth Clemen Fustamante Fernández[1], Maria Milagros Dueñas Mendoza[1], Danitza Griselda Dávila Villacorta[1], Cesar M. Gavidia[2], Manuela R. Verástegui[1], Robert H. Gilman[3], Cysticercosis Working Group in Peru[1]

[1]Infectious Diseases Laboratory Research-LID and Faculty of Science and Philosophy, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Bloomberg School of Hygiene and Public Health, Johns Hopkins University, Baltimore, MD, United States

Neurocysticercosis (NCC) is a parasitic disease of the CNS that causes acquired epilepsy in people from endemic countries in Latin America, Africa and Asia, generated by the larval form of the cestode *Taenia solium*. It is a chronic disease, which in symptomatic patients is characterized by seizures and epilepsy that make it impossible for them to carry out their daily activities. Infection studies in laboratory rats have identified that in NCC there is axonal damage characterized by the accumulation of proteins (neurofilament, amyloid precursor protein) in areas of axonal swelling or axonal spheroids, which could be related to a probable deterioration in the axonal transport and would contribute to the degeneration and death of neuronal cells. Therefore, in this study, the reactivity of the motor proteins kinesin and dynein in brain tissue of rats with NCC treated and not treated with antiparasitics at different post-treatment sacrifice times (up to 12 months) was evaluated by immunohistochemistry. It was identified that rats with NCC present accumulation of kinesin and dynein in the axonal spheroids surrounding the parasite, with no significant difference between the treated and untreated group; with absence of spheroids in the control group. Likewise, there is a greater number of axonal spheroids reactive to these motor proteins in gray matter than in white matter. These results indicate that in NCC there is damage in axonal transport characterized by the pathological accumulation of these proteins that would contribute to the process of neuronal degeneration, and that is maintained over time indicating irreversible axonal damage.

7396

IDENTIFICATION OF PROTEINS WITH TGF- β FUNCTION IN THE EXCRETORY SECRETORY PRODUCTS OF *TAENIA SOLIUM* LARVAL STAGE

Oscar Nizama, Nancy Chile, Gino Castillo, Michael Orejon, Ana Palacios, Manuela Verástegui, Robert Gilman

Universidad Peruana Cayetano Heredia, Lima, Peru

Helminth parasites have the ability to modulate the host's immune response through their secretory excretory products (ES) that activate TGF-β

signalling. *Taenia solium* is a cestode helminth whose larval stage affects the central nervous system in humans, causing neurocysticercosis which is associated with seizures. The mechanism that this parasite uses to establish itself and remain in its host is not yet known. The aim of this study was to identify proteins with TGF- β function. For these, the ES products were fractionated by ion exchange chromatography, then each fraction was incubated in MFB-11 cells that release alkaline phosphatase enzymes in the presence of TGF-β-like proteins (TGF- β bioassay). Each fraction was also observed using SDS-PAGE and silver stain. Protein fractions positive in the TGF-β bioassay were analyzed by LC-MS/MS. The results showed a total of 12 fractions of the ES products, and 4 fractions were positive in the TGF- β bioassay. In the SDS-PAGE, we observed differences in the banding pattern in each fraction. Besides, we evaluated these fractions by immunoblot using an anti-TGF β antibody, and we observed that no band was recognized by this antibody, suggesting that these proteins have TGB function but are structurally different from TGF β. These positive fractions were evaluated by LC-MS/MS.

7397

DEFINING THE CELLULAR COMPOSITION OF THE CSF IN SUBARACHNOID NEUROCYSTICERCOSIS THOUGH MULTIDIMENSIONAL SPECTRAL FLOW CYTOMETRY

Janitzio J. Guzmán, Thomas B. Nutman, Elise M. O'Connell
NIAID, Bethesda, MD, United States

The most severe manifestation of neurocysticercosis is subarachnoid disease (SANCC), causing chronic relapsing-remitting inflammation, arachnoiditis, and significant morbidity and mortality if untreated. Improved understanding of the inflammatory milieu in the central nervous system (CNS) may improve targeted immunomodulation as an adjunct to anthelmintic therapy. To characterize the cellular nature of the CNS inflammation, fresh CSF was obtained from patients at their entry to care ("pre-treatment"), prospectively every 3-6 months ("mid-treatment"), and at the time of presumed cure (CSF antigen and qPCR tests for *T. solium* were negative) from 2022-present. Cells were analyzed by multidimensional spectral flow cytometry. In the 7 pre-treatment CSF, each had elevations of leukocytes (GM 10 leukocytes/μL; normal 0-5/μL). Lymphocytes were the primary cells present, with CD3+ T lymphocytes making up 66.4% (GM 2.3/μL, normal 0.15-1.83/μL) and B cells forming the next largest group of cells identified in all specimens at 14.1% (GM 0.43/μL, normal 0-0.03/μL). CSF from untreated SANCC was characterized by expansion of a sizeable effector memory (Tem) CD4+ T population (84.8% of CD4+ cells, GM 1.2/μL, normal 0-0.02/μL), with smaller populations of TEMRA (GM 0.04/μL, normal 0.00-0.02/μL), T regulatory (FoxP3+, GM 0.03, normal 0.00-0.12/μL), T central memory (GM 0.03/μL, normal 0.05-1.6/μL) and naïve T cells (0.3%, 0.003/μL, normal 0.00-0.08/μL). CXCR3+/CD4+ cells (Th1) made up 38.4% of the Tem cells (39.4%). Among B cells, plasmablasts represented 5.4%, naïve B cells 7.5%, and central memory B cells 5.4%. Cluster analysis (FlowSom) identified a CD3+/TCRgd-/CD4-/CD8- population as being notably expanded (GM 6.7% of T cells, range 1.8-35.8%) along with a CD3-/CD19+/CD27-/IgD- population (GM 14.7% of B cells, range 7.9-42.1%), both of which have been shown to be associated with other non-infectious autoimmune inflammatory disease. Post cure analyses are underway using paired samples (n=2) but await additional subjects. Our data help provide a single cell landscape that underlies some of the contributors to pathology seen in SANCC.

7398

SARS-COV-2 EXPOSURE BEFORE OR AFTER PLASMODIUM VIVAX INFECTION EXACERBATES THE HUMORAL RESPONSE AGAINST THE LATTER

Alonso Cruz-Echevarría[1], Katherine Garro[1], Françoise Donnadieu[2], Joseph Vinetz[3], Stéphane Pelleau[2], Dionicia Gamboa[4], Michael White[2], Katherine Torres[1]
[1]Laboratorio de Malaria, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias e Ingeniería, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Infectious Disease Epidemiology and Analytics G5 Unit, Institut Pasteur, Université Paris Cité, Paris, France, [3]Laboratorio ICEMR-Amazonia y Enfermedades Infecciosas Emergentes, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias e Ingeniería, Universidad Peruana Cayetano Heredia, Lima, Peru, [4]Laboratorio de Malaria: Parásitos y Vectores, Laboratorios de Investigación y Desarrollo, Facultad de Ciencias e Ingeniería, Universidad Peruana Cayetano Heredia, Lima, Peru

Loreto is a region of the Peruvian Amazon with a high risk of transmission of malaria whose health system suffered deeply early in the COVID-19 pandemic. Previously it has been shown that a *Plasmodium* infection diminishes the humoral response against respiratory viruses. We hypothesize that symptomatic (Sym) acute malaria and asymptomatic (Asym) malaria reduces pre-existing natural IgG antibody levels against SARS-CoV-2 in people living in the Peruvian Amazon. This study performed a multiplex assay in a Luminex platform to analyze IgG antibody levels against a 11-antigen (Ag) panel of *P. falciparum*, 10-Ag panel of *P. vivax* (*Pv*) and a 6-Ag panel of SARS-CoV-2. The study population was a total of 93 individuals. Samples of healthy endemic controls from Iquitos city (n=9) (no history of malaria in the past 3 years and no confirmed *Plasmodium* infection); Asym (n=24) and Sym (n=34) Amazonian subjects with only a confirmed *Pv*-infection; subjects with a *Pv*-infection first and a latter SARS-CoV-2 exposure (n=20) and the opposite sequence: exposure to SARS-CoV-2 first and a latter Pv-infection (n=6) were evaluated. *Pv*-infection was determined by positive microscopy and/or qPCR and SARS-CoV-2 exposure by positive antigenic, serological, or molecular testing or vaccination against COVID-19 self-reported by the subject. MFI (mean fluorescence intensity) log-transformed data was compared between study groups for each antigen by permutation ANOVA. Individuals with SARS-CoV-2 exposure before or after *Pv* exposure have lower IgG anti-PvEBPII and anti-PfMSP1 and higher IgG anti-PvMSP1-19 and anti-PvMSP8 levels compared to the only *Pv*-infected Asym group. In addition, these individuals have higher IgG anti-Spike, anti-RBD, and anti-NP levels for the Wuhan and Omicron strains compared to the only *Pv*-infected group whether they were Asym or Sym. This analysis shows that SARS-CoV-2 exposure before or after *Pv* exposure has an Ag-dependent effect on the response against *Pv* and that the order of coexposure to *Pv* and SARS-CoV-2 does not affect the response against SARS-CoV-2.

EVALUATION OF NEUROCYSTICERCOSIS PRESENTATION AND MANAGEMENT IN HOUSTON, TEXAS

Theresa Sepulveda, Fernando H. Centeno, Jose A. Serpa-Alvarez, Jill Weatherhead, Eva H. Clark
Baylor College of Medicine, Houston, TX, United States

Neurocysticercosis (NCC) is a neglected tropical disease affecting 2-8 million people globally and results in ~30% of epilepsy cases in endemic countries. While the causative agent, Taenia solium, is not endemic in the United States (US), experts estimate 4,000 annual US cases. Data from our health system in Houston, TX, describe >10 new NCC diagnoses yearly. Infectious Disease Society of America (IDSA) guidelines recommend treatment based on location and viability of cysts in the central nervous system (CNS). Here we describe NCC cases presenting to our system serving at-risk patients in Houston, TX between 2017-2021. We retrospectively identified patients ≥18 years old tested for NCC in the Harris Health System [HHS], systematically extracted demographic, clinical, imaging, and treatment variables from the patients' records, and recorded this data via a REDCap instrument. We classified NCC patients by NCC type and performed descriptive statistics. Of the 113 unique patient NCC records found, most were born in Mexico (n=65, 57%) and lived in the US for >5 years prior to NCC diagnosis (n=66, 58%). 67 (59%) initially presented as inpatients. 72 had calcified parenchymal lesions and 57 (50%) had viable cysts (24 with extra-parenchymal NCC [EPN]). Patients with calcified disease frequently reported chronic headaches (n=29, 56%), whereas patients with viable parenchymal NCC (VPN) more often presented with seizures (n=18, 55%). Considering IDSA guideline-directed management, 25 (76%) of patients with VPN cysts received corticosteroids. 16 (66%) of 22 patients with 1-2 VPN cysts received albendazole monotherapy, and 5 (56%) of 13 patients with >2 VPN cysts were treated

with dual anti-parasitic therapy for at least 7-14 days. Regarding patients with EPN, only 15 (63%) received corticosteroids and only 8 (33%) received dual anti-parasitic therapy of which 4 (50%) were treated with shorter duration (7-14 days). In summary, in our healthcare system, management of NCC varied greatly and often did not follow IDSA guidelines. Improving frontline provider education on NCC may enhance adherence to guideline-based treatment and neurologic outcomes.

ASSOCIATIONS BETWEEN C-REACTIVE PROTEIN, MALARIA, AND MALNUTRITION AMONG CHILDREN WITH FEBRILE ACUTE RESPIRATORY ILLNESS IN UGANDA

Caitlin A. Cassidy[1], Di Hu[1], John S. Preisser[1], Lydia Kabugho[2], Emmanuel Baguma[2], Georget Kibaba[2], Fred Mwembembezi[2], Jonathan J. Juliano[1], Edgar M. Mulogo[2], Ross M. Boyce[1], Emily J. Ciccone[1]

[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, [2]Mbarara University of Science and Technology, Mbarara, Uganda

C-reactive protein is a useful biomarker in differentiating bacterial from viral acute respiratory illnesses (ARI) in resource-constrained settings. In malaria endemic regions, however, CRP production may be influenced by malaria infection. The relationship between nutritional status and CRP levels is unclear. We conducted a posthoc analysis of data from the intervention group of a stepped-wedge cluster-randomized controlled trial evaluating the use of a clinical algorithm including a CRP rapid diagnostic test (RDT) to guide antibiotic treatment among children with febrile ARI. We enrolled 1220 children aged 2 months to 5 years old evaluated by a village health worker (VHW) in the Kasese district of western Uganda. CRP was measured by a semi-quantitative rapid test (<10, 10-40, 40-80, 80+ mg/L). Malnutrition status was assessed using MUAC (mid upper arm circumference). Participants were tested for malaria using an antigen RDT specific for *Plasmodium falciparum*. The association between CRP and malaria RDT results was assessed with a Cochran-Mantel-Haenszel chi-squared test. We accounted for the sensitivity and specificity of the CRP RDT. The association between CRP and MUAC was assessed with a Kruskal-Wallis chi-squared test. Of the 632 children evaluated during intervention periods, both CRP and malaria RDT results were available for 629 children. 50.4% tested positive for malaria. Malaria positive children tended to have higher CRP levels compared to those who were malaria negative ($p<0.0001$). Among those with MUAC measurements, 12.7% had severe or moderate malnutrition (MUAC < 13.5 cm). CRP levels were similar between those with severe or moderate malnutrition and those without ($p=0.24$). CRP levels among children with malaria in our study tend to be elevated and may be like those observed with bacterial infection. Additionally, CRP levels among children with severe or moderate malnutrition were like those without malnutrition. The presence of malaria should be considered when designing treatment algorithms to guide antibiotic decisions for febrile children in malaria-endemic regions.

7401

UNRAVELLING THE ENIGMA: HOW SIMULATION-BASED CLINICAL TRAINING ENHANCES THE DIAGNOSIS OF VIRAL ENCEPHALITIS - INSIGHTS FROM GHANA'S SECOND LARGEST REFERRAL HOSPITAL

Richmond Yeboah[1], Joseph Bonney[2], Richmond Gorman[1], Yaw A. Amoako[3], Richard O. Phillips[1], Augustina A. Sylverken[1]

[1]kumasi Centre For Collaborative Research In Tropical Medicine, Kumasi, Ghana, [2]emergency Medicine Directorate, Komfo Anokye Teaching Hospital, Kumasi, Ghana, [3]department Of Medicine, Komfo Anokye Teaching Hospital, Kumasi, Ghana

Viral encephalitis poses a significant global health challenge, particularly in developing countries like Ghana. However, accurate diagnosis is hindered by low rates of essential lumbar puncture (LP) and cerebrospinal fluid (CSF) analysis. A 3-year retrospective study at Ghana's second largest tertiary hospital showed that only 26% (15/57) of patients with suspected Central Nervous System infection underwent LP subsequent CSF fluid analysis. To address this, clinical skills training was implemented to enhance healthcare professionals' proficiency in lumbar puncture. Training materials were developed using the Modified Delphi Approach. Pre- and post-training knowledge assessments were conducted using online data collection forms. The training was conducted by expert clinicians and included didactic and hands-on practice sessions. Customized mannequins were used for LP simulation training, with intracranial pressure (ICP) measuring devices utilized to demonstrate proper techniques. All training items were donated to the hospital's skills development and simulation centre for continuous skills enhancement. Twenty-one healthcare professionals participated in the training. The pre-training assessment showed that 85% (18) clinicians encountered more than 3 suspected cases of viral encephalitis monthly but were likely to request LP in only 10% of cases. Barriers to LP performance included contraindications (15, 71%), absence of intracranial pressure (ICP) measuring devices (7, 33%), inadequate tools (6, 29%), and lack of expertise (6, 29%). After the training, participants experienced notable improvements: 90% (19) reported fulfillment of training expectations, 81% (17) gained confidence in LP, and 77% (16) enhanced their LP skills. LP performance surged from 15 to 77 over 3 years, representing a 413% increase. The improved LP proficiency led to identifying viral agents causing encephalitis for the first time in Ghana. This advanced medical knowledge and diagnosis strengthened the healthcare system, and potentially improved patient outcomes.

7402

SEVERE *PLASMODIUM FALCIPARUM* MALARIA WITH SYMMETRIC PERIPHERAL GANGRENE: A REPORT OF TWO CASES

Alassane Dia, Francois Ndiaye, Elhadji Ndiasse DIOP, Ndeye Faty Massata DIOP, Khalifa Ababacar Wade

Principal Hospital of Dakar (HPD), Dakar, Senegal

Malaria remains a leading cause of morbidity and mortality in sub-Saharan Africa, particularly in its severe forms. Symmetric peripheral gangrene (SPG) occurring with disseminated intravascular coagulation (DIC) during severe *Plasmodium falciparum* malaria is a rare and serious event, more commonly reported in Asia than in West Africa. SPG is defined as symmetric distal ischemic lesions on two or more sites without major vessel obstruction. The pathophysiological mechanisms involve complex consumptive coagulopathy, which is increasingly understood.We report two cases from the medical intensive care unit at the Principal Hospital of Dakar, Senegal. The patients, aged 60 and 66, presented with severe malaria evidenced by blood smears showing >10% parasitemia with *P. falciparum*. Both developed DIC with multi-organ failure (neurological, hemodynamic, renal, hematological, hepatic, and metabolic) requiring supportive treatments. They subsequently developed SPG affecting all four limbs, leading to bilateral lower limb amputations for one and disarticulation of fingers for the other. The use of anticoagulants (unfractionated heparin for Case 1 and low molecular weight heparin for Case 2) played a crucial role in managing the coagulation-inflammation cycle. Early diagnosis of infection, prompt antimalarial treatment, intensive care management, and anticoagulation therapy are critical for improving prognosis in patients with severe malaria complicated by SPG.

7403

PERFORMANCE OF QUANTITATIVE POINT-OF-CARE TESTS TO MEASURE G6PD ACTIVITY: A META-ANALYSIS

Arkasha Sadhewa[1], Ari W. Satyagraha[2], Mohammad Shafiul Alam[3], Vinod K. Bhutani[4], Gonzalo J. Domingo[5], Michael E. von Fricken[6], Muzamil Mahdi Abdel Hamid[7], Bernard A. Okech[8], Sampa Pal[5], Ric N. Price[1], Kamala Thriemer[1], Ronald J. Wong[4], Stephanie Zobrist[5], Benedikt Ley[1]

[1]Menzies School of Health Research and Charles Darwin University, Global and Tropical Health Division, Darwin, Australia, [2]Eijkman Research Center for Molecular Biology, National Research and Innovation Agency, Jakarta, Indonesia, [3]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, [4]Department of Pediatrics,

Division of Neonatal and Developmental Medicine, Stanford University School of Medicine, Stanford, CA, United States, [5]Diagnostics, PATH, Seattle, WA, United States, [6]Department of Environmental and Global Health, University of Florida, Gainesville, FL, United States, [7]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan, [8]Department of Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, F. Edward Hébert School of Medicine, Bethesda, MD, United States

Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the main risk factor for severe haemolysis following treatment with 8-aminoquinolines (8AQ). The WHO recommends G6PD testing prior to 8AQ-based hypnozoitocidal treatment. We undertook an individual level meta-analysis of the performance of commercially available quantitative point of care assays (PoCs) compared to reference spectrophotometry. A systematic literature search identified 588 articles of which 14 (2.4%) fulfilled pre-defined inclusion criteria and were included; 3 unpublished datasets were also included. In total 12,545 paired measurements were included, 10,313 (82.2%) by STANDARD G6PD Test (SD Biosensor, RoK, "SDB"), 2,042 (16.3%) by CareStart G6PD Biosensor (AccessBio, USA, "CSA"), 150 (1.2%) by CareStart Biosensor (WellsBio, RoK "CSW"), and 40 (0.3%) by FINDER (Baebies, USA, "FBA"). The pooled sensitivities of the SDB when diagnosing G6PD activity <30% of normal were 0.82 (95%CI: 0.72-0.89) and 0.93 (95%CI: 0.73-0.98) for capillary and venous blood samples, respectively. The corresponding values for diagnosing <70% G6PD activity were 0.93 (95%CI: 0.67-0.99) and 0.87 (95%CI: 0.70-0.95), respectively. The pooled specificity of the SDB was high (>98%) for all blood samples and thresholds. Irrespective of the blood samples and threshold applied, the sensitivity of the CSA did not exceed 62%, although the specificity remained high at both the 30% and 70% thresholds (>88%). Only one study each from CSW and FBA were included. Sensitivity of the CSW was 0.04 (95%CI: 0.01-0.14) and 0.81 (95%CI: 0.71-0.89) at the 30% and 70% thresholds, respectively (venous blood samples). Sensitivity of the FBA was 1.00 (95%CI: 0.29-1.00) and 0.75 (95%CI: 0.19-0.99) at the 30% and 70% thresholds (venous blood samples). The specificities of the CSW and FBA were consistently high (>90%) at both diagnostic thresholds. The SDB performed significantly better than other tested PoCs except for the FBA. More evidence is available for the performance of the SDB compared to other PoCs, giving higher confidence in its utility in diagnosing G6PD deficiency.

7404

UNBIASED METAGENOMIC SEQUENCING OF ACUTE ENCEPHALITIS AND MENINGOENCEPHALITIS FOR IDENTIFICATION OF INFECTIOUS ETIOLOGIES IN NEPAL

Nishan Katuwal[1], Babita Khanal[2], Dilliram Kafle[2], Dipesh Tamrakar[1], Cristina M Tato[3], Juliana Gil[3], Rajeev Shrestha[1]

[1]Dhulikhel Hospital Kathmandu University Hospital, Dhulikhel, Nepal, [2]Nobel Medical College Teaching Hospital, Biratnagar, Nepal, [3]Chan Zuckerberg Biohub, San Francisco, CA, United States

The burden of acute encephalitis syndrome (AES) and meningoencephalitis is significant in Nepal. Their causative agents mostly remain unknown because of use of conventional approach which fails to identify the etiologies, leading to delays in treatment, causing morbidity and mortality. We hypothesize presence of several organisms, including vaccine preventable etiologies causing AES, meningoencephalitis and febrile illness, when identified directs public health efforts for prevention and surveillance. This study employs unbiased metagenomic sequencing to investigate infectious etiologies causing AES, undiagnosed febrile illness and meningoencephalitis, in 200 subjects (3mth-75yr) from east Nepal. Cerebrospinal fluids (190) were collected, during May-Dec'23, with process controls from skin and procedure area and clinical metadata. Until now, 38 CSF have been sequenced using Illumina iSeq100. The initial clinical diagnoses of the subjects were meningoencephalitis, AES and sepsis with fever, seizure and vomiting. Most of these subjects had elevated WBC (>11×10^9/L) but normal CSF cell-count (≤5WBC/mm^3) indicating infectious etiology, which was confirmed by sequencing: *Enterovirus C* (5), *Pseudomonas putida* (2) and *Elizabethkingia meningoseptica* (2). The *Enterovirus C* was closely related to isolates from outbreaks in Pakistan and northeast India, near to our enrollment site. Other studies have linked these pathogens as etiologies: *E. meningoseptica* reported as emerging hospital-based pathogen causing meningitis and *P. putida* as a rare pathogen causing central nervous system infections. The subject infected with *P. putida* had high CSF glucose indicating early infection and possible disruption of blood-brain barrier due to sepsis. Another subject which had coinfection of all 3 pathogens, showed higher CSF protein, confirming viral etiology. This novel study was able to identify several etiologies, including depiction of co-infection. Further, this study elevates the utilization of unbiased metagenomic sequencing to complement diagnosis, identify coinfections, conduct surveillance and track transmission.

7405

ENVIRONMENTAL ENTERIC DYSFUNCTION IN NON-SLUM-DWELLING WELL-NOURISHED WOMEN IN DHAKA CITY, BANGLADESH

Mustafa Mahfuz[1], Rumana Sharmin[1], A. H. M. Rezwan[1], Md. Shabab Hossain[1], S. M. Khodeza Nahar Begum[2], M. Masudur Rahman[3], Tahmeed Ahmed[1]

[1]International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, [2]Bangladesh Specialized Hospital, Dhaka, Bangladesh, [3]Sheikh Russel National Gastroliver Institute and Hospital, Dhaka, Bangladesh

Environmental Enteric Dysfunction (EED) is a subacute inflammation of the gut mucosa associated with undernutrition and prevalent in regions with inadequate sanitation facilities. Previous investigations indicated a high prevalence of histologically confirmed EED among undernourished women residing in the slums of Dhaka, with over ninety percent exhibiting the condition. However, scant data exist on histology-confirmed EED among well-nourished women residing outside of slum areas. In the present study, we screened normal Body Mass Index (BMI) (20-24.9 kg/m2) non-pregnant non-lactating women (18-45 years), residing in non-slum areas of Dhaka, who presented with functional dyspepsia according to the ROME IV criteria. Participants consenting to the study underwent upper gastrointestinal endoscopy, with mucosal biopsies obtained from the distal duodenum and subsequently subjected to histopathological examination for EED. Diagnosis of EED was established based on the following criteria: Mild EED, characterized by the presence of at least one EED feature (i.e., lymphocyte infiltration); Moderate EED, defined by the presence of two EED features (comprising mild features along with villous atrophy or crypt hyperplasia); Severe EED, identified by the presence of all three aforementioned features. Between October 2, 2022, to March 30, 2024, a total of 888 women were screened for eligibility, among whom 33 participants provided consent for endoscopic evaluation. The mean age of the participants was 28.7±6 years with a mean BMI of 23.2±1.4 kg/m2. Histological examination revealed that 21% (n=7) of the participants exhibited features indicative of EED, whereas the remaining 79% (n=26) exhibited no histological evidence of the condition. Among those diagnosed with EED, five individuals demonstrated mild EED, while two exhibited moderate EED. This study contributes novel insights into the epidemiology of EED, suggesting a lower prevalence among well-nourished women residing in non-slum areas. Furthermore, it underscores the pivotal role of environmental sanitation and nutritional status in the pathogenesis of EED.

7406

ADAPTIVE DENGUE ANTIVIRAL PLATFORM TRIAL (ADAPT): A RANDOMIZED, ADAPTIVE, OPEN LABEL TRIAL FOR ANTIVIRAL SCREENING IN PATIENTS WITH EARLY SYMPTOMATIC DENGUE

Angela McBride[1], Vuong Nguyen Lam[2], Huyen Tran Bang[2], Trieu Huynh Trung[2], Nguyet Nguyen Minh[2], Tran Luu Hoai Bao[2], Chanh Ho Quang[2], Dong Thi Hoai Tam[2], Evelyne Kestelyn[2], James Watson[1], Sophie Yacoub[1]

[1]University of Oxford, Oxford, United Kingdom, [2]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam

Dengue virus infection is the most abundant and rapidly spreading vector borne disease globally (est. 105million cases/year). Climate change is driving disease emergence in altitudes and latitudes not previously endemic. There are currently no licensed antiviral therapies. Severe manifestations occur between day 4-6 of illness, allowing only a brief window to intervene with a directly acting antiviral drug. There is no consensus pharmacometric approach to evaluate antivirals in early symptomatic dengue. Previous phase 2 trials have used either time to viral clearance or area under the viraemia curve, but these are insensitive measures and generalise poorly. We will present the protocol for our multi-center, phase 2 open label, randomised adaptive platform trial for the rapid screening and dose optimisation of antiviral drugs in early symptomatic dengue. This will be a continuously running adaptive platform, with capacity to add new intervention arms as therapeutic agents become available, and terminate arms if efficacy/futility endpoints are met. We will enrol participants with dengue confirmed by positive NS1 antigen test, and <48hrs of symptoms. Where safety data is available for individual drug candidates, we will recruit children ≥10yrs. Patients will be randomised 1:1 to eligible intervention arms, or the control arm (supportive care, no placebo). Initial therapeutic candidates include a monoclonal antibody (Serum Institute of India), Baricitinib and Molnupiravir. After enrolment, participants will have serial plasma samples collected for viral load measurement every 12 hours for 5 days. The primary virological endpoint will be rate of viral clearance estimated under a hierarchical log-linear model fit to serial viral load measurements. The initial efficacy endpoint will be a ≥10% increase in viral clearance rate in the intervention arm relative to control arm. We anticipate that this trial will provide proof of concept for the rapid assessment of in-vivo antiviral activity for dengue using rate of viral clearance, and provide evidence to justify progression of promising antiviral agents to phase 3 trials.

7407

SURVIVING SNAKEBITE ENVENOMING: DECADES-LONG WAR WITH CHRONIC KIDNEY DISEASE: A CASE SERIES FROM RAJASTHAN, INDIA

Divya Tanwar, Samarth Bhat K S, Akhilesh Kumar PH, Sudharshan Jagennath, Akash Virupaxi Bhagoji, M K Garg, Maya Gopalakrishnan

All India Institute Of Medical Sciences, Jodhpur, India

Snakebite envenoming is a neglected tropical disease. Vipers- *Daboia russelii*, *Echis carinatus* and *Hypnale hypnale* are commonly responsible for Acute kidney injury (AKI) that resolves with antivenom and supportive care. However, antivenom ineffectiveness in Rajasthan poses a special challenge. Here, we report 2 young patients who developed CKD decades following probable *Echis carinatus sochureki* envenoming. *Case 1:* A 22-year-old lady with a snakebite at 5y of age, and again at 11y of age presented to us with status epilepticus. She had experienced local swelling on both occasions but developed a superadded infection, requiring incision and drainage during the second bite. She did not receive any antivenom for either event. Her pregnancy (18 y) was complicated by preeclampsia. She had elevated urea, creatinine, bilateral contracted kidneys, hypocalcemia (4.2 mg/dL) and raised PTH (1409 pmol/l). Symptoms resolved with parenteral calcium. She is currently on bi-weekly maintenance haemodialysis (HD) for CKD. *Patient 2*: A 30-year-old lady, CKD on maintenance HD, presented with MRSA central-line associated blood stream infection (CLABSI) complicated by spinal epidural abscess (C7-T1 destruction), cord compression and spastic quadriparesis. She had a snakebite at 18y of age during complicated by bleeding and anuria. She improved with antivenom, 2 HD sessions and remained asymptomatic for 10 years before developing CKD. She further developed *Pseudomonas* CLABSI. She received daptomycin, meropenem and brief empirical anti-tubercular therapy. Despite this and change of HD catheter thrice, she succumbed to septic shock. Throughout her medical journey, CKD was a focal point, significantly impacting her prognosis and contributing to her eventual demise. CKD is reported in 26-37% after Russell's viper bites. Though, AKI occurs in ~20% of *Echis* bites, to our knowledge, this is the first report of CKD after possible *E. c. sochureki* bite. We highlight the long-term productivity loss, financial burden and suffering of snakebite survivors.

7408

PREVALENCE OF *PLASMODIUM FALCIPARUM* INFECTION AMONG CHILDREN HOSPITALIZED WITH ACUTE RESPIRATORY ILLNESS IN WESTERN UGANDA

Elise R. King[1], Ronnie Ndizeye[2], Emmanuel Baguma[2], Georget Kibaba[2], Ross Boyce[1], Edgar M. Mulogo[2], Emily Ciccone[1]

[1]UNC Chapel Hill, Chapel Hill, NC, United States, [2]Mbarara University of Science & Technology, Mbarara, Uganda

Previous studies suggest malaria co-infection with influenza in sub-Saharan Africa is uncommon, but coinfected children are more likely to experience more severe illness. However, the prevalence of malaria in influenza-infected children in sub-Saharan Africa may have changed due to the expanded global efforts to decrease the burden of malaria in the past decade. From July to November 2022, we enrolled 265 children aged 2 months to 18 years admitted to the inpatient departments of one rural (Bugoye Health Centre [BHC]) and one semi-urban (Rukoki Health Center [RHC]) health facility in Kasese District, Uganda with acute respiratory illness defined as onset of documented fever (≥38°C) and respiratory symptoms (i.e., cough, respiratory rate > 30 breaths per minute, and/or oxygen saturation < 90%) in the prior 7 days. All participants were tested for influenza A and B, respiratory syncytial virus (RSV), and SARS-CoV-2 by polymerase chain reaction (Cepheid, Inc., GeneXpert platform). Rapid Plasmodium falciparum malaria HRP-2 antigen testing (mRDT) was performed on capillary blood. A total of 12 participants were excluded because of missing data. Overall, 36% (86/253) of children tested positive for Influenza A (24%) or B (13%), while 42% (106/253) had a positive mRDT. Among influenza-positive children, 48% (41/86) had a positive mRDT, compared to 39% (65/167) of influenza-negative children. Influenza was not significantly associated with a positive malaria RDT, (Unadjusted Prevalence Ratio: 1.2, 95% CI: 0.90, 1.78). When stratifying by study site, 54% (36/67) of influenza-positive children at the rural site had a positive malaria RDT whereas the prevalence of co-infection at the semi-urban site was lower at 26% (5/19). Our findings demonstrate that malaria parasitemia among children hospitalized with acute respiratory illness in western Uganda is frequent, but similar between influenza-positive and influenza-negative children. These results highlight the need for further research assessing the impact of malaria co-infection on the transmission and pathogenesis of influenza.

7409

IMPROVING INFECTION PREVENTION AND CONTROL COMPLIANCE IN CAMEROONIAN HEALTHCARE FACILITIES USING THE WORLD HEALTH ORGANIZATION CORONAVIRUS SCORECARD TOOL

Boris Arnaud Kouomogne Nteungue

Texila American University, Georgetown, Guyana

Infection prevention and control (IPC) is a clinical and practical evidence-based-approach aiming at protecting patients, health workers and visitors from avoidable infections. We conducted a study to determine the baseline level of infection prevention and control and to determine if repeated evaluations of healthcare facilities after prior trainings of healthcare workers could lead to the improvement of IPC. The study took place

from March 2020 to November 2023. Trainings of healthcare workers in selected healthcare facilities were followed by baseline assessments and reassessments. From 2020 to 2023, we evaluated and analyzed 2,188 IPC assessments from 1,358 healthcare facilities during the 3-year period. IPC assessments included 1,358 (62%) at baseline, 485 (2%) IPC first reassessment, 234 (1%) IPC second reassessment, 65 (0.3%) IPC third reassessment, 33 (0.1%) IPC fourth reassessment, 7 (0.03%) IPC fifth reassessment, 5 (0.2%) IPC sixth reassessment and 1 (0.04%) IPC seventh reassessment. Among all the healthcare facilities evaluated, only 497 (36.5%) have been evaluated more at least 2 times. The median IPC score was 52.4% at baseline and increased to 88.1% in some facilities. Between the baseline and reassessments, there were significant differences in the median IPC score between healthcare facilities, translating a better compliance after trainings. These differences were maintained during the multiple reassessments. Our findings are in accordance with previous studies in other sub-Saharan African countries which found a significant association between the ownership status and IPC performance, an improvement in the median IPC score from baseline and higher IPC scores in healthcare facilities dedicated to COVID-19. Our findings could guide policy implications, since there is a recognized low utilization and effectiveness of validated IPC tools in low- and middle-income countries, particularly in Sub-Saharan Africa. Emergencies are opportunities to improve and monitor IPC compliance in LMIC.

7410

COULD EARLY CARE SEEKING AND INCREASED ACCESS TO COMMUNITY-LEVEL HEALTH SERVICES STOP THE INCREASING MALARIA-RELATED DEATHS IN ZIMBABWE?

Amanda Thakataka

Zimbabwe Assistance Program in Malaria II, Jhpiego, Harare, Zimbabwe

Mashonaland Central and East provinces are among the highest malaria burden provinces in Zimbabwe with an average annual incidence of 24/1000 in 2023. During the peak period January to June, there were 42 malaria deaths in 2022 and 94 deaths in 2023; the case fatality rate increased 63% from 0.08% to 0.13%. A retrospective review of deaths reported in Mashonaland Central and East provinces was completed using a structured investigation form to extract patient data from clinical charts, including demographics, reasons for delays in care, appropriate clinical management, and associated complications. Out of 94 malaria-attributed deaths, 88 (94%) had records available and were reviewed. Overall, 14% were <5 years, 24% were aged 5-14 years, 43% were aged 15-59 years, and 19% were ≥60 years. Males accounted for 52% of all deaths. Seventy-seven percent of all deaths obtained care more than 24 hours after the onset of malaria symptoms, and 28% of these delayed reaching a healthcare provider because of a lack of transportation. Most cases (68%) first sought care at a health facility, while 25% sought care first from a community health worker. Seventy-four percent of the cases were diagnosed as severe malaria at the initial presentation. Shortages in diagnostic equipment and consumables for assessing kidney function, blood glucose levels, parasite levels, and temperature were reported in 30% of deaths. Ninety-one percent of deaths occurred at the health facility, while 9% were in the community. The most commonly reported complications requiring specialized care were impaired consciousness (64%), acute respiratory distress (40%), and acute kidney injury (17%). A lack of specialized services and expertise for intensive care and hemodialysis to manage associated complications was reported in 36% of deaths. The clinical courses of individuals dying secondary to malaria infection suggest that use of community health services may play a role in reducing mortality by preventing delays in seeking care. Limited resources and expertise to manage complications of severe malaria disease may be a contributing factor and could represent a target for intervention.

7411

ESTIMATES AND SPATIAL PREVALENCE OF *TRYPANOSOMA CRUZI* INFECTION AMONG CHILDREN IN NEW YORK CITY

Priya Mallikarjuna, Nicholas DeFelice, Juan David Ramirez, Alberto Paniz

Mount Sinai Hospital, New York, NY, United States

Chagas disease, caused by the protozoa *Trypanosoma cruzi*, is the leading cause of parasitic death in Latin America. Humans are primarily infected when a Triatomine bug defecates while feeding and the feces are scratched into the bite; other modes include vertical transmission, ingestion of contaminated food, transplantation, and blood transfusion. Acute *T cruzi* infection is typically asymptomatic and undiagnosed. If untreated, however, nearly 30% of individuals progress to debilitating chronic Chagas disease decades later after initial infection. In 2023, it is estimated that 37,500 migrants younger than 18 years of age arrived in New York City (NYC) primarily from *T cruzi* endemic countries in Latin America. To date, there has not been a large-scale pediatric prevalence study of *T cruzi* in NYC.*T cruzi* infection in NYC's Latin American pediatric migrant population is highly variable and dependent of socio-demographic factors, country of origin, and built environment. We aim to screen roughly 300 pediatric migrants of Latin American origin for *T cruzi* at Mount Sinai affiliated outpatient pediatric clinics as well as to administer a demographic survey to identify risk factors for exposure. We will develop risk profiles for *T cruzi* infection and create a statistical model to extrapolate prevalence estimates for the five boroughs of NYC using geo-located information on migrant age structure and origin. This work represents an initial step in developing a cost-effective pediatric *T cruzi* screening protocol for NYC.

7412

EPIDEMIOLOGY OF NEUROCYSTICERCOSIS: A 30 YEAR PILOT STUDY OF HOSPITALIZED PATIENTS IN FLORIDA

Maggie Zawoy[1], Waverly Leonard[1], Norman Beatty[2]

[1]University of Florida College of Medicine, Gainesville, FL, United States, [2]Division of Infectious Diseases and Global Medicine, University of Florida College of Medicine, and Emerging Pathogens Institute, University of Florida, Gainesville, FL, United States

Neurocysticercosis (NCC) is a parasitic disease of the CNS caused by the pork tapeworm, *taenia solium*, and is the leading cause of acquired seizure disorder worldwide. Although there have been international and out-of-state studies characterizing the epidemiology of patients presenting with NCC, this study is the first to characterize the burden of NCC in Florida. The inclusion criteria for this retrospective chart review included any patient presenting to UF Health Shands Hospital, Gainesville, FL, with symptomatic NCC (defined as one or more of the following symptoms unexplained by another disorder: seizures, focal neurologic deficits, headaches, hydrocephalus, nucal rigidity, psychiatric disturbances, and altered mental status plus or minus systemic symptoms) between June 1993-June 2023 given an ICD-9 or ICD-10 code of NCC. 34 patients in total met this criteria. Demographic characteristics of these patients included country of origin (76% non-USA, 24% unspecified), sex (59% Male, 41% Female), ethnicity (65% Hispanic, 32% non-Hispanic, 3% unspecified), age (68% 21-50, 18% 51-70, 15% 0-20), race (47% white, 12% black/AA, 9% Asian, 3% AIAAN, 29% unspecified), insurance status (41% uninsured, 21% insured, 38% unspecified), language preferred for medical correspondence (47% Spanish, 38% English, 6% other, 9% unspecified), and per capita income of Florida county of origin (53% bottom 50%, 41% top 50%, 6% unspecified). Selected hospitalization outcomes were also collected and compared between groups. 97% of patients reported NCC symptoms prior to receiving an NCC diagnosis and 72% of patients presented to at least one healthcare facility for similar symptoms without receiving a diagnosis of NCC. 21% of patients were readmitted at least once for NCC symptoms or complications. 18% of patients stayed in the hospital for more than 10 days. Although the power of this study is limited, this research identifies

delays in patient presentation and diagnosis and may aid clinicians in identifying common patient presentations associated with NCC in order to promote prompt diagnosis and close follow-up for these patients.

7413

TARGETED CLINICAL MENTORSHIP IMPROVES PERFORMANCE OF MALARIA SERVICES IN ZIMBABWE

Leocadia Mangwanya

Zimbabwe Assistance Program in Malaria II, Jhpiego, Harare, Zimbabwe

The PMI-funded Zimbabwe Assistance Program in Malaria II (ZAPIM II) project uses targeted clinical mentorship to improve case management and malaria in pregnancy service provision in health facilities (HFs) with observed service provision gaps. In September 2022, ZAPIM II conducted a malaria quality standards assessment (QSA), using a structured tool, to evaluate facility readiness and 108 health workers' (HWs) clinical performances at 70 HFs in Mashonaland Central and Mashonaland East provinces. The project assessed HF readiness to provide malaria services, including availability of material and human resources trained in malaria case management, HW clinical skills, and use of standard operating procedures (SOPs) for diagnosis, classification, and treatment of malaria cases. Action plans were made for assessed health facilities to address identified gaps through mentorship. Fifty-two health facilities received onsite mentorship, 15 virtual mentorship and 3 onsite supportive supervision between October 2022 and August 2023. In September 2023, ZAPIM II conducted another QSA at the same 70 HFs and 124 HWs were assessed to document the improvements in malaria service delivery after mentorship. There was a 21% significant decrease in the proportion of HWs trained in malaria case management (CI: 17%-24%, p<0.0001) due to newly recruited HWs. Overall, HW clinical skills scores improved by 9.3% (CI: 5.6%-13.1%; p =0.000) despite the decrease in the percentage of providers trained in malaria case management. Use of SOPs during rapid diagnostic testing for malaria increased by 10% (CI: -24.9%-7.5%; p =0.272). Correct classification of malaria cases, documentation of treatment doses and duration, and explanation and advice on malaria prevention given to patients increased by 10.6% (CI: -48.8%-27.6%; p=0.5322). Lack of statistically significant increases in these parameters could be due to the high number of untrained new staff in the second assessment. Findings suggest that targeted mentorship can improve HW malaria case management clinical skills. More analysis is needed to assess the overall impact on malaria services.

7414

A SYSTEMATIC REVIEW AND META-ANALYSIS OF CLINICAL PROGNOSTIC MODELS AMONG CHILDREN WITH SEPSIS IN LOW- AND MIDDLE-INCOME COUNTRIES

Celinie Nguyen[1], Jessica Jordan[1], Lauren Fletcher[2], Stephanie C. Garbern[3]

[1]Alpert Medical School, Brown University, Providence, RI, United States, [2]Health and Biomedical Library Services, Brown University, Providence, RI, United States, [3]Brown University, Providence, RI, United States

Sepsis is the leading cause of child death worldwide, with the majority of these deaths occurring in low- and middle-income countries (LMICs). The aim of this systematic review and meta-analysis was to describe clinical prognostic scores and models for pediatric sepsis outcomes and assess the performance of these scores for predicting mortality in LMICs. Ovid Medline, CINAHL, Cochrane Library, EBSCO Global Health, Web of Science, were searched through September 2022 for citations related to the development or validation of a clinical prognostic score or model among children with sepsis, conducted in an LMIC. Titles, abstracts, and full texts were screened by two independent reviewers and data extracted regarding population characteristics, variables included, outcomes, and model performance. Risk of bias was assessed with the Prediction Model Risk of Bias Assessment Tool (PROBAST). 4,251 titles/abstracts and 315 full-text studies were screened, with 12 studies meeting inclusion criteria. Study countries included India, China, Egypt, Indonesia, Tanzania, and a multi-site study in Latin America. Prognostic scores/models included existing scores such as PELOD-2, pSOFA, PRISM, P-MODS, refractory shock criteria. There was high risk of bias in all studies. Meta-analysis was possible for pSOFA and PELOD-2 with pooled area under the receiver-operator characteristic curve of 0.86 (95%CI 0.78-0.94) and 0.83 (95% CI 0.76-0.91), respectively. Relatively few clinical scores and models have been externally validated for prognostication and risk-stratification among children with sepsis in diverse LMIC settings. Notably there were no studies from low-income countries. Some potentially relevant studies were excluded due to lack of clarity regarding the presence of sepsis in the study populations. More widespread and standardized use of sepsis criteria may aid in better understanding the burden of sepsis and prognostic model performance among children in LMICs. Further research to externally validate, implement and adapt these models is needed to account for challenges in use of these scores at the bedside in resource-limited settings.

7415

STRONG HEARTS: A NOVEL PRIMARY-CARE BASED DIAGNOSIS AND TREATMENT SUPPORT PROGRAM FOR CHAGAS DISEASE IN EAST BOSTON, MA, USA (2017-2023)

Ashley Maldonado[1], Javier Huerta[2], Carly E. Milliren[1], **Helen Mahoney West**[1], Jillian Davis[3], Katherine Collins[1], Jim Gomes[1], Alejandra Salazar[4], Daniel L. Bourque[5], Natasha Hochberg[4], Davidson Hamer[4], Leonard L. Levin[1], Jaime Gallegos Salazar[1], Elizabeth D. Barnett[4], Juan Huanuco[3], Jennifer Manne-Goehler[1], Julia R. Köhler[1]

[1]Boston Childrens Hospital, Boston, MA, United States, [2]OHSU-PSU School of Public Health, Portland, OR, United States, [3]East Boston Neighborhood Health Center, East Boston, MA, United States, [4]Boston Medical Center, Boston, MA, United States, [5]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, United States

Chagas disease is a neglected infection of poverty estimated to affect 300,000 people in the US, with a prevalence of 49 per 100,000 in Massachusetts. If left untreated, it progresses to irreversible heart disease and death in 20-30%, but <1% of the infected in the US receive treatment. Strong Hearts is a Chagas disease diagnostics and treatment initiative centered at the East Boston Neighborhood Health Center (EBNHC) in Boston, MA, whose goal is to uphold the preciousness of every person and the human right to healthcare. We present the program structure, diagnostics uptake, local epidemiology, and Chagas care continuum. Following provider and East Boston community information sessions, a protocol for EBNHC was developed and approved by its Board. Confirmed Chagas patients were referred to Boston Medical Center for evaluation and treatment. Our chart reviews identified continuum of care barriers, addressed by Strong Hearts' care navigators. 14,354 patients were screened at EBNHC from Mar 2017-May 2023. 3.4% of screening tests were positive. After confirmation, the overall population prevalence was 0.7% (95% CI: 0.6% - 0.9%) with no sex difference. Steep barriers at most steps of the care continuum would have been insurmountable for most patients without a care navigator. Of 90 patients diagnosed at EBNHC Mar 2017-Sep 2022, 44 (49%) began and 28 (31%) completed antiparasitic therapy. Major barriers to diagnosis and treatment were complexity of the confirmation process for positive screening results, number of steps between referral and initial appointment, challenges for patients taking time from work and traveling for appointments, lack of insurance, and medical bills. While some barriers to care are specific to Chagas disease and its lack of optimal diagnostic and treatment modalities, others exemplify barriers faced by many low-income Latin American community members in accessing medical care in the US. We identified important barriers to care that could be attenuated by medical institutions. We find that motivated primary care clinicians provide Chagas care when support for confirmatory testing and care navigation are in place.

7416

BURULI ULCER CASE DETECTION AND DIAGNOSIS IN THE OBOM SUB MUNICIPAL IN GA SOUTH MUNICIPALITY OF THE GREATER ACCRA REGION, GHANA.

Seth Baffoe

University of Ghana, Accra, Ghana

Mycobacterium ulcerans is the cause of Buruli Ulcer Disease (BUD), a chronic, debilitating condition that mostly affects the skin and sometimes the bone. Patients who have BUD may have long-term disability, irreversible deformity, and a decline in their quality of life. There is no known way to prevent M. ulcerans, mode of transmission is yet unknown. BUD is still a public health concern in Ghana's endemic communities. Hence, there is the need for periodic assessment in endemic areas to control the diseases. The current study examines Buruli ulcer prevalence, case detection, and diagnosis in the Obom sub municipality of the Ga South Municipality in the Greater Accra Ghana.**A** community-based cross-sectional study was conducted. The Obom community, Konkon Lebene, Nyormishie, was specifically chosen because to its history of Buruli ulcer endemicity. Residents who had resided in the research area for the previous six months and were present throughout the study's duration were the study's potential participants. The survey used simple random sampling to choose participants from houses. Furthermore, health screening was done to look for Buruli ulcer case in the community. Samples from potential participants were taken for laboratory testing. To identify the possible variables linked to Buruli Ulcer case detection, information on demographic traits, awareness of Buruli ulcer, health-seeking behaviour. Tables and figures were used to report the findings.All the 32 suspected buruli ulcer samples tested negative for buruli ulcers using both PCR and microscopy. About 6% of participants had no knowledge about Buruli Ulcer while males are 10 percent less likely to be knowledgeable about the Buruli Ulcer compared to females in the community with an odds ratio of OR = 0.9(95%C. I, -1.2 – 1.3). The study concludes zero prevalence of Buruli ulcer within the study area. The knowledge of Buruli ulcer is high among community members and majority of individuals visits health facilities upon detection of symptoms of Buruli ulcer. The study recommends targeted public health programs that address diverse beliefs and practices related to BU detection in Obom community.

7417

DENGUE SEVERITY PREDICTION IN A HYPERENDEMIC REGION IN COLOMBIA

Jorge Emilio Salazar Flórez[1], Katerine Marín Velasquez[2], Luz Stella Giraldo Cardona[1], Ángela María Segura Cardona[3], Berta Nelly Restrepo Jaramillo[2], Margarita Arboleda[2]

[1]San Martín University Foundation, Medellín, Colombia, [2]Colombian Institute of Tropical Medicine, CES University, Medellín, Colombia, [3]Epidemiology and Biostatistics Group, CES University, Medellín, Colombia

Early detection of severe dengue (SD) warning signs is crucial in preventing life-threatening complications. Despite its importance, comprehensive knowledge about these early indicators is still limited. This study aims to identify predictors of SD in a hyperendemic region of Colombia. A cross-sectional analysis was conducted using data from 2018 to 2022, encompassing 233 patients. Utilizing the 2009 World Health Organization dengue classifications, cases were differentiated between severe dengue (SD) and non-severe dengue (non-SD). Among these, 47 were confirmed as SD. Associations between clinical, demographic, and laboratory data and disease severity were examined using Fisher's exact tests or the Mann-Whitney U test ($p<0.05$). Profiles for SD and non-SD cases were established through multiple correspondence analysis, and a logistic regression-based predictive model was validated using training and test sets. The model's performance was evaluated using the area under the receiver operating characteristic curve (AUC-ROC), accuracy, sensitivity, F1-score, and precision. Differences in place of residence, comorbidities, type of infection, and signs and symptoms were observed between the severe dengue (SD) and non-severe dengue (non-SD) groups. Median levels of platelets, white blood cells (WBC), aspartate aminotransferase (AST), and alanine aminotransferase (ALT) were found to be higher in the SD group compared to the non-SD group. Key hematological markers, including neutrophils, leukocytes, platelets, AST, and primary infection, were identified as significant predictors of SD. The model demonstrated an area under the receiver operating characteristic curve (AUC) of 0.91 (95% CI, 0.85-0.96). The developed predictive model significantly assists clinicians in assessing SD risk and optimizing triage, which is particularly crucial during dengue outbreaks.

7418

ACCIDENTS BY CATERPILLARS IN THE VALLEY OF CARACAS, VENEZUELA: AN OUTBREAK STUDY

David A. Forero-Peña[1], Fhabián Carrión-Nessi[1], Jose E. Piñango[2], Daniela Restuccia[1], Jorge Hosmi[1], Ivan Mendoza[3], Juan D. Ramirez[4], Alberto E. Paniz-Mondolfi[5], José A. Suérez[6]

[1]Biomedical Research and Therapeutic Vaccines Institute, Ciudad Bolívar, Venezuela, Bolivarian Republic of, [2]Africam Safari,, Puebla,, Mexico, [3]Cardiology Department, Instituto de Medicina Tropical "Dr. Félix Pifano", Universidad Central de Venezuela., Caracas, Venezuela, Bolivarian Republic of, [4]Department of Pathology, Molecular and Cell-Based Medicine, Icahn School of Medicine at Mount Sinai,, New York, NY, United States, [5]Department of Pathology, Molecular and Cell-Based Medicine, Icahn School of Medicine at Mount Sinai, New York, NY, United States, [6]National Research System, Secretariat of Science, Technology and Innovation,, Panama, Panama

Most accidents by caterpillars are mild, self-limited hypersensitivity reactions and occur in tropical areas with limited access to medical care, making the epidemiology of lepidopterism poorly understood. Several clinically important species are subject to dramatic variations in density, resulting in infestations of large numbers of caterpillars or moths and subsequent outbreaks of coincident cases. In August 2023, an unexpected increase in accidents by caterpillars was observed in the valley of Caracas, Venezuela, including a small group with cardiovascular alterations. This outbreak study describes the clinical cases of accidents and analyzes the geographical behavior of the reported caterpillar sightings during the study period. A total of 32 sighting reports were recorded, with 117 caterpillars observed, including 13 accidents. Most reports occurred in Miranda state (n=115, 98.2%). Most of the caterpillars were identified as belonging to the family *Saturniidae*, genus *Dirphia* (*n*=101; 86.3%) and *Automeris* (*n*=11; 9.4%). Two (1.7%) caterpillars were identified as *Megalopygidae Megalopyge*. More than half of the accidents occurred in children under 9 years of age (53.8%). Accidents occurred more frequently in residential gardens and parks (*n*=7; 53.8%), and public parks and pedestrian paths (*n*=4, 30.7%). In addition to all of them presenting skin lesions, six patients presented systemic symptoms, the most common being fever (n=3) and palpitations (*n*=3). A 9-year-old child showed an EKG with a negative T wave from V1-V4; a 5-year-old boy presented bradycardia, atrial extrasystoles, and CK-MB elevation; another child under 2 years old presented CK-MB elevation; and a 31-year-old girl had T-wave repolarization disorder. All these alterations were resolved in the follow-up control. This study describes a period of occurrence of caterpillar accidents consistent with multiple sightings of different caterpillars in the Valley of Caracas. It describes not only cutaneous alterations but also previously undescribed electrocardiographic and cardiac enzyme alterations.

7419

POTENTIAL RISK INCURRED BY HEALTH CARE PROVIDERS ATTENDING TO MALARIA PATIENTS ACROSS KENYA

Michal Mbinji[1], Doris Njoroge[1], Benjamin Opot[1], Dennis Juma[1], Raphael Okoth[1], Gladys Chemwor[1], Risper Maisiba[1], Edwin Mwakio[1], Redemptah Yeda[1], Farid Abdi[1], Agnes Cheruiyot[1], Kirti K. Tiwari[2], Eric Garges[2], Timothy Egbo[2], Gurdeep Buttar[2], Hosea Akala[1]

[1]Kenya Medical Research Institute/ Walter Reed Army Institute of Research-Africa, Kisumu, Kenya, [2]Walter Reed Army Institute of Research-Africa, Kisumu, Kenya

Management of malaria patients necessitates close monitoring, which exposes healthcare providers (HCPs) to increased risk. In many malaria-endemic regions, effective mosquito control is inadequate. Research shows a higher mosquito affinity for individuals infected with the gametocyte stage of malaria. This situation risks increasing the population of malaria-infected mosquitoes within healthcare facilities. Further, recent changes in mosquito feeding patterns reveal peaked activity during daylight hours—a time that coincides with patient visits. The potential for health facilities to become malaria transmission hotspots due to these combined factors needs further investigation. Understanding the infectiousness of individuals seeking malaria treatment is crucial for assessing the risk to HCPs in Kenyan hospitals. This knowledge helps in formulating guidelines for countermeasures aimed at reducing transmissions within hospitals. Between January 2023 and March 2024, 991 blood samples were collected from individuals with naturally acquired *Plasmodium* species infections presenting with uncomplicated malaria from six different sites countrywide. 295 samples from Busia, 50 from Kericho, 238 from Kisumu, 224 from Kombewa, 51 from Kisii, and 133 from Marigat. These samples were diagnosed for the presence of *Plasmodium species* before downstream screening for *P. falciparum* gametocyte life-cycle stage composition using real-time PCR. About 78.3% (766/991) of individuals tested positive for malaria by PCR. 87.37% (678/766) of these harbored gametocytes lifecycle stage comprising Marigat 93.41% (85/91), Kombewa 88.54% (170/192), Busia 87.39% (194/222), Kisii 86.05% (37/43), Kericho 85% (34/40) and Kisumu 84.04% (158/188). The substantial proportion of gametocytes in infections indicative of potential for patients to infect mosquitoes roosting within the hospital poses a risk of transmission of the disease to health workers. There is need for effective preventative strategies to protect healthcare providers exposed to malaria patients from possible transmission while in the health care facilities.

EXPLORING ACUTE UNDIFFERENTIATED FEVERS AT A TERTIARY CARE HOSPITAL IN INDIA: ETIOLOGICAL PROFILE, CLINICAL CHARACTERISTICS AND BIOMARKERS

Anandi Goel, Monika Matlani, Sheetal Arora, Rupali Malik, Satish Kumar Meena, Shilpee Kumar, Deepthi Nair

Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi, India

This observational study was conducted at Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi to determine the seroprevalence and clinical & laboratory profiles of malaria, scrub typhus, leptospirosis, typhoid, hepatitis A, hepatitis E, chikungunya, and dengue among patients presenting with acute undifferentiated fever (AUF). From July 2022 to November 2023, 18,362 patients with febrile illnesses lasting 2-14 days were included. Blood samples were tested for malarial parasites, dengue NS1 antigen, antibodies against typhoid, dengue IgM, Leptospira IgM, Scrub typhus IgM, Chikungunya IgM, hepatitis A IgM, and hepatitis E IgM antibodies. Additionally, C-Reactive Protein, Procalcitonin levels, and complete blood counts were assessed. Cases were defined according to IDSP, 2019 P and L form criteria. Out of 18,362 febrile patients screened, 4,259 tested positive for at least one of the 8 pathogens studied. Among these cases, 75% had single infections, while 25% had co-infections. Dengue was the most common single infection (2,049 cases), followed by typhoid (667) and chikungunya (353). Symptoms varied by pathogen, but fever was universal. Anaemia was observed in 85% of malaria and 82.5% of scrub typhus cases. Thrombocytopenia was seen in 15.9% of dengue and chikungunya cases. Higher CRP levels (4.8 mg/dl) were predominantly found in bacterial infections, followed by malaria, dengue, and chikungunya. Procalcitonin levels were elevated in scrub typhus, typhoid, malaria, and leptospirosis cases, indicating PCT to be a poor indicator of viral infections Dengue emerged as the most common mono-infection, while dengue-typhoid combination was the most frequent co-infection. This study offers robust epidemiological data on AUF, providing valuable insights for diagnosing single as well as multiple infections. The comprehensive data on clinical and laboratory findings in conjunction with levels of biomarkers presents valuable tools for improved diagnosis, management, and awareness of AUF and its associated aetiologies.

7421

SUBCUTANEOUS MYCOSES: ENDEMIC BUT NEGLECTED AMONG THE NEGLECTED TROPICAL DISEASES IN ETHIOPIA

Wendemagegn E. Yeshanh

Bahir Dar University, Bahir Dar, Ethiopia

Subcutaneous mycoses are a chronic infectious disease of the skin and underlying structures endemic in tropical countries. The disease has serious medical and socioeconomic consequences for patients, communities and health services in endemic areas. The inclusion of mycetoma and other deep fungal infection in the list of Neglected Tropical Diseases by WHO highlights the need to assess the burden of these diseases and establish control programs where necessary. In Ethiopia no strategies can be devised because of a lack of epidemiologic information. To address this evidence gap, we performed a national rapid assessment of the geographic distribution of subcutaneous mycoses. We conducted a rapid retrospective assessment using hospital records to identify all suspected and confirmed cases of subcutaneous mycoses in 13 referral hospitals across the country between 2015 and 2022. In each hospital the logbooks were reviewed for diagnoses of deep fungal infections, as diagnosed per routine practice. Descriptive analysis was done. From 12 hospitals we extracted 85 cases of subcutaneous mycoses, registered from July 2018 to September 2022. 60 (70.6%) patients were diagnosed as mycetoma, 21 (24.5%) as chromoblastomycosis and the remaining 4 (4.7%) as sporotrichosis. The median age of patients was 35 years (IQR=18). 61 (71.8%) patients were male and 80.8% patients were farmers. 30 (36.9%) cases were from the Amhara national regional state. 56 (65.9%) patients had information on diagnostic microscopic evaluation: for mycetoma histopathologic evaluation and fine needle aspiration cytology have a higher positivity rate while for chromoblastomycosis Potassium hydroxide (KOH) staining had abetter yield. The main clinical presentations were nodules, sinuses and infiltrative plaques on the skin. Mycetoma and other subcutaneous mycoses are endemic in Ethiopia, with cases reported from almost all regions albeit with variation in case distribution. A routine program and systems should be developed to identify and document the burdens of subcutaneous fungal infections in the country.

7422

IMPACT OF INTESTINAL PARASITE INFECTIONS ON HUMAN PAPILLOMA VIRUS INFECTION AND REPRODUCTIVE HEALTH: EXPLORING ALTERATIONS IN INTESTINAL AND CERVICOVAGINAL MICROBIOME

Jishna Shrestha[1], Sory Vasquez Alves[2], Neusa Vasquez Alves[2], Xiaofan Huang[3], Charles Minard[3], Elizabeth Y. Chiao[4], Patti E. Gravitt[5], Robert H. Gilman[6], Peter Hotez[7], Joseph Petrosino[8], Eva H. Clark[9]

[1]Department of Medicine, Section of Infectious Diseases, Baylor College of Medicine, Houston, TX, United States, [2]Asociacion Benéfica PRISMA, Lima, Peru, [3]Institute for Clinical and Translational Research, Baylor College

of Medicine, Houston, TX, United States, [4]Department of Epidemiology and General Oncology, MD Anderson Cancer Center, Houston, TX, United States, [5]Center for Global Health, National Cancer Institute, Rockville, MD, United States, [6]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, [7]Department of Pediatrics, Section of Tropical Medicine, National School of Tropical Medicine, Houston, TX, United States, [8]Center for Metagenomics and Microbiome Research, Baylor College of Medicine, Houston, TX, United States, [9]Department of Medicine and Pediatrics, Section of Infectious Diseases, Section of Tropical Medicine, National School of Tropical Medicine, Baylor College of Medicine, Houston, TX, United States

Intestinal parasite infections (IPIs) pose significant public health risks in areas with limited sanitation and healthcare, like the Peruvian Amazon. As they establish chronicity in the human gut, they downregulate host immunity to ensure survival, potentially facilitating the establishment of other pathogens, like HPV. While helminths clearly impact the gut microbiome, a major regulator of the systemic immune system, their impact on the cervicovaginal (CV) microbiome is uncertain. *Lactobacillus* spp. comprise >70% of CV microbiota in healthy women and promote protective immunity. Severe or prolonged CV dysbiosis, characterized by predominance of non-*Lactobacillus* spp., has been linked to increased HPV risk. This study aims to investigate intestinal and CV microbiome changes among Peruvian women aged 30–50 with and without IPIs, to understand IPI impact on these microbiomes and their association with HPV infection risk. We enrolled 353 women undergoing cervical cancer screening in Iquitos, Peru, between August 2022 and November 2023. Participants provided demographic, clinical, and risk factor information; underwent sexually transmitted infection (STI) and stool ova and parasites testing; and submitted CV and stool specimens for microbiome analysis via 16s rRNA sequencing. We used multiple logistic regression to evaluate IPI risk factors. Of 353 participants, the median age of sexual debut was 17 years [IQR 16-18], 6% were smokers, and 1.7% reported prior STI. CV infection frequencies were: HPV 21% [71/336], HIV 0.5% [2/353], syphilis 0.5% [2/353], chlamydia 0% [0/50], BV 32% [112/345], and TV 3.2% [11/342]. 312 submitted stool specimens. 41% had IPI; 7.4% had helminths (69.5% [16/23] *Ascaris*, 13.04% [3/23] hookworm, 8.69% [2/23] *Enterobius* and 8.69% [2/23] *Hymenolepis*) and 37% had protozoa (99.1% [114/115] *Giardia* and 65% [75/115] *Entamoeba histolytica*). Comparative analysis of CV and intestinal microbiota distributions is ongoing. We expect CV *Lactobacillus* spp. will be less abundant in women with IPIs. Study results will pave the way for a larger longitudinal analysis.

7423

DOES THE RUN- IN PHASE ADD WHEN ASSESSING SAFETY OF TRYPANOCIDAL THERAPIES? THE EXPERIENCE OF THE EQUITY TRIAL

Juan Carlos Villar, Helena Arango, Luis David Sáenz, Antonia Camacho

Fundación Cardioinfantil, Bogotá, Colombia

The run-in phase is a design tool seeking to select compliant participants in randomized trials. This may be relevant when assessing long-term interventions or those with low tolerance, such as trypanocidal therapy. The EQUITY trial tested a 120 day treatment including Nifurtimox, Benznidazole or placebo (PBO) among *T. cruzi* seropositive young adults with no cardiomyopathy. Treatments were assigned in two consecutive 60 day periods, with participants receiving either active treatments or PBO in a blinded fashion. Before randomization, participants underwent a 10 day run-in phase with PBO. Only those showing acceptable tolerance or adherence (>80% of treatment) were randomized. The treatments assigned over the study periods led to four possible situations after introducing, continuing, or interrupting the active treatment (OFF-ON, OFF-OFF, ON-ON, or ON-OFF). We recorded the occurrence of adverse events (AE) defined as moderate to severe symptoms, including those leading to additional prescriptions, dose reductions or study treatment discontinuation. Participants were assessed in the first 20 days of each study period (day 20 and 80 after the run-in). We computed McNemar's chi square statistics for 2x2 tables of paired observations (appearing/disappearing events) for each situation. After the run-in phase, 44 (12.5%) of 351 candidates were excluded (34 due to diverse complaints). In 307 randomized, when introducing active treatments (the OFF-ON group, n=232) AE appeared/receded in 64/18 participants (X^2 25.8, p <.001). These figures differed by the continuation of PBO (groups OFF-OFF, n=126, 15/10, X^2 1.00, p 0.31) or active treatment (ON-ON, n=110, 16/12 X^2 0.571, p 0.45) and its interruption (ON-OFF, n=44, 6/7, X^2 0.076, p 0.78). Using a run-in period in this trial allowed a better estimation and discrimination of AE after introducing active treatments, suggesting causality. Twenty days may not be enough to notice receding symptoms after stopping active treatment. At the cost of inducing some nocebo effect and excluding some candidates, the run-in improves the risk-benefit assessment of therapies for neglected tropical diseases.

7424

BRUGIA IMPACT SURVEY AS AN ALTERNATIVE METHOD FOR LYMPHATIC FILARIASIS TRANSMISSION ASSESSMENT SURVEY IN INDONESIA

Endri Budiwan[1], Imran Pambudi[2], Regina Sidjabat[2], Lusy Levina[2], Sunardi /[2], Femmy Imelia Pical[2], Yayuk Agustin Hapsari[2], Arya H. M. Purba[3], Ria Purwita Larasati[1], Ahmad Junaedi[1], Kemal Alfajar[1], Clara Burgert-Brucker[4], Molly Brady[4], Herty Herjati[1]

[1]Act to End Neglected Tropical Diseases | East, RTI International, Jakarta, Indonesia, [2]Neglected Tropical Diseases Work Team, Ministry of Health, Jakarta, Indonesia, [3]Bengkayang District Health Office, Bengkayang, Indonesia, [4]Act to End Neglected Tropical Diseases | East, RTI International, Washington, DC, United States

Indonesia's 236 districts endemic with *Wuchereria bancrofti*, *Brugia malayi*, and *Brugia timori* worms require at least five years of mass drug administration (MDA) to interrupt lymphatic filariasis (LF) transmission. The subsequent transmission assessment surveys (TAS) determine whether an evaluation unit (EU) can safely stop MDA. Indonesia has a current backlog of surveys in districts with *Brugia spp* due to global supply challenges with diagnostic tests. As such, the World Health Organization (WHO) recommended the Brugia impact survey (BIS) as an alternative method to TAS. The traditional TAS employs rapid tests among students in sampled schools, whereas the BIS requires night blood collection from adults for microscopic identification of microfilaria. Indonesia has conducted BIS in 42 EUs in 41 districts since September 2022; 41 EUs used a method-specific complex cluster sampling and 1 smaller EU used systematic sampling. The median sample size in EUs using cluster sampling was 1050 while the smaller EU had a sample size of 794; all surveys met required minimum sample sizes. Microscopists identified microfilaria in 17 EUs (range 1-12 positive samples). The threshold for passing the BIS was 4 or fewer positive samples; 2 EUs were over this threshold and therefore failed. The collection of microfilariae from randomly selected adults in the BIS makes it a robust methodology but challenging to implement. To be used as an assessment survey, the BIS needs to be a reliable proxy indication of low enough transmission to safely stop MDA, and Indonesia's experience has shown feasibility with proper training and supervision. However, the BIS had increased costs and higher refusals due to overnight sampling, required accurate population registers, and relied on a network of 76 skilled lab technicians with prior night blood sample experience. Indonesia's experience may be useful for other settings considering microfilaria testing in combination with rapid tests. The BIS implementation also established a precedent for other emerging methodologies with complex sampling; such novel approaches are essential to maintain momentum towards LF elimination.

7425

ASSESSMENT OF DISABILITY AND HEALTH-RELATED QUALITY OF LIFE USING WHODAS 2.0 TOOL IN A POPULATION LIVING IN *LOA LOA* ENDEMIC AREAS OF THE REPUBLIC OF CONGO (THE MORLO PROJECT)

Marlhand C. Hemilembolo[1], Jérémy T. Campillo[2], Sébastien D S Pion[3], Elodie Lebredonchel[4], Samuel Beneteau[3], Valentin Dupasquier[5], Ludovic Rancé[5], Francois Missamou[1], Michel Boussinesq[3], **Cédric B. Chesnais**[3]

[1]Programme National de Lutte contre l'Onchocercose, Brazzaville, Congo, Republic of the, [2]Inserm, Montpellier, France, [3]Institut de recherche pour le développement, Montpellier, France, [4]AP-HP, Paris, France, [5]Montpellier University Hospital, Montpellier, France

Loa loa filariasis, a parasitic infection endemic to Central Africa, is considered a frequent cause of medical consultation in this region. To evaluate the quality of life (QoL) of individuals living in loiasis endemic areas, we enrolled 991 subjects (one-third being microfilaremic) in the general population of a rural area of the Republic of Congo. WHODAS 12-items and information on the number of eye worm (Ew) and Calabar swellings episodes experienced throughout their lives, were collected. We analyzed the overall WHODAS score and its six domains (mobility, self-care, cognition, life activities, social activities, and participation). Nested analyses of baseline data showed that individuals with more than 10 Ew episodes had significantly higher scores than those without such history, which was particularly significant in the domains of mobility, cognition, and social participation. These individuals had also an increased risk of experiencing moderate (score >25/100) and severe impairment (score > 50/100) by nearly 3-fold (adjusted OR = 3.13, 95% CI 1.28-7.64, P = 0.012) and 2.69-fold (95% CI 1.41-5.13, P = 0.003), respectively, compared to individuals without any history of Ew. No other variable related to loiasis (Calabar swelling frequency, *L. loa* microfilaremia, and positivity to *L. loa* antibody rapid test) was associated with the various scores. Assuming that the frequency of Ew episodes throughout life could be a suitable proxy for overall exposure to the infection and/or the number of adult worms present in the individuals, the impact of loiasis on daily QoL appears to be primarily attributable to adult worms rather than to the microfilarial density. Adult worms would primarily affect everyday activity through peripheral symptoms, such as joint-related discomfort (with notable mobility impairment), while microfilariae would primarily induce organ dysfunction. Further studies are needed to better understand the respective clinical impacts of adult worms and *L. loa* microfilariae.

7426

BASELINE EVALUATION OF ONCHOCERCIASIS TRANSMISSION IN FIVE DISTRICTS OF BENIN

Romaric B. Tchebe[1], Pelagie M. Boko-Collins[2], Andrew Abbott[3], Ben Masiira[4], Lakwo Thomson[4], E. Scott Elder[3], **Ndeye-Marie Bassabi-Alladji**[1], Paul T. Cantey[3]

[1]Programme National de Lutte contre les Maladies Transmissibles du Bénin, Cotonou, Benin, [2]Sightsavers, Cotonou, Benin, [3]US Centers for Disease Control and Prevention, Atlanta, GA, United States, [4]African Field Epidemiology Network, Kampala, Uganda

Onchocerciasis, or river blindness, is a disease caused by the filarial parasite, *Onchocerca volvulus*. Achieving the World Health Organization (WHO) recommended Ov16 seroprevalence threshold of <0.1% in children under 10 to stop mass drug administration (MDA) is a major challenge for most endemic countries. Modeling studies suggest that the seroprevalence threshold could be increased to ≤2%. To evaluate the 2% threshold, Benin conducted serological and entomological surveys in five onchocerciasis-endemic districts where seroprevalence by Ov16 rapid diagnostic test (RDT) in 2020 was ≤2%. If the baseline survey shows an Ov16 seroprevalence ≤2% in children 5–9 years and blackfly infectivity by O150 PCR meets the WHO threshold, MDA will be stopped, and the area monitored for recrudescence. Results from the entomologic survey are not available and will not be discussed here. Samples were collected from children aged 5–9 years in the districts of Ouaké, Tchaourou, Bassila, Bante and Savè in 2023. Villages were selected by probability proportional to estimated size method, plus one additional first-line village. In villages, a multi-stage random sample of children was enrolled with parental authorization. Dried blood spots (DBS) were prepared from venipuncture samples, then eluted for analysis using the DBS Ov16 RDT method. From the 5 districts, 51 villages were selected and 1,884 children were enrolled: 53% were girls and 47% boys. In Bantè, no children had positive RDT results. Seroprevalence by RDT was 0.41% [95%CI: 0.00–1.21] in Ouaké, 0.54% [95%CI: 0.01–1.07] in Tchaourou, 0.98% [95%CI: 0.02–1.95] in Bassila, and 3.26% [95%CI: 0.88–5.63] in Savè. Overall seroprevalence was 0.9% [95%CI: 0.5%–1.4%]. The results in Savè might suggest an increase in seroprevalence between the 2020 and 2023 studies. These results need to be confirmed by Ov16m ELISA and analyzed with the results of the blackfly qPCR analysis to decide whether to discontinue MDA in the districts that have met the serological criteria. Demonstrating that transmission is interrupted at a higher serological threshold would facilitate progress towards the WHO targets for 2030.

7427

SUBSTANTIAL PROGRESS TOWARDS ENDING LYMPHATIC FILARIASIS AS A PUBLIC HEALTH PROBLEM IN DELTA STATE, NIGERIA

Emmanuel Emukah[1], Paul Yinkore[2], Adamu Sallau[1], Lindsay Rakers[3], Emily Griswold[3], Jenna Coalson[3], Emmanuel S. Miri[1], Vincent Anighoro[4], Blessing Ikponmwosa[1], Solomon Adelamo[1], Philomena Dikedi[1], Ndudi Okocha[1], Emeka Uzoma[5], Ununumah Egbelu[5], Maryam Abduljeleel[5], Chinwe Okoye[5], Fatai Oyediran[5], Frank O. Richards[3], Gregory S. Noland[3]

[1]The Carter Center, Jos, Plateau State, Nigeria, [2]Primary Health Care Development Agency, Asaba, Delta State, Nigeria, [3]The Carter Center, Atlanta, GA, United States, [4]Primary Health Care Development Agency, Asaba Delta State, Nigeria, [5]Federal Ministry of Health, Abuja, Nigeria

Lymphatic filariasis (LF) is a neglected tropical disease endemic in Nigeria. In Delta state, in southern Nigeria, 16 of 25 districts were found to be LF-endemic with prevalence of circulating filarial antigen (CFA) by immunochromatographic test ranging from 1- 4% in baseline mapping (2005-2011). Annual mass drug administration (MDA) with ivermectin and albendazole delivered by community directed distributors (CDDs) started in 2014 in the 16 districts. Pre-transmission assessment surveys (Pre-TAS) were conducted in 16 districts in 2022 using filariasis test strips (FTS) among 22,400 people ≥ 5 years in each of 32 sites (one sentinel and one spot-check per district). Among 9,251 people tested, 9,246 (99.9%) were negative, and all 16 districts had <2% positive by FTS meaning they passed Pre-TAS and progressed to TAS-1 in 2023. The 16 districts were grouped into 11 evaluation units (EUs) based on geographic and epidemiological similarity. An average of 45 schools per EU were randomly selected for sampling from a list of registered schools. Students were sampled according to WHO guidance using survey sample builder. Refusal rate was low (0.6%), likely the result of a multi-pronged approach that engaged Parent Teachers Association (PTA) meetings in every selected school to obtain consent and dispel rumors and radio and television jingles to combat misinformation in addition to typical community mobilization for surveys. Valid FTS results were available for 16,887 children from 497 schools; only 6 children (0.04%) were CFA-positive. No EU had more than 2 positives, less than the critical threshold in each EU (range 14-18). Thus, all 11 EUs passed TAS-1, stopped MDA, and entered post-treatment surveillance for LF. Over 2.9 million people in the 16 districts no longer require LF MDA, representing a significant achievement toward national LF elimination. The national LF elimination program and partners should sustain the involvement of health workers and stakeholders like PTAs in subsequent TAS to support high participation in these surveys.

7428

MIXED TREATMENT STRATEGIES ARE AN EFFECTIVE HEALTH CAMPAIGN TO IMPROVE DRUG COVERAGE FOR RIVER BLINDNESS ELIMINATION IN INSECURE AREAS OF EDO STATE, NIGERIA.

Emmanuel Emukah[1], Emily Griswold[2], Jenna Coalson[2], Emmanuel S. Miri[1], Victor Irabor[1], Bertram E. B Nwoke[3], Omosigho Izedonmwen[4], Efeomon Eseigbe[4], Happy Poko[5], Elfrida Omogun[5], Esther Ajayi-David[5], Adamu Sallau[1], Solomon Adelamo[1], Blessing Ikponmwosa[1], Emalee Martins[2], Chukwuemeka Makata[6], Fatai Oyediran[6], Frank Richards[2], Gregory S. Noland[2]

[1]The Carter Center, Jos, Plateau State, Nigeria, [2]The Carter Center, Atlanta, GA, United States, [3]Imo State University, Owerri Imo State, Nigeria, [4]Edo State Primary Health Care Agency, Benin City, Edo State, Nigeria, [5]Edo State Primary Health Care Agency, Benin City Edo State, Nigeria, [6]Federal Ministry of Health, Abuja, Nigeria

The region of Edo state, Nigeria along the Osse River has ongoing transmission of onchocerciasis and perennially low coverage of semi-annual mass drug administration (MDA) treatments. To improve MDA coverage, a health campaign involving mixed treatment strategies was deployed between November and December 2023 in six districts in Edo, bordering Ondo state. Methods consisted of integrating traditional house-to-house community-directed treatment with ivermectin (CDTI) with the immunization program's outbreak response (OBR), use of mobile health teams, providing medicines house-to-house, at fixed locations, and special teams of health workers, along with indigenous residents with security operatives to treat insecure areas termed "hit and run". This special strategy included identifying safe periods when intervention teams could travel to the security-compromised areas. A total of 990,813 treatments were distributed in the mixed strategy approach in the 6 districts November-December 2023—an 8.5% increase over the 913,367 treatments distributed in the prior June 2023 CDTI-only MDA. Correspondingly, the reported coverage increased from 65% overall in June 2023 (districts ranged from 54 – 70%) to 71% in December 2023 (districts ranged from 68 – 74%). Independent coverage surveys across all 6 districts confirmed this increase with significantly higher coverage in December 2023 than in the prior round (76.2% vs. 66.8%, $p<0.001$). Mixed treatment strategies were an effective health campaign that enhanced MDA coverage over CDTI alone in this area of Nigeria with persistently low coverage and offer a way to hasten disease elimination in other areas where terrain and insecurity pose challenges to house-to-house CDTI.

7429

POST-TREATMENT SURVEILLANCE FOR LYMPHATIC FILARIASIS SUPPORTS CESSATION OF TRANSMISSION IN HISTORICALLY CLASSIFIED ENDEMIC FOCI IN THE DOMINICAN REPUBLIC

Karen E.S. Hamre[1], Luccène Désir[1], Keyla Ureña[2], Julio Alexis Batista[2], Francisca Araujo Jimenez[2], Angelita Méndez Florian[2], Carmen Cuello Montilla[2], Esmilke Urbaez[2], Antonio Feliz[2], Luisa Aurora Feliz Cuevas[2], Jose Luis Cruz Raposo[2], Gregory S. Noland[1], Manuel Gonzales[2]

[1]The Carter Center, Atlanta, GA, United States, [2]Ministerio de Salud Pública, Santo Domingo, Dominican Republic

The Dominican Republic aims to eliminate lymphatic filariasis (LF) as a public health problem by 2025. Nationwide baseline mapping using lot-quality assurance sampling identified 3 endemic foci in need of mass drug administration (MDA) - Southwest, La Ciénaga, and East. By 2018, prevalence of circulating filarial antigen (CFA) was < 2% in all foci, meeting the criteria to stop MDA and begin post-treatment surveillance (PTS). The World Health Organization (WHO) recommends a minimum 4-year period of PTS to confirm that LF prevalence remains significantly below sustainable transmission levels. A community-based transmission assessment survey (TAS-3) was conducted in the East focus from December 2023-February 2024, six years after the halt of MDA in 2018 and two years after a TAS-2. In total, 154 bateyes (agricultural settlement villages targeted for MDA in the East region) were visited to exceed the target population of 909 children ages 6-7 years to test for CFA by Filariasis Test Strip. The threshold to pass TAS was 11. CFA was not detected among any of the 933 children tested with valid results, and the TAS passed. Similarly, CFA was not detected among 811 "adults" (85% female; age range [15-93 years], mean: 37 years) also invited for testing in the same household with valid results. WHO criteria to validate a country as having eliminated LF as a public health problem includes alleviating suffering through morbidity management and disability prevention (MMDP). A morbidity assessment was concurrently conducted in these bateyes where 4 members of 3 HHs self-reported lymphedema, all from the same province. These results, combined with finding no CFA-positive children or adults in the most recent PTS surveys conducted in the Southwest (2020) and La Ciénaga (2021) foci, indicate that LF transmission has been eliminated in all historically-classified endemic foci in the Dominican Republic. Remaining steps include scaling up MMDP services, dossier submission to WHO for validating elimination of LF as a public health problem, and maintaining post-validation surveillance until LF transmission is interrupted across Hispaniola.

7430

COMORBIDITY BETWEEN LYMPHATIC FILARIASIS AND HYPERTENSION AND DIABETES: A PROSPECTIVE CASE-COHORT STUDY IN KENYA

Michael O. Ofire[1], Christine A. Onyango[2], Robert O. Ofwete[1], Wyckliff P. Omondi[3], Sultani H. Matendechero[3], Irene Chami[4], Ivy Sempele[4]

[1]Amref Health Africa, Nairobi, Kenya, [2]Maseno University, Kisumu, Kenya, [3]Ministry of Health, Nairobi, Kenya, [4]END Fund, Nairobi, Kenya

Lymphatic Filariasis (LF) can lead to unilateral or bilateral swelling (Lymphoedema) in the legs, which in its advanced stage is known as elephantiasis, one of the world's leading causes of permanent and long-term disability. Due to its disfiguring nature, LF may directly or indirectly interfere with a person's mobility, predisposing a patient to a sedentary lifestyle and thus increasing the risk of non-communicable diseases like Type 2 diabetes and hypertension. A prospective case-cohort study was conducted in Kwale County in Kenya among 123 lymphoedema patients to screen them for type-2 diabetes and hypertension. Socio-demographic data, nutrition status, tobacco use, and physical activity (PA) levels were collected. Blood pressure and diabetes assessment was done over two subsequent days. PA assessment followed the Global Physical Activity Questionnaire (GPAQ) guidelines, with metabolic equivalent (MET) scores calculated based on frequency and type of exercise. Participants were grouped into diabetic/non-diabetic and hypertensive/normotensive categories. Those with either disease were treated as cases, while the rest were controls. Most of the study participants were female (60.2%), with the majority aged above 60 (61.8%). All of them were either minimally active, 19.5% (95% CI: 13.1 - 27.8), or moderately active, 80.5% (95% CI: 72.2% - 86.9%), with none classified as health-efficient physically active. The prevalence of hypertension was 79.7% (95% CI: 71.3 - 86.2), while 17.1% (95% CI: 11.1% - 25.1%) were diabetic, with hypertension higher among women and diabetes higher among men. Linear model revealed significant association between lower MET scores and presence of disease (hypertension and diabetes) (Estimate: -264.4; 95% CI: -437.8 to -91.0; $p=0.003$) among lymphoedema patients. This study demonstrates that lymphedema patients need to be enrolled in PA under the guidance of physiotherapists to improve their MET scores and prevent them from secondary diseases like type 2 diabetes and hypertension. If already diagnosed with both conditions, they should be targeted for glycaemic and blood pressure control, respectively.

7431

ONCHOCERCIASIS SEROPREVALENCE IN BIÉ PROVINCE, ANGOLA: A CROSS-SECTIONAL SURVEY TO GUIDE EFFORTS TOWARDS ELIMINATION

Marta Sólveig Palmeirim[1], Martins Imhansoloeva[1], Mohamad Assoum[1], Luis Lufunda[2], Teresa Nóbrega[2], Cecília Almeida[3], José Franco Martins[4], John Kaldor[1], Elsa Mendes[4], Susana Vaz Nery[1]
[1]Kirby Institute, Sydney, Australia, [2]The Mentor Initiative, Luanda, Angola, [3]Ministry of Health, Lunda, Angola, [4]Ministry of Health, Luanda, Angola

Despite intensive control efforts in many countries, it is estimated that onchocerciasis still affects over 19 million people globally and continues to be a cause of considerable morbidity including blindness. Recently, a program of mass drug administration (MDA) with ivermectin was introduced to areas of Angola including Bié province that had been determined to be endemic through surveys conducted between 2003 and 2015 using either nodule palpation or microscopy of blood specimens. In Bié, prior to the initiation of MDA, we conducted a cross-sectional survey across three areas to determine suitability for a planned cluster-randomised trial of moxidectin versus ivermectin MDA. We randomly selected 10 villages in each area, with 10-12 households randomly selected per village, aiming to enrol 50 participants aged one year and above with informed consent per village; to reach a total of 500 participants in each study area. Finger-prick blood samples were collected from consenting participants for dry blood spots (DBS) and thick blood smears for onchocerciasis and *Loa loa* diagnosis, respectively. The Ov-16 rapid diagnostic test was conducted on the DBS eluates, with results read 24 hours later. Thick blood smears were stained with Giemsa and examined under light microscopes for *Loa loa* detection. Additionally, participants aged 15 years and above were invited to respond to a questionnaire on black fly exposure. We also conducted an exploratory entomological survey, assessing blackfly breeding sites along rivers in the study areas and collected blackfly larvae for subsequent laboratory analysis. Preliminary findings of Ov-16 seroprevalence adjusted for clustering at village and household level revealed it varied across the three study areas, ranging from 8.2% to 46.6%. Older age groups had higher Ov-16 prevalence. One *Loa loa* case was detected. The breeding site assessments confirmed the presence of blackfly larvae in all three study areas. Our findings confirm the urgent need for MDA against onchocerciasis in this province.

7432

POST-TREATMENT SURVEILLANCE FOR LYMPHATIC FILARIASIS IN HAITI: RESULTS FROM TRANSMISSION ASSESSMENT SURVEY (TAS-3) IN NIPPES AND SOUTH-EAST.

Luccène Désir[1], Karen E.S Hamre[1], Gregory smith Noland[1], Victoria Krauss[1], Valery Madsen Beau De Rochars[1], Marc-Aurèle Telfort[2], Mérilien Jean-Baptiste[2], Linda Ferdé[2]
[1]The Carter Center, Atlanta, GA, United States, [2]Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Lymphatic filariasis (LF) is a leading cause of permanent disability globally with over 882 million people in 44 countries at risk for infection. Haiti is one of 4 remaining LF-endemic countries in the Americas. Baseline mapping determined that 88% of Haiti's districts were endemic, however, the Haitian Ministry of Public Health and Population decided to implement nationwide annual mass drug administration (MDA) of diethylcarbamazine and albendazole. The World Health Organization recommends transmission assessment surveys (TAS) to determine whether the prevalence of circulating filarial antigen (CFA) is below 2%--the putative threshold for interrupting *Wuchereria bancrofti* in *Culex* or *Anopheles* transmission areas. Repeated TAS are recommended at 2-3-year intervals during 4-5 years of post-treatment surveillance (PTS). Nippes and Sud-Est *departments* (regions) of Haiti's southern peninsula halted MDA after passing TAS-1 in 2014-2015. Following successful TAS-2 surveys in 2017, TAS-3 was conducted in November and December of 2023 in 21 districts grouped into 3 evaluation units (EUs): Miragoane (a single district in Nippes), Nippes (the remaining 10 districts), and Sud-Est (10 districts). A total of 4,610 children aged 6-7 years old were tested for CFA by filariasis test strips in community-based TAS: 1,416 children in 30 localities in Miragoane, 1,607 children in 39 localities in Nippes, and 1,587 in 64 localities in Sud-Est. Among these, 3 (0.21%), 1 (0.06%), and 0 (0%) were CFA-positive—all beneath the critical cut-off values (range 16-18) for each EU. All 4 CFA-positive individuals were microfilaria-negative in follow-up night blood testing. Children were also tested for malaria by rapid diagnostic test, with prevalence estimates of 0.07% (1/1,414), 0.44% (7/1,608), and 0.13% (2/1,587) in Miragoane, Nippes, and Sud-Est, respectively. Results indicate that LF and malaria are rare in these areas. Passing TAS-3 fulfills the epidemiological criteria for eliminating LF as a public health problem, yet follow-up is needed to investigate persistent CFA-positive signals and to maintain PTS given displacement and insecurity in Haiti.

7433

HIGH MORTALITY AMONG PERSONS WITH SUSPECTED EPILEPSY: A FOCUS ON ONCHOCERCIASIS-ENDEMIC COUNTIES OF SOUTH SUDAN

Luís-Jorge Amaral[1], Stephen Raimon Jada[2], Jane Y. Carter[3], Yak Yak Bol[4], Joseph N Siewe Fodjo[1], Robert Colebunders[1]
[1]University of Antwerp, Antwerpen, Belgium, [2]Amref Health Africa, Juba, South Sudan, [3]Amref Health Africa Headquarters, Nairobi, Kenya, [4]Neglected Tropical Diseases Unit, Ministry of Health, Juba, South Sudan

Onchocerciasis, a neglected tropical disease, has been consistently associated with epilepsy. We investigated epilepsy prevalence and mortality in four onchocerciasis-endemic counties in South Sudan: Maridi, Mvolo, Mundri and Wulu. House-to-house cross-sectional surveys from 2021 to 2024 identified suspected persons with epilepsy (sPWE) and ascertained deaths among sPWE and individuals without epilepsy (IWE). Epilepsy diagnoses were confirmed by trained clinicians. Epilepsy prevalence ranged from 3.3% in Mundri (86/2588) to 4.5% in Mvolo (672/15092), with Maridi (586/14402) and Wulu (55/1355) having a rate of 4.1%. In Maridi and Mundri, with access to free antiseizure medication (ASM) at a treatment centre, ASM adherence was 91% and 95%, respectively, compared to Wulu (9%) and Mvolo (23%) without such access. The median age of death for sPWE varied from 19 years in Maridi to 22 years in Mundri. sPWE mortality rates per 1,000 person-years were 44 in Maridi (95%CI: 36-55), 46 in Mvolo (95%CI: 38-56), 66 in Mundri (95%CI: 37-113) and 70 in Wulu (95%CI: 34-133). In comparison, IWE mortality rates per 1,000 person-years were significantly lower, ranging from 5 in Mvolo (95%CI: 4-5) and Mundri (95%CI: 4-8) to 10 in Wulu (95%CI: 7-15) and Maridi (95%CI: 9-11). The resulting mortality rate ratios indicated that sPWE were 4-12 times more likely to die than IWE. Limitations include potential recall bias on mortality data and the cross-sectional design preventing confirmation of epilepsy diagnoses among deceased sPWE. Additionally, self-reported ASM access may be inflated in the counties with treatment centres due to social desirability bias. Our study highlights a significant mortality burden among PWE in onchocerciasis-endemic areas. The observed high mortality burden may be explained by the combination of high epilepsy prevalence and related mortality, exacerbated by a substantial epilepsy treatment gap. Thus, more advocacy is needed to strengthen onchocerciasis elimination programmes associated with decreased epilepsy incidence in endemic areas and ensure uninterrupted free access to ASM in primary healthcare settings for all PWE.

7434

INTEGRATED LYMPHATIC FILARIASIS, SCHISTOSOMIASIS AND SOIL TRANSMITTED HELMINTHIASIS IMPACT ASSESSMENT IN OHAUKWU, EBONYI STATE, NIGERIA

Abel Eigege[1], Jenna Coalson[2], Kenrick Nwodu[1], Christopher Nwuzor[1], Adamu Sallau[1], Imaobong Umah[3], Chinwe Okoye[3], Solomon Jacob[3], Emeka Uzoma[3], Solomon Adelamo[1], Gideon Ntuen[3], Kehinde Busari[3], Maryam Abduljaleel[3], Halima Toro[3], Chidiebere Njoku[1], Obasi Andrew[1], Samuel Ifeanyichukwu[1], Yohanna Sambo[1], Lindsay Rakers[2], Emily Griswold[2], Emmanuel Miri[1], Gregory Noland[2], Hyacinth Ebenyi[4], Fatai Oyediran[3], Chukwuma Anyaike[3], Rita Urude[3], Ununumah Egbelu[3], Ifeanyi Nwofoke[4], Edwin Okpani[4]

[1]The Carter Center, Jos, Nigeria, Nigeria, [2]The Carter Center, Atlanta, GA, United States, [3]Federal Ministry of Health, Abuja, Nigeria, Nigeria, [4]Ebonyi State Ministry of Health, Abakaliki, Nigeria, Nigeria

Lymphatic filariasis (LF), Schistosomiasis (SCH), and soil-transmitted helminthiasis (STH) are co-endemic in Ohaukwu local government area of Ebonyi State and have been treated by mass drug administration (MDA) since 2014, 2015, and 2014, respectively. Impact assessments for SCH/STH are recommended every 2-3 years, but none have occurred since baseline surveys in 2013 due to funding constraints. We integrated an SCH/STH assessment into a planned LF transmission assessment survey (TAS-1) in Ohaukwu to attempt cost-effective impact assessment. LF TAS-1 was conducted in January 2024 according to standard WHO protocol, with filariasis test strips (FTS) used for all children from classes 1 and 2 (~age 6-7 years) in 40 systematically selected schools from the LGA. The target sample was 1,380 with a critical cut-off of 16 positives. We randomly included 10 selected schools in the SCH/STH survey, and purposively added the 5 still-extant schools from the 2013 baseline survey. Urine and stool samples were collected from a target of 50 school-aged children (SAC) aged 5-14 years in each school and 50 adults in each surrounding community and microscopically examined with urine filtration and Kato-Katz methods. None of 1,473 SAC had positive FTS results, meaning that Ohaukwu passed TAS-1 and qualifies to stop LF MDA. Of 701 adults, 36 (5.1%) were positive for any STH and 12 (1.7%) for SCH. Of 736 SAC, 64 (8.7%) were positive for any STH and 68 (9.2%) for SCH. The prevalence in SAC reflects a reduction in SCH from 19.7% in 2013 and in STH from 58.4%. In the 5 resurveyed villages, SCH prevalence reduced in 4 and increased in 1, while STH reduced in all 5. We estimate that the integrated survey reduced costs by approximately 19% compared to the costs of conducting the TAS and SCH/STH surveys separately. We conclude that integrating SCH/STH impact assessment into an LF TAS is feasible and reduces costs, and that SCH/STH control and LF elimination efforts in Ohaukwu have been successful.

7435

COMPREHENSIVE ASSESSMENT OF ONCHOCERCIASIS TRANSMISSION DYNAMICS AND COMMUNITY PERCEPTIONS: A CASE STUDY IN HYPO-ENDEMIC COMMUNITIES OF OGUN STATE, NIGERIA

Ifeoluwa Adeniyi George[1], Olaitan Omitola[1], Hammed Mogaji[2], Uwem Ekpo[3]

[1]Federal University of Agriculture Abeokuta., Abeokuta, Nigeria, [2]Federal University of Oye-Ekiti Nigeria, Ekiti, Nigeria, [3]Federal University of Agriculture Abeokuta., Abeokuta, Nigeria

Onchocerciasis persists as a significant neglected tropical disease in Africa, causing notable morbidity and socioeconomic strain, leading to a rise in disability-adjusted life years. Control efforts have mainly focused on preventive chemotherapy (PC) in moderate to high endemic areas. However, extending PC to hypo-endemic regions is crucial for meeting 2030 elimination targets. An epidemiological and entomological survey was conducted in hypo-endemic areas of Ogun State to assess onchocerciasis prevalence, associated risk factors, and blackfly vectors' abundance and infectivity over 12 months. 230 participants aged 5-70 were recruited from three communities within hypo-endemic implementation units (IUs). Parasitological and entomological surveys, along with questionnaires, were employed, and findings revealed a 10.04% and 15.79% prevalence microscopically and via O-150 screen pool analysis, respectively. Visual impairment (4%), Onchodermatitis (6.27%), and nodules (10.45%) were observed among adults aged 50 and above, with no significant gender difference. 418 blackflies were collected, with higher numbers during the rainy season (27% wet, 56% dry), notably in November and December. Larvae were absent upon dissection. Biting rates surged during early rainfall (April-June 2023) and continued rising till December, paralleled by an increase in blackflies' parous level. Participant interviews highlighted symptoms caused by microfilariae, but a lack of knowledge regarding blackfly breeding sites (69%) and prevention methods (87%). Traditional remedies were commonly used post-bites, while anti-malarial drugs, herbs, and local concoctions were mentioned for treatment. This study underscores the onchocerciasis status in hypo-endemic communities, stressing the need for intensified control efforts aligned with WHO objectives.

7436

INTESTINAL HELMINTHIASIS IS NOT ASSOCIATED WITH CLINICAL AND THERAPEUTIC ASPECTS OF DISSEMINATED LEISHMANIASIS CAUSED BY *LEISHMANIA BRAZILIENSIS* IN AN ENDEMIC AREA OF BRAZIL

Brady Page[1], Alexsandro Lago[2], Edgar Carvalho[2]

[1]University of California, San Diego, La Jolla, CA, United States, [2]Universidade Federal da Bahia, Salvador, Brazil

Disseminated leishmaniasis (DL) is an emerging but poorly characterized form of cutaneous leishmaniasis (CL) caused by metastatic infection with *Leishmania braziliensis*. We recruited participants with PCR-confirmed CL (n=99) and DL (n=20) between January and December 2017 at a dedicated leishmaniasis center in Bahia, Brazil. At enrollment, participants provided a stool sample, which was evaluated for presence of intestinal helminth infection and the number of helminth ova per gram of stool was quantified. Initial clinical examination consisted of an evaluation of the size and number of cutaneous lesions. Upon 60- and 90-day follow-up, participants were evaluated for the appearance of new lesions and response to treatment of existing lesions. Participants were considered cured by the presence of complete re-epithelialization of all lesions after the initiation of antimonial treatment. The median age of participants was 26 years (13-69) and 76.5% were male. Individuals with DL were significantly older than those with CL (42 vs 24 years; p=0.02), though univariate analysis among individuals with DL did not demonstrate a correlation between age and time to cure (R^2 0.06, p=0.5). The cure rate after 90 days of treatment was significantly lower in individuals with DL compared to those with CL (30% vs 65.9%; p=0.003), and the median time to cure was significantly longer (154.5 vs 65 days; p<0.001). There was no significant difference in the median number of lesions, median area of largest lesion, cure rate at 90 days, or median time to cure between DL patients with or without intestinal helminthiasis. The prevalence of intestinal helminthiasis was 40.3% (48/119), with no difference between the CL and DL populations. The most commonly identified organisms were *Necator americanus* (23/119), *Trichuris trichiuris* (19/119), and *Ascaris lumbricoides* (14/119). Coinfection with *L. braziliensis* and intestinal helminths does not affect clinical aspects or response to therapy in DL. Compared to individuals with localized cutaneous leishmaniasis, those with DL are significantly older.

7437

AN INVESTIGATION OF MUCOSAL LEISHMANIASIS IN THE U.S. MILITARY HEALTH SYSTEM

James J. Pierre[1], Julian Davies[2], Saira Shaikh[2], Patrick Hickey[1]

[1]Uniformed Services University, Bethesda, MD, United States, [2]Henry M. Jackson Foundation, Inc., Bethesda, MD, United States

Leishmaniasis is a protozoal infection with an increased risk of transmission to those serving in the United States (U.S.)military due to theaters of

operation in endemic regions.There has, in recent decades, been robust experience with old-world leishmaniasis in the MilitaryHealth System (MHS); however, new-world leishmaniasis, which may result in mucosal leishmaniasis, has been less studied. A total of 88 patients from 2012-2022 with diagnosis codes for "mucocutaneous leishmaniasis"or "leishmaniasis, unspecified"were identified in the Military Data Repository and reviewed. Within this cohort, there were two validated cases of mucosal leishmaniasis. Case one was a 28-year-old Active Duty (AD) male with recent travel to Belize who presented with a mucosal lip lesion that was biopsied and had inconclusive species confirmation, but was thought to be either *L. braziliensis* or *L. mexicana*. The second case involved a 30-year-old AD male with a history of travel to French Guyana who had a cutaneous lesion on his left hand that was identified as *L. guyanensis*, a causative species for mucosal leishmaniasis. Neither had evidence of any further mucosal involvement on otolaryngologic evaluation, and both subsequently received systemic therapy with a good clinical response. Although only two cases were identified over this period, this disease remains an important medical consideration when conducting military operations within endemic regions as both cases had recent military-specific travel to these areas.

7438

FIRST DETECTION OF *LEISHMANIA MAJOR* IN DOGS LIVING IN AN ENDEMIC AREA OF ZOONOTIC CUTANEOUS LEISHMANIASIS IN TUNISIA

Lilia Zribi[1], Maria Paola Maurelli[2], Nour el Houda Ben Fayala[3], Valentina Foglia Manzillo[3], Ines Balestrino[3], Noureddine Hamdi[4], Aida Bouratbine[1], Manuela Gizzarelli[3], Karim Aoun[1], Gaetano Oliva[3]

[1]Institut Pasteur of Tunis, Tunis, Tunisia, [2]University Federico II, NAPLES, Italy, [3]University Federico II, Naples, Italy, [4]CRDA, Kairouan, Tunisia

Dogs are considered the main domestic animals reservoir for *Leishmania infantum* parasite, the agent of Zoonotic Visceral Leishmaniasis (ZVL) in several Countries of the World. Dog may host other *Leishmania species* but its epidemiological role in the maintaining and spreading of these parasites is not completely elucidated. Zoonotic Cutaneous Leishmaniasis (ZCL) caused by *Leishmania major* affects thousands of people every year in North Africa. In ZCL endemic Countries few reports of *Leishmania major* positive dogs have been reported, probably because most human cases occur in poor rural areas where the social role of the dog and its medical management is not well considered. The aim of the present study is to add information on the possible involvement of domestic dog in the epidemiology of ZCL. Our research focused on a well-established endemic focus of ZCL, in the area of Echrarda, Kairouan Governorate, Central Tunisia. Fifty-one dogs with no apparent clinical signs of vector borne diseases were selected in small villages where human cases of ZCL are yearly present. Most of them appeared not well managed and were infested by ticks and fleas. All dogs were sampled for the *Leishmania spp*. diagnosis, by using the following procedures: blood sample for serology and buffy coat qPCR, popliteal fine needle aspiration and cutaneous biopsy punch for lymph node and skin qPCR. The results demonstrated a high percentage (21.56%) of dogs positive at least at one or more test, the most sensitive technique was the lymph node qPCR that detected 8/11 positive dogs. Nine, out of the eleven positive dogs, resulted infected by *Leishmania infantum*; ITS1-PCR-sequencing allowed *Leishmania major* identification in the remaining 2 cases, both from the popliteal lymph node samples that can suggest a possible visceral spread of a cutaneous *Leishmania* species in dog. Interestingly, one of the two *Leishmania major* positive dogs was living in the same house where 6-year-old children showed cutaneous lesions referred to ZCL. To our knowledge, this is the first report of *Leishmania major* positive dogs in Tunisia, the epidemiological role of which remains under investigation.

SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS OF LIPOSOMAL AMPHOTERICIN B (AMBISOME) EFFECTIVENESS DATA FROM CLINICAL TRIALS FOR THE TREATMENT OF VISCERAL LEISHMANIASIS IN SOUTHEAST ASIA

Kirsten Carter[1], Rashidkhan Pathan[2], Ekkehard Glimm[1], Aparajita Mandal[2], Gerhild Angyalosi[1]

[1]Novartis Pharma AG, Basel, Switzerland, [2]Novartis Healthcare Pvt. Ltd, Hyderabad, India

Leishmaniasis is transmitted by sandflies and caused by obligate intracellular protozoa of genus *Leishmania*. Visceral leishmaniasis (VL) is a neglected tropical disease, lethal if untreated, with 50 000- 90 000 cases/ year, caused by *L. donovani* in South-East (SE) Asia and East Africa, and *L. infantum* in Latin America and Mediterranean regions. The regimen of AmBisome approved by FDA in 1997 for VL is intravenous (IV) 3 mg/ kg, on D1-5, 14, and 21 (total: 21 mg/kg). This currently recommended regimen was based on studies with VL patients with *L. infantum* infection where AmBisome was administered in various regimens. Since then, in SE Asia, multiple studies have been run to optimize the treatment regimen in patients with *L. donovani*. Since 2014 in India, the treatment of choice for primary, immunocompetent patients with VL by the national elimination program has been IV 10mg/kg single dose AmBisome (SDA), in line with WHO recommendation. Systematic literature review and meta-analysis were conducted to review efficacy of 10mg/kg SDA. The estimate of clinical efficacy of 10mg/kg SDA obtained from this meta-analysis will inform future phase 3 studies. Following the systematic literature review, the meta-analysis limited inclusion to those studies conducted in the last 37 years on primary VL patients treated with AmBisome in SE Asia. Analysis of all 13 studies, totaling 3563 patients, based on Intent to Treat (ITT) set was conducted. These studies included treatment of patients at various doses and regimens of AmBisome and revealed cure rate of 92% at six months (CI 91-93%). A subsequent analysis of six of the 13 studies including 2768 patients treated with the SE Asia current treatment of choice, SDA 10mg/ kg, revealed cure rate of 93% at six months (CI 92-94%). The systematic literature review identified a significant number of studies conducted in the region, with over 3000 VL patients treated with AmBisome. The meta-analysis showed consistently high effectiveness of 10mg/kg SDA (>90%), which is the treatment of choice for VL patients in SE Asia, and is in the same range as multiple dose regimens of AmBisome that have been tested.

7440

GENOTYPING OF *BLASTOCYSTIS* SP. ISOLATES FROM FECAL SAMPLES FROM CHILDREN OF THE EDUCATIONAL INSTITUTION "128 LA LIBERTAD" (SAN JUAN LURIGANCHO), LIMA, PERU

Juan Jimenez[1], Yanina Huachopoma[2], Carol Sanchez[2], Julia Castro[2], Maritza Calderon[3], Edward Valencia[2]

[1]Universidad Nacional Mayor de San Marcos. Inmunologia Parasitaria de Humanos y Animales de Importancia en Salud Publica, Lima, Peru, [2]Universidad Nacional Mayor de San Marcos, Lima, Peru, [3]Univerisdad Peruana Cayetano Heredia, Lima, Peru

Diseases caused by intestinal parasites are among the most common public health problems, mainly in developing countries. *Blastocystis* sp. It is a single-celled, cosmopolitan intestinal protozoan that affects the intestinal tract of humans and various animals. *Blastocystis* sp. is considered commensal and is currently recognized as an emerging, opportunistic, zoonotic agent with broad genetic diversity. Its extensive diversity is evidenced by the 39 subtypes identified to date, whose assignment depends on the sequence analysis of the RNA gene (*SSU-rRNA*). This study aimed to genotype and characterize the subtypes of *Blastocystis* sp. from isolates of fecal samples from children in Lima, Peru. Seventy-two fecal samples from school-age children were analyzed, corresponding to 53% (38/72) and 47% (34/72), respectively, with age ranges ranging from 6 to 11 years. Four diagnostic techniques were used: direct examination,

culture in Jones medium, spontaneous sedimentation, and staining with Gomoris Trichromic. The 72 stool samples were cultured in Jones culture medium, from these samples, 35 positive cultures were obtained for *Blastocystis* sp.; likewise, DNA extraction was carried out using the commercial kit "High pure PCR Template Preparation". *Blastocystis* sp. was identified through PCR- SSU-rRNA gene. The genotypes of *Blastocystis* sp. were identified by RFLP using the restriction enzymes AluI and HinfI. For the identification of subtypes, specific primers. By direct observation and culture of Jones, *Blastocystis* sp. was the most prevalent species with 36% (26/72) and 48.6% (35/72) in the positive samples, respectively. An 1800 bp band evidenced the presence of *Blastocystis* sp. The RFLP with the two restriction enzymes (*Alu*I and *Hinf*I) showed varied band patterns; the ST3 subtype was the most predominant. *Blastocystis* sp., the RFLP allowed the identification of genotypes, and the ST1, ST3, and ST5 subtypes were also identified; these results suggest a genetic diversity associated with pathogenesis and zoonosis of the parasite.

7441

EPIDEMIOLOGICAL DYNAMICS OF LEISHMANIASIS IN THE SOUSS-MASSA REGION, MOROCCO (2017-2022)

Zohra Lemkhente[1], Amal Rhars[1], Ahmed Belmouden[1], Hafida Naoui[2]

[1]Ibnou Zohr University, Agadir, Morocco, [2]Mohamed V University, Rabat, Morocco

Leishmaniasis, identified as the second leading cause of mortality among global parasitic diseases, represents a significant public health challenge in Morocco, particularly in the Souss-Massa region. This study aims to elucidate the epidemiological dynamics of leishmaniasis within this region. We analyzed data from 1,103 cases across the six provinces of Souss Massa recorded between 2017 and 2022, using Jamovi software version 2.3.2.1 for statistical analysis. The vast majority of these cases were cutaneous leishmaniasis, accounting for 98% (1,084 cases) of the infections, with visceral leishmaniasis making up only 1.7% (19 cases). A notable 88% of the cases occurred in rural areas. The leading causative agent was *Leishmania major*, responsible for 56% (619 cases) of the infections, followed by *Leishmania tropica* at 42%, and *Leishmania infantum* at 2%. The average age of the affected individuals was 15.6 years, with a standard deviation of 16.4 years, indicating a wide age range among patients. The median age was 11 years. Males showed a statistically significant higher incidence, representing 56.1% of cases, compared to 43.9% in females ($p < 0.05$). Peaks in the number of cases were observed in May and January, while lower case numbers were typically seen in October and November. Tata province was identified as the main hotspot, contributing 57% of the cases, primarily due to *Leishmania major*, with an epidemic center in Akka. In Agadir province, accounting for 20% of all cases, 52% were attributed to *Leishmania tropica*, with a new epidemic focus in Drarga. These findings suggest a potential correlation with climate change and highlight the need for targeted public health interventions sensitive to the region's demographic and environmental factors influencing the spread of leishmaniasis. Alongside climate change, urbanization also emerges as a significant factor affecting disease dynamics. Passive screening played a crucial role, detecting 66.4% of the cases and proving essential for effective disease surveillance.

7442

THE EFFECTS OF ADVERSE ENVIRONMENTAL EXPOSURES ON RISK FOR CONGENITAL CHAGAS TRANSMISSION AND ADVERSE BIRTH OUTCOMES IN SANTA CRUZ, BOLIVIA

Matthew J. Ward[1], Natalie M. Bowman[2], Heather H. Burris[3], Chris Gennings[1], Robert H. Gilman[4], Aman Patel[1], Nicholas B. DeFelice[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY, United States, [2]UNC School of Medicine, Chapel Hill, NC, United States, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, [4]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Nearly 8 million people in Latin America are infected with *Trypanosoma cruzi* (*Tc*), the parasite causing Chagas disease, and most infections are initially asymptomatic and go undiagnosed. Chagas results in ~12,000 deaths annually, which is ten-times the number of deaths caused by Malaria in this region, making it the leading cause of parasitic death in the Americas. While treatable if diagnosed early, left untreated, *Tc* evades the immune system and decades later becomes a chronic cardiac, gastrointestinal, and/or neurological disease. *Tc* is also known to cause adverse birth outcomes in infants born to infected mothers, and congenital transmission occurs in about 5% of these births and can result in delayed childhood development. How *Tc* evades the immune system to traverse the placental barrier and establish congenital infection isn't well known. One theory is that a complex interaction between parasite, placenta, and inflammatory and oxidative stressors weakens the placental barrier from repeated activation of the innate immune system allowing the parasite to cross the placental barrier. Similarly, it is known that environmental exposures during pregnancy can have deleterious effects on birth outcomes. Repeated gestational exposure to ambient PM2.5 has been shown to result in adverse birth outcomes due to oxidative and inflammatory stress and PM2.5 can cross the placental barrier resulting in placental maladaptation. Extreme heat exposure can also have negative effects on pregnancy. Studies indicate that a 1°C increase in temperature correlates to double the risk for both pre-term and stillbirths. This ongoing study leverages two existing congenital chagas cohorts with ~10,000 mother-child dyads with a maternal *Tc* prevalence of 23.7% combined with freely available girded remote sensing environmental data to identify the effect of environmental exposures on congenital Chagas transmission and negative birth outcomes in Santa Cruz, Bolivia. This is a status update on an ongoing pilot-study and to our knowledge this is the first study to investigate the effects of environmental exposures on congenital Chagas transmission.

7443

MODELING CLIMATE DRIVERS OF CUTANEOUS LEISHMANIASIS INCIDENCE IN NORTHERN SYRIA

John W. Carew[1], Maia C. Tarnas[2], Nour Al Zouabi[1], Ibrahim Aladhan[3], Yasir Elferruh[4], Naser Mhawish[4], Aula Abbara[5]

[1]Yale School of Public Health, New Haven, CT, United States, [2]University of California, Irvine, CA, United States, [3]Environmental Protection Agency of Syria, Gaziantep, Turkey, [4]Assistance Coordination Unit, Gaziantep, Turkey, [5]Imperial College London, London, United Kingdom

Modeling climate drivers of cutaneous leishmaniasis incidence in northern SyriaLeishmaniasis is a Neglected Tropical Disease of global epidemiological importance caused by *Leishmania* parasites. Leishmaniasis is associated with high morbidity and impacts on quality of life, as it results in large open wounds during infection, which are associated with severe social stigmatization. In northern Syria, cutaneous leishmaniasis (CL) is endemic and its incidence exhibits significant geographic and temporal variation. Furthermore, CL incidence in northern Syria is dependent on the presence of the dipteran vector, which displays high variation in relation to environmental factors and public health vector control interventions. This study examines historical associations between CL due to *Leishmania tropica* and *Leishmania major* and environmental variables including rainfall, temperature, humidity, and vegetation cover in 63 subdistricts in 21 districts in the Al-Hasakeh, Aleppo, Raqqa, Deir-ez-Zor, and Idlib Governorates of northern Syria. Specifically, this study employs a time-lag generalized linear model to examine the relationship between the environmental variables and CL incidence over 479 weeks between December 2014 and March 2024. Weekly case counts varied from zero cases per week in many subdistricts to 2185 cases per week in the Ras Al Ain subdistrict in the 45th week of 2021. On the governorate level, over the study period, CL cases were highest in Al-Hasakeh governorate, peaking at 2216 cases in the 45th week of 2021. Seasonal trends were particularly apparent in Deir-ez-Zor governorate, where cases peaked in January every year between 2018 and 2022. This study found significant intra-governate and intra-district variability

in weekly case counts. Variations in temperature, rainfall patterns, humidity, and vegetation cover associated with climate change are likely to have a significant impact on future CL transmission patterns in endemic regions. These models suggest that climate monitoring is an important tool in the control and prediction of future CL incidence.

7444

SPECIES IDENTIFICATION OF CUTANEOUS LEISHMANIASIS CAUSING PARASITES IN NEPAL

Narayan Raj Bhattarai[1], Keshav Rai[1], Surendra Uranw[1], Basudha Khanal[1], Dhan K. Khadka[1], Gokarna R. Dahal[2], Sushmita Pradhan[3], Sushil Dhakal[4], Tanyth D. Gooyer[5], Kristien Cloots[5], Epco Hasker[5], Gert V. der Auwera[5]

[1]B P Koirala Institute of Health Sciences, Dharan, Nepal, [2]Epidemiology Disease Control Division, Ministry of Health, Kathmandu, Nepal, [3]Province Hospital, Karnali Povince, Birendranagar, Surkhet, Nepal, [4]Maya Metro Hospital, Dhangadi, Nepal, [5]Institute of Tropical Medicine, Antwerp, Belgium

The ongoing Kala-azar elimination programme in Nepal is based on anthroponotic transmission of Kala-azar caused by the protozoan parasite *Leishmania donovani*. In recent years, a shift of reported cases from classical lowland foci in the east to hilly and mountainous areas of the western and far western regions of Nepal was well documented by the national control programme. In addition, cutaneous leishmaniasis cases are increasingly being reported, mainly from the west of the country, though the causative parasite species is not yet fully elucidated. Hence, to support of the ongoing country disease programme and to generate further evidence on the causative parasite species for cutaneous leishmaniasis in Nepal, a study was set up, in which we collected detailed patient information as well as skin biopsies from several hospitals located in the western and far western regions of Nepal. Altogether, 24 skin samples were collected and subjected to PCR and sequencing to determine the infecting parasite at species level. Samples were obtained from 11 different hilly districts, all from patients who didn't have a travel history outside of the country. Out of 24 skin samples, PCR detected *Leishmania* infection in 13 samples. Further molecular analysis confirmed the presence of *L. donovani* in 12 of them. Although these findings do not exclude other causative species to be involved in cutaneous leishmaniasis in Nepal as well, the confirmation of *L. donovani* in these cutaneous leishmaniasis patients could have important implications for the Kala-azar elimination programme. Furthermore, there is no evidence yet that this particular *L. donovani* strain could also cause visceral leishmaniasis, there is a clear need for genomic surveillance of visceral and cutaneous leishmaniasis cases in Nepal to rule out any potential threat to the Kala-azar elimination initiative in the region.

7445

BLASTOCYSTOSIS INFECTIONS AMONG CHILDREN ATTENDING FOUR HOSPITALS IN WESTERN KENYA

Nancy C. Kipkemoi[1], Mary C. Kirui[1], Ronald Kirera[1], Janet Ndonye[1], Erick C. Kipkirui[1], Margaret Koech[1], Kirti Tiwari[2], Elizabeth Odundo[1]

[1]Microbiology Hub Kericho, Kenya Medical Research Institute (KEMRI)/ Walter Reed Army Institute of Research -Africa (WRAIR-A), Kericho, Kenya, [2]Walter Reed Army Institute of Research -Africa, Kericho, Kenya

Blastocystis spp, is a common intestinal parasite affecting both humans and animals worldwide. Although the role of Blastocystis *spp* as an enteric pathogen is disputed, it has been associated with infections including gastrointestinal discomfort. *Blastocystis spp* is thought to have harmful functions in the presence of certain enteric pathogens, in addition, having a potential pathogenic role in the gut, affecting growth and development in children. This study determined the prevalence of *Blastocystis spp* infection or carriage in children 15years and below, characteristic symptoms and association of infection with water source and water treatment. Faecal microscopy was conducted on 976 stool samples (488 symptomatic, 488 asymptomatic) from children enrolled in a case-control study in four County Hospitals in western Kenya. The samples were processed using Mini Parasep SF Faecal Parasite concentrator. Blastocystis *spp* was detected in 73/ 976 (7.5%) of the stool samples from both symptomatic and asymptomatic subjects with a distribution of 36/488 (7.4%) infections in cases and 37/488 (7.6%) in controls. Among the 73 infections, 56 /73 (76.7%) were Mono-infections while 17/73 (23.3%) were co-infections. Of the 73, 34/73 (46.6%) were females while 39/73 (53.4%) were males. General gastrointestinal symptoms reported were mainly; abdominal pain/ cramps (42.5%), diarrhea (15.1%), and loss of appetite/vomiting (12.3%). Additionally, cough (15.0%) and fever (12.3%) were reported as secondary symptoms, while headache (6.8%) was less frequently reported. The highest number of infection 35/73(47.9%) was among subjects who used municipal/tap water, followed by 30/73 (41.1%), 28/73 (38.4%) and 7/73 (9.6%) among those who used water from the river/springs, rainwater and borehole/well respectively. 50/73 (68.5%) of the *Blastocystis spp* were found in subjects who did not treat water. However, 23/73 (31.5%) infections were found in those who treated water. There is asymptomatic carriage of *Blastocystis spp* in children of up to 15years of age is 7.5%, however, no follow-up was done to see if the participant got diarrhea or not.

THE GROWING PROBLEM OF LEISHMANIASIS IN TUSCANY, ITALY: AN INVESTIGATION OF UNDERREPORTED HUMAN CASES AND COMPARISON WITH CANINE INCIDENCE USING A MULTIDISCIPLINARY APPROACH.

Claudia Cosma[1], Marco Del Riccio[2], Enrico Loretti[3], Maria Infantino[4], Mariangela Manfredi[4], Francesca Veneziani[5], Francesco Innocenti[6], Patrizia Casprini[5], Fabio Voller[6], Guglielmo Bonaccorsi[2]

[1]Medical Specialization School of Hygiene and Preventive Medicine, University of Florence, Florence, Italy, [2]Department of Health Sciences, University of Florence, Florence, Italy, [3]Lazio-Tuscany Zooprophylactic Institute, Rome, Italy, [4]Immunology and Allergology Laboratory Unit, S. Giovanni di Dio Hospital, AUSL Toscana Centro, Florence, Italy, [5]Laboratory of Clinical Pathology, S. Giovanni di Dio Hospital, AUSL Toscana Centro, Florence, Italy, [6]Regional Agency for Public Health of Tuscany, Florence, Italy

The Mediterranean basin, including Italy, hosts endemic areas for leishmaniasis, mainly attributable to the presence of sand flies. Leishmaniasis has gained importance in Europe, fuelled by factors such as climate change, globalisation and migration. For at least 10 years in Tuscany (Italy) there has been an important discrepancy between official notifications on reports of human visceral and cutaneous leishmaniasis cases and the number of hospital admissions, highlighting an important underreporting, despite the Italian reporting obligation. Moreover, official reports have increased alarmingly over the last three years. Human leishmaniasis is a disease that does not always require hospitalisation: it often presents cutaneous manifestations, whereas in the immunocompetent individual it may not manifest itself at all. For this reason, it is reasonable to assume that the number of cases is higher than the number of hospitalisations. The project aims to investigate the underreporting of human leishmaniasis cases from 2014 to 2023 by analysing laboratory diagnoses (considering any laboratory test that according to the guidelines of the Italian Ministry of Health is useful in identifying a 'confirmed case', thus serological tests; parasitological tests; culture tests; PCR). To estimate the extent of the underreporting, the capture-recapture method will be used, taking into account laboratory data, official reports and hospital data. Subsequently, a comparison will be made with the incidence, in the same territory, of veterinary cases, particularly in dogs, using data obtained from the Lazio-Tuscany Zooprophylactic Institute, to compare the trend of human and canine cases over time. Analyses are in progress and currently confirm a significant underreporting of up to five times the official number of notifications. The results will be presented at the conference. Poor surveillance leads to ineffective prevention policies. The impact of the project is to strengthen the leishmaniasis surveillance system in Tuscany in order to reinforce prevention systems and face emergencies.

7447

UNTANGLING THE LEISHMANIASIS THREAT: A MULTIFACETED ANALYSIS OF TRANSMISSION NETWORKS, ECOLOGICAL FACTORS, AND GEOGRAPHIC IMPLICATIONS IN A LEISHMANIASIS ENDEMIC REGION IN THE EASTERN MEDITERRANEAN

Oscar David Kirstein, Shirly Elbaz, Debora Diaz, Liora Studentsky, Irina Ben Avi, Laor Orshan, Tamar Grossman, Maya Davidovich-Cohen

Israel Ministry of Helth, Jerusaelm, Israel

The Leishmaniases, a group of neglected tropical diseases exhibiting significant anthropo-zoonotic transmission, are experiencing a worrying upsurge across the Mediterranean and Middle East, particularly in Israel. This review delves into the multifaceted factors driving this concerning trend.Israel, a Leishmaniasis hotspot within the Middle East, presents a unique case study. Four Leishmania species (*Leishmania major*, *Leishmania tropica*, *Leishmania infantum*, and the recently identified *Leishmania donovani*) co-exist, each engaged in intricate zoonotic cycles involving specific sandfly vectors and mammalian reservoirs. This intricate interplay between specific Phlebotominae sand flies of the genus *Phlebotoums*, diverse mammalian reservoirs, and Israel's varied ecological landscapes results in a spectrum of clinical presentations in both humans and animals. This complex transmission web underscores the critical need for in-depth research to develop effective control strategies.Factors such as cross-border transmission, the detection of novel transmission cycles, local conflicts, and evolving transmission dynamics all contribute to the escalating risk. Climate change adds another layer of complexity by potentially altering sandfly distribution and parasite development.This work emphasizes the urgent need for further investigation into the dynamic interplay between Leishmania parasites, sandfly vectors, animal reservoirs, and environmental factors. Only through a comprehensive approach can effectively combat the growing threat of Leishmaniasis in the Middle East and beyond.

ASSESSING *TOXOPLASMA GONDII* SEROPREVALENCE AMONG IMMUNOCOMPETENT AND IMMUNOCOMPROMISED INDIVIDUALS LIVING IN PERU: A COMPARATIVE STUDY BETWEEN LIMA AND IQUITOS

Cusi Ferradas[1], Edith S. Malaga[2], Andrea Diestra[2], Guillermo Salvatierra[3], Hannah E. Steinberg[4], Jaeson Calla[5], Ricardo Medrano[2], Cesar Ramal[6], Viviana Pinedo-Cancino[7], Marilyn Donayre[7], Juan Jiménez[8], Natalie M. Bowman[9], Maritza Calderon[2], Robert H. Gilman[10]

[1]Emerge, Emerging Diseases and Climate Change Research Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Infectious Diseases Research Laboratory-LID, School of Science and Engineering, Universidad Peruana Cayetano Heredia, Lima, Peru, [3]School of Veterinary Medicine, Faculty of Health Sciences, Universidad Peruana de Ciencias Aplicadas, Lima, Peru, [4]Department of Medicine, University of Washington, Seattle, WA, United States, [5]Department of Pediatrics, School of Medicine, University of California San Diego, La Jolla, CA, United States, [6]Hospital Regional de Loreto, Iquitos, Peru, [7]Universidad Nacional de la Amazonía Peruana, Iquitos, Peru, [8]School of Biological Sciences, Universidad Nacional Mayor de San Marcos, Lima, Peru, [9]Division of Infectious Disease, School of Medicine, University of North Carolina, Chapel Hill, NC, United States, [10]Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States

Toxoplasmosis, caused by *Toxoplasma gondii*, is a disease that may produce severe consequences among immunocompromised individuals. The seroprevalence of Toxoplasmosis among immunocompromised patients has not been well studied in Peru. Our study aimed to: 1) evaluate the performance of an in-house ELISA using the commercially available Vircell ELISA kit as a reference; 2) estimate the seroprevalence of Toxoplasmosis among individuals living in Lima, located in the coastal region of Peru, and Iquitos, in the Peruvian Amazon basin; and 3) evaluate factors associated with *T. gondii* seropositivity. We enrolled HIV positive individuals with neurological signs in hospitals in Lima (n=50) and Iquitos (n=50), and healthy individuals working at a university from Lima (n=73) and from houses randomly selected in Iquitos (n=108). We processed 90 randomly selected samples for performance evaluation of our in-house ELISA. Our ELISA showed 98.3% and 100% positive and negative percent agreements, with the Vircell ELISA kit. In Iquitos, individuals had a median age of 38.5 (IQR 27-51), with 77 (48.7%) males and 50 (31.65%) HIV positive. In Lima, individuals had a median age of 26 (IQR 23-34), with 70 (56.9%) males and 50 (40.65%) HIV positive. Toxoplasmosis seroprevalence was 88% in Iquitos (139/158) and 29.3% in Lima (36/123). In Lima, older individuals (PR 1.04, [95% CI 1.03-1.06]) and in Iquitos, males (PR 1.13, [95% CI 1.01-1.27]) showed higher seropositivity rates. HIV positive individuals from both study sites were more likely to be seropositive (PR 2.29, [95% CI 1.30-4.05] for Lima; and 1.18, [95% CI 1.07-1.29] for Iquitos). Our in-house ELISA presented a high performance. Future studies should determine the performance of this in-house test with other human and animal samples. Our results highlight important seroprevalence levels of Toxoplasmosis in Iquitos, Peru. Although this seroprevalence was not low among HIV negative persons living in Lima (14/73, 19.2%) and Iquitos (90/108, 83.3%), it was even higher among HIV individuals (22/50, 44%; and 49/50, 98% in Iquitos), which represents a risk for neurological complications among these patients.

7449

DEFORESTATION, LAND REVERSION, AND *TRYPANOSOMA CRUZI* INFECTION IN DOGS LIVING IN RURAL COMMUNITIES IN CENTRAL PANAMA

Kimberly D. Archbold Ramos[1], Vanessa Pineda[2], Adelys Reina[2], Chystrie Rigg[2], Milixa Perea[2], Vanessa Vásquez[2], Kadir González[2], Daniel Mendieta[2], Ayesha Rodríguez[2], Azael Saldaña[3], Tania Gómez[3], Raíssa Nogueira de Brito[1], Julie Velásquez Runk[4], Susan Tanner[1], Luis F. Chaves[5], Heidy De Gracia[3], Armando Bonilla[3], Yanelis Pinto[3], Cindy Ledgister[3], Jose E. Calzada[2], Nicole L. Gottdenker[1]

[1]University of Georgia, Athens, GA, United States, [2]Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama City, Panama, [3]Universidad de Panamá, Panama City, Panama, [4]Wake Forest University, Winston-Salem, NC, United States, [5]Indiana University Bloomington, Bloomington, IL, United States

Given dogs' roles as sentinels and reservoirs for *Trypanosoma cruzi*, the etiologic agent of Chagas disease, it is important to understand host and environmental factors associated with *T. cruzi* infection in dogs. The objective of our study is to measure *T. cruzi* infection in dogs from 12 rural communities and to evaluate intrinsic (e.g., sex, age, body condition, hemogram) and environmental (e.g., land cover) relationships between *T. cruzi* infection in dogs. We hypothesized that deforestation and land reversion influence *T. cruzi* infection rates in dogs and that *T. cruzi* infection will be higher in areas dominated by secondary forest growth. We performed physical examinations and sampled blood from 483 dogs from 203 households. We collected epidemiological variables (e.g., age, sex, body condition score) and performed rapid immunochromatographic tests, western blot, indirect immunofluorescence, and multiplex microsphere immunoassay to evaluate previous *T. cruzi* exposure. Additionally, we evaluated *T. cruzi* parasitemia by conventional PCR using S35/S36 targeting the 330bp region of the kinetoplast. Dogs positive for two or more serological tests or PCR were considered positive. Preliminary results show that across the communities,15.21% (95% CI, 11.89-19.04) (63/414) of dogs were positive for two or more *T. cruzi* serological tests. In addition, 3.54% (95% CI, 1.63-6.62) (9/254) had *T. cruzi* parasitemia confirmed by PCR. Overall, there were no significant associations between *T. cruzi* infection in relation to dog sex, body condition, and age. However, there were community level differences in *T. cruzi* infection/exposure in dogs- communities surrounded by secondary forest growth had positive associations with *T. cruzi* prevalence. Preliminary results suggest that complex interactions between land cover types around communities and households influence *T. cruzi* infection in dogs.

The knowledge of health professionals about Chagas disease among health professionals is essential for controlling this Public Health problem. We aimed to identify the knowledge about this public health problem among these Primary Health Care professionals. We performed a cross-sectional, exploratory study, with 257 professionals between April and September 2023 in Irecê city, Brazil. Data were collected using a standardized questionnaire and data were analyzed descriptively. From the total number of professionals, 87.9% recognized the etiological agent is a protozoan, and identified the following forms of transmission: vector (100%), blood transfusion (55.3%), and oral (61.9%); the main organs affected were: heart (99.2%) and spleen (58.4%). The signs/symptoms identified in the acute phase were fever (76.6%), adenomegaly (59.4%), edema (85.2%), splenomegaly (68.0%), hepatomegaly (65.2%), Romaña sign (50.4%); at chronic cases, it was recognized that it may occur asymptomatically, but electrocardiographic changes (99.2%), megacolon (64.6%), megaesophagus (59.1%), congestive heart failure (99.2%) may be present.), thromboembolic phenomena (58.4%), and respiratory distress (80.9%). Regarding etiological treatment, 72.0% recognized its existence, but 47.5% were unable to inform which medication was recommended; and for 73.5% of participants, the disease is incurable. Regarding the insect vector, 81.7% recognized it. When asked about the service where triatomines should be sent, 65.7% recognized the Zoonosis Control Center. The care to be taken when handling triatomines was to use gloves or protect your hands with a plastic bag (92.2%); the guidance to be given when faced with an insect bite in humans was to carry out serological tests (91.8%) and personal access to information occurred informally in everyday daily work (30.0%) or during the training course in the health area (28.8%). It is of fundamental importance that health professionals are trained on Chagas disease for early recognition and specific treatment, and that health surveillance and vector control actions are effective.

IMPACT OF *BLASTOCYSTIS* SUBTYPES ON POLYPARASITISM IN COLOMBIAN CHILDREN

Lindsey Vongthavaravat[1], María I. Osorio-Pulgarin[2], Juan David Ramírez[3], Rojelio Mejia[1], Miryan M. Sanchez Jimenez[2]

[1]Baylor College of Medicine, Houston, TX, United States, [2]Universidad CES, Sabaneta-Antioquia, Colombia, [3]Universidad del Rosario, Bogotá, Colombia

Polyparasitism is prevalent in developing communities and peri-urban areas of large cities. Factors contributing to persistent polyparasitism include recurrent environmental exposure and reinfection. Identifying the primary risk factors is crucial for effective intervention. *Blastocystis* is a common intestinal protozoan with a contested role as a human pathogen, with pathogenicity dependent on the *Blastocystis* subtype. In a peri-urban area of Medellín, Colombia, stool samples were taken from 202 children under five years old, and we conducted stool-based multi-parallel real-time quantitative PCR. Preliminary results revealed that 57.9% of children tested positive for *Blastocystis* DNA, 20.3% *Cryptosporidium*, 20.3% *Giardia intestinalis,* 9.4% *Necator americanus,*1.9% *Trichuris trichiura,*1.9% *Entamoeba histolytica*, and 1.5% *Ascaris lumbricoides*. No positive samples were found for *Ancylostoma duodenale* and *Strongyloides stercoralis.* We found varying degrees of polyparasitism, with 57.2% of children testing for one parasite, 34.9% for two, and 7.9% for three. The children infected with *Blastocystis* and a helminth had a significantly different burden of *N. americanus*, *T. trichiura*, and *A. lumbricoides* (0.011 vs 0.12 vs 0.59, p = 0.0018). There is a greater burden of *G. intestinalis* within *Blastocystis* negative children than *Blastocystis* positive children (1.36 versus 0.26 fg/µl, p = 0.0340). Also, a significant positive correlation was identified between *Blastocystis* and *G. intestinalis* with Spearman R = 0.37898, p = 0.0385. These findings suggest *Blastocystis* is a valuable indicator of GI parasite exposure rates. Given its reported transmission through fecal-oral contamination and cyst-infected water sources, further studies will explore *Blastocystis* subtypes and their associations with helminth/protozoan infections.

7452

IMPACT OF EDUCATIONAL ACTIVITIES AND AN ELECTRONIC MEDICAL RECORD TEMPLATE ON CHAGAS DISEASE SCREENING

Madolyn Dauphinais[1], Katherine Reifler[1], Alyse Wheelock[1], Maja Carrion[2], Sarah Kimball[1], Elizabeth Barnett[1], Natasha Hochberg[3], Daniel Bourque[1], Davidson H. Hamer[1]

[1]Boston Medical Center, Boston, MA, United States, [2]Drugs for Neglected Diseases Initiative, Boston, MA, United States, [3]Novartis Institutes for BioMedical Research, Boston, MA, United States

Given a lack of comprehensive screening programs or standardized screening recommendations for clinicians, the estimated prevalence of 300,000 people with Chagas disease in the United States (US) is likely an underestimate. In 2021, clinicians and public health experts began the Implementing Novel Strategies for Education and Chagas Testing (INSECT) study at Boston Medical Center (BMC) to improve awareness and knowledge of Chagas disease and enhance healthcare provider screening. As a quality improvement initiative, we examined the influence of educational activities and implementation of an electronic medical record (EMR) template on changes in screening rates at BMC. Educational sessions were conducted in the BMC departments of internal medicine, obstetrics/gynecology, pediatrics, and family medicine and sections of nephrology, transplant nephrology, cardiology and infectious diseases. Audience members included medical students, resident, fellow and attending physicians, nurses, midwives and public health experts. From 2014 to the start of BMC educational activities in 2021, 729 tests were ordered, including screening and confirmatory testing at the Centers for Disease Control and Prevention. The top five ordering departments were obstetrics/gynecology (OB/GYN) (152, 21%), adult inpatient medicine (123, 17%), transplant surgery (92,13%), cardiology (80, 11%), and infectious diseases (60, 8%). From 2021-2024, INSECT study members conducted 23 Grand Rounds and lectures to approximately 870 individuals at BMC. Since INSECT implementation, 3,731 tests were ordered (2021-April 17, 2024), displaying increased testing overall and a shift towards more primary care testing. Top ordering departments included OB/GYN (1802, 48%), transplant surgery (844, 23%), adult outpatient primary care (407, 11%), adult inpatient medicine (159, 4%), and family medicine (116, 3%). With the implementation of educational programming for providers and an EMR template for ordering ease, we increased testing for Chagas disease at BMC. We anticipate that other sites with at-risk patients may benefit from similar activities.

7453

BIBLIOMETRIC META-ANALYSIS OF CHAGAS DISEASE AND EQUITABLE ACCESS TO HEALTH CARE

Ceili Milagros Zuta Chamoli, Rodney López Loja, Victor Juan Vera Ponce, Stella Maris Chenet Carrasco, Juan Rigoberto Tejedo Huaman, Alonso Rafael Tapia Limonchi

Instituto de Investigación de Enfermedades Tropicales de la UNTRM, Chachapoyas, Peru

Chagas disease, transmitted by *Trypanosoma cruzi*, has been historically reported in endemic areas of Latin America. However, an increasing

presence of this disease is currently observed in urban habitats with domestic transmission cycles and adapted to different ecological environments. Currently, the total burden of Chagas disease is approximately 7 million cases worldwide. The objective of the study was to investigate the vertical transmission of *Trypanosoma cruzi*, its presence in blood banks and donors, its epidemiological distribution in urban areas, and its appearance in non-endemic regions. We conducted a bibliometric meta-analysis through searches in Scientific Technical Health Literature of Latin America and the Caribbean (LILACS), PubMed, multilingual collaborative health evidence database (epistemonikos), Cochrane, and Scopus. The search for scientific articles was conducted in English, Portuguese, and Spanish, with a cutoff date of December 27, 2022. The data network was constructed using VOSviewer software to: a) visualize any possible overlapping between the analyses by applying the association strength normalization technique, and b) analyze the information by a clustering technique, with relevant co-authorship publications between countries. The distance from one country to another reflects the strength of co-authorship each country exerts. The obtained results highlighted trends and patterns on Chagas disease research, its transmission, and epidemiology in the context of current knowledge and its implications for public health, especially in urban areas and non-endemic regions. In conclusion, this analysis focused on the infection of the parasite *T. cruzi* and its association in urban environments of both endemic and non-endemic countries, based on data collected from various studies published in scientific journals. The results underscore the need to strengthen disease surveillance and control programs in urban settings, and to implement strategies for early detection and timely treatment.

7454

CAPACITY-BUILDING IN MOLECULAR SURVEILLANCE OF INFECTIOUS DISEASES: PROGRESS AND ACHIEVEMENTS OF THE INSTITUTE OF RESEARCH IN TROPICAL DISEASES IN AMAZONAS, PERU

Stella M. Chenet, Rafael Tapia-Limonchi, Juan R. Tejedo, Jorge L. Maicelo-Quintana

Universidad Nacional Toribio Rodríguez de Mendoza de Amazonas, Chachapoyas, Peru

Amazonas is a northeastern region located between the Andean mountains and the Amazon plain with a population of 429 483 inhabitants. This region has seven provinces with areas where native communities do not have access to public services such as electricity, drinking water or sewage. Amazonas is affected by several infectious and tropical diseases such as malaria, leishmania, Chagas, HIV, dengue and other arbovirus. The UNTRM was the first university in Amazonas to implement, in collaboration with the Regional Direction of Health, molecular tools for the research of infectious diseases that constitute a severe burden to the region. By January 2020th, the IET was created with three main laboratories: molecular epidemiology and genomics, cell culture and advanced therapies, and biosensors and biomedical devices. Molecular confirmation tests for the previously mentioned diseases were implemented and by September 2020th the COVID-19 laboratory for molecular diagnosis and genome sequencing received its operating license, becoming the first in the region. Additionally, we made major progress in implementing a surveillance platform for parasitic diseases such as malaria, reporting an outbreak of *Plasmodium falciparum* and a recent clonal expansion in the district of Rio Santiago, with its vector *Anopheles benarrochi*. We also managed to implement a reader device for electronic differential measurement to detect nucleic acid of Plasmodium in blood samples to be used in the field. On the other hand, the immunomodulatory cytokine profile of the secretome of mesenchymal stem cells cultured in the presence of Leishmania antigens was characterized. As a result of these investigations, over 15 papers have been published so far and several undergraduate and graduate students have participated and benefited by performing their thesis and dissertations. In conclusion, the UNTRM in collaboration with partner institutions was successful in building an institute with the latest technology in a hard-to-reach area, transferring capabilities to improve the diagnostic capacity of infectious diseases in Amazonas.

TSLP UPREGULATES IFN-GAMMA PRODUCTION IN CUTANEOUS LEISHMANIASIS PATIENTS

Marina B. Santana, Jamile Lago, Augusto M. Carvalho, Edgar M. Carvalho, Lucas P. Carvalho

Instituto Gonçalo Moniz- Fiocruz, Salvador, Brazil

Patients with cutaneous leishmaniasis (CL) due to *Leishmania braziliensis* infection develop ulcerative skin lesions that are associated with inflammatory response. Activation of macrophages by IFN-gamma is the main mechanism of *Leishmania* parasite killing, whereas Th2 environment with IL-5 production is associated with parasite replication. Our previous results show intense inflammatory infiltrate with high production of TNF and IL-1-beta in lesions from CL patients. Thymic stromal lymphopoietin (TSLP) is an epithelial cell-derived cytokine expressed in skin, gut, lungs, and thymus that induce Th2 cytokines and is produced during helminth infection and atopy. Our aim was to assess the production and effect of TSLP in cells from CL patients. By analyzing single-cell RNAseq we found that TSLP is not significantly expressed in lesion C57BL/6 mice upon infection with *L. major*, or in lesion from CL patients due to *L. braziliensis* infection. To assess the effect of TSLP on CL patients we added recombinant (r) TSLP to Soluble *Leishmania* Antigen (SLA)-stimulated peripheral blood mononuclear cells (PBMC) from CL patients. Surprisingly, addition of rTSLP increased IFN-gamma in SLA-stimulated PBMC culture supernatants without affecting the production of TNF, IL-5 and IL-10. Our data suggest that presence of TSLP may benefit CL patients by increasing IFN-gamma production, thus contributing to parasite killing.

7456

FOLLICULAR T HELPER (TFH) VERSUS HYBRID TH1/TFH CELLS AND THE OUTCOME B CELL RESPONSE IN *TRYPANOSOMA CRUZI* INFECTION OF SUSCEPTIBLE AND RESISTANT MICE

Ana Carolina Leao, Maria José Villar, Rakesh Adhikari, Cristina Poveda, Leroy Versteeg, Peter Hotez, Maria Elena Bottazzi, Kathryn Jones

Baylor College of Medicine, Houston, TX, United States

Trypanosoma cruzi is the etiologic agent of Chagas disease (CD). Endemic to Latin America, CD affects 6 to 7 million people worldwide and is responsible for over 800,000 disability-adjusted life-years due to digestive and cardiac manifestations. Immune response studies in the context of *T. cruzi* infection are mostly focused on T cells, due to their well-known role associated with better outcomes by the generation of a CD4$^+$ T helper Th1 profile and a strong CD8$^+$ T response that is, however, unable to resolve the infection. Contrarily, B cell response in CD models has been overall under investigated. It's known that *T. cruzi* infection induces a polyclonal B lymphocyte proliferation with unspecific antibody response unable to clear the parasites, resulting in chronic infection. In this work, we performed a thorough characterization of the B cell immune response and Follicular T helper (Tfh) cells, a subset of CD4$^+$ T cells required for the T-dependent germinal center (GC) response, in *T. cruzi* infection. Comparing two different mouse models: C57BL/6 mice described as a resistant model to *T. cruzi* infection, and BALB/c mice, susceptible. Female mice of both strains were infected with 5000 blood form trypomastigotes of the bioluminescent H1 *T. cruzi* strain. Flow cytometry analysis showed that C57BL/6 mice model, associated with type I immunity, produced hybrid Th1/Tfh cells with reduced expression of the transcription factor Bcl6 and increased expression of IFN-γ. Comparatively, BALB/c mouse model, associated with type 2 immunity, produced mainly classic Tfh cells with increased Bcl6 expression leading to IgG 1 hypergammaglobulinemia and an exacerbated expansion of germinal center B cells. In both models, the expression of Bcl6 in germinal center B cells, associated with the production of high-quality antibodies, is delayed appearing only 28 dpi. These results point to the development of different evasion mechanisms by the parasite with the late production of specific high-affinity antibodies.

7457

GALNAC AND GLCNAC CARBOHYDRATES INCREASE THE PRESENCE AND ACTIVITY OF THE MYELOPEROXIDASE ENZYME DURING *ENTAMOEBA HISTOLYTICA* AND NEUTROPHIL INTERACTIONS, POSSIBLY BY BLOCKING AMEBIC ADHESION

Nadia M. Pérez-Vielma[1], Ivonne M. Arciniega-Martínez[2], Aldo A. Reséndiz-Albor[2], David Levaro-Loquio[2], Germán Higuera-Martínez[2], Munich Guevara-Rubio[2], **Judith Pacheco-Yepez**[2]

[1]Centro Interdisciplinario de Ciencias de la Salud, CICS, Santo Tomás, Instituto Politécnico Nacional, Ciudad de México, Mexico, [2]Sección de Estudios de Posgrado e Investigación, Escuela Superior de Medicina, Instituto Politécnico Nacional, Ciudad de México, Mexico

The present study analyzes the effect of the presence of carbohydrates N-acetyl-D-galactosamine (GalNAc) and N-acetyl-D-glucosamine (GlcNAc) on the myeloperoxidase (MPO) activity of neutrophils during their interaction (mouse model of resistance to amebiasis) with trophozoites of *Entamoeba histolytica* (*E. histolytica*). GalNAc and GlcNAc block the amoebic 260 kDa and 220 kDa lectins, respectively. *E. histolytica* trophozoites (5×10^4 amebas/ml) were interacted with mouse neutrophils (1×10^6 cells/mL) in presence of the carbohydrates at 25 mM and the effect was evaluated at 20, 40, 60, and 90 min. MPO activity was explored with the addition of TMB (chlorhydrate of 3,3', 5,5'-tetramethylbenzidine) and hydrogen peroxide solution. The microscopy analysis was carried out with an anti-ameba polyclonal rabbit IgG antibody, which was detected with a secondary donkey anti-rabbit IgG (H + L) antibody Alexa Fluor-647. MPO was detected with an anti-MPO polyclonal rabbit IgG conjugated to the Alexa Fluor-350 antibody. The samples were counterstained with SYTOX green to observe the DNA and images were collected and analyzed with confocal fluorescence microscopy. A significant increase was observed in the activity and presence of MPO at the different times of the interactions in presence of the carbohydrates compared with the interactions in absence of the carbohydrates. The greatest increase in MPO activity was found in the presence of GalNAc. The increase in the activity and presence of MPO in ameba/neutrophil interactions in the presence of carbohydrates suggests that MPO could be involved in amoebic damage by blocking amebic adhesion, thus making it possible for the MPO of neutrophils to be activated.

7458

LACK OF INFORMATION AS A REASON FOR NON-PARTICIPATION IN MASS DRUG ADMINISTRATION TARGETING ONCHOCERCIASIS: A MIXED METHOD STUDY

Yaya Ibrahim Coulibaly[1], Moussa Sangare[2], Abdoul Fatao Diabate[3], Diadje Tanapo[3], Sekou Oumarou Thera[3], Mahamoud Mahamadou Koureichi[3], Siaka Yamoussa Coulibaly[3], Salif Seriba Doumbia[3], Housseini Dolo[3], Yacouba Sangare[4], Dukharmel Nazaire[5], Thomas B Nutman[6], Alison Krentel[7]

[1]International Center for Excellence in Research, | University of Sciences, Techniques and Technologies of Bamako, Mali; Dermatology Hospital of Bamako, Bamako, Mali, [2]International Center for Excellence in Research, | University of Sciences, Techniques and Technologies of Bamako, Mali; School of Epidemiology and Public Health, University of Ottawa, Bamako, Mali, [3]International Center for Excellence in Research, | University of Sciences, Techniques and Technologies, Bamako, Mali, [4]National Onchocerciasis control program, Bamako, Mali, [5]Bruyere Research Institute, Ottawa, ON, Canada, [6]National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States, [7]Bruyere Research Institute; School of Epidemiology and Public Health, University of Ottawa, Ottawa, ON, Canada

The World Health Organization recommends mass ivermectin administration to eliminate onchocerciasis as a public health problem. However, despite efforts to achieve sufficient coverage over time, some targeted individuals report never receiving information about the mass drug administration (MDA) campaigns. Our study aimed to understand why some individuals in endemic areas did not receive information about the MDA campaign over multiple rounds in KA-05, one transmission zone in Mali. We conducted a mixed method study, combining community surveys with qualitative and participatory methods. Data collection took place in February 2023 in the health districts of Sagabari, Kita, and Kenieba. We interviewed participants aged 18 years and above using a pre-established questionnaire to collect sociodemographic characteristics and the reasons associated with the lack of information, such as the main source of income, health districts, the travel history, and level of knowledge of the disease. We also conducted individual interviews and focus group discussions using an interview guide. Finally, we performed a thematic analysis for qualitative data using NVIVO v14. We used SPSS v26 to conduct a binary logistic regression for quantitative data to identify factors associated with the lack of information about the MDA campaign. Lack of information was the most frequently reported reason for non-participation in onchocerciasis targeted MDA [20% (187/921)]. People who knew nothing about onchocerciasis were 1.93 times more likely to be unaware of the campaign as compared to those who had heard of onchocerciasis (CI: 1.18 - 3.14). Qualitative study revealed that this lack of information can be attributed to various factors, such as the lack of awareness, education, seasonal movements, rumors, and available communication channels. Despite many years of MDA for onchocerciasis in this location, some people remain unaware about the disease and the MDA. As programs reach the endgame of elimination, new approaches are needed to reach the unreached.

7459

EVALUATION OF SOIL-TRANSMITTED HELMINTHIASIS AND SCHISTOSOMIASIS COVERAGE FOLLOWING SIX YEARS OF MASS DRUG ADMINISTRATION IN FIVE NIGERIA STATES

Temitope Michael Ogunbi[1], Ifeanyiwa Chime[1], Jerry Mbaka[1], Kate McCracken[2], Mark Minnery[2], Ayoola Adegbile[1], Anam Abdulla[2], Rodgers Curtis[2], Ima Umah[3], Fatai Oyediran[3], Toochi Ohaji[1], Ima Chima[1]

[1]Evidence Action, Abuja, Nigeria, [2]Evidence Action, Washington DC, WA, United States, [3]Nigeria Federal Ministry of Health, Abuja, Nigeria

Achieving the WHO recommended treatment threshold during every round of preventive chemotherapy (PC) is essential to reach elimination of parasitic worm infections as public health problems. Reported administrative coverage data, though essential for program monitoring, can sometimes vary from the actual treatment coverage due to weaknesses in health information systems (use of outdated population census data, inaccurate count of persons treated etc). WHO recommends Coverage Evaluation Surveys (CES) to understand reporting accuracy and to determine if there are data reporting problems. This study evaluates CES conducted post-PC in 55 implementing units (IUs) across five Nigerian states for soil transmitted helminths (STH; 38 IUs) and schistosomiasis (SCH; 17 IUs), from 2018 - 2023. Following the WHO CES protocol, households and schools in 1,650 communities were visited and 62,683 individuals surveyed to estimate treatment coverage over six years. The surveyed coverage showed that 45.5% (25; STH- 16, SCH-9) of IUs met/exceeded the 75% target treatment threshold with 95% CI ranging from 75% - 97%, an adequate marker for a well-functioning programme and successful MDA. Only 3% (1,894) of individuals did not swallow the medicines when offered, indicating high compliance. The reported administrative coverage ranged from 42% - 133% in the 55 IUs, but were similar to the surveyed coverage in only 13% (7) and validated in 7% (4) of the IUs, evidence of critical data reporting issues across board. A significant 23% (14,457) reported they were not offered medicines during the PC round; predominant reasons include absence on deworming day (26.4%); school did not participate or receive medicines (20%); and lack of awareness of the PC (11.5%). Data quality assessment post-PC is recommended to check issues around the variances between the survey and reported coverage and strengthen PC reporting. Additionally, strengthening community engagement and sensitization, as well as proper program planning to address medicine quantification and positioning will be necessary to improve awareness and boost participation in PC.

7460

CHALLENGES IN MEASURING AND DISCUSSING ELIMINATION GOALS: FROM MODELLING TO POLICY

Samuel A. Sutherland[1], Jason J. Madan[2], Kat S. Rock[1]

[1]Zeeman Institute for Systems Biology and Infectious Disease Epidemiology Research, University of Warwick, Coventry, United Kingdom, [2]Warwick Medical School, University of Warwick, Coventry, United Kingdom

The World Health Organisation (WHO) have targeted *gambiense* human African trypanosomiasis (*g*HAT) for elimination of transmission (EoT) by 2030. Unfortunately, it is not possible to directly observe new infections, so a proxy indicator is needed to be able to measure progress towards this target. The WHO HAT elimination Technical Advisory Group have recently defined the indicator for EoT as five years of no cases, along with a sufficient level of surveillance. To support programs in achieving this goal, mathematical modelling is being used to predict and quantitively evaluate the effectiveness of interventions and measure progress towards elimination. Unlike in the real world, modelling can find the exact point at which transmission ceases in the model and many papers have been published using this modelled point of EoT to predict when real-world EoT will be reached. Unfortunately, despite sharing a name, these two definitions of EoT are not the same, and in fact can differ very significantly. In this presentation we discuss the difference between these indicators and show with some examples how severely these indicators can disagree. Similarly, models can predict the exact point at which there is no more infection in the population – Elimination of Infection (EoI), an even stronger criterion than EoT, and also not directly measurable in the real world. The difference between EoT and EoI is particularly pertinent for *g*HAT, which has a very long infection time (often multiple years, sometimes over a decade) meaning that cases can be found substantially after infection was first transmitted to the patient. While this presentation focuses specifically on these three benchmarks for *g*HAT, the general points made here about seemingly trivial differences in the definition of elimination and its indicators could have significant consequences on decision making for any infections approaching the endgame. Modellers and policymakers, both in *g*HAT and beyond, need to work closely together and communicate clearly to ensure that they are in alignment when discussing elimination.

7461

COVERAGE EVALUATION SURVEY OF LYMPHATIC FILARIASIS RE- MASS DRUG ADMINISTRATION AFTER PRE-TAS FAILURE IN 4 DISTRICTS OF MOZAMBIQUE, 2023

Clecio Sitoe[1], Henis M. Sitoe[2], Mawo Fall[1], Tamimo Momade[1], Erica Shoemaker[1], Nafissa Johnson[1], Molly Brady[1]

[1]RTI, Research Triangle Park, NC, United States, [2]Ministry of Health, Maputo, Mozambique

The Department of Disease Prevention and Control conducted a post-lymphatic filariasis (LF) MDA coverage evaluation survey (CES) from August to September 2023 in Cuamba, Murrupula, Mulevala & Ile. The survey aimed to validate the reported coverage and explore factors affecting MDA implementation. The CES is a community-based cross-sectional survey where 30 clusters are randomly selected using probability proportionate to estimate size (PPES), segmented, and then households are selected for interviews based on a numbered list. Surveyed coverage ranged from 64.1% to 83.5% across the four districts, with only Mulevala failing to meet the WHO coverage threshold of 65%. Across all districts, the main reasons for not consuming drugs were “not being at home during distribution”, “unaware of the MDA”, or “distributors did not visit their house, school, or distribution point”. Respondents that were unaware of the MDA ranged from 23% to 44% across districts and 48% to 90% of participants indicated drugs were received during a household visit. Those that had never participated in an LF MDA ranged from 10% to 26%, and despite upwards of 10 years of treatment in some districts, 52% to 87% indicated that they participated only once. Of the 120 clusters surveyed, 32 failed to meet the coverage threshold, suggesting a more focal issue. When cluster coverage data was compared to daily monitoring reports from the MDA, it revealed potential implementation and data quality issues at the community level. Despite sufficient coverage at the district level, low surveyed coverage in some clusters underscores the need for a more targeted, community-based approach. Future MDAs should focus on community preparation & sensitization, engaging community leaders in planning and pre-MDA meetings, ensuring robust IEC, and implementing innovative strategies to reach the absent people. Enhancing CDD training, conducting daily data monitoring at the community level, and planning for post-MDA mop-up in low coverage communities will ensure more uniform coverage across the districts, as missed populations may sustain LF transmission despite achieving recommended thresholds.

7462

COMPLETING THE TRACHOMA MAP IN SOUTH SUDAN: RESULTS OF THREE BASELINE PREVALENCE SURVEYS IN EASTERN EQUATORIA STATE, 2023-2024

Stephen Ohidor[1], Nicholas A. Presley[2], Angelia M. Sanders[2], Tania A. Gonzalez[2], Yak Y. Bol[3], Albino W. Nyibong[3], Chabier Coleman[4], E. Kelly Callahan[2], Sarah E. Gwyn[5], Diana L. Martin[5], Scott D. Nash[2]

[1]The Carter Center, Juba, South Sudan, [2]The Carter Center, Atlanta, GA, United States, [3]Ministry of Health, Juba, South Sudan, [4]Oak Ridge Institute for Science and Education, Oak Ridge, TN, United States, [5]Centers for Disease Control and Prevention, Atlanta, GA, United States

Estimating the baseline prevalence of trachoma is required for trachoma control programs to determine a district’s eligibility to receive SAFE (Surgery, Antibiotics, Facial cleanliness, and Environmental improvement) interventions. The Ministry of Health of the Republic of South Sudan (MoH-RSS) is dedicated to eliminating trachoma as a public health problem and since 2001 has implemented aspects of the SAFE strategy in parts of the country. However, as of 2022, three counties (districts) in Eastern Equatoria State (EES) had not completed baseline mapping. From 2023-2024, the three counties of Torit, Magwi, and Ikotos were surveyed by the MoH-RSS Trachoma Control Program using a multistage cluster-randomized sampling design. Trained and certified graders examined participants for trachoma clinical signs and county level prevalence was estimated. Dried blood spot (DBS) specimens were collected from individuals one year of age or older in all three counties. In addition, ocular swabs for *Chlamydia trachomatis* (*Ct*) infections were collected from children ages 1-9 years in Torit. During the 2023 surveys of Torit and Magwi, a total of 59 clusters with 6,222 individuals from 1,577 households were examined for trachoma, with 6,213 DBS and 1,346 swabs collected. Prevalence of trachomatous inflammation—follicular (TF) among children ages 1-9 years was 0.8% (95% confidence interval [CI]: 0.4-1.7%) in Magwi and 7.3% (95% CI: 3.3-15.7%) in Torit. Trachomatous trichiasis (TT) in adults 15 years and older was 1.05% (95% CI: 0.59-1.86%) in Magwi and 1.41% (95% CI: 0.81-2.44%) in Torit. The analysis of the 2024 Ikotos survey results, and the results of the infection and serological analysis, will be complete by summer 2024. Based on these results, Torit is slightly above the World Health Organization elimination thresholds of TF<5% and TT<0.2% and will require all SAFE interventions, whereas Magwi will only require S, F, and E interventions until TT levels are <0.2%. With the completion of baseline surveys for all counties in EES, the MoH-RSS has the data needed to drive progress towards the elimination of trachoma.

7463

ANALYSIS OF THE SITUATION OF LEPROSY CASES IN CHILDREN AGED FROM 5 TO 14 YEARS FROM 2022 TO 2023 IN CONAKRY (GUINEA)

Sadan Sidibé

Ministère de la Santé et de L’Hygiène Publique, Conakry, Guinea

Depuis 2010, la Guinée a atteint le seuil d’élimination de la lèpre comme problème de santé publique, avec moins d’un cas pour 10 000 habitants dans toutes les préfectures du pays. Malgré les efforts du Ministère de la Santé et de l’Hygiène Publique à travers le Programme National de

Lutte contre les Maladies Tropicales Négligées avec Prise en Charge des Cas (PNLMTN-PCC) en collaboration avec les partenaires techniques et financiers, il y a eu une sous-déclaration ces dernières années dans tous les centres de prise en charge des cas du pays. pays. Plusieurs facteurs peuvent expliquer cette sous-déclaration, notamment un dépistage retardé entraînant une proportion élevée de cas multibacillaires (MB), un nombre important d'invalidités de grade 2, un financement insuffisant pour une surveillance solide de ces maladies et le départ à la retraite du personnel qualifié. Fin 2022, 185 nouveaux cas ont été recensés, dont 4 cas chez les enfants (2,2%). En 2023, 244 nouveaux cas ont été détectés, dont 6 cas chez des enfants, tous scolarisés (1,8%). La moitié de ces enfants résident à Conakry. Plusieurs indicateurs clés mettent en évidence les défis rencontrés pour mettre en œuvre la stratégie de l'Organisation mondiale de la santé visant à interrompre la transmission. Le pourcentage d'enfants supérieur à 1% constitue un indicateur crucial signalant la présence persistante de la maladie dans la population, notamment dans la région de Conakry et ses deux villes du nord. La proportion croissante de cas multibacillaires (80 % et 88 % en 2022 et 2023, respectivement) parmi les nouveaux cas signifie un risque accru de transmission de la maladie au sein de la population, notamment dans les milieux éducatifs où les étudiants interagissent étroitement pendant des périodes prolongées. Seize de ces cas provenaient de Conakry, dont 3 cas impliquant des enfants (19%). Une évaluation de la situation indique une résurgence potentielle de la lèpre en Guinée. Face à ce scénario, il est essentiel d'intensifier les efforts de détection précoce de la lèpre.

ADDRESSING "LEAVING NO ONE BEHIND" IN AN NTD PROGRAMMATIC CONTEXT: EXPERIENCE FROM THE DEWORMING INNOVATION FUND

Mary K.A. Nyamongo[1], Clare Amuyunzu[1], Agnes Kithinji[2], Juma Chitiavi[3], Florence Wakesho[2], Wyckliff Omondi[2], Irene Chami[4]
[1]African Institute for Health and Development, Nairobi, Kenya, [2]Ministry of Health, Nairobi, Kenya, [3]Amref Health Africa, Nairobi, Kenya, [4]END Fund, Nairobi, Kenya

As NTD endemic countries implement the World Health Organization Sustainability Framework for Action Against NTDs 2021-2030, the need to ensure all at risk populations are reached has become urgent. Kenya is implementing interventions on Schistosomiasis (SCH) and soil transmitted helminthiasis (STH) in the Western Region with a view to reaching affected communities with information and services and influence adoption of positive behaviors by prioritizing inclusivity, equity and social justice. One aim of the Kenya NTD Master Plan 2023 -2027 is to interrupt transmission of SCH and STH through adopting comprehensive approaches, one being, leaving no one behind (LNOB). Under the Deworming Innovation Fund, a community consultative process was applied to identify people at risk of infection and the their social networks, while survey data were used to determine effective channels of communication. Key groups identified as needing special attention included street families, prisoners, people in remote areas, persons with disabilities, older persons and minority groups. Tailor-made strategies were implemented including: identifying and sensitizing influencers and change agents; developing culturally acceptable sensitization materials with NTD messages such as religious training manuals with Muslim and Christian groups; collaborating with other sectors such as prisons and social services departments; holding community dialogue forums; working closely with community-based organizations and private sector in implementing social behavior change and social mobilization initiatives. These actions resulted in improved access to information, treatment and increased avenues for structured in-depth conversations triggering behavior change. Quarterly monitoring reports in 2022/23 show increased levels of knowledge and a consistent high uptake of treatment (over 80%). Success stories have been documented in the intervention sites to demonstrate how the program is positively changing lives. Implementing targeted social mobilization and treatment interventions are key strategies to leaving no one behind.

7465

FACTORS ASSOCIATED WITH PERSISTENT AND RECRUDESCENT ACTIVE TRACHOMA: RESULTS FROM ADAPTIVE COVERAGE EVALUATION SURVEYS IN UGANDA

Stephen Begumisa[1], Rapheal Opon[2], Joyce Achan[1], Charles K. Kissa[2], Alfred Mubangizi[2], Sharone L. Backers[1], Stella Agunyo[1], Edwin A. Mayoki[1], Alex Rutagwabeyi[1], James Lemukol[3], Vincent Muron[3], Peter Lokwang[4], Denis Olaka[4], Clara R. Burgert-Brucker[5], Allison Shaffer[5], Erica Shoemaker[5], Jessica Douglas[5], Upendo Mwingira[5], Jeremiah M. Ngondi[5]
[1]RTI International, Kampala, Uganda, [2]Ministry of Health, NTD Program, Kampala, Uganda, [3]Moroto District Local Government, Moroto, Uganda, [4]Nabilatuk District Local Government, Nabilatuk, Uganda, [5]RTI International, Washington DC, DC, United States

Through implementation of the surgery, antibiotics, facial cleanliness, and environmental change (SAFE) strategy, Uganda has made progress towards elimination of trachoma with 59 of 61 previously endemic districts having stopped mass drug administration (MDA). Moroto and Nabilatuk have persistent and recrudescent active trachoma. The population in these districts are predominantly nomadic pastoralists where coverage of water, sanitation, and hygiene (WASH) is low and hard to reach, making MDA campaigns challenging. We investigated the factors associated with trachomatous inflammation-follicular (TF) in children aged 1–9 years following completion of MDA. Trachoma examination was added onto a routine coverage evaluation survey conducted one month after MDA. A two-stage sampling design was used to select 30 clusters and 10 to 12 households per cluster. MDA coverage was assessed in all eligible household members using standard WHO tools while trachoma examination was undertaken by graders certified using Tropical Data standards. Univariate and multivariate logistic regression analysis was used to explore association of TF and explanatory variables. A total 1806 children were included in the analysis and majority (51%) were male. In the univariate analysis, factors associated with increased odds of TF were residing in Moroto district, odds ratio (OR)=6.0 (95% confidence interval [CI] 2.3-16.1); not attending school, OR=9.6 (95% CI=1.3-71.2); not treated during MDA, OR=12.9 (95%CI=5.8-25.5); and low access to water source (p-value<0.001). Adjusting for age and gender, factors independently associated with TF were: residing in Moroto, OR=3.6 (95% CI1.1-9.2); not treated during MDA, OR=8.4 (95%CI=3.1-23.2); and low access to water source (p-value=0.002). The results showed lack of participation in MDA was an important driver of persistent trachoma, especially in Moroto district. The findings also suggest that low access to WASH remains an important driver of trachoma in these mobile and migrant pastoralist populations. Enhanced MDA and WASH interventions are needed to eliminate trachoma in Moroto and Nabilatuk.

7466

DETERMINANTS FOR UPTAKE OF MASS DRUG ADMINISTRATION FOR SCHISTOSOMIASIS CONTROL IN BUTIABA, UGANDA

Gloria Kakoba Ayebazibwe[1], Yusuf Wananda[2], Juliet Nambatya[2], Denis Omara[1], John Charles Okiria[3], Andrew Edielu[1]
[1]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [2]District Health Office, Buliisa, Uganda, [3]Institute of Public Health and Management, Clarke International University, Kampala, Uganda

Schistosomiasis is targeted for elimination in Uganda by 2025 through Mass Drug Administration (MDA) using praziquantel. To achieve this, WHO estimates indicate that MDA coverage and uptake of 75% is required. However, coverage remains suboptimal. There is need to add to the body of knowledge to enable more robust mitigation measures. This study aimed to assess the uptake of praziquantel for MDA and associated factors in Butiaba sub-county along the shores of Lake Albert in Uganda. A cross-sectional study was conducted in five randomly selected villages between July and September 2021 using quantitative and qualitative approaches. Semi-structured questionnaires were administered to 450 adults, with two

Focus Group Discussions and Key Informant interviews held with village and district leaders. Self-reported uptake of praziquantel within twelve months of the most recent MDA exercise was 71.56% (95% CI: 67.14 - 75.68). Of all the participants, 5.78% reported having never swallowed praziquantel in their lifetime and 75% (96/128) of participants who didn't swallow praziquantel in the last twelve months reported having at least swallowed the drug in the last ten years. Respondents were less likely to have swallowed praziquantel if they had no knowledge about schistosomiasis signs (AOR= 0.18, 95% CI: 0.08-0.39) and more likely if they were between the ages 30-39years (AOR= 2.31, 95% CI: 1.35-3.95) or 40 years and above (AOR= 2.86, 95% CI: 1.45 - 4.95). Operational challenges such as inadequate supply of praziquantel and financial constraints also influence uptake of praziquantel during MDA in Butiaba sub-county. Uptake of praziquantel was high but still below the WHO target of 75%. People with limited knowledge on schistosomiasis symptoms and those aged 18 - 29 years were less likely to take Praziquantel. Irregular drug supply was also a key challenge. Rigorous health education and ensuring continuous supply of Praziquantel are key in improving MDA uptake.

7467

FORECASTING OF ONCHOCERCIASIS PREVALENCE IN WEST AFRICA THROUGH TIME SERIES MODELING

Kaustubh Wagh[1], Diana Stukel[2], Gerardo Chowell[3]

[1]FHI360, Washington DC, DC, United States, [2]FHI360, WASHINGTON DC, DC, United States, [3]Department of Population Health Sciences, School of Public Health, Georgia State University, Atlanta, GA, United States

Act to End NTDs | West is a five-year USAID-funded program that aims to eliminate or control five Neglected Tropical Diseases across 11 West African countries. WHO's roadmap for NTD elimination targets five diseases for preventive chemotherapy: Lymphatic Filariasis (LF), Trachoma, Onchocerciasis (OV), Schistosomiasis, and Soil-Transmitted Helminth. Disease prevalence is assessed by population-based surveys.As LF and Trachoma are near elimination in several West African countries, the focus of funders and governments is increasingly shifting to eliminating OV. Therefore, this paper sets out to forecast OV prevalence using forecasts through modeling. Utilizing ESPEN site-level prevalence data spanning from 1975 to 2018, we focused on seven countries: Burkina Faso, Benin, Cote d'Ivoire, Ghana, Guinea, Mali, and Togo. Maximum prevalence at the site level was utilized to summarize the data for each year across the selected countries. In instances of missing data, prevalence from the preceding year was used.Various time series modeling techniques, including Autoregressive Integrated Moving Average (ARIMA), Generalized additive model (GAM), Generalized linear model (GLM), and Facebook's Prophet models, were employed using RStudio (version 3.3.0). For these models, we set a calibration period of 43 years and a forecasting horizon from 2019 to 2030 (12 years). Data management was facilitated through MS Excel pivot tables. Despite ARIMA and GAM models showing a minimal decline in prevalence, GLM and Prophet model forecasts suggest that by 2030, OV prevalence will decline to 0% (with a 95% prediction interval of 0% to 2.8%) across the seven countries, indicating the achievement of onchocerciasis elimination by 2030. The Prophet model demonstrated the best fit based on fit statistics, including average Mean Absolute Error (MAE), Prediction Interval Coverage, and Weighted Interval Score (WIS).This talk will additionally explore more complex models, such as the n-sub epidemic and spatial wave framework, for future analyses to forecast OV prevalence. Finally, we aim to expand our analysis to provide country-specific forecasts.

7468

MIND THE GAP: GENDER DIFFERENCES IN PREVENTATIVE TREATMENT OF SEVEN NEGLECTED TROPICAL DISEASES

Karen Danielson, Maureen Headland, Jennifer Arney, Diana Stukel

FHI360, Washington DC, DC, United States

Ensuring gender equity is a core goal of USAID as well as of Act to End NTDs | West, a USAID-funded program supporting Ministries of Health in 11 West African countries to manage seven neglected tropical diseases (NTDs). A key strategy of NTD management is mass drug administration (MDA) of preventative chemotherapy (PC) to populations at risk. Determining the presence and magnitude of gender disparities in MDA is crucial both to ensuring health equity, and to identifying pathways of ongoing NTD transmission. This study assessed 3,832 USAID-funded MDA events covering the seven PC-NTDs across 792 districts in 11 countries from 2019 to 2023, disaggregated by sex. We estimated sex-disaggregated program coverage rates for each MDA by dividing reported male and female treatment data by estimated male and female target populations, respectively. The distributions of, and differences between, male and female coverage rates were analyzed by country and targeted disease. Broadly, NTD programs appear to achieve high MDA coverage, but differences between males and females do exist. Average coverage across all MDA events was 92.8% for females and 85.1% for males. However, 355 MDA events (9.3%) had differences of at least 20 percentage points, and 41 (5.2%) of the 792 districts studied had differences of at least 20 percentage points in three or more MDA held during the study period. Coverage differences vary by the disease being treated, and across countries. MDA treating schistosomiasis had the smallest differences (female coverage exceeded that of males by 6.5 percentage points) while those treating lymphatic filariasis had the largest (female coverage exceeded that of males by 10.6 percentage points). The lowest country-level average difference was 3.3 percentage points, while the highest was 15.2 percentage points. This study will explore country- and disease-specific context to interpretate the drivers of coverage differences that must be addressed to improve gender equity in future MDA programming.

7469

TRACHOMA ZONES OF CONCERN: IDENTIFYING AREAS OF TRACHOMA RISK BEFORE AND AFTER ELIMINATION USING NOVEL GEOSPATIAL ANALYSIS

Clara R. Burgert-Brucker[1], Donal Bisanzio[1], Rachel Stelmach[1], George Kabona[2], Rapheal Opon[3], Titus Watitu[4], Rebecca Flueckiger[1], Jeremiah Ngondi[1], Anthony Solomon[5], Emma Harding-Esch[6]

[1]RTI International, Washington, DC, United States, [2]Njombe Regional Referral Hospital, Njombe, Tanzania, United Republic of, [3]Vector-Borne and Neglected Tropical Diseases Division, Ministry of Health, Uganda, Kampala, Uganda, [4]Vector Borne and Neglected Tropical Diseases Unit, Ministry of Health, Kenya, Nairobi, Kenya, [5]World Health Organization, Geneva, Switzerland, [6]London School of Hygiene & Tropical Medicine, London, United Kingdom

Enhanced analysis methods can help identify areas at high risk for persistent and/or recrudescent active trachoma within and between trachoma endemic Evaluation Units (EUs). Geospatial analysis could identify "zones of concern" likely to have above-threshold trachomatous inflammation—follicular prevalence in children aged 1-9 years (TF1-9) within and between EUs, including within and between countries. This study is a secondary data analysis using trachoma baseline, impact (TIS), and surveillance (TSS) survey data collected with Global Trachoma Mapping Project (GTMP) and Tropical Data support from 2012 to 2022 in Uganda, Kenya, and neighboring countries. Previous work has explored the spatial distribution of trachoma and the spatial relationship of trachoma to spatial covariates in these countries. Leveraging these results and an understanding of trachoma geospatial dynamics, a new analysis approach was developed. The approach borrows information from nearby survey clusters within a certain distance or buffer of a survey cluster and uses these data to estimate a zonal mean TF1-9 prevalence for each survey cluster area. This approach was piloted in several areas of Uganda with different epidemiological and survey profiles. Data from the most recent survey in one area of was used to identify a "zone of concern" with several overlapping 10-kilometer cluster buffers of more than 5% TF1-9 across several districts in the study area. In another area, the results show several zones of concern, including a large zone overlapping international borders. Trachoma is highly focal in distribution, and spatial models need to be tailored to each area of interest. The spatial scale of analysis, including

considering the use of data beyond the borders of a single EU or even country, could be important in some areas. Simple geospatial analysis, such as this "zone of concern" approach, may provide initial information for programs to target interventions in areas at risk of persistent and/or recrudescent trachoma or for post-validation surveillance activities.

7470

IMPROVING THE QUALITY OF MASS DRUG ADMINISTRATION IN GHANA USING ELECTRONIC DATA CAPTURE.

Charles Brown-Davies[1], Irene Dzathor[1], Egide Ndayishimye[1], Diana Stukel[2], Maureen Headland[2], Ernest Mensah[3], Emmanuel Nyarko[3]

[1]FHI 360, Accra, Ghana, [2]FHI 360, Washington, DC, United States, [3]Ghana Health Service, Accra, Ghana

Ghana has conducted Mass Drug Administration (MDAs) as a means of controlling neglected tropical diseases for over two decades. These MDAs have used traditional community registers and community drug distributors (CDD) as a channel to distribute essential MDA medicines to community members. Data from these MDAs are sometimes not reported in a manner that is timely, complete, inaccurate and hence NTD programs have challenges making informed decisions timely for improved or quality MDA. This shortcoming leads to even dire consequences as the deficiencies are only discovered a few months after implementation making introduction of strategies to improve MDA during the period impossible. At the implementation level supervisors are constrained in identifying areas with low coverage whiles MDA is ongoing because data does not get to them in real time. The Ghana NTD program is piloting the use of the Lymph App's MDA module for the annual integrated Lymphatic Filariasis (LF) and Onchocerciasis (OV) MDA. The main objective of the study is to demonstrate how the Lymph App MDA module can help improve MDA data accuracy, completeness and timeliness and provide adequate data to support supervisors with the identification of underserved areas. There will also be a rapid assessment of the acceptability and convenience of the app to CDDs and health workers. Five LF and OV endemic sub districts will be purposively selected for this pilot. Supervisors and CDDs in these sub districts will be trained on the use of the app. After training and pretesting, there will be an initial registration of all community members in all study sites. This registration will capture the bio data of all household members and household's geo coordinates. This data which forms the registration for the communities will be cleaned thoroughly and will be used as the community register. MDA medicines given will also be recorded as part of this register. Data from the app will be downloaded, cleaned, analyzed, and presented as maps and tables daily and shared with supervisors to facilitate the identification of areas with poor coverage and address MDA issues immediately to ensure maximum coverage.

7471

OCULAR *CHLAMYDIAL TRACHOMATIS* INFECTION IMMEDIATELY FOLLOWING AN ENHANCED MASS DRUG ADMINISTRATION STRATEGY FOR TRACHOMA IN AMHARA, ETHIOPIA: THE CHILD MDA PILOT STUDY

Scott D. Nash[1], Fikre Seife[2], Mohammed F. Shaka[3], Tania A. Gonzalez[1], Eshetu Sata[3], Ambahun Chernet[3], Nicholas A. Presley[1], Demelash Gessese[3], Kimberly A. Jensen[1], Gizachew Yismaw[4], Taye Zeru[4], Ayalew Shiferaw[3], Abebe Fisseha[3], Zerihun Tadesse[3], E. Kelly Callahan[1]

[1]The Carter Center, Atlanta, GA, United States, [2]Ministry of Health, Addis Ababa, Ethiopia, [3]The Carter Center, Addis Ababa, Ethiopia, [4]Amhara Public Health Institute, Bahir Dar, Ethiopia

The Ministry of Health of Ethiopia has recently recommended an enhanced mass drug administration (MDA) strategy, "Child MDA" for trachoma, consisting of a standard community-wide round of MDA followed by a child only round (ages 6 months to 9 years) 4 weeks later. Child MDA was piloted in the Amhara region in 2023 in 2 districts, Lasta and Wadilla. As of 2022, the trachomatous inflammation-follicular (TF) prevalence among children ages 1-9 years was 30.0% in both districts, and the *Chlamydia trachomatis* (*Ct*) infection prevalence among children ages 1-5 years was 15.5% in Lasta and 9.4% in Wadilla. This study's aim was to determine the prevalence of *Ct* infection 3 weeks post-Child MDA intervention by embedding conjunctival swabbing within MDA coverage surveys. A period of 3 weeks was chosen to allow for enough time for infection to clear and to be recent enough to minimize recall bias. The surveys used multi-level sampling, selecting 30 communities and 30 households within each community. Following household and individual level MDA questionnaires, one swab was collected per child ages 1-9 years. All swabs were tested for *Ct* infection in Amhara. The July 2023 coverage surveys interviewed 1,752 children ages 1-9 years across the 2 districts to assess self-reported MDA coverage for both rounds, and 1,632 (93%) children were swabbed. The MDA coverage among children was >82% at all rounds in both districts. The district-level prevalence of *Ct* infection was 3.5% (CI: 1.7-7.3%) among children ages 1-9 years and 4.6% (CI: 2.3-8.9%) among children ages 1-5 years in Lasta. In Wadilla, the *Ct* prevalence among children ages 1-9 years and children ages 1-5 years was 1.7% (CI: 0.5-5.7%) and 1.3% (CI: 0.4-3.9%) respectively. Across both districts, the *Ct* prevalence among children who reported not taking either dose of MDA (n=95) was 15.9% (CI: 8.0-29.2%), and among those who reported taking both doses (n=1,343), it was 1.2% (CI: 0.7-2.2%). The *Ct* infection prevalence was lower after the Child MDA treatment, however, considerable infection remained 3 weeks post-treatment. One year of Child MDA treatment is likely not sufficient in highly endemic settings.

7472

ANTIBODY-OMICS REVEALS BIOMARKERS OF SCHISTOSOMIASIS AND CROSS-TALK WITH TUBERCULOSIS.

Pedro Marcal[1], Deborah Bloch-Goldstein[2], Anushka Saha[1], Divya Bhakta[1], Abhipsa Panigrahi[1], Dalton Wamalwa[3], Irene Njuguna[4], Cheryl Day[5], Lisa M. Cranmer[5], Aniruddh Sarkar[1]

[1]Georgia Institute of Technology, Atlanta, GA, United States, [2]St. Christopher's Hosp. for Children, Philadelphia, PA, United States, [3]University of Nairobi, Nairobi, Kenya, [4]Kenyatta National Hospital, University of Washington, Seattle, WA, United States, [5]Emory University, Atlanta, GA, United States

Lack of accurate accessible diagnostics for Schistosomiasis (schisto) is a critical bottleneck in its elimination. In the absence of microscopic evidence of parasite, antibody (Ab) tests cannot distinguish past from current infection. Recently developed antigen detection tests (CAA) are promising for detection of current infection but not widely available. Additionally, schisto is associated with higher risk for Tuberculosis (TB), although the mechanism for this is not clear. We have developed a multiplexed 'Ab-omics' platform for deep characterization of a broad set of antigen-specific Abs (isotype, subclass, glycosylation and Fc receptor binding). Machine-learning applied to these data can reveal unique Ab signatures predictive of disease state and outcome. Here, sera from subjects (n=41, from Kenya), previously screened using a CAA test, were characterized with the Ab-omics workflow, using multiple *S. mansoni* (SEA, Sm25, Sm29, MEG, CD63, Calumenin), *M. tuberculosis* (PPD, Ag85A, ESAT6, CFP10 HspX, PstS1, LAM) and other helminth and non-helminth antigens. Antigen-coated barcoded beads were incubated with serum and probed. With a total of 270 measured Ab features from each subject LASSO-based feature selection led to a unique biomarker to differentiate CAA+ from CAA- individuals accurately (AUC>0.9). These findings suggest that a purely Ab-based biomarker, including Sm-29 specific IgG2, Ab galactosylation and Sm25-specific Ab FcR2b binding can achieve accurate diagnosis of current schistosome infection in endemic areas. Further, this approach was also able to distinguish early, late and past infection. Mtb-specific Abs also showed different Ab Fc profiles between CAA+ and CAA- individual's, specifically higher Ab sialylation, galactosylation and Fc2b binding. This is indicative of an anti-inflammatory tuning of the Fc profiles of Mtb-specific

Abs in Schisto patients, which has been earlier shown to be correlated with reduced Ab function and higher risk of reactivation of TB infection to active TB.

7473

IMMUNOLOGICAL BIOMARKERS FOR DETECTING SUBCLINICAL LEPROSY INFECTION: CROSS-TALK BETWEEN LID-1 AND PGL-1 IN INDIVIDUAL IMMUNE RESPONSES

Heloine Leite[1], **Pedro Marcal**[2], Lorena Oliveira[2], Marcos Pinheiro[2], Maisa Vieira[2], Marlucy Rodrigues[2], Olindo A. Martins-Filho[3], Joaquim P. Brito-de-Sousa[3], Alexandre Castelo Branco[4], Julie Clennon[5], Lance Waller[5], Thomas R. Ziegler[5], Jeffrey Collins[5], José Ferreira[6], Jessica Fairley[5], Lucia A.O Fraga[1]

[1]Universidade Federal de Juiz de Fora, campus GV - PMBqBM, Governador Valadares, Brazil, [2]Universidade Vale do Rio Doce - Univale, Governador Valadares, Brazil, [3]Grupo Integrado de Pesquisas em Biomarcadores, Instituto René Rachou, FIOCRUZ-Minas, Belo Horizonte, Brazil, [4]Centro de Referencia em Doenças Endemicas e Programas Especiais - CREDEN/PES, Governador Valadares, Brazil, [5]Emory University, Atlanta, GA, United States, [6]Universidade de Alfenas - Unifenas, Belo Horizonte, Brazil

Brazil ranks second globally in the number of annual new leprosy cases. Active surveillance is ideal for early detection and interruption of the transmission chain. In this context, identifying immunological biomarkers for the detection of subclinical infection represents a strategy to achieve this goal. A random sampling strategy was utilized to select 1315 asymptomatic individuals residing in hyperendemic municipalities in eastern Minas Gerais. Blood samples were collected and tested to detect antibodies against the *Myocbacterium leprae* protein (LID-1) on a multiplexed beaded assay. Following categorization into anti-LID1+ or anti-LID- groups, individuals were paired based on age and sex, resulting in a total of 160 participants. Immunological assays assessed chemokines (CXCL8, CCL2, CXCL9, CCL5, and CXCL10) and cytokines (IL-6, TNF, IFN-ϒ, IL-17, IL-4, IL-10, and IL-2) using PBMC culture supernatants stimulated by M. leprae antigens. Participants were evaluated for clinical disease, with 14 diagnosed, and an additional serological test for anti-phenoglycolipid-1 (PGL1) was performed. IFN-γ was able to identify LID1+ well (AUC= 0.73, p= 0.01, sensitivity= 71.79%, specificity = 86.30%) indicating its potential as a biomarker for subclinical infection. Conversely, the chemokine CCL2 demonstrated superior characterization of the LID1- group (AUC= 0.61, p= 0.02, sensitivity= 34.18%, specificity = 88.31%), albeit with low sensitivity. The analysis of PGL-1 showed that anti-PGL-1(-) subjects had higher CXCL10 levels. Also, the network correlation between the biomarkers, showed a specific pattern in the IFN-γ, TNF and IL-17 correlation among the subgroups [LID(-)PLG1(-), LID(-)PLG1(+), LID(+)PLG1(-) and LID(+)PLG1(+)]. Overall, the differential biomarker profile and correlation between the groups suggest a promising avenue for developing future diagnostic tests for subclinical infection. Despite being asymptomatic, the participants in this study reside in regions with high endemicity, underscoring the critical need for early leprosy diagnosis. Financial support: CNPq, FAPEMIG, NIH.

7474

EXPLORING THE IMPACT OF DECENTRALIZATION IN IN THE LEPROSY ENDEMIC REGION OF EASTERN MINAS GERAIS USING GEOSPATIAL AND QPCR TECHNIQUES

Marcos Pinheiro[1], Nathan G. de Oliveira[2], Daisy Santos[3], Heloine Leite[4], Lorena Oliveira[4], **Pedro Marcal**[5], Maisa Vieira[1], Alexandre Castelo Branco[6], Ida Baptista[7], Jessica Fairley[8], Lucia A.O. Fraga[1]

[1]Universidade Federal de Juiz de Fora, campus GV - PMBqBM, Governador Valadares, Brazil, [2]Instuto Lauro de Souza Lima, Bauru, Brazil, [3]Universidade Federal de Juiz de Fora, campus GV, Governador Valadares, Brazil, [4]Universidade Vale do Rio Doce - Univale, Governador Valadares, Brazil, [5]Georgia Institute of Technology, Atlanta, GA, United States, [6]Centro de Referencia em Doenças Endemicas e Programas Especiais - CREDEN/PES, Governador Valadares, Brazil, [7]Instuto Lauro de Souza Lima, Governador Valadares, Brazil, [8]Emory University, Atlanta, GA, United States

Many studies have explored the qPCR technique for leprosy diagnosis, having successfully identified undiagnosed cases or sites of disease outbreaks. In parallel, the techniques of spatial epidemiology have also been making significant contributions to leprosy control, highlighting differences in the spatial distribution of the disease between regions, states, and municipalities, where places of greater social inequality and accessibility to health services can impact local epidemiology. This study aimed to map asymptomatic individuals examined at the reference center - CREDEN/PES (spontaneous demand or referral) with skin smears positive for the RLEP gene of *M. leprae* in Governador Valadares. Additionally, through a network analysis using point interpolation algorithms, an estimation of the coverage areas of primary health units (ESF/UBS) was conducted in the census sectors of the municipality. Using quantum GIS 3.14 Pi software, maps were created using shape files of census sectors, streets, and sociodemographic data sourced from the Brazilian Institute of Geography and Statistics (IBGE). Individuals' qPCR+ were heterogeneously distributed across census sectors, with a higher proportion of female individuals ($p = 0.0451$), predominating literate individuals ($p = 0.0405$), black ($p = 0.0072$) and mixed race ($p = 0.0020$). Around 70% of the urban area of GV is covered by a health unit. However, only 41.2% of qPCR+ individuals lived in these areas. The remaining 58.8% of qPCR+ individuals lived in areas without coverage by a Health Unit. The estimated average distance traveled by participants to the nearest ESF/UBS was 0.515 km, while the distance to CREDEN-PES (reference center) was 3.77 km. In conclusion, combined molecular and geoprocessing techniques proved effective in identifying critical areas for disease control in Governador Valadares. This study highlighted the importance of expanding ESF/UBS and potentially decentralizing leprosy care, particularly in regions inhabited by individuals from lower socioeconomic strata.

7475

MYCOBACTERIUM LEPRAE AND *SCHISTOSOMA MANSONI* CO-INFECTION IN COMMUNITIES OF EASTERN MINAS GERAIS, BRAZIL

Maisa Vieira[1], **Pedro Marcal**[2], Heloine Leite[3], Marcos Pinheiro[3], Lorena Oliveira[3], Marlucy Rodrigues[3], Alexandre Castelo Branco[4], Jessica Fairley[5], Lucia A.O Fraga[1]

[1]Universidade Federal de Juiz de Fora, campus GV - PMBqBM, Governador Valadares, Brazil, [2]Georgia Institute of Technology, Atlanta, GA, United States, [3]Universidade Vale do Rio Doce - Univale, Governador Valadares, Brazil, [4]Centro de Referencia em Doenças Endemicas e Programas Especiais - CREDEN/PES, Governador Valadares, Brazil, [5]Emory University, Atlanta, GA, United States

Leprosy, caused by *Mycobacterium leprae*, exhibits varied clinical forms depending on the immune response, Th1 or Th2. The coexistence of infections by parasites, particularly *Schistosoma mansoni*, and micronutrient deficiencies with leprosy is observed in endemic regions of Brazil. S. mansoni infection is known to negatively modulate the Th1 response, favoring M. leprae infection and progression to severe clinical forms. In this sense, the identification of risk factors associated with leprosy includes socio-demographic, immunological, and parasitological factors. A random sampling strategy was utilized to select 1315 asymptomatic individuals residing in hyperendemic municipalities in eastern Minas Gerais. IgG reactivity tests to Leprosy IDRI diagnostic antigen 1 (LID-1) and anti-PGL-1 IgM were conducted to identify individuals potentially infected by M. leprae without clinical manifestations. Tests for presumptive detection of schistosomiasis, including Detection of Circulating Cathodic Antigen (CCA) in urine and detection of anti-SEA and anti-SWAP antibodies in serum, were performed. Preliminary results showed 79 participants had anti-LID IgG, designated LID+. Among 156 sera evaluated for anti-PGL-1, 47 were positive (30.12%). ELISA assays revealed 28 sera (17.72%) reactive for SEA and 27 (17.0%) for SWAP. Using the rapid CCA test, 83 urine samples were collected, revealing co-infection in ten cases (12.05%), where patients tested positive for both LID+ (leprosy) and CCA (schistosomiasis). Notably,

14 new cases of leprosy were confirmed among LID+ individuals. Ongoing clinical evaluation and monitoring of participants are crucial for immediate treatment of newly diagnosed cases.

7476

MODEL-BASED GEOSTATISTICS TO SELECT SITES FOR MONITORING LYMPHATIC FILARIASIS TRANSMISSION INTERRUPTION FOLLOWING MASS DRUG ADMINISTRATION WITH IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE IN EAST NEW BRITAIN, PAPUA NEW GUINEA

Simon Westby[1], Joycelyn Salo[1], Emanuele Giorgi[2], Norman Vakore[3], Joachim Kais[3], Catherine Bjerum[4], Michael Payne[4], Daniel Tisch[4], John Turmur[1], Ronnie Wakol[1], Christopher L. King[4], Moses Laman[1]

[1]Papua New Guinea Institute of Medical Research (PNGIMR), Goroka, Papua New Guinea, [2]Lancaster Medical School, Lancaster, United Kingdom, [3]East New Britain Provincial Health Authority, Kokopo, Papua New Guinea, [4]Center for Global Health and Diseases, Case Western Reserve University School of Medicine, Cleveland, OH, United States

After two rounds of mass drug administration (MDA) with ivermectin, diethylcarbamazine, and albendazole (IDA) for lymphatic filariasis (LF) elimination, the World Health Organization (WHO) recommends the IDA Impact Survey (IIS) to assess if LF transmission has ceased. This involves population proportional sampling (PPS) of 30 sentinel sites to assess LF infection parameters in those ≥20 years. Model-based geostatistics (MBS) is also recommended if capacity exists, but only some countries have used MBS for IIS. Here we used MBS for IIS sentinel site selection in East New Britain province (ENB), Papua New Guinea (PNG). ENB completed two rounds of IDA MDA in 2019 and 2022, with 82% and 67% epidemiological coverage, respectively. We conducted IIS from June 2023 - February 2024 and examined the impact of MDA on sites (villages) with known high LF infection before MDA. Subsequent selection with MBS prioritized sites whose LF infection probability was most uncertain based on prior data. In selected sites we sampled approximately 110 adults ≥20 years with filarial test strips (FTS) followed by night blood smears for microfilaria (Mf) if FTS positive. We tested 4,164 individuals in 42 sites across ENB. Sites were selected based on prior LF infections (N=10), MBS (N=26), and convenience where MBS villages became inaccessible (e.g. weather, security, etc, N=6). The sampled individuals averaged 38 years old, and 42.8% were male. 193 individuals were FTS positive, with a mean of 4.5%, (95% CI 1.8, 7.2). Fourteen of the 26 MBS sites contained FTS-positive individuals, with two containing Mf positives. Overall, ten Mf positives were identified with a mean Mf positivity across ENB of 0.24%, (95% CI 0.02, 0.45). Two sites exceeded 1% Mf positivity. Thus, MBS selected unrecognized sites of FTS and Mf positivity, mainly in remote areas where LF transmission and poor MDA coverage are more likely. We showed that LF transmission has been interrupted across most of ENB. PPS IIS is now underway, and results can be compared to MBS. We will work with the provincial health authority to administer additional MDA in smaller evaluation units encompassing sites with >1% Mf positivity.

7477

LONGITUDINAL ANALYSIS OF THE PREVALENCE OF MINOR *PLASMODIUM* SPP. INFECTING HUMANS THROUGH SEQUENTIAL INTERVENTIONS IN NORTHERN GHANA

Cecilia A. Rios-Teran[1], Kathryn E. Tiedje[1], Oscar Bangre[2], Samantha L. Deed[1], Dionne C. Argyropoulos[1], Mercedes Pascual[3], Kwadwo A. Koram[4], Patrick Ansah[2], Abraham R. Oduro[2], Karen P. Day[1]

[1]Department of Microbiology and Immunology, The University of Melbourne, Bio21 Molecular Science and Biotechnology Institute and Peter Doherty Institute, Melbourne, Australia, [2]Navrongo Health Research Centre, Ghana Health Service, Navrongo, Ghana, [3]Department of Biology and Department of Environmental Studies, New York University, New York, NY, United States, [4]Epidemiology Department, Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Ghana

Current interventions targeting malaria control are focused on *Plasmodium falciparum*, the major species infecting humans. Despite renewed efforts for malaria elimination in sub-Saharan Africa, little attention has been paid to the neglected parasites, *P. vivax, P. malariae,* and *P. ovale* spp. and the impact of interventions, like indoor residual spraying (IRS), and/or seasonal malaria chemoprevention (SMC) on these minor *Plasmodium* spp. To address this research gap, this study was undertaken to assess the efficacy of IRS and SMC combined with long-lasting insecticidal nets (LLINs), on minor *Plasmodium* spp. infections in an area characterized by high seasonal transmission in northern Ghana. Using an interrupted time-series study, five age-stratified surveys, each of ~2,000 participants, were undertaken at the end of the wet seasons between 2012 and 2022. Across this 10-year study period infections with *P. malariae* and *P. ovale* spp. were detected using a species-specific PCR targeting the *18S rRNA* gene, while no *P. vivax* was detected. In 2015, following IRS, the prevalence of the minor *Plasmodium* spp. declined in all ages, with participants being significantly less likely to be infected with *P. malariae* (1.4% vs. 13.7%) and *P. ovale* spp. (0.4% vs. 5.7%) compared to 2012. Despite this decline, in 2017, 2-years after IRS was withdrawn and SMC was introduced, the prevalence of *P. malariae* (2.9%) and *P. ovale* spp. (4.0%), rebounded 2- and 10-fold, respectively. Finally, when we examined this population in 2020 and 2022 after sustained use of SMC, the prevalence of *P. malariae* continued to increase (7.4% and 5.8%), while the prevalence for *P. ovale* spp. declined (2.6% and 1.3%). The rebound in the minor species was observed in all age groups, except for the younger children (1-5 years) targeted by SMC where no *P. malariae* or *P. ovale* spp. infections were detected in 2017 to 2022. Results show that the transmission of *P. malariae,* and to a lesser extent *P. ovale* spp., were affected by the interventions deployed in Bongo District. However, infections with minor species rebounded following the discontinuation of IRS in the age groups not targeted by SMC.

7478

OPTIMIZING DRUG DISTRIBUTOR PERFORMANCE IN NEGLECTED TROPICAL DISEASE MASS DRUG ADMINISTRATION PROGRAMS; RESULTS FROM A MULTI-COUNTRY EVALUATION

Arianna Means[1], Katy Sharrock[1], Kumudha Aruldas[2], Saravanakumar Puthupalayam Kaliappan[2], Abiguel Belou Elijan[3], Hugo Legge[4], Chawanangwa Mahebere Chirambo[5], Rajeshkumar Rajendiran[2], Chinnaduraipandi Paulsamy[2], Comlanvi Innocent Togbevi[3], Félicien Chabi[3], Euripide Avokpaho[3], Khumbo Kalua[5], Rachel Pullan[4], Robin Bailey[4], Sitara Swarna Rao Ajjampur[2], Moudachirou Ibikounlé[3], Adrian Luty[6], Judd Walson[7]

[1]University of Washington, Seattle, WA, United States, [2]Christian Medical College, Vellore, India, [3]IRCB, Cotonou, Benin, [4]LSHTM, London, United Kingdom, [5]BICO, Blantyre, Malawi, [6]IRD, Paris, France, [7]Johns Hopkins University, Baltimore, MD, United States

Community drug distributors (CDDs) and other similar cadres of lay and professional staff are the backbone of neglected tropical disease (NTD) mass drug administration (MDA) programs. These personnel often volunteer time or receive minimal financial incentive for their work. These individuals are often selected to serve their own communities and are asked to participate in periodic trainings to deliver health promotion and counseling, drug distribution, and adverse event monitoring services. There is minimal information available about the characteristics of CDDs associated with program performance, defined as the proportion of individuals accepting treatment from a CDD when offered. We tracked this information in the DeWorm3 project, a large cluster randomized trial testing the feasibility of interrupting transmission of soil-transmitted helminths (STH) in Benin, Malawi, and India. We documented CDD attributes during six rounds of biannual community-wide MDA and, using electronic data collection, linked CDD attributes to treatment coverage for households assigned to a given CDD. We conducted multivariate logistic regression with an interaction term to determine if treatment refusal varied by gender of participants and

CDDs. We engaged 444 CDDs total (113 in Benin, 57 in Malawi, and 274 in India). CDDs were 35% (Benin), 63% (Malawi), and 87% (India) female. In Malawi, CDDs were professional Health Surveillance Assistants while in Benin the majority (21%) worked in agriculture and in India 41% identified as housewives. In Benin and India, the majority of CDDs were ages 18-29 while in Malawi the majority were older (30-39 years). CDDs were able to reach a range of 15.3 (median) households per day in urban areas of Benin and up to 30.4 (median) in rural areas of Malawi. In Benin, women were more likely to refuse treatment from male CDDs as compared to female CDDs (p=0.03). In Malawi, both men and women were more likely to refuse treatment from male CDDs (p<0.001) as compared to female CDDs. These findings are useful for other NTD programs as they consider opportunities to recruit, finance and plan for CDD engagement and to optimize CDD performance.

7479

ASSESSMENT OF QUALITY OF ONCHOCERCIASIS MASS DRUG ADMINISTRATION, INSIGHTS FROM A COVERAGE SURVEY IN NINE DISTRICTS OF OROMIA REGION, ETHIOPIA

Tewodros S. Mohammed[1], Aderajew M. Abdulkadir[1], Desalegn Jemberie[1], Yewondwossen Bitew[1], Geremew Haileyesus[1], Fanta Nigussie[2], Abdo Aliyi[1], Belay Techan[1], Kedir Abdela[2], Yakub Ragu[2], Husen Abate[2], Anley Haileyesus[1], Zerihun Tadesse[1], Emily Griswold[3], Jenna E. Coalson[3], Gregory S. Noland[3], Kadu Meribo[4], Fikre Seife[4]

[1]The Carter Center, Addis Ababa, Ethiopia, [2]The Carter Center, Oromia, Ethiopia, [3]The Carter Center, Atlanta, GA, United States, [4]Ministry of Health, Addis Ababa, Ethiopia

Onchocerciasis control with community distributed treatment with ivermectin started in 2001 in Ethiopia, with mass drug administration (MDA) expanding to new endemic districts as they are identified until recently. MDA began in nine newly identified districts from 2019 to 2022. Cross-sectional community-based coverage surveys were conducted in the nine districts one month after MDA in 2023 to validate reported MDA coverage, assess service quality, and identify factors affecting ivermectin intake in these new program areas. Two-stage random sampling was used, starting with the random selection of 8 villages per district (72 villages in total). Then, within each selected village, at least 16 households (1,431 households in total) were chosen using systematic random sampling. All household residents were asked whether they took ivermectin during MDA. Overall, surveyed ivermectin coverage was 78% (95% CI 77-79%), with districts ranging from 56% to 86.9%. Three districts reported coverage that was higher than that surveyed by 11% to 26% and 6 districts reported coverage lower than that surveyed by 6% to 7%. Six districts from East and West Hararge zones met the acceptable coverage threshold of ≥80%, but 3 (Girar Jarso and Aleltu of North Shoa zone and Digalona Tijo of Arsi zone) did not. There were high rates of underdosing in Digaluna Tijo (16%) and Aleltu (12%) and high rates of overdosing in Oda Bultum (17%) and Habro (14%) and Melka Belo (13%). Individuals who received health education had 7.6 times the odds of swallowing ivermectin as those who did not (95% CI: 6.6-8.8). In summary, underdosing and overdosing were identified in specific districts, highlighting the importance of quality assurance during MDA campaigns. Health education was strongly associated with ivermectin intake. Based on the observed discrepancies, enhanced training on dosing and reporting for drug distributors is required. Areas of North Shoa and Arsi zones with sub-standard coverage require improvements in both coverage and quality through increased community engagement and empowerment of Community Drug Distributors.

7480

PRODUCTIVITY RETURNS FROM TEN YEARS OF THE KENYAN NATIONAL SCHOOL BASED DEWORMING PROGRAM

Mark Minnery[1], Savannah Newman[1], Andrew Wang[1], Kate McCracken[1], Brett Sedgewick[1], Collins Okoyo[2], Charles Mwandawiro[2], Chrispin Owaga[3]

[1]Evidence Action, Washington DC, DC, United States, [2]Kenyan Medical Research Institute, Nairobi, Kenya, [3]Evidence Action, Nairobi, Kenya

Many areas of Kenya are endemic for soil-transmitted helminths (STH) and schistosomiasis (SCH). Preventive chemotherapy (PC) among school-aged children (SAC) has been applied to endemic counties since 2012 as part of the National School Based Deworming Program (NSBDP). Providing PC to endemic children results in long-term productivity gains. Previous evaluations of PC my underestimate impact of intestinal helminths, as they often only focus on short-term morbidity without addressing productivity. We aim to quantify total productivity gains from the NSBDP and compare them to estimated program cost for a return on investment from 10 years of the NSBDP's operation. We first constructed a deterministic epidemiological model using a series of ordered differential equations to estimate child time-months spent in different intensity classes of STH/SCH, when subject to different levels of PC. The model was calibrated to national prevalence and coverage data with parameters derived from existing literature. An annual 2022 productivity gain range was estimated and assigned to each class of infection. Total cumulative lifetime productivity gains were estimated for averted child-years of infection from the assumed beginning of a dewormed child's productive life to 20 years in the future. Detailed program costing records were consulted to estimate total costs of the program implementation over 10 years. Overall, $1,100,000,000 2023 USD cumulative productivity returns are estimated to be realized 2012 to 2042 due to 10 years of operation (2012-2022) of the Kenyan NSBDP. The total spend on the program was estimated at $27,000,000 2023 USD suggesting a $30 return on investment for every $1. These results are conservative due to a limited time frame, do not include infections averted through reduced environmental contamination, and do not include other avoided costs such as to the health system. They highlight substantial impact which can be achieved through preventing STH/SCH infections in SAC. Deworming in Kenya and in other endemic countries remains a sound investment due to very high returns comparable to many other health and development programs.

7481

MORBIDITY MANAGEMENT OF LYMPHATIC FILARIASIS: STRENGTHENING SURGICAL APPROACHES TO FILARIAL HYDROCELES IN KENYA

Paul Kibati[1], Michael Ofire[2], Patrick Gitahi[1], Victor Omanje[2], University of Nairobi Surgery, Anesthesia, Nursing --[3], Robert Ofwete[2], Sammy Njenga[4], Irene Chami[5], Ivy Sempele[6], Rebecca Nyankieya[5], Wyckliff Omondi[1], Charles Waihenya[7], Sunny Mante[8], Francis Owillah[7], Peter Mungai[7], Julius Kiboi[7]

[1]Ministry of Health, Nairobi, Kenya, Kenya, [2]Amref Health Africa, Nairobi, Kenya, Kenya, [3]--, Nairobi, Kenya, [4]Kenya Medical Research Institute, Nairobi, Kenya, Kenya, [5]END FUND, Nairobi, Kenya, Kenya, [6]END FUND, New York, NY, United States, [7]University of Nairobi, Department of Surgery, Nairobi, Kenya, Kenya, [8]Africa Filariasis Morbidity Project, Accra, Ghana

Lymphatic Filariasis (LF) is prevalent in Kenya's coastal region, where hydrocele cases have been documented. Due to inadequate local capacity to manage hydroceles, the Ministry of Health Neglected Tropical Disease program partnered with Amref Health Africa, the University of Nairobi Department of Surgery, and the African Filariasis Morbidity Project (AFMP) to train local surgeons and medical officers on a new technique involving total excision of the tunica. We sought to evaluate the impact of the training camp and surgical outcomes of treated patients. Community Health Promoters screened and referred patients with scrotal swelling from LF-endemic counties in May and October 2023. Health workers from endemic

counties underwent training modelled on the AFMP protocol. The training incorporated didactic sessions, selecting eligible patients, and practical theatre sessions in 8 health facilities. Follow-up was done upon discharge on day 3 and in the subsequent training camp. Data collected included the number of cases performed, intraoperative findings, and post-operative complications. Descriptive statistics was used to summarize the findings. Overall, 105 health workers underwent training, including 3 urologists, 5 general surgeons, and 33 medical officers. Furthermore, 22 clinical officer anaesthetists and 42 theatre nurses were trained in perioperative management of hydrocele patients. Of 166 referred patients, 111/166 (66.9%) underwent surgery, 70/111 (63.3%) in May, and 41/111(36.9%) in October 2023 respectively. The median age was 58 years (IQR 52.5 years), with 45 (40.5%) having bilateral hydrocele and 30 (27%) presenting with both hernia and hydrocele. All patients with hernias underwent repair in addition to hydrocelectomy. No post-operative complications were noted upon discharge; minimal complications were noted in 2/37(5.4%) followed up after 5 months. All follow up patients self-reported improvement in psychosocial and overall health status. The training camps increased the local capacity of healthcare workers to manage hydroceles. We recommend continued use of the new technique to manage hydroceles.

7482

FACTORS ASSOCIATED WITH FAILING ASSESSMENTS TO STOP MASS DRUG ADMINISTRATION FOR ONCHOCERCIASIS IN KONTA SPECIAL WOREDA, SOUTHWEST ETHIOPIA PEOPLE'S REGION

Desalegn J. Mitiku[1], Aderajew Mohammed[1], Tewodros Seid[1], Yewondwossen Bitew[1], Tekola Endeshaw[1], Geremew Haileyesus[1], Mustefa Abbamilki[1], Yohannes Eshetu[1], Bassa Betela[1], Zerihun Tadesse[1], Emily Griswold[2], Jenna E. Coalson[2], Gregory S. Noland[2], Kadu Meribo[3]

[1]The Carter Center, Addis Ababa, Ethiopia, [2]The Carter Center, Atlanta, GA, United States, [3]Ministry of Health, Addis Ababa, Ethiopia

Mass drug administration (MDA) with ivermectin is the key strategy in the elimination of onchocerciasis in Ethiopia. Community ownership and health education through community drug distributors (CDDs) and community supervisors play a vital role in achieving quality MDA and high coverage. Mapping data from 2000 reported a baseline nodule prevalence of 14.4% in Konta Special Woreda, classifying it as hypoendemic. MDA began in 2015. This district is surrounded by endemic districts of Kaffa, Jimma and Dawuro zones, all bordering the Gojeb river. An impact assessment in 2020 found 1% prevalence of Ov16 antibodies by ELISA, prompting a full stop-MDA evaluation in 2022. The stop MDA survey tested 3,200 children 10 years of age and under. With 23 Ov16 positives (0.7%), the woreda failed to meet the stop-MDA threshold of <0.1%. While MDA continued, the program conducted a retrospective investigation into factors that might have contributed to the failure by evaluating data from MDA coverage surveys conducted in the woreda in 2019 and 2022. Two-stage cross-sectional community-based surveys were done to assess MDA coverage and other CDTI activities. In 2019, from the total 697 participants, 535 were treated with therapeutic coverage of 76% (95% confidence limits [CL] 73-79%), which was lower than the recommended 80%. Of untreated eligible people, 78 (46%) participants in 2019 and 25 (28%) of participants in 2022 were not treated due to absenteeism. From total 127 household (HH) participants in 2022, 22 (14%) of the HH heads participated in MDA site selection. Community participation in CDD selection declined from 2019 (24%) to 2022 (15%). Of those treated in 2019 and 2022, 50 (9%) and 72 (15%) of participants, respectively, did not have their height measured for dosing, and 144 (16%) and 155 (31%) did not get the right dose. The program should work on strengthening community participation in MDA activities as well as focus on overall program quality and responsiveness. Since the district has high density of *Simulium damnosum* along the Gojeb river, further epidemiological and entomological investigation could identify hotspots for special intervention.

7483

OPTIMIZATION APPROACHES FOR INTEGRATION OF NEGLECTED TROPICAL DISEASES INTO HEALTHCARE SYSTEMS IN KENYA

Lenson Kariuki

Ministry of Health-Kenya

Kenya strategy for incorporating Neglected Tropical Diseases (NTDs) into its healthcare systems reflects a notable departure from previous practices, aiming for sustainability and self-reliance in combating these ailments. By adhering to WHO guidelines and aligning with Kenya's health agenda, the country has taken proactive measures to ensure that NTD programs are efficiently managed and seamlessly integrated into existing healthcare structures. A crucial aspect of this integration involves transitioning from isolated approaches to a more comprehensive one. Through the utilization of WHO's health system building blocks and alignment with Kenya's Bottom-up Economic Transformation Agenda (BETA), the Ministry of Health – NTD Programme has facilitated the provision of comprehensive NTD treatment and care by integrating it into the Social Health Insurance Fund (SHIF). This was by engaging the health financing and SHIF team in an NTD costing workshops. This transition not only secures sustainable funding but also underscores the importance of embedding NTD interventions within broader healthcare frameworks. Furthermore, involving implementing and development partners in integrating NTD indicators into Kenya Health Information Systems (KHIS) exemplifies a commitment to evidence-based decision-making and transparency. To improve the timely referral of suspected NTD cases by Community Health Promoters (CHPs) and to ensure efficiency, accountability, and effective supervision during mass drug administration, the NTD program has integrated essential indicators into electronic Community Health Information System (eCHIS) platform which feeds into KHIS. This integration facilitates better monitoring and evaluation of NTD interventions while ensuring efficient resource allocation. Additionally, integrating NTD components into the country's community health strategy training modules and formulating a draft integrated vector management strategy showcases a multifaceted approach to disease control. By bolstering vector surveillance and control in collaboration with other health programs like the National Malaria Program, Kenya is optimizing resources and addressing the interconnected nature of vector-borne diseases. The accomplishments described above have been made possible through the strict adherence to a well-designed NTD coordination framework, which serves as a guiding document for the coordination of NTD integration efforts throughout Kenya.In summary, Kenya's integration approach serves as a model for other nations seeking to incorporate NTD interventions into their healthcare systems. By prioritizing sustainability, efficiency, and collaboration, Kenya is well-positioned to accelerate progress toward NTD elimination and eradication goals, all while alleviating strain on health systems, especially amidst reduced external financing.

7484

EMPOWERING WOMEN IN BIHAR, INDIA TO ELIMINATE LYMPHATIC FILARIASIS

Rajshree Das, Kiran Agrahari, Sudipta Mondal

Project Concern International-India, New Delhi, India

Lymphatic Filariasis (LF) poses a significant threat to Bihar, India, affecting over 130 million individuals across its 38 districts. Administering anti-LF drugs through Directly Observed Therapy (DOT) to the eligible 120 million population is a formidable task. Leveraging the State Rural Livelihood Mission's (SRLM) network of 11.6 million women's collectives (Self-Help Groups - SHGs), which touch every other household in rural Bihar, presents a promising solution. A pilot study in 2023 demonstrated the efficacy of SHG platforms, with SHG members exhibiting a 74% DOT compared with 45% among non-SHG members. Building on this success, in February 2024, 24 districts with 6.3 million SHG members were targeted for Mass Drug Administration (MDA). Prior to MDA, SHG members were educated on LF and MDA during their weekly meetings, to disseminate information

to their families and communities. The SHGs were engaged in various awareness activities, including discussions, oath-taking ceremonies, slogan competitions, and community rallies, fostering preparedness for anti-filarial drugs at the household level. Post-MDA, SRLM reported a 66% drug consumption rate among SHG members, contributing to a 6% increase in DOT overall. Further assessment of the intervention revealed that SHG households exhibited a 40% higher unadjusted DOT compared to non-SHG households. Within the SHG network, community mobilizers played a crucial role, increasing the odds of DOT compliance by 12 times (OR: 12.07, p: 0.00, 95% CI: 3.4-42.7) when promoting MDA activities. Moreover, timely information delivery (received 10-20 days before MDA), doubled the odds of DOT (OR: 2.52, p: 0.04, 95% CI: 1.2-2.1). This success underscores the potential of SHGs in enhancing anti-filarial drug compliance and aiding LF elimination efforts. Leveraging millions of women's networks could serve as a model for other endemic regions, amplifying outreach and impact. To mainstream women's involvement in LF elimination, capacity-building initiatives for SRLM staff and cadre could be implemented by health departments.

7485

STATUS OF LYMPHATIC FILARIASIS TRANSMISSION IN PASTORALIST AREAS OF SOUTH AND SOUTHWEST ETHIOPIA

Mustefa Abbamilki Abbabulgu[1], Aderajew A. Mohammed[1], Zerihun Tadesse[1], Anley Haile[1], Yohannes Eshetu[1], Daniel Tamrat[1], Habtamu Haile[1], Nigusse Haile[1], Jenna Coalson[2], Emily Griswold[2], Desalegn Jemberie[1], Fedlu Yasin[1], Gedefaw Ayenew[1], Addisu Sahile[1], Yewondwossen Bitew[1], Geremew Haileyesus[3], Tewodros Seid[3], Gregory Noland[2]

[1]The Carter Center, Addis Ababa, Ethiopia, [2]The Carter Center, Atlanta, GA, United States, [3]The Carter Center, Addis Ababa, GA, United States

Lymphatic filariasis (LF) is targeted for global elimination through treatment of endemic populations with annual mass drug administration (MDA). WHO guidelines call for a transmission assessment survey (TAS) after at least five effective MDA rounds to determine if MDA can be stopped. LF commonly affects pastoralist areas and tends to be persistent since these areas are often hard to reach and have low access to and coverage of MDA. Five rounds of MDA were conducted in pastoralist areas of South and West Omo zones in Ethiopia between 2018 and 2022 with reported average coverage of >81% in all districts, achieved through close follow-up, monitoring, and support with expanded house-to-house attention by community directed distributors (CDDs) given the nomadic nature of the populations. Pre-TAS and TAS1 were conducted in 2023 in pastoralist communities of eligible districts of South and Southwest Ethiopia regional states. Pre-TAS involved sampling ~300 people aged 5 and older in each of sentinel and spot-check communities per evaluation unit (EU) in Hammer, Turmi, and Selamago districts. TAS-1 involved community-based surveys to sample children aged 6-7 years cluster sampled in 322 villages from 570 total villages in pastoralist woredas in South Ari, Surma, Hammer, Turmi, and Selamago districts. Samples were tested for LF antigen by Filarial Test Strips (FTS), and survey data were collected electronically with open data kit software. Pre-TAS included 1,939 FTS results, of which there was one positive from Hammer and one from Selamago. The prevalences in Hammer (0.15%), Selamago (0.15%), and Turmi (0%) were all less than the WHO threshold of 1%, and the EUs proceeded to TAS-1. TAS-1 included FTS results for 4,164 children, of which all were negative. LF transmission has been successfully reduced below sustainable levels such that MDA can be stopped in South Ari, Surma, Hammer, Turmi, and Selamago districts, with ~339,206 people at risk. This reflects the success of program implementation for these hard-to-reach pastoralist populations, though strong post-treatment surveillance is required to ensure that transmission does not recrudesce.

7486

OUTCOME OF SNAKEBITE VICTIMS MANAGED BY TRAINED HEALTH ASSISTANTS AT A SNAKEBITE TREATMENT CENTER IN NEPAL

Aarjav Sharma[1], Arun Gautam[1], Urza Bhattarai[1], Srista Manandhar[1], Sunit Chhetri[1], Rohan Basnet[1], Aakriti Sapkota[2], Khem Adhikari[3], Sanjib K. Sharma[1]

[1]BP Koirala Institute of Health Sciences, Dharan, Nepal, [2]Damauli Hospital, Vyas, Nepal, [3]Sankebite Treatment Center, Damak, Damak, Nepal

Snakebite envenoming is a neglected tropical disease. The World Health Organization (WHO) roadmap on snakebite envenoming targets snakebite related death reduction to 50% by 2030. Strengthening the health system is one of the four pillars of WHO snakebite strategy for snakebite prevention and control. Unfortunately, skilled physicians are scarce in the areas where snakebite is prevalent. Empowering health assistants (HA) for task sharing to manage snakebite may help prompt management of snakebite and reduce mortality. The aim of this study is to evaluate the outcome of snakebite cases managed by trained HAs at a snakebite treatment center. The study is a fifteen years (2008 AD to 2023 AD) retrospective audit of outcome of snakebite victims from a snakebite treatment center, Damak Red Cross, Damak, Nepal. A six-week training course organized for Health Assistant, to identify the features of envenomation, management, early identification of adverse reactions to anti-venom and need of referral were the focus of the training. Management of snakebite cases were done as per protocol provided by Ministry of Health and Population, Nepal. Anti-venom and other essential medicines were made available by the center itself. Six HA received training in 1998. Two to four days reinforcement of training was provided in subsequent years. HA had access to telephonic consultation with a faculty of medicine at B.P. Koirala Institute of Health Sciences. All records were kept in a structured case record and outcomes were analyzed using SPSS Version 26. A total of 30 HAs were trained. A total of 15,513 snakebite cases were managed in the center. Among the envenomation cases, neurotoxicity was the predominant manifestation. Majority of snakebite victims improved (98.4%), with a low referral rate (0.6%), and case fatality rate (1.2%). Mortality was found to be lower in comparison to national figures and other centers managing snakebite. Structured training and task sharing with paramedics may contribute to reduction in snakebite-related death.

7487

GENDER AND AGE MODULATING THE HEMATOLOGICAL PROFILES OF LEPROSY PATIENTS: ADISCURSIVE ANALYSIS

Daisy Monteiro[1], Anabella Almeida[1], Jose Neto[1], **Lorena Bruna Pereira de Oliveira**[2], Pedro Marcal[2], Marcos Pinheiro[2], Alexandre Castelo Branco[3], Jessica Fairley[4], Lucia Fraga[1]

[1]UFJF/GV, Governador Valadares, Brazil, [2]Universidade Vale do Rio Doce, Governador Valadares, Brazil, [3]Centro de Referencia em Doenças Endêmicas e Programas Especiais, Governador Valadares, Brazil, [4]Emory University, Atlanta, GA, United States

Leprosy is a chronic infectious disease characterized by slow progression. Theobjective of this study was to analyze how age and sex can modify hematological data,as well as plasma levels of Vitamin A and D in patients with leprosy. The study groupcomprised 77 patients, being 44 (57,14%) males, diagnosed at the Reference Centerfor Endemic Diseases and Special Programs (CREDEN-PES/SMS/GV) in GovernadorValadares, eastern Minas Gerais, Brazil, age between 5 to 86 years old and exhibitingclinical forms classified as Paucibacillary (PB) and Multibacillary (MB) according to theWHO's operational classification. Mean values, standard deviations, and confidencelimits were stratified by age group and by gender. Significant differences were observedin the global leukocyte count in both genders (males - p=0.047 and females p=0.043),with higher values observed between 5-30 years old, with significant differences forglobal lymphocyte count (p-0.025) and basophils (p=0.028) only in males, with highervalues between 2-20 years and lower values between

31-40 years. Hematologicalvalues for RBC, hemoglobin and hematocrit were significantly higher in males (p<0.001)than in females. Age significantly modulated only the hematocrit (p=0.033) in males,while it significantly modulated the values for Hgb (p=0.041), HCT (p=0.037), MCV(p=0.015) and MCH (p=0.007) in females. Age significantly modulated the absoluteplatelet count only in males, with higher values between 21-30 and lower valuesbetween 41-50 years. Age significantly modulated only vitamin A values, this beingsignificant only in females (0.016), with the lowest levels between 5-20 years old. Thesefindings underscore the importance of considering variables such as age and gender inthe interpretation of hematological results in leprosy patients. However, further studiesare needed to better understand these differences and their clinical impact on diseaseprogression and management.

7488

SPATIOTEMPORAL DISTRIBUTION AND DIVERSITY OF AIRBORNE RESISTANT BACTERIA: AN EXPLORATORY ONE HEALTH STUDY IN THE URBAN AND RURAL ENVIRONMENTS OF BANGLADESH

Muhammad Asaduzzaman

Foundation for Advancement of Innovations in Technology and Health (faith), Dhaka, Bangladesh

Antimicrobial resistance (AMR) is a widespread One health issue with planetary impacts. However, there is dearth of knowledge and scientific evidence on the magnitude of resistant bacteria in air and their transmission pathway. Therefore, an exploratory observational study in Bangladesh was conducted to quantify the clinically significant drug resistant bacteria in air with their spatial diversity. This study employed the collection of air samples from both urban and rural settings in four distinct environments – i) Urban live bird markets (LBM) ii) Urban residential area (URA) iii) Commercial poultry farms(CPF) and iv) Rural households (RHH). MacConkey agar supplemented with 3rd generation cephalosporin (3GC) and meropenem respectively was used to obtain 3GC resistant (3GCr) and carbapenem resistant *Enterobacteriaceae* (CRE). Mannitol Salt agar supplemented with oxacillin and Slanetz-Bartley medium supplemented with vancomycin were utilized to obtain Methicillin (Oxacillin) resistant Staphylococci (MRS) and Vancomycin resistant Enterococci (VRE). The bacterial identification and susceptibility testing were conducted by VITEK 2 system. The presence of 3GCr, CRE, MRS and VRE in 85%, 60%, 100% and 80% air samples was observed respectively. 3GCr, CRE and MRS were highest in CPFs and VRE in LBMs. The abundance (>90%) of MRS, VRE and 3GCr in URA is alarming whereas the air samples from RHHs were heavily burdened with 3GCr and MRS (60-100%). The CRE in poultry environment also establishes the threat added by current farm practice. The diversity and richness of resistant organisms were measured by Shannon diversity index, which was higher in both seasons at LBMs and CPFs (H-2.17-2.21 and H-1.99-2.03 respectively). Considering the organism family, the major bacteria were Staphylococcaceae (35%), Pseudomonadaceae (20%), Enterobacteriaceae (15%), Moraxellaceae (10%), Lactobacillaceae (7%) and Enterococcaceae (6%). This study findings emphasize on the inclusion of air in the system approach and surveillance to tackle AMR due to its high potential for acting as both reservoir and medium of spread of resistance.

7489

FINDINGS FROM A SIMULATION EXERCISE UTILIZING THE ONE HEALTH TRANSBOUNDARY ASSESSMENT FOR PRIORITY ZOONOSES (OHTAPZ) TOOL TO MEASURE HEALTH SECURITY PREPAREDNESS, DETECTION, AND RESPONSE CAPACITIES AT THE JORDAN-IRAQ BORDER

Alanna S. Fogarty[1], Alexander G. Linder[1], Aishwarya Nagar[1], Kathryn M. Hogan[1], Rachel R. Vahey[1], Benjamin Wakefield[1], Rachel Dodeen[2], Majed Hawaosha[2], Nour A. Elizz[2], Ibtehal Khreesha[2], Alaa Hamdallah[3], Bilal Shtaiyat[4], Ekhlas Hailat[5], Karim M. Al Zadawi[6], Mohammed J. Ahmed[7], Aso Zangana[8], Sinan G. [1]Johns Hopkins University, Baltimore, MD, United States, [2]Ministry of Agriculture, Amman, Jordan, [3]Ministry of Health, Amman, Jordan, [4]Jordan Center for Diseases Control, Amman, Jordan, [5]Consultant, Amman, Jordan, [6]Consultant, Baghdad, Iraq, [7]Ministry of Health, Baghdad, Iraq, [8]Ministry of Health, Erbil, Iraq, [9]Ministry of Agriculture, Baghdad, Iraq, [10]Ministry of Agriculture, Baghdad, Jordan, [11]Georgetown University, Washington, DC, United States

Strengthening global health security efforts for the prevention, detection, and response to transboundary zoonotic diseases (TZDs) within and between nations requires multisectoral and multilateral approaches. The One Health Transboundary Assessment for Priority Zoonoses (OHTAPZ) tool is a published methodology that engages human, animal, environmental, and border health stakeholders at various levels to assess and prioritize One Health (OH) capacities at points of entry (POEs), where the exchange of people, livestock, goods, and infectious diseases often takes place. The OHTAPZ tool, which encourages bilateral collaboration between two neighboring nations; includes the development of an agreed joint list of priority TZDs; stakeholder mapping through an interactive tabletop exercise; and completing a POE self-assessment which provides a baseline of the current OH capacities at the POEs assessed. Through implementation of the methodology in Jordan and Iraq, our team at Johns Hopkins University then conducted a simulation exercise (SimEx) that tested the self-evaluated OH capacities at each POE. The SimEx assessed current preparedness and response communication and coordination mechanisms within and between the formal land border POEs for during a TZD event, resulting in not only the first bilateral assessment of OH capacities across formal land borders in Jordan and Iraq, but also demonstrating this methodology fills an important role in the global health security research and practice spheres.

7490

PHARMACOKINETIC PROPERTIES AND MOSQUITO-LETHAL EFFECTS OF A NOVEL LONG-LASTING FORMULATION OF IVERMECTIN IN CATTLE

Piyanan Assawasuwannakit[1], Kevin Kobylinski[1], Karine Mouline[2], Sié Hermann Pooda[3], Roch Dabiré[4], Sophie Le Lamer-Dechamps[5], Richard Hoglund[1], **Joel Tarning**[1]

[1]Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand, [2]Université de Montpellier, Montpellier, France, [3]Université de Dédougou, Dédougou, Burkina Faso, [4]Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, [5]MedinCell, Montpellier, France

Ivermectin is an antiparasitic drug, used in human and animals for decades. It has recently been developed as a novel vector control tool for malaria as ivermectin-treated humans and animals are lethal to blood-feeding *Anopheles* mosquitoes. The aim of this work was to characterise the population pharmacokinetic (PK) and pharmacodynamic (PD) properties of a newly developed long-acting ivermectin formulation (BEPO® technology) in cattle. Two PK studies were conducted in Burkina Faso (Study 1: n=20 and Study 2: n=24). Plasma samples were shipped to Thailand for drug quantification by LC-MS/MS and for membrane feeding mosquito-killing evaluations. Plasma samples were mixed with fresh red blood cells obtained from cattle for mosquito feeding experiments. Only ivermectin and one major human metabolite (M1) were detectable in plasma samples and combined with mosquito mortality data, and evaluated using population PK/

PD modelling (i.e. nonlinear mixed-effects modelling; NONMEM). Specific emphasis was placed on characterising the absorption properties of this novel formulation. Mosquito mortality was modelled using a sigmoidal Emax model. A three-compartment disposition model for ivermectin and a two-compartment disposition model for M1 were used to describe the observed drug concentration data. The final population PK model adequately described the dual absorption processes of fast and slow first-order absorption after subcutaneous injection. The estimated IC_{50} of ivermectin and its metabolite was 12.9 nmol/L for *Anopheles dirus* mortality and 1.48 nmol/L for *Anopheles minimus*. The developed novel formulation demonstrated sustained mosquito mortality after a single injection. Translational simulations were also conducted to inform a prospective first-in-human clinical study. Body weight-scaled doses used in cattle (0.6, 1, 1.5 mg/kg) were predicted to result in sustained ivermectin exposure and sustained *dirus* and *minimus* killing for >35 days and >90 days, respectively, after a single injection. This could be a promising novel tool for transmission blocking of malaria and for the treatment of NTDs in humans.

7491

MOLECULAR CHARACTERIZATION AND PHYLOGENETIC ANALYSIS OF BOVINE *FASCIOLOSIS* IN UPPER EAST REGION, GHANA

Abraham Anane[1], Francis Addy[2], Ebenezer Nartey[3], Osman Dufailu[4]

[1]Department of Virology, Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, [2]Department of Biotechnology, Faculty of Biosciences, University for Development Studies, Tamale, Ghana, [3]Department of Ecological Agriculture, School of Agriculture, Bolgatanga Technical University, Bolgatanga, Ghana, [4]Department of Microbiology, Faculty of Biosciences, University for Development Studies, Tamale, Ghana

Fascioliasis, a disease transmitted between animals and humans, is caused by liver flukes. The primary cause of this ailment are two species: *Fasciola gigantica* and *F. hepatica*. These parasites can have a severe impact on both public health and the livestock industry due to their prevalence. To understand the occurrence and genetic properties of these *Fasciola* parasites in the Upper East Region of Ghana, a study was conducted. The research involved examining 246 cattle from this region to determine the presence of *Fasciola* infections. The scientists utilized the polymerase chain reaction (PCR) technique and sequenced a specific portion (290 bp) of the nad5 gene. The findings revealed that around 23.58% (58 out of 246) of the cattle were infected with Fasciola. However, after analyzing the data, no significant correlation (with a p-value greater than 0.05) was found between Fasciola infection and the animals' gender or age. Interestingly, a noteworthy and statistically significant relationship (with a p-value of less than 0.001) was discovered between Fasciola infection and the animals' body condition scores (BCS). When the obtained DNA sequences were compared using the BLAST tool, it was confirmed that the isolated *Fasciola* specimens belonged to the *F. gigantica* species. Five distinct haplotypes were identified, with one haplotype showing similarities to those found in Niger's haplogroups. Notably, two of these haplotypes were previously undocumented.

7492

POSITIVE ASSOCIATION OF ORAL INFECTION BY *TRICHOMONAS TENAX* WITH PERIODONTITIS IN THE DOMESTIC DOG

Maurice A. Matthew, Chaoqun A. Yao, Jennifer Ketzis, Samson Mukaratirwa

Ross University School of Veterinary Medicine, Basseterre, Saint Kitts and Nevis

Trichomonas tenax, an anaerobic protozoan, colonizes the oral cavities of humans and animals, particularly in individuals with compromised oral hygiene and periodontal disease. Transmission occurs through droplet spray, kissing, or exposure to contaminated utensils and water. The established association between *T. tenax* and periodontal disease in humans is noteworthy, given the global prevalence of this inflammatory condition leading to tooth loss, impaired chewing function, aesthetic concerns, social disparities, and reduced quality of life. In humans, periodontal disease ranges from 1-57%, while in domestic dogs, it varies from 15-25%. Recognized as a parasite and potential zoonotic agent, *T. tenax* raises concerns about cross-species transmission between humans and their pet dogs. This study aims to correlate *T. tenax* infection with periodontal disease in domestic dogs by comparing its prevalence in dogs with periodontitis to that in healthy dogs. Oral swabs were collected from the gumline of dogs on St. Kitts between October 2023 and January 2024. A total of 50 samples underwent microscopy for *T. tenax* detection. The dogs were categorized into healthy (Stage 0-1, with or without gingivitis) and diseased (Stage 2-4, with periodontitis) groups based on periodontal disease severity. Three swabs were obtained from each dog: two for culture using the classic Diamond media and a newly modified Diamonds media, and one in alcohol for LAMP. *T. tenax* was detected in 14% of all dogs (7/50), specifically, 33% prevalence in the diseased group (7/21) compared to 0% in the healthy group (0/29). Statistical analysis revealed a significant association between *T. tenax* presence and diseased dogs (P=0.0008). The newly modified media exhibited greater sensitivity, detecting 14% of samples (7/50), compared to the classis Diamonds media, which detected only 2% of samples (1/50, P=0.0270). Subsequent LAMP analysis of alcohol-preserved samples will further compare the prevalence and sensitivity of the two detection methods, contributing valuable insights to the observed statistical significance between periodontitis and *T. tenax* infection in mouth.

7493

BEHAVIORAL AND BIOLOGICAL SURVEILLANCE OF EMERGING INFECTIOUS DISEASES AT THE HIGH-RISK HUMAN-ANIMAL INTERFACE IN BANGLADESH

Ariful Islam[1], Shusmita Dutta Choudhury[2], Josefina Abedin[2], Monjurul Islam[2], Emily Hagan[3], Shahanaj Shano[2], Mohammed Ziaur Rahman[4], Tahmina Shirin[2], Meerjady Sabrina Flora[2], Leilani Francisco[3], Peter Daszak[3], Jonathan H Epstein[3]

[1]EcoHealth Alliance, Dhaka, Bangladesh, [2]Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh, [3]EcoHealth Alliance, New York, NY, United States, [4]One Health laboratory,International center for diarrheal disease research (icddr,b), Dhaka, Bangladesh

Human-animal interactions are the key drivers of zoonotic spillover, highlighting the better understanding of human behaviors to mitigate disease emergence at high-risk communities. Hence, we conducted an integrated biological and behavioral surveillance to detect novel and known zoonotic viruses in potential high-risk populations and identify risk factors for viral spillover in Bangladesh. Between 2017 and 2019, we enrolled a total of 1106 participants for behavioral interviews at three communities and one hospital site. We obtained biological specimens (throat swab, rectal swab, urine, and blood) from 862 participants and tested for coronaviruses, filoviruses, flaviviruses, influenza viruses, and paramyxoviruses using pan (consensus) RNA Virus assays. Overall, 64/862 (7.4%) tested positive for viral families including influenza viruses (51.6%), coronaviruses (20.3%), flaviviruses (12.5%), and paramyxoviruses (15.6%). Participants reported highly contact with poultry (92.4%) and domestic animals (74.6%) comprising raising, handling, slaughtering, scratched or bitten. A significant percentage of participants also reported consuming sick animals' meat (44.3%) and raw meat (5.9%). In case of wild animal, participants had high level of rodent contact (92.5%) and having rodent feces near their food (75.9%), followed by 6.3% contact with bat hunting and processing. Moreover, 17.5% of participants kept the bitten or scratched wound open. Lasso regression model revealed that most salient risk factors of self-reported influenza-like illness (ILI) in the past year were slaughtering animals, had contact with poultry, scratched or bitten by animals and most prominent protective factors were living in urban areas having a smaller family (less than 5 person). The findings underscore the significant level of interaction between humans, livestock, and wildlife in communities, which might lead to transmit emerging pathogens in Bangladesh. We recommend One health surveillance and to develop targeted interventions to mitigate the risk of zoonotic disease spillover at animal-human interface in Bangladesh.

7494

MYCOBACTERIUM AVIUM SUBSP. *PARATUBERCULOSIS* AND MICROBIOME: A ONE HEALTH CONCERN

Wisal Abdalrahman Abdalwahab Elmagzoub[1], Sanaa Idris[1], Marwa H.E Elnaiem[2], Maha Isameldin[3], Nassir Arabi[4], Abdelmonem Abdo[5], Mustafa Ibrahim[6], Md Anik Ashfaq Khan[1], Franziska Tanneberger[1], Mohamed E. Mycobacterium avium subsp. *paratuberculosis* (MAP) causes the notifiable disease in ruminants, Johne's disease, or paratuberculosis (PTB). Besides, it is a potential zoonotic pathogen as it is implicated in inflammatory bowel disease and many other chronic conditions in humans. Also, MAP is thought to change the gut microbiome, which in turn is connected to some MAP- linked diseases. Animal health and welfare, economic impacts and public health concern are key drivers of PTB control; however, such programmes are costly and hindered by lack of sensitive diagnostics. Microbiome could serve as footprint for MAP infection and/disease; indeed, it could be targeted to control MAP- attributed inflammation. A dairy cattle herd with history of clinical PTB was investigated by serology and molecular detection of MAP in the faeces for 10 months. Also, 103 faecal samples were obtained from patients with chronic gastrointestinal conditions after they consented to participate. Faecal metagenomic analysis was performed using Oxford Nanopore Sequencing Technology. All animals were positive in MAP test(s) except two, while in humans, MAP DNA was detected in 8.7% and MAP was isolated from 28.2%. Most species were depleted from faecal microbiome of MAP positive subjects. In MAP- positive patients, firmicutes and proteobacteria dominated and the colitogenic bacteria, *Klebsiella pneumoniae*, was enriched. In animals, firmicutes and bacteroidetes were highly enriched with a small contribution of proteobacteria. Furthermore, animals with increasing frequency of MAP positivity showed comparable microbial content. Overall, richness and evenness indices decreased with increasing MAP positivity rate. These findings reflect a potential influence of MAP on faecal microbiome, also, demonstrated the unique microbiome of the animals progressively shed MAP in their faeces, the highly infectious animals. This of significance in control such zoonotic pathogen, thus remains for further investigations.

7495

ONE HEALTH AWARENESS, INTERPRETATION AND PRIORITIZATION IN THE GAMBIA: A PARTICIPATORY SITUATIONAL ANALYSIS OF NATIONAL STAKEHOLDERS ACROSS GOVERNMENT, ACADEMIA AND CIVIL SOCIETY

Tessa Rose Cornell[1], Edrisa Nyassi[1], Abdou Ceesay[2], Ousman Ceesay[2], Eric Maurice Fèvre[1]

[1]Institute of Infection, Veterinary and Ecological Sciences (IVES), University of Liverpool, Liverpool, United Kingdom, [2]Department of Livestock Services, Ministry of Agriculture, Livestock and Food Security, Abuko, Gambia

The Gambia currently lacks active and coordinated One Health (OH) institutional frameworks or a national strategic plan. Despite the formation of multisectoral task forces *ad hoc* in response to national health emergencies, OH activities remain siloed within a group of governmental and academic bodies, and have lacked the momentum, resources, cross-sectoral engagement and political will to operationalise OH in a sustainable and equitable manner. At the community level, OH beneficiaries are mostly excluded from stakeholder exercises. This study identified national OH stakeholders across government, academia, health agencies and civil society. Semi-structured interviews and focus group discussions were conducted with engaged stakeholders at national and regional levels. Inductive thematic analysis was conducted to identify themes relating to OH interpretation, awareness, prioritisation and operationalisation in The Gambia. Study outcomes were rapidly disseminated to stakeholders at an in-person meeting and in a policy briefing document. Interconnected themes were identified relating to: awareness of the OH concept; OH definition in the context of the participants' working, study or community environment; national activities or frameworks related to OH; community, regional and national level collaborations between OH stakeholders; OH priority areas; and barriers and solutions to OH operationalisation. Awareness levels of the term OH were variable between stakeholder groups, with overall low awareness demonstrated by community and student groups. Upon explanation of OH, the majority of stakeholders successfully related the concept to their diverse working, study or community environments. Between sectors and disciplines, and varying levels of society, shared and diverging OH interpretations, awareness levels, priority areas and challenges were demonstrated. This study provided novel evidence of OH awareness and prioritisation in The Gambia, which could be used to inform OH participatory research activities, policies and national frameworks.

7496

BRUCELLOSIS SEROPREVALENCE AND RISK FACTORS AMONG HIGH-RISK GROUPS AT TWO URBAN SITES IN KENYA

Esra Buyukcangaz[1], Bethel Bayrau[1], Ananya Pinnamaneni[1], Caroline W. Ichura[1], Francis M. Mutuku[2], Bryson A. Ndenga[3], A. Desiree LaBeaud[1]

[1]Stanford University, Stanford, CA, United States, [2]Department of Environmental and Health Sciences; Technical University of Mombasa, Mombasa, Kenya, [3]Center of Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

Brucellosis is a zoonotic bacterial disease that can affect humans and animals. It is often transmitted to humans through the consumption of contaminated animal products or by direct contact with infected animals. In Kenya, data on human and animal brucellosis are limited. To investigate the seroprevalence of human brucellosis in Kenya, we randomly selected from the participants had possible animal exposure and tested 348 out of 2,779 human blood samples, from a longitudinal cohort study of dengue and chikungunya exposure in western (Kisumu) and coastal (Ukunda) Kenya. The inclusion criteria consisted of those who demonstrated positive responses to any of the following risk factors: ownership of livestock or ruminants, usage of raw animal blood, consumption of raw milk (either fresh or fermented), involvement in animal butchering, and providing of animal care. Our study included 126 males (36%), 222 females (64%) in

different age categories, and 61 children aged 16 years and younger (18%), with an overall median age of 29.5 years [2 -75-year age range]. Samples were tested by Abnova Brucella IgG ELISA Kit (KA0954). Of the tested individuals, anti-Brucella IgG antibodies were detected in 96 (28%) in 348 randomly selected participants. Brucella exposure was not associated with study site, gender, age, socioeconomic status, specific livestock ownership (cattle, goats, and sheep), or consumption of raw animal products. Highly educated individuals were more likely to have brucella exposure (OR = 2.02, 1.20-3.41, *P = 0.01)*. In comparison to previous seroprevalence-based studies conducted in non-pastoral Kenyan communities, our study revealed significantly higher seropositivity. This study highlights the neglected significance of brucellosis exposure among urban human populations in Kenya, which could serve as a baseline to guide future research on brucellosis in humans.

7497

THE HIGHEST MPOX OUTBREAK EVER REPORTED IN CAMEROON; THE CASE OF MBONGE HEALTH DISTRICT OF THE SOUTH WEST REGION: A CROSS SECTIONAL ANALYTICAL STUDY, JUNE 2023.

Keka Fredrick Chi[1], Agwe S. Mbah[1], Eko F. Eko[1], Daonyle V. Ndassi[1], Linda E.[2], Priscilla Anya[2], Georges E. Mballa[2], Moctar M. Mouiche[3], Patricia Mendjime[2]

[1]South West Regional Delegation of Public Health, Buea, Cameroon, [2]Ministry of Public Health, Yaounde, Cameroon, [3]United States Agency for International Development, Yaounde, Cameroon

Human mpox is a viral zoonotic disease endemic in Central and West Africa. On May 10th 2023, a laboratory confirmed case was notified in the South West Region. We conducted an investigation to assess the outbreak. We carried out a cross-sectional analytical study in Mbonge District from May 15th to June 3rd 2023. Community-health-workers and leaders were engaged after being trained on simplified case definitions, active case search and sensitization. We reviewed registers in five major hospitals. A suspected case was anybody in Mbonge District between April 19th and May 14th 2023 with acute fever >38.3°C, headache, lymphadenopathy, followed after one to three days by maculopapular rash. Swabs and blood samples were collected from suspected cases. A line-list for all suspected and confirmed cases was analyzed for descriptive epidemiology and binary logistic regression for associated factors. We identified 48 suspected cases of which 15(31,2%) were confirmed positive, 8(53,3%) were Clade-II. Amongst confirmed cases, 7(46,6%) were females and median age was 33 years, [3-52]. Persons who spent at least two-weeks in the bush had four times the likelihood of getting mpox (P:0,007, C.I [0,006 - 0,443]). Sensitization on preventive measures while in the bush and engagement of community actors in a crisis zone remains vital.

7498

SURVEILLANCE AND HOME RANGE ANALYSIS OF OLIVE BABOONS TO INFORM PROGRAMMATIC DECISIONS FOR GUINEA WORM ERADICATION IN GAMBELLA, ETHIOPIA

Alexandra Sack[1], Fitsum Alemayehu[2], Misgana Amenu[3], Kassahun Demissie[4], Yimer Mulugeta[4]

[1]The Carter Center, Atlanta, GA, United States, [2]The Carter Center Ethiopia, Addis Ababa, Ethiopia, [3]Ethiopian Wildlife Conservation Authority, Addis Ababa, Ethiopia, [4]Ethiopian Public Health Institute, Addis Ababa, Ethiopia

The first Guinea worm infection in Olive baboons (*Papio anubis*) in Ethiopia was reported in 2013. Since then, questions have been raised about the role of Olive baboons in ongoing Guinea worm transmission among both humans and domestic dogs in Ethiopia. In support of eradication and to better understand transmission risks, the Ethiopia Dracunculiasis Eradication Program (EDEP) conducts active surveillance activities among Olive baboon troops in the Gambella region considered high risk for Guinea worm due to previous infections or proximity to human or other animal infections. Surveillance includes weekly tracking of baboon movement and water source use, as well as trapping and sedation of baboons to physically check for emerged worms or signs of Guinea worm. Since 2021, EDEP has screened more than 200 baboons for Guinea worm through active surveillance. During trapping in March 2024, we screened 68 baboons for Guinea worm among nine troops, with no Guinea worm detected. In response to the 2023 animal infection detected in Ethiopia, EDEP is expanding the number of baboon troops under surveillance, with additional trapping sessions planned for July and October 2024. In March, we placed GPS collars on baboons from five troops, and plan to place more collars on baboons during the July trapping. Data from GPS collars, captured year-round, will clarify baboon movement, and troop overlap with both nearby baboon troops and water sources used by communities. Preliminary results indicate variation in total troop home ranges between 2.2 and 7.9 kilometers squared. Daily averages for the troop with the largest total home range during the peak dry season varies from 0.2 to 2.0 kilometers squared. These results are programmatically meaningful given baboon home ranges encompass water sources used by humans and domestic dogs, which could have implications for Guinea worm transmission. EDEP is leveraging findings from baboon surveillance activities to inform programmatic implementation strategies, including surveillance intensity, community mobilization, and water treatment to prevent Guinea worm transmission.

7499

(UN)SUSTAINABLE SCIENCE: ENVIRONMENTAL FOOTPRINT OF RESEARCH, CLINICAL MICROBIOLOGY AND VETERINARY LABORATORIES LOCALLY AND GLOBALLY

Bethel A. Bayrau[1], Esra Buyukcangaz[1], Sapna P. Sadarangani[2], Bartholomew N. Ondigo[3], Andrea Prinzi[4], A. Desiree LaBeaud[1]

[1]Stanford School of Medicine, Palo Alto, CA, United States, [2]National Centre for Infectious Diseases, Singapore, Singapore, [3]Egerton University, Njoro, Kenya, [4]bioMérieux, Medical Affairs, Salt Lake City, UT, United States

Recently, the scientific and healthcare research communities have increased their efforts to study the causes, implications, adaptation, and mitigation strategies for climate change. It is also important to address our fields' contributions to climate pollution. In this review, we present the scale of the problem, potential interventions, and a case study on waste management from hospitals in Kenya to give a global perspective. Research laboratories produce 12 billion pounds of plastic waste each year and use up to 70% of their institutions' energy despite occupying a significantly smaller proportion of their institutions' total space. –80°C freezers and fume hoods alone use energy that is equivalent to a single and 3.5 households, respectively, and a single laboratory can have multiple freezers and hoods. Clinical microbiology laboratories have significant carbon footprints that can be reduced through diagnostic stewardship, a process focused on ensuring the collection of the right test from the right patient at the right time. Opportunities exist for reducing reagent waste in frequently ordered clinical tests such as complete metabolic panels. Veterinary laboratories also contribute significant carbon emissions from excessive waste from phlebotomy supplies, packaging, animal carcasses, and other biohazardous waste. Green initiatives have been shown to decrease the carbon footprint of laboratories, provide cost savings, and do not have to be resource- or time-intensive. Reducing waste production by purchasing reusable and refillable materials, autoclaving for reuse whenever possible, participating in recycling programs, using low-faucet valves to reduce water use, shutting off hoods and other equipment when not in use, and increasing freezer temperature from –80°C to –70°C are some eco-friendly practices laboratories might adopt. In addition to reducing carbon footprint and saving costs, these practices can also help advance health equity as waste is often disposed of in areas proximal to marginalized communities causing human morbidity and mortality.

AVIAN VACCINATION VIA RECOMBINANT *LACTOBACILLUS*-BOUND BIRDSEED TO CURB THE SPREAD OF WEST NILE VIRUS

Michelle J. Savran, Benjamin Swartzwelter, Janahan Loganathan, Kathryn Coffin, Preston Schweiner, Allison Vilander, Brian D. Foy, Gregg A. Dean

Colorado State University, Fort Collins, CO, United States

West Nile virus (WNV) is the leading cause of domestically acquired mosquito-borne disease in the United States. Despite significant investment, no effective human WNV vaccines have been developed, so current mitigation efforts remain limited to environmentally toxic insecticidal sprays. While humans and other animals can develop disease, they are dead-end hosts because they do not develop high enough viremia to infect other mosquitoes. Rather, propagation of WNV is primarily maintained between mosquitoes and birds. We hypothesize that immunizing WNV-susceptible birds will reduce WNV transmission to mosquitoes, protecting both people and animals from infectious bites and disease. To this end, we are genetically modifying strains of the probiotic *Lactobacillus acidophilus* (LA) to express WNV antigenic proteins premembrane (prM), envelope (E), and non-structural protein 1 (NS1). The bacteria will be administered orally to deliver intact viral protein to mucosal immune inductive sites in birds. Immunogenicity is enhanced by the addition of a dendritic cell targeting peptide (DCpep). Protein expression by the LA-based vaccine (rLA-WNV) will be assessed by Western blot and flow cytometry. Immunogenicity will be measured by vaccinating chickens and assessing development of anti-WNV antibodies via ELISA-based techniques and plaque-reduction neutralization assays. We will lyophilize rLA-WNV and bind it to seed to assess its environmental stability and immunogenicity. We selected this strategy because 1. it is only practical to immunize wild birds orally with food baits in WNV endemic areas, and 2. LA can be lyophilized, allowing for preservation and binding to bird seed. The strategy, if successful, will result in an innovative and cost-effective strategy for control of vector-borne disease.

THE FINANCIAL IMPACT OF LIVESTOCK SCHISTOSOMIASIS AND UNDERSTANDING THE IMPORTANCE OF POLICY BUY-IN ON INTERVENTION SUCCESS

Praise A. Adeyemo[1], Elsa Léger[2], Elizabeth Hollenberg[2], Nicolas Diouf[3], Mariama Sène[4], Poppy H L Lamberton[1], Joanne P. Webster[5], Barbara Häsler[2]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Royal Veterinary College, University of London, London, United Kingdom, [3]Institut Supérieur de Formation Agricole et Rurale, Université de Thiès, Bambey, Senegal, [4]Université Gaston Berger, Saint-Louis, Senegal, [5]London Centre for Neglected Tropical Disease Research, School of Public Health, Imperial College, London, United Kingdom

Schistosomiasis is a neglected parasitic disease that poses major threats to human and animal health, as well as the economy, especially in sub-Saharan Africa. It is second only to malaria in its socioeconomic and public health importance with an estimated 1.864 million disability-adjusted life-years (DALYs) lost, 240 million people infected globally and estimated productivity losses due to human schistosomiasis at $11.9 billion/year for 2021-2030. It also has debilitating effects on animals. However, knowledge about the impact of the disease on economic livelihoods and how policy buy-in at various stakeholder levels affects interventions and economic outcomes is limited. A One Health financial analysis of livestock schistosomiasis was conducted to estimate the financial impact of the disease in northern Senegal. Stochastic partial budget models were developed for traditional ruminant farmers in 12 villages. These models were parameterised using data from a cross-sectional survey, focus group discussions (FGDs), scientific literature, and available statistics. Two scenarios were defined: scenario 1 modelled farmers who tested and treated their livestock for schistosomiasis, while scenario 2 modelled no tests or treatment. Sensitivity analyses were conducted to assess the impact of uncertain variables on disease costs. Results revealed that livestock schistosomiasis has a substantial impact on farmers. Schistosomiasis in a herd reduces the farmers' livelihood and may lead to an inability to meet basic needs. Therefore, treating livestock schistosomiasis has the potential to generate considerable benefits for farmers and their families. These findings will be discussed in the context of policy buy-in across stakeholders. They will be presented alongside work on a literature review and community surveys, where we are identifying current interventions in affected communities; measuring the impacts, accessibility, and cost-effectiveness of these interventions through empirical research; and assessing barriers and facilitators to policy buy-in for intervention uptake and success through FGDs and in-depth interviews.

COMPARATIVE ANALYSIS OF STEROID-RDV COMBINATION THERAPY VERSUS STEROIDS ALONE IN HOSPITALIZED COVID-19 PATIENTS: A SARS-COV-2 VIRAL LOAD DYNAMICS STUDY

Alexandra Do[1], Clinton Onyango[2], Jens Langsjoen[1], Kristan Schneider[3], Douglas J. Perkins[3], Ivy Hurwitz[3]

[1]University of New Mexico School of Medicine, Albuquerque, NM, United States, [2]Maseno University, Maseno, Kenya, [3]University of New Mexico Health Sciences Center, Albuquerque, NM, United States

Treatment with steroids and/or remdesivir (RDV) are standard treatments in hospitalized COVID-19 patients. Studies with conflicting findings have investigated how steroids and/or RDV affected SARS-CoV-2 viral load (VL) dynamics in the upper respiratory tract (URT). Our studies in hospitalized patients showed that elevated SARS-CoV-2 in peripheral blood (PB), but not the URT, are predictors of severe disease. To investigate the influence of standard treatments on PB and URT VL dynamics, we examined the impact of steroids alone or in combination with RDV in hospitalized COVID-19 patients (n=475) recruited between 4/2020-12/2021 at the University of New Mexico Hospital. To account for the influence of disease severity, only severe COVID-19 patients (n=190), defined by ICU requirements and/or death, were included in the study. Severe patients were stratified into those who received steroids alone (n=37, 19.5%) or steroids/RDV (n=130, 68.4%). Patients (12.1%) who did not receive treatment due to RDV unavailability, contraindications to steroids and/or RDV, completion of prior therapies, or undergoing alternative treatments were excluded. PB and URT VLs at enrollment and cumulative VLs across 14 days were similar between treatment groups. Refined analyses with linear mixed-effects models were employed to analyze the general trend and individual variations in VL changes over time. VLs in PB (P=4.40E^{-9}) and URT (P=9.00E^{-10}) decreased in both groups across 14 days. Patients who received steroids/RDV had higher initial PB VLs (P=0.049) that decreased at a faster rate (P=0.0019). In contrast, patients treated with steroids/RDV had comparable initial URT VLs (P=0.31) and similar decreases across time to those treated with steroids alone (P=0.406). Importantly, patients receiving combination therapy had a shorter average length of stay (20 vs. 23 days) vs. steroids alone (P=0.041). Collectively, findings presented here indicate that severe COVID-19 is defined by higher PB VLs across time and that combination therapy (steroids/RDV) is more effective than steroids alone for reducing SARS-CoV-2 in blood, as well as length of hospitalization.

7503

MULTIPLE VIRAL COINFECTIONS IN TUBERCULOSIS PATIENTS IN BAMAKO, MALI

Antieme Combo Georges Togo[1], Fousseyni Kane[1], Bassirou Diarra[1], Amadou Kone[1], Yeya Sadio Sarro[1], Dramane Diallo[1], Mamoudou Maiga[2], Gagni Coulibaly[1], Mohamed Tolofoudie[1], Amadou Somboro[1], Djeneba Dabitao[1], Djeneba Bocar Fofana[1], Mahamadou Diakite[1], Katy Shaw-Saliba[3], Ray Chen[4], Seydou Doumbia[1]

[1]University of Sciences,Techniques and Technologies of Bamako (USTTB), Bamako, Mali, [2]Center for Innovation in Global Health Technology (CIGHT), Northwestern University, Chicago, Illinois, USA, Chicago, IL, United States, [3]Collaborative Clinical Research Branch (CCRB), Division of Clinical Research (DCR) National Institute of Allergy and Infectious Diseases (NIAID)., Baltimore, MD, United States, [4]3Collaborative Clinical Research Branch (CCRB), Division of Clinical Research (DCR) National Institute of Allergy and Infectious Diseases (NIAID)., Baltimore, MD, United States

Tuberculosis (TB) infection is often found with other chronic pathologies. While morbidity and mortality fromopportunistic diseases have declined recently, some infections such as cytomegalovirus (CMV), TB, andhepatitis B remain significant health issues in person living with HIV (PLWH). Viral co-infections can disrupthost defenses which may impact the risk of developing active TB disease. Thus, our study aimed todetermine, on an exploratory basis, the frequency of other viruses in patients co-infected with TB and CMVin Bamako, Mali using VirCapSeq-VERT. We conducted a cross-sectional study by enrolling TB patients atthe University Clinical Research Center (UCRC) in an IRB approved protocol between October 2018 andOctober 2019. TB was confirmed by positive culture, and sera were tested for viral coinfections. The originalstudy was designed to look at the impact of CMV on TB. IgM/CMV was determined from all samples usingELISA. For this exploratory analysis, only positive serum samples were extracted using the DNA/RNA MiniKit (Qiagen, Hilden, Germany) and then unbiased metagenomic sequencing for viruses was performed usingVirome Capture Sequencing for vertebrate viruses (VirCapSeq-VERT) followed by captured amplification andsequencing with the illumina NextSeq 2000 system. Out of 100 TB patients enrolled, the prevalence ofIgM/CMV was 17%. Among the 17 TB+/CMV IgM+ participants, 11 were male and the mean age was 26.29years old. VirCapSeq-VERT detected various viruses in the 17 participants: Tenovirus/Teno-midi virus(N=11), hepatitis B (N=9), Human Herpes virus (HHV)-4/SEN virus (N=5), GB virus C (N=4), HHV-8/HHV-5(N=2). HHV-6A, HIV, Betapapillomavirus 1, Human endogenous retrovirus, Murine leukemia virus, TilapiaLake virus, Gemycircularvirus NP were all identified in a single participant. While the pathogenicity of mostdetected viruses remains uncertain, VirCapSeq-VERT was useful in detecting a diverse set of viruses.Further research using VirCapSeq-VERT in all TB patients could provide a more comprehensive profile ofviral coinfections in TB patients and their clinical impact.

7504

EFFECT OF PRIOR ANTIBIOTICS USE ON BLOOD CULTURE POSITIVITY IN CHILDREN UNDER 5 YEARS WITH SUSPECTED INVASIVE PNEUMOCOCCAL DISEASES IN RURAL GAMBIA

Muhammed Wally, Molfa Minteh, Ousman Barjo, Rasheed Salaudeen, Baleng M. Wutor, Abdulsalam O. Yusuf, Williams O. Adefila, Modou L. Keita, Isaac Osei, Grant Mackenzie

Medical Research Council Until the Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia

Blood culture plays a crucial role in the diagnosis and treatment of invasive diseases. However, the effect of antibiotics use before blood culture collection among children under 5 years with suspected invasive disease is not well understood. We describe the effect of antibiotic activity on blood culture outcomes in children under 5 years with suspected invasive pneumococcal diseases in rural Gambia. Between September 2019 and December 2021, we collected blood cultures and whole blood at the pediatric outpatient departments of two hospitals from children <5 years old with suspected pneumonia, sepsis, and meningitis who had been enrolled in a pneumococcal vaccine schedule study. Information on antibiotic use in the last week before presentation at the health facilities was collected from parents/caregivers. Blood cultures and pathogen identification were performed using standardized methods. An antimicrobial activity assay was performed on whole blood samples to test for the presence of antibiotics. Descriptive statistics and logistic regression analyses were performed. Of the 1715 samples, the blood culture positivity rate was 77 (4.5%), and 95 (5.5%) had positive antibiotic activity. Blood culture was positive in 9/95 (9.5%) of patients with positive antibiotic activity compared to 68/1620 (4.2%) in those with negative antibiotic activity. Antibiotic activity was detected in 34/420 (8.1%) patients who had reported prior antibiotic use. Blood culture positivity rate was 25/420(6.0%) and 52/1295 (4.0%) among those who reported and those who did not report prior antibiotic use respectively. Those with positive antibiotic activity were 2.4 times more likely to have a positive blood culture compared to those with no antibiotic activity (odds ratio, 2.40; 95% CI, 1.15-4.95; p = 0.02). In contrast to findings from similar studies, we found a positive correlation between positive antibiotic activity and blood culture positivity. Thus, there is still considerable value in performing blood cultures for patients with prior antibiotic use in our setting. Further research is recommended to determine the factors associated with our findings.

7505

RAPID IDENTIFICATION OF NON-TUBERCULOUS MYCOBACTERIAL SPECIES USING FLUOROCYCLER® XT IN SUSPECTED PATIENTS IN BAMAKO, MALI

Fah Gaoussou TRAORE[1], Gagni Coulibaly[1], Aissata Cisse[2], Antieme Combo Georges Togo[1], Fatima Diallo[1], Bassirou Diarra[1], Aminata Maiga[1], Fanta Sanogo[1], Boureima Degoga[1], Bocar Baya[1], Yeya dit Sadio Sarro[1], Mahamadou Kone[1], Hawa Baye Drame[1], Mamadou Diakite[1], Shaw Saliba Katy[3], Seydou Doumbia[1]

[1]University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, [2]National Tuberculosis reference laboratory, National Institute of Public Health (INSP), Bamako, Mali, Bamako, Mali, [3]Collaborative Clinical Research Branch (CCRB), Division of Clinical Research (DCR) National Institute of Allergy and Infectious Diseases (NIAID), Balimore, MD, United States

Non-tuberculous mycobacteria (NTM) are ubiquitous organisms causing neglected and highlycomplex infections. The lack of epidemiological studies of NTM infections has ultimately led toan underestimation of NTM cases, thus resulting in an increase frequency worldwide. Treatmentof NTM infections is challenging due to their relative resistance to a wide range of antibiotics, andtoxicity of sensitive ones. Therefore, rapid and reliable identification of NTM infected patients isessential to implement specific treatment and preventive measures. To discriminate NTM rapidlyand efficiently from *Mycobacterium tuberculosis complex* (MTBc), we carried out a cross-sectional study in new and previously treated tuberculosis (TB) patients between January 2021 andDecember 2023 at the University Clinical Research Center (UCRC), Bamako in an IRB approvedprotocol. Two separate sputum samples were collected from NTM suspected patients (those withpositive auramine staining microscopy and negative GeneXpert MTB/RIF results). BACTEC™MGIT 960 system was used for the cultivation of mycobacteria, and positive cultures were usedfor molecular identification of the different species using the FluoroCycler® XT (Fluorotype®Mycobacteria V1.0) in accordance with the manufacturer's recommendations. Of the 76 patientsenrolled, 34 (44.7%) were NTM confirmed. The prevalence of HIV/NTM co-infection was 5%.The sex ratio was 4.05 and the age ranged of 31-44 years old was the most represented (17/34).Among the 34 isolates, 25 were from previously treated, and nine from new TB patients.FluoroCycler® XT identified ten different species, and more specifically, *M. avium complex*(N=11), *M. massiliensei* (N=7), *M. fortuitum* (N=5), *M. simiae* (N=4), *M. bolletii*/*M. chimaera*(N=2 each), and *M. interjecum*, *M. mucogenicum*, *M. abscessus* were all identified once. Whilethe pathogenicity of most detected NTM remains uncertain, FluoroCycler® XT was useful indetecting a diverse set of NTM in a relatively

short period of time. NTM is more common onpreviously treated TB patients, and *M. avium* complex is the more common isolated species in oursetting.

7506

EVALUATION OF TRENDS IN PNEUMOCOCCAL ANTIBIOTIC RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASES IN RURAL GAMBIA

Molfa Minteh, Rasheed Salaudeen, Ousman Barjo, Grant Mackenzie, Isaac Osei, Baleng Mahama Wutor, Modou Lamin Keita, Yusuf Abdulsalam, Williams Adefila

The MRC Unit The Gambia at LSHTM, Banjul, Gambia

Management of pneumococcal diseases is complicated by high rates of antimicrobial resistance (AMR) which poses a significant challenge for treating pneumococcal diseases. This study assessed AMR trends of *Streptococcus pneumoniae* in invasive pneumococcal diseases (IPD) in rural Gambia. We evaluated invasive S. pneumoniae, isolated in rural Gambia over a 15-year period between 2008-2022. Standardized, population-based Surveillance for invasive bacterial causes of pneumonia, sepsis, and meningitis was conducted in Basse Health & Demographic Surveillance System from 2008-2017 and 2019-2022, while in Fuladu West Health & Demographic Surveillance System surveillance covered 2011-2014 and 2019-2022. *S pneumoniae* was identified by morphology and optochin sensitivity and ATCC 6583 was used as a reference strain. Antibiotic sensitivity was assessed using Kirby-Bauer disk diffusion method, apply CLSI standards to categorize isolates as resistant, intermediate, or sensitive to antibiotics. We used descriptive statistics to characterize the percentage and the trends of AMR in four time periods, 2008-2010, 2011-2013, 2014-2017, and 2019-2022. Of 450 S. pneumoniae isolates, were isolated in the four time periods, 34% (153/450) of patients were aged <1 year, and 75% were from blood culture. Almost all isolates (94%) were resistant to cotrimoxazole. Proportions resistant to tetracycline were 56%, oxacillin 26%, chloramphenicol 20%, and ciprofloxacin 9%. The resistance to ampicillin was a very little (2.36%). There was limited variation in resistance to individual antibiotics over time. There was a decrease in tetracycline resistance over time (60% to 44%) and also resistance to ≥3 drugs (33% to 16%). There are modest levels of AMR in invasive S. pneumoniae isolates in rural Gambia. Resistance over time was relatively stable with some reductions in the proportion of tetracycline and multi-drug resistance. Amoxicillin and Ceftriaxone, First and second line drugs respectively for for pneumococcal diseases in The Gambia, remain effective.

7507

COMMUNITY PERCEPTION AND IMPACT OF A MOBILE VAN FOR POST-MORTEM SAMPLE COLLECTION IN KARACHI, PAKISTAN: CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS)

Saima Jamal[1], Nazia Ahsan[1], Fauzia Malik[2], Farah Jabeen[1], Sameer Belgaumi[2], Hannah Melchinger[1], Tehreem Maqsood[1], Abdul Momin Kazi[1], Saad Be Omer[2]

[1]Aga Khan University, Karachi, Pakistan, [2]UT Southwestern, Dallas, TX, United States

Although post-mortem sampling is essential to mortality surveillance, it can be logistically and culturally challenging to conduct in Muslim societies like Pakistan. Funerary preparations and burial often occur within hours of death, and there is little time in which it is appropriate to collect a sample from the dead. A mobile van, modified for the sterile collection of minimally invasive tissue samples (MITS), allows for sample collection with minimal disruption to community values and funerary logistics. Initially designed to conduct neonatal MITS for a respiratory syncytial virus (RSV) study, the van can navigate narrow streets and densely populated spaces in the catchment area, which includes several peri-urban areas of Karachi. Retrofitted with a sterilizable laboratory interior, the van has an operating table, storage space, ventilation, and sink, with space for a specialist and observer. During the study, the van enabled on-site and immediate MITS collection, eliminated time spent transporting the body, and minimised delays in burial preparations. The van also fulfilled caregivers' desire to observe sample collection and allowed for flexibility in location of sample collection. In preparation for the Child Health and Mortality Prevention Surveillance (CHAMPS) study, we asked the community for their perceptions of the MITS van. Caregivers viewed it as convenient and culturally respectful. They recommended parking strategically to avoid attention from funerary congregations, allowing families to observe sample collection, and using the van to perform *ghusl*, a ritual bath. MITS specialists suggested improvements to van design, including optimising storage, rearranging tables, and increasing ceiling height. New vans were modified and used for CHAMPS MITS according to community and expert feedback. The MITS van has transformed our post-mortem sampling, offering a sterile, efficient, and culturally sensitive solution to mortality surveillance in conservative settings like Pakistan. Its success demonstrates the importance of involving the community in the design of innovative research solutions.

7508

HOW CROSS-BORDER COLLABORATION BETWEEN CAMEROON AND GABON ENHANCED PROMPT RESPONSE TO A DIPHTERIA OUTBREAK, DECEMBER 2023

Ngo Sol Marie[1], Mbila Arielle[2], Roukwe Bamo[1], Alli Owe Mariame[2], Ncham Evaristus[3], Tchualeu Kameni Albert[4], Acho Alphonse[5], Esso Endalle Linda[5], Mbongo Alain[6], Antchouey-Ambourhouet Anne-Marie[6], Evouna Armel[3]

[1]Ministry of Health/ Field Epidemiology Training Program, Yaounde, Cameroon, [2]Ministry of Health/ Field Epidemiology Training Program, Libreville, Gabon, [3]Ministry of Health/ Field Epidemiology Training Program/ Departement of disease control, Epidemics and Pandemics, Yaounde, Cameroon, [4]National Public Health Laboratory/ Ministry of Public Health, Yaounde, Cameroon, [5]Department of Disease Control, Epidemics and Pandemics/ Ministry of Public Health, Yaounde, Cameroon, [6]Epidemiology Institute for Control of Endemics/ Ministry of Health, Libreville, Gabon

In 2023, there was an upsurge of diphtheria cases with epidemics reported in five African countries. In december 2023, a diphtheria case was reported in Ebolowa, South Cameroon, originating from Bitam a border district in North Gabon, raising fears of an epidemic. A joint team from Cameroon and Gabon conducted an investigation in the border districts to describe the case, identify and trace contacts, and assess vaccine coverage. We conducted a cross-sectional descriptive study from december 18-26, 2023. We searched for cases in health facilities registers and in the community. A case was anyone living in the Ebolowa, Ambam, Kye-Ossi, and Bitam districts with pharyngitis, rhinopharyngitis, tonsillitis or laryngitis and adherent pseudomembrane of the throat or nose from november 23, 2023. A contact was anyone who had physical or respiratory contact with a case in the 14 days preceding symptoms onset. Identified contacts were followed up for 14 days by phone. We administered questionnaires to 30 households around each identified case to assess vaccine coverage in children 6 weeks to 9 years. Two suspected cases and one confirmed case of diphtheria were identified in Bitam aged 6, 9 and 10 years, with a M/F sex ratio of 1/2. All three cases were unvaccinated and all three are dead. We identified and traced 69 contacts, none of them developed diphtheria symptoms. Overall, 83% (169/203) of parents were able to present a vaccination record. Estimated diphtheria vaccine coverage was 79% (162/203). The main reasons for non-vaccination were refusal (8/21), difficulty in purchasing a booklet (7/21) and distance from the vaccination site (5/21). Reactive vaccination of 260 unvaccinated children was implemented. This cross-border collaboration led to prompt detection and response to diphteria outbreak in Gabon. Strengthening community and cross-border surveillance, and vaccination in both countries could help to reduce the burden of this deadly disease.

7509

COMPARATIVE MORTALITY ANALYSIS: ERADICATION VS PERSISTENCE OF *PSEUDOMONAS* INFECTIONS

Daniel Bustamante[1], David De la Rosa Carrillo[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Chronic obstructive pulmonary disease (COPD) is a significant cause of mortality worldwide. Chronic bronchial infection (CBI) in these patients increases exacerbations and severity. Pathogen isolation is important for treatment, prognosis, and monitoring. Isolation of *Pseudomonas aeruginosa* (PA) is associated with a worse prognosis in CBI, but further studies on treatment and management in COPD patients are needed. We carried out a multicenter observational study of historical cohorts of COPD patients with diagnostic criteria for COPD who had received at least one dose of any inhaled antibiotic between 2013 and 2018. , we only included those with at least one positive culture for PA prior to starting inhaled antibiotic treatment. Mortality was our outcome of interest. Discrete variables are presented as frequencies and percentages. Mantel Haenszel method was applied to estimate the effect of the main exposure (eradication of PA) and our outcome by each variable stratum in order to identify any effect modifier. Next, we determined the relationship between our exposure of interest and our outcome of interest considering as a priori confounder age and sex; logistic regression was performed to investigate the relationship between variables and the outcome. 279 patients eradicated PA infection and 318 didn't. Among those who didn't 122 (38.36%) died compared to 66 (23.66%) that died even when they eradicated the infection ($p<0.001$). Univariate analysis showed that individuals who do not eradicate the infection have 2 times the OR of dying compared to those who eradicate it (CI 95% 1.4-2.8, $p<0.001$). Multivariate analysis showed strong evidence that those who do not eradicate the infection have higher odds of dying compared to those who do, when adjusted by sex, age, extension of bronchiectasis, time of inhaled antibiotic treatment, type of antibiotic and schedule of administration. We finally conclude that individuals who fail to eradicate the PA infection are at significantly higher risk of mortality compared to those who successfully eradicate it; therefore it is important to continue improving treatment in order to have better survival outcomes.

7510

DRIVERS OF COMMON MENTAL HEALTH DISORDERS AMONG TUBERCULOSIS KEY VULNERABLE POPULATIONS IN ASHANTI REGION GHANA

Samuel Frimpong Odoom[1], Solomon Idan[2], Michael Owusu[3], Dominic Gyedu[4], Ebenezer Adangabe[3], Alhaji Ibrahim Cobbinah[3], Emmanuella Oppong[3], Barbara Gariba[1], Nicholas Karikari Mensah[1], Francis Taylor[5], Francis Adjei Osei[3], Aliyu Mohammed[3]

[1]Komfo Anokye Teaching Hospital, Kumasi, Ghana, [2]University Health Service, University of Education Winneba, Winneba, Ghana, [3]Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, [4]Ghana Education Service, Kumasi, Ghana, [5]Wisconsin University College of Ghana, Kumasi, Ghana

Tuberculosis (TB) continues to be a significant global health challenge. Despite the global burden of TB and the recognized importance of addressing mental health issues, there remains a gap in understanding the specific drivers of common mental health disorders (CMHD) among TB patients. Therefore, this study aims to investigate the key drivers of CMHD among TB key vulnerable populations (TB-KVPs) in Ashanti region, Ghana. Cross-sectional study design was employed in sampling 302 TB-KVPs at some selected TB treatment centres in Ashanti Region from September to October 2023. CMHD were evaluated using the Self-Reporting Questionnaire, developed by the World Health Organization. In our study, multi-stakeholder of TB engagement was done to prioritized individuals who are at high risk of TB. The TB-KVPs included rural poor individuals, children, informal miners, person living with HIV (PLHIV), inmates and smokers. The lists of TB-KVPs who tested positive for TB were obtained from the selected TB treatment centres. Multiple linear regression analysis was employed to identify the key drivers of CMHD among the TB-KVPs. The prevalence of CMHD was 13 (4.30%). TB-KVPs diagnosed with pulmonary TB *(PTB) (*β*=1.41, CI=0.21, 2.61)* and those reporting fair *(*β*=2.40, CI=0.13, 4.67)* and poor *(*β*=7.06, CI=3.91, 10.20)* health status exhibited higher mental health disorder. Conversely, cohabiting TB-KVPs (β=-1.54, CI=-2.85, -0.23) and those with treatment supporters (β=-0.92, CI=-1.72, -0.12) had lower CMHD scores. Our study found a relatively low prevalence of CMHD among TB-KVPs. Key drivers associated with these disorders included the type of TB diagnosed (PTB), self-reported health status (fair and poor), having a treatment supporter and marital status (cohabiting. Specifically, patients diagnosed with pulmonary TB (PTB), and those reporting fair or poor health statuses exhibited higher scores indicative of mental health disorders. Our study emphasizes the importance of screening for mental health issues among TB-KVPs and addressing key drivers like TB diagnosis and psychosocial factors in intervention strategies.

7511

CARDIOVASCULAR DISEASES ASSOCIATED WITH INFLUENZA INFECTION: SYSTEMATIC REVIEW AND META-ANALYSIS

María del Carmen Caycho Torres[1], Johnny Clavo Yamahuchi[1], Cory X. Cornejo Ramos[1], Oscar A. Gayoso Liviac[1], Omar F. Zanoni Ramos[1], Victor Vega Zambrano[1], **Cesar Ugarte-Gil**[2]

[1]Universidad Peruana Cayetano Heredia, Lima, Peru, [2]University of Texas Medical Branch, Galveston, TX, United States

Since 1930, a potential association between cardiovascular diseases and influenza virus infection has been posited. Given the substantial burden of cardiovascular diseases in contemporary society, there is a paucity of recent systematic reviews that delineate the risk of cardiovascular diseases following confirmed influenza infection. The aim of this study is to assess the association between prior influenza infection and cardiovascular diseases through systematic review and meta-analysis. A systematic review was conducted following PRISMA guidelines. Electronic searches encompassed databases including EMBASE, PubMed, Global Index Medicus, Google Scholar, and the Cochrane Library. Initially, articles were screened based on titles and abstracts, followed by full-text evaluation. The included studies required laboratory-confirmed influenza cases, excluding those involving pregnant women and children. Quality assessment of studies utilized the standardized tool from the National Heart Lung and Blood Institute, with potential biases evaluated. Additionally, meta-analysis was performed using Cochrane Software Review Manager 5.4.1. Three studies (n=943) were evaluated (one study published twice with the same population, so was considered the more complete publication). A combined odds ratio (OR) was computed for the association between influenza A infection and acute myocardial infarction, yielding 2.52 (95% CI: 1.59 to 4.00). For influenza B infection, an association with acute myocardial infarction was observed with an OR of 4.78 (95% CI: 1.57 to 14.61). One study reported an OR of 5.23 (95% CI: 1.00-27.32) for the association with myocarditis. The evidence indicates a robust and statistically significant positive association between prior influenza infection and acute myocardial infarction. Further studies are warranted to evaluate the long-term effects of influenza on cardiovascular diseases.

7512

TUBERCULOSIS TREATMENT COMPLETION AND CHALLENGES IN RURAL TANZANIA

Saning'o Lukumay[1], Ghassan Ilaiwy[2], Domitila Augustino[1], Paulo Mejan[1], Kusulla Simeon[1], Estomih Mduma[1], Scott Heysell[2], Tania Thomas[2]

[1]Haydom Global Health Research Center, Haydom, Tanzania, United Republic of, [2]University of Virginia, Charlottesville, VA, United States

Tuberculosis (TB) patients residing in rural settings often encounter difficulties in successfully completing prescribed treatment due to a variety of factors such as geographical distance from healthcare facilities, poverty, limited educational opportunities, and scarce resources. In this report, we

describe the challenges faced by TB patients in a rural setting in Tanzania in an effort to propose strategies to improve TB treatment completion. We used data from a prospectively enrolled cohort of index PWTB in Haydom, Tanzania. We describe TB treatment outcomes for the cohort, explore challenges and solutions as reported by participants, and search for predictors of TB disease treatment completion using a multivariate regression model. 120 index PWTB were enrolled in the study, median was age 35 years (interquartile range [IQR] 23-51) and 45 (38%) were women. 63 of participants (67.7%) completed treatment successfully out of 93 participants whose outcomes were verifiable. 23 participants (19.1%) were lost to follow up and 27 participants (22.5%) transferred TB care to non-participating health facilities and their outcomes were not verifiable. Most participants reported challenges related to cost and missing household activities: 96 (86%) and 89 (80%) respectively. Home visits and health insurance were the most suggested interventions to facilitate care, mentioned by 103 (85.8%) and 102 (85%) participants respectively. None of the evaluated variables significantly predicted TB treatment completion. Many PWTB continue to experience worse treatment outcomes in rural areas with high burden of TB. Additional investment in programmatic support and universal healthcare coverage is needed to help bridge the gap with urban areas.

7513

MATERNAL SARS-COV-2 INFECTION, VACCINATION, AND INFANT STUNTING IN UGANDA

Karen B. Jacobson[1], Bruce Fireman[1], Abel Kakuru[2], Joaniter Nankabirwa[2], Moses Kamya[2], Scott D. Boyd[3], Katharina Röltgen[4], Grant Dorsey[5], Stephanie Gaw[5], Philip Rosenthal[5], Nicola Klein[1], Prasanna Jagannathan[3]

[1]Kaiser Permanente Vaccine Study Center, Oakland, CA, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Stanford School of Medicine, Stanford, CA, United States, [4]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [5]University of California, San Francisco, San Francisco, CA, United States

Gestational SARS-CoV-2 infection may adversely impact infants, particularly males. We evaluated maternal SARS-CoV-2 infection, vaccination, and infant growth in a Ugandan birth cohort. From 3/2021-12/2022, HIV-negative pregnant women between 12-20 weeks gestation enrolled in a malaria chemoprevention trial; their infants were followed longitudinally. In a “pre-vaccine” group of SARS-CoV-2-unvaccinated women delivering 9/2021-2/2022, we tested stored plasma specimens collected at enrollment (12-20 weeks gestation) and delivery for SARS-CoV-2 antibodies to identify maternal infections, and fit linear mixed effects models to examine the association between maternal SARS-CoV-2 infection and infant length-for-age Z (LAZ) scores. SARS-CoV-2 vaccines became locally available late 2021. In a “post-vaccine” cohort delivering 3/2022-5/2023, we examined the association between maternal SARS-CoV-2 vaccination and infant stunting (LAZ-score <-2) with conditional logistic regression stratified by birth month. Of 101 “pre-vaccine” mothers, 82 (81.2%) became SARS-CoV-2 seropositive. At age 12 weeks, 27 (32.9%) infants of infected mothers were stunted, while no infants of uninfected mothers were stunted. In male infants, early pregnancy SARS-CoV-2 infection was associated with lower LAZ scores (Coef= -2.00, 95%CI -3.46 - -0.54) when compared to male infants of uninfected mothers. There was no difference in female infants (Coef=-0.53, 95%CI -3.00-1.95). Of 868 “post-vaccine” mothers, 515 (59.3%) were vaccinated. At 12 weeks, 160 (18.4%) infants were stunted. In males, maternal SARS-CoV-2 vaccination was associated with less stunting (OR 0.52, 95%CI 0.31-0.86, p=0.01) compared to male infants of unvaccinated mothers. No difference was seen in females (OR 1.08, 95%CI 0.62-1.89, p=0.78). In male infants in a malaria-endemic setting, maternal SARS-CoV-2 infection was associated with stunting, while maternal SARS-CoV-2 vaccination was associated with less stunting. More data from larger cohorts should determine if maternal vaccination can prevent developmental sequelae in infants, particularly males.

7514

DISENTANGLING THE SEROCONVERSION AND SEROREVERSION RATES OF SEASONAL CORONAVIRUSES USING AGE-STRATIFIED SEROPREVALENCE DATA

Sophie Larsen[1], Junke Yang[1], Huibin Lyu[1], Alicia Kraay[2], Saki Takahashi[3], Nicholas Wu[1], Pamela Martinez[1]

[1]University of Illinois, Urbana-Champaign, IL, United States, [2]Gates Foundation, Seattle, WA, United States, [3]Johns Hopkins University, Baltimore, MD, United States

Despite increased investigation driven by the SARS-CoV-2 pandemic, the dynamics of endemic human coronavirus species are challenging to disentangle. Previous studies have estimated seroconversion and seroreversion rates using serological data but only considered seropositive vs. seronegative, without taking into account heterogeneity due to multiple exposures or variation in individual immune responses. Additionally, previous work has drawn from serological data in different settings, creating challenges in comparing across strains. Using Gaussian mixture models, we classified cross-sectional serological data for four seasonal coronaviruses into seronegative and gradients of seropositivity across the lifespan. These methods identified four (NL63, 229E, OC43) to five (HKU1) distinct seropositive groups, suggesting that among seropositive individuals, there may be varying levels of prior immune history or response to infection. Serocatalytic models are standard to capture disease parameters, and we expanded them to account for varying levels of seropositivity. By fitting these models to the cross-sectional serological data, we found significant differences in the seroconversion rate across strains and serostatus. At lower serostatus, the time to seroconvert was rapid for all strains (0.4-2 years). At the highest level of serostatus, the time to seroconvert was 2.8 years for OC43, but 10.4-11.9 years for the alphacoronaviruses and 34.5 years for HKU1. Additionally, in each pair of alphacoronaviruses and betacoronaviruses, we found that one strain will have a faster rate of seroconversion and reversion, especially at lower levels of serostatus. By parameterizing individual-based models with rates estimated from the serocatalytic models, we compared with cohort studies to validate our findings. Whereas the reported impact of prior seasonal coronavirus immunity on SARS-CoV-2 outcomes is conflicting, understanding patterns in seroconversion at higher levels of immune history can help us contextualize these findings.

7515

PREDICTING TUBERCULOSIS TREATMENT RELAPSE USING STATISTICAL DATA MINING TOOLS. A CASE STUDY OF CAPE COAST TEACHING HOSPITAL, GHANA

Alberta Bedford Moses[1], Yaw Marfo Missah[2], Frederick Kumi-Ansah[1], Dennis Adu-Gyasi[3]

[1]Cape Coast Teaching Hospital, Cape Coast, Ghana, [2]Kwame Nkrumah University of Science and Technology, Ashanti Region, Ghana, Kumasi, Ghana, [3]Kintampo Health Research Centre and University of Energy and Natural Resources, Kintampo North, Ghana

Tuberculosis (TB) continues to be a global public health issue and the leading cause of infectious mortality globally. Despite diagnostic advances and treatment programs, some patients experience relapse after treatment. The study used numerical, analytical, and statistical data mining techniques to develop a predictive treatment relapse model for TB patients in the Central Region of Ghana. A total of 465 records of patients receiving care at the Cape Coast Teaching Hospital from 2017 to 2018, and tested for TB with GeneXpert and sputum smear for acid fast bacilli by microscopy, were used to build a model for predicting the treatment relapse of patients by using R software version 2021.9.1.372.Using addresses, the centroids of geographical position of communities where patients lived were recorded to aid in mapping infections in the study area. Purely Spatial analysis using the Discrete Poisson model was done with software for the Spatial and Space-Time scan statistics (SaTScan version 10.1, Harvard, USA) to explore to identify clusters of the TB burden in the study area.From the study outcome, patients between the ages of 40.5 and 49.5 years were predicted to have

high TB prevalence, TB-HIV co-infections, RIF resistance, PTB, treatment, and test outcomes. However, the burden of TB was significantly high (p< 0.05) within KEEA and CCMA with an incidence of 8.41 and 24.5 cases per 100000 population annually, respectively. Relapse associated with TB treatment was generally low across the study population. Conclusively, a prediction model using GeneXpert and Microscopy test method outcomes, age, and sex predicted unfavourable treatment outcomes of patients. The study highlights the importance of considering age and sex in predicting treatment outcomes of patients. The findings of the study can help improve clinical management and treatment outcomes for TB patients in Ghana.

7516

TIERED MULTIPLEX PCR DETECTION OF RESPIRATORY PATHOGENS IN CAMBODIA'S SEVERE ACUTE RESPIRATORY INFECTION SENTINEL SURVEILLANCE SYSTEM, MAY-DECEMBER 2023

Savuth n/a CHIN

National Institute of Public Health, Phnom Penh, Cambodia

Surveillance of respiratory pathogens with outbreak potential is key to enhancing global preparedness and response measures. Cambodia recently expanded molecular testing of respiratory pathogens as part of their severe acute respiratory infection (SARI) sentinel surveillance network. Patients hospitalized with SARI, defined as fever within 10 days, cough or sore throat, and dyspnea, were identified at 9 hospital-based SARI sites. Nasopharyngeal and oropharyngeal swabs (NP/OP) were collected and sent to the National Public Health Laboratory. RNA was extracted and tiered testing performed: first PCR of all samples for Influenza A, B, SARS-CoV-2; then PCR of negative samples using the FTD™ Respiratory pathogens 21 assay.From May to December 2023, NP/OP swabs were collected from 3,396 SARI patients. Median age was 7.8 years: 1,572 (46.3%) <5 years, 5, 251 (7.4%) 5-17 years, and 1,573 (46.3%) >18 years. PCR detected respiratory pathogens in 2,086 (61.4%) patients and case fatality was 1.1%. First tier testing identified influenza, 368 (10.1%), SARS-CoV-2, 159 (5.0%), and both pathogens, 11 (0.3%). Second tier testing of the remaining 2,867 patients identified Respiratory Syncytial Virus (RSV), 764 [26.6%], rhinovirus 559 [19.5%], and more than one pathogen, 277 (9.6%). RSV and rhinovirus were the most common pathogens detected among children <5 years (688 [48.6%], and 417 [29.4%], respectively), while Influenza and SARS-CoV-2 were the most frequent among adults (193 [12.2%], and 120 [7.6%], respectively). No pathogens were identified in 1,026 (65.2%) adults and 211 (13.4%) children <5 years. Surveillance trends captured two peaks of influenza transmission in June and November and a peak of RSV in August 2023.Healthcare facilities in low- and middle-income countries may not have diagnostic resources to identify priority pathogens, undermining the rigor of national surveillance. Integrated, expanded respiratory surveillance was feasible using the existing SARI surveillance network, identified important outbreaks, and captured diverse respiratory pathogens among young children.

7517

SUPPORTING INNOVATION IN PNEUMONIA DIAGNOSIS - KEY FINDINGS FROM A RANGE OF STUDIES EVALUATING RESPIRATORY RATE COUNTERS AND PULSE OXIMETERS IN SUB-SAHARAN AFRICA AND ASIA

Kevin Baker[1], Tedila Habte[2], Ani Steele[1], Elizabeth Berryman[1]

[1]Malaria Consortium, LONDON, United Kingdom, [2]Malaria Consortium, Addis Ababa, Ethiopia

Pneumonia is the leading infectious cause of death in under-five children. Community health workers currently count respiratory rate (RR) as a proxy diagnostic sign for pneumonia. Manually counting RR is challenging as it is hard to define a breath, and easy to lose count as the child may be moving, crying, or breathing rapidly. Misdiagnosis of suspected pneumonia is common and can lead to over and under treatment with antibiotics and potential death. New, automated RR counters and pulse oximeters offer a potential solution. To introduce new diagnostic aids their performance must first be validated. Developing a robust reference standard for evaluating the performance of new RR counters and pulse oximeters is challenging and there is currently no gold standard. A series of cross-sectional studies in sub-Saharan Africa (Ethiopia, South Sudan and Uganda) and Asia (Cambodia and Nepal) were conducted to measure the agreement of test devices to several reference standards, including human RR counters, video review panels and automated reference standards. The primary outcome was the agreement between the test device and the reference standard, as measured by intra-class correlation (ICC) coefficient ρ. Secondary outcomes included mean time taken to review a video and the usability and acceptability of the different reference standards by users. There was a low level of agreement found between human counters (ICC=0.3). Better agreement was found between automated reference standards (ICC=0.6), with the highest level of agreement for the video reference panel using an annotation tool (ICC=0.77). Users found video annotation software easy to use and helpful in standardizing RR counting, across a range of ages and situations. Reviewers highlighted the importance of quality video capture. Video annotation has the greatest potential as a reliable reference standard as it better supported reviewers when counting respiratory rate. Visual reference standards have inherent limitations due to human subjectivity, particularly when there is distortion, and can be overcome through adequate training and standardization of panel members.

7518

DESIGN AND VALIDATION OF MULTIPLEXED RESPIRATORY RT-LAMP ASSAYS FOR THE DETECTION OF SARS-COV-2, INFLUENZA A AND RESPIRATORY SYNCYTIAL VIRUS (RSV) IN COVID-19 PANDEMIC SAMPLES FROM WESTERN KENYA.

Caitlin Greenland-Bews[1], Monika Suwara[2], Ilaria Voto[2], Sonal Shah[3], Morine Achieng[4], Emilie S. Badoum[5], Hellen C. Barsosio[4], Helena Brazal-Monzó[3], Jennifer Canizales[6], Anna Drabko[7], Alice J. Fraser[1], Luke Hannan[1], Jean-Moïse T. [1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [2]Mast Group, Liverpool, United Kingdom, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Kenya Medical Research Institute, Kisumu, Kenya, [5]Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso, [6]National Heart and Lung Institute Imperial College London, London, United Kingdom, [7]Quantitative Engineering Design, Sheridan, WY, United States, [8]National Heart and Lung Institute, Imperial College London, London, United Kingdom

The COVID-19 pandemic has highlighted the importance of widespread, accessible and effective viral surveillance to ensure pandemic-preparedness. The quick diagnosis of respiratory infections is crucial not only for effective patient management but also to inform ongoing viral surveillance for the detection of outbreaks. Reverse Transcription Loop-mediated isothermal amplification (RT-LAMP) assays are an attractive alternative to RT-PCR for rapid, point of care testing. Here we present the design and evaluation of two multiplexed probe-based RT-LAMP assays for the simultaneous detection of SARS-CoV-2, Influenza A (H1N1 and H3N2) and Respiratory Syncytial Virus (RSV). Nasopharyngeal swabs collected from 153 participants on the day of enrolment in the MALCOV Cohort study in Kisumu, Kenya were used in the evaluation of two RT-LAMP assays to distinguish between SARS-CoV-2, Influenza A and RSV. Overall 93 SARS-CoV-2, six Influenza A, one Influenza B and zero RSV samples were identified in the cohort by AllPlex SARS-CoV-2/FluA/FluB/RSV RT-PCR kit as well as 53 negative for all targets. Sensitivity and specificity of the SARS-CoV-2/FluA LAMP assay when compared to RT-PCR was 94.85% (CI95%:88.38 - 98.31) and 98.11%(CI95%:89.93-99.95) respectively. Sensitivity and specificity of the SARS-CoV-2/FluA/RSV LAMP assay when compared to RT-PCR was marginally higher at 95.96% (CI95%:94.50-

99.97) and 100%(CI95%:93.40-100.00) respectively. The mean time to a positive result was 10.99minutes, highlighting the speed of this technology compared to the more commonly used RT-PCR.

7519

SENSITIVITY OF CLUSTER, PRACTICAL AND SENTINEL IMPACT ASSESSMENT METHODOLOGIES FOR ADJUSTING PREVENTIVE CHEMOTHERAPY FOR SCHISTOSOMIASIS ELIMINATION IN NIGERIA

Uwem Ekpo[1], Francisca Olamiju[2], **Hammed Mogaji**[3], Samuel Ovia[2], Olanike Oladipupo[4], Imaobong Umah[5], Fatai Oyediran[5], Moses Aderogba[6], Louise Makau-Barasa[6]

[1]Federal University of Agriculture Abeokuta, Ogun State, Nigeria, [2]Mission To Safe The Helpless, Lagos, Nigeria, [3]Federal University Oye-Ekiti, Ekiti State, Nigeria, [4]Neglected Tropical Diseases Program, Ondo State Ministry of Health, Ondo State, Nigeria, [5]Neglected Tropical Diseases Program, Federal Ministry of Health, Abuja, Nigeria, [6]EndFUND, New York, NY, United States

Impact assessment remains a critical step in redefining the endemicity profile necessary for adjusting decisions on preventive chemotherapy (PC), enabling optimized resource allocation, and minimizing implementation costs. Here, we evaluated the sensitivity of three impact assessment methodologies (sentinel, cluster and practical) in adjusting PC decisions in three endemic LGAs (Ese-Odo, Ile-Oluiji and Irele) in Ondo State. Stool and urine samples were collected from 2,093 school-aged children aged 5-14 years across 45 schools. Samples were processed using Kato-Katz and urine filtration techniques to recover *Schistosoma* ova. Findings reveal significant decline in aggregated prevalence estimates in Ese-Odo (0.1% versus 1.2% at baseline, d = -91.7%, p=0.03), and Ile-Oluiji (1.8% versus 58.0% at baseline, d = -97%, p=0.00), respectively. However, in Irele, an increase in prevalence was observed from 3.2% at baseline to 5.3% (d=66%, p=0.13). Sensitivity analysis revealed prevalence was 0.1% (95% CI: 0.01-0.95), 0.3%(95% CI: 0.01-1.7), and 0.0%(95% CI: 0-1.6) for cluster, practical, and sentinel methodologies, respectively in Ese-Odo. In Irele, the prevalence was 5.3% (95% CI: 3.8, 7.3), 5.8% (95% CI: 3.8, 8.8), and 5.4% (95% CI: 3.2, 9.0) respectively. In Ile-Oluji, the prevalence was 1.8% (95% CI: 0.9, 3.3), 2.2% (95% CI: 0.9, 4.7), and 1.5% (95% CI: 0.5, 4.4) respectively. The sentinel approach when compared to the cluster approach had lower sensitivities in Ese-Odo (d= -100%, p=0.554) and Ile-Oluiji (d=-14.5%, p=0.874), but was higher in Irele (d=2.61%, p=0.938). However, the practical assessment had higher sensitivities over cluster approach in Ese-Odo (d=83.1%, p=0.664), Irele (d=10.6%, p=0.715) and Ile-Oluiji (d=21.7%, p=0.687). Findings from the three methodologies adjudged low endemicity in Ese-Odo and Ile-Oluiji, with decision to stop PC. However, the practical approach revealed heterogeneous endemicity in Irele, with 3 schools having prevalence >10%, which requires continuing PC. Our findings suggest that practical assessment is a more sensitive method for refining preventive chemotherapy (PC) decisions.

7520

RAPID VISUAL DETECTION OF *SCHISTOSOMA HAEMATOBIUM* USING RECOMBINASE POLYMERASE AMPLIFICATION FROM SERIALLY DILUTED AND FIELD-COLLECTED HUMAN URINE SAMPLES

Nilanjan Lodh, Lauren Zorn

Marquette University, Milwaukee, WI, United States

Schistosomiasis, a prevalent waterborne and blood-borne parasitic disease stems from blood parasites classified as Schistosomes. The principal species for human Schistosomiasis include *Schistosoma mansoni* and *S. haematobium*. Presently, an estimated 220 million individuals worldwide are affected by this disease, predominantly in sub-Saharan Africa, South America, East Asia, and the Middle East. However, this is an underestimation. Accurate determination of infection prevalence faces challenges due to the insufficiency of highly sensitive and specific diagnostic tests. Currently, traditional diagnostic testing is contingent on the detection of eggs in urine samples for *S. haematobium*, by techniques such as urine microscopy. Such techniques are often seen as inadequate during different phases of the infection, especially the control phase where the infection level is low. Therefore, the objective of this study is to develop a highly sensitive and specific test for *S. haematobium* by amplifying species-specific cell-free repeat DNA from serially diluted urine samples mixed with genomic DNA and field-collected human urine samples from Zambia utilizing the recombinase polymerase amplification (RPA) technique. Utilizing this technique, 50 filtered urine samples from females and males between the ages of 8 - 16 years were collected in Zambia and filtered with Whatman#3 filter papers. DNA extracted from the filter papers and serially diluted genomic DNA (three each for *S. mansoni*, *S. haematobium*, and *S. japonicum*) were amplified by RPA, followed by column clean-up and gel electrophoresis to visualize and confirm the RPA amplified product. *S. haematobium* DNA was detected at a level of 1ng/µl from serial dilution, while *S. mansoni* and *S. japonicum* serially diluted DNA did not amplify. The study strongly indicated RPA's suitability for diagnostic testing, especially in future use for *S. haematobium* detection with developed probes on lateral flow strips, offering faster, cost-effective, and accurate results compared to other molecular tests.

7521

USING HUMAN-CENTERED DESIGN TO SUPPORT DEVELOPMENT AND IMPROVEMENT OF A MOBILE ENABLED DIAGNOSTICS FOR SCHISTOSOMIASIS CONTROL ANALYTICS (MEDSCAN) SOFTWARE FOR SCHISTOSOMIASIS DIAGNOSIS IN WESTERN KENYA

Gladys Odhiambo[1], Carson Moore[2], Austin Hardcastle[2], Kennedy Andiego[1], Meredith Odhiambo[1], Fredrick Rawago[1], Matthew Boisse[2], Thomas Scherr[2], Maurice Odiere[1]

[1]Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, [2]Department of Chemistry, Vanderbilt University, Nashville, TN, United States

WHO has called for development of new tools and diagnostics to help prevent, control and eliminate neglected tropical diseases. In this regard, there has been rapid emergence of mobile health tools but very few studies have been conducted to understand user priorities, acceptability and usability for schistosomiasis. Human-centered design is important in increasing end-user ownership and consistent uptake of mobile phone applications. Therefore, we sought perspectives on functionality of and user experience with a newly developed mobile app, MEDSCAN. In 2023, we conducted 4 focus group discussions (FGDs) with 38 participants purposively selected and usability threshold was determined using System Usability Scale (SUS) 5-point Likert scale. Participants included end users, administrators and experts from schistosomiasis-endemic areas in Siaya and Kisumu Counties. The MEDSCAN App was introduced to the participants who were given time to interact with it in small groups using phones. Qualitative data was transcribed, translated, coded, and analyzed thematically using NVivo version 12 software. Custom Python code was used to analyze the SUS data. All SUS scores passed the usability threshold (>68%). Dashboard was the lowest scoring feature. Overall, participants were comfortable using MEDSCAN's main features and the app was highly acceptable. Participants stated that it was easy to navigate, had a logical flow, and would help accelerate sample collection and analysis processes. They found the screens to be effective and straightforward, with simple and direct language. While participants believed that MEDSCAN app incorporated all components and features necessary for electronic surveillance of schistosomiasis, they raised concern with the app's dependency on internet connectivity and lack of ability to edit some records before submission. They emphasized the need to increase font size, add age and include gender of participants. They also recommended overhauling of the dashboard. Feedback from FGDs will be used to iteratively improve the platform until the application and dashboard meet expectations of the stakeholders.

7522

EXPLORING THE *PARAGOMINUS KELLICOTTI* LIFE CYCLE PROTEOME: IMPLICATIONS FOR THE DISCOVERY OF NEW DIAGNOSTIC TARGETS

Iucia S. Di Maggio, Bruce A. Rosa, Robert W. Sprung, Young Ah Goo, Makedonka Mitreva, R. Reid Townsend, Gary J. Weil, Peter U. Fischer

Washington University in Saint Louis, saint louis, MO, United States

Paragonimiasis is a food-borne trematode infection that affects about 21 million people. More than 30 *Paragonimus* species have been described from Asia, Africa, and the Americas, and about one third of them are confirmed to infect humans. Humans become infected by the consumption of raw or undercooked freshwater crustaceans that contain infective metacercariae. *Paragonimus kellicotti* is the agent of North American paragonimiasis, and an excellent model for other *Paragonimus* infections. To investigate the parasite soluble proteins, we took advantage of the fact that infective stage can be found in crayfish in streams of the Ozark region, near Saint Louis, Missouri and the adult stage can be obtained from experimentally infected gerbils. We performed mass spectrometry analysis of *P. kellicotti* soluble somatic protein of adults (SSPA) and freshly excysted juveniles (SSPJ), metacercarial cyst fluid (MC) after excystation, excretion/secretion products produced by adult worms after in vitro culture (ESP), and lung cyst fluid proteins (CFP) of infected gerbils. We identified more than 2,000 *P. kellicotti* proteins that were found in at least 2 of 3 biological replicates and were supported by at least 2 peptides. Among those were 1,914 proteins found in SSPA samples, 219 proteins in SSPJ, 947 in ESP samples, 37 in CFP samples and 11 in MC samples. The samples that contain excreted or secreted proteins (MC, ESP, CFP) had only one protein in common, a cysteine protease (CP6), that is a well described immunogenic protein. The total soluble fluke extracts SSPA and SSPJ had 171 proteins in common. This extensive proteomic study identified proteins that are not only present in adult flukes but also in freshly excysted juveniles. Furthermore, the protease CP6 was identified as a prominent excreted/secreted protein after in vitro culture of adults and in vivo in the lung cysts with adults and the cyst of the metacerariae. Therefore, CP6 is a promising biomarker candidate for development of an antigen test for paragonimiasis.

7523

MULTI-CONTRAST MACHINE LEARNING IMPROVES SCHISTOSOMIASIS DIAGNOSTIC PERFORMANCE

María Díaz de León Derby[1], Charles B. Delahunt[2], Isaac I. Bogoch[3], Anne-Laure M. Le Ny[2], Daniel A. Fletcher[1]

[1]University of California, Berkeley, Berkeley, CA, United States, [2]Global Health Labs, Bellevue, WA, United States, [3]University Health Network (UHN), University of Toronto, Toronto, ON, Canada

Schistosomiasis remains a public health burden despite ongoing global control efforts. Sensitive diagnostic and screening tools are needed to help accelerate these efforts. In this work, we present an artificial intelligence (AI)-based strategy for automated detection of *Schistosoma haematobium* that combines two imaging contrasts, brightfield (BF) and darkfield (DF), to improve diagnostic performance. We used a compact, digital microscope, the LoaScope, to collect BF and DF images of *S. haematobium* eggs in patient samples during two different field visits to Côte d'Ivoire (March 2020, November 2021). We trained AI models (using YOLOv8) to detect parasite eggs in the BF and DF images from March 2020. We evaluated performance of the models on the November 2021 holdout data in four different ways: BF model alone, DF model alone, or both models in combination (with positive diagnosis given by Boolean "AND" or "OR"). We determined the model's patient-level sensitivity at various specificities required by WHO Diagnostic Target Product Profiles (TPP) for schistosomiasis control programs. The Monitoring and Evaluation (M&E) use case has target sensitivity and specificity of 75% and 96.5%, respectively. The AI models, when evaluated at 96.5% specificity, had sensitivities of 76% (BF alone), 83% (DF alone), and 81% (for AND and OR models). The Transmission Interruption and Surveillance (TI&S) use case has target sensitivity and specificity of 88% and 99.5%. The models, when evaluated at 99.5% specificity, had sensitivities of 53% (BF alone), 63% (DF alone and OR model), and 73% (AND model). The Boolean AND sensitivity is the closest to the TI&S target sensitivity of 88%. Our central finding is that using two imaging contrasts, BF and DF, markedly improved diagnostic performance for the high specificity TI&S use case. Capture of the two image contrasts requires minimal changes in microscope optics and no additional sample preparation. Multi-contrast machine learning thus offers a practical means to improve performance of automated diagnostics for *S. haematobium* egg detection and could be applied to other microscopy-based diagnostics.

7524

MAPPING RISKS FOR FEMALE GENITAL SCHISTOSOMIASIS IN URBAN SETTINGS TO GUIDE PUBLIC HEALTH INTERVENTIONS

Kyra Dols[1], Sandra Adelaide King[2], Martins O. Imhansoloeva[3], Akinola S. Oluwole[4], Richard Selby[3], **Omosefe O. Osinoiki**[4]

[1]University of Oxford, Oxford, United Kingdom, [2]Sightsavers, Accra, Ghana, [3]Sightsavers, Hayward Heath, United Kingdom, [4]Sightsavers, Abuja, Nigeria

Female Genital Schistosomiasis (FGS) is a Neglected Tropical Disease that disproportionately impacts the sexual and reproductive health of women. FGS has been linked with several social and physical impacts. Poor knowledge, attitude, and sociocultural practices also influence behavior of women and girls at risk. Comprehensive examination of women's lived experiences around the risk of FGS are notably scarce in the existing literature. Furthermore, the impact of rapid urbanization, unregulated migration, and environmental changes on the risk of FGS have been largely unexplored. Different levels of urbanicity and rural-urban migration, contributes to increasing risk of FGS among adult females living in such localities. This research seeks to understand how women living in urban endemic areas in Ghana experience risks related to contracting female genital schistosomiasis. Using qualitative approach, investigation will explore how women experience the risk factors for FGS differently in distinct contexts as well as the role of rural-urban migration, and its contribution to expanding urban risk. The study will be conducted in selected endemic areas of the Greater Accra Region in Ghana. Data will be thematically analysed for the risks, including how women in endemic urban areas experience risks related to female genital schistosomiasis. Reports will also provide insights into the challenges and experiences specific to females in urogenital schistosomiasis endemic urban and rural communities of Greater Accra in Ghana. Findings will encapsulate participants' indigenous recommendation to design potential intervention, progressing urogenital schistosomiasis and FGS management guidelines for Ghana and other endemic countries in Sub-Saharan Africa. Data collection will be finalized by July and preliminary findings will be available for dissemination in August 2024.

Hepatosplenic schistosomiasis caused by *Schistosoma mansoni* remains a significant public health concern, particularly in areas of persistent transmission. Understanding the metabolic changes induced by *S. mansoni* infection is crucial for discovering host signatures of infection and disease pathogenesis. We conducted LC-MS untargeted metabolomic profiling on plasma samples obtained from school-aged children in areas of low and moderate endemicity for *S. mansoni* in Cameroon, strongholds of parasite persistent transmission. Diagnosis of *S. mansoni* infection was conducted using the Kato Katz thick smear method and complemented by circulating anodic antigen assay. Children were later stratified based on their S. mansoni infection status. Through successive discovery, validation, and polyparasitism runs, we identified significant alterations in multiple metabolic pathways associated with *S. mansoni* infection. Notably, the perturbation of tyrosine metabolism emerged as a robust biomarker candidate across runs, suggesting its potential for complementary diagnostics. The polyparasitism run, wherein we observed the persistence of alterations in tyrosine metabolism in *S. mansoni*-infected hosts even in the presence of coinfections, was used to assess the molecular and biochemical mechanisms underlying these metabolic changes. Initially, we utilized quantitative polymerase chain reaction (qPCR) techniques to quantify the expression levels of key enzymes involved in tyrosine metabolism in cDNA from whole blood samples, obtained from low endemicity *S. mansoni*-infected individuals. These quantitative measurements provided insights into the transcriptional regulation of tyrosine metabolism genes in response to *S. mansoni* infection, further validating the dysregulation observed in our metabolomic analyses, particularly in polyparasitism and low infection burden and settings. This advancement is particularly significant for resource-limited settings where traditional diagnostic methods may be inadequate and further targeted studies on other endemic settings are highly recommended.

7526

ADVANCEMENTS IN SCHISTOSOMIASIS DIAGNOSIS: IS RECOMBINANT ANTIBODY POINT-OF-CARE CIRCULATING CATHODIC ANTIGEN TEST (POC-CCA), MORE RELIABLE?

Mahbod Entezami[1], Elias Kabbas-Piñango[2], Theresia Abdoel[3], Moses Adriko[4], Sergi Alonso[2], Moses Arinaitwe[4], Pytsje T. Hoekstra[5], René Paulussen[3], Govert van Dam[5], Lisette van Lieshout[5], Poppy HL Lamberton[2], Joaquin M. Prada[1]

[1]University of Surrey, Guidlford, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]Mondial Diagnostics, Amsterdam, Netherlands, [4]Ministry of Health Uganda, Kempala, Uganda, [5]Leiden University Center for Infectious Diseases, Leiden, Netherlands

Schistosomiasis control programmes have historically relied on Kato-Katz thick smears (KKs) to detect *Schistosoma mansoni* eggs in stool, however, this diagnostic technique has limited sensitivity. An alternative, point-of-care circulating cathodic antigen test (POC-CCA), has been available since 2008 but suffers from batch-to-batch variation and issues surrounding reader variation and trace results, which limits its implementation and interpretation in the field. Here, in *S. mansoni* endemic communities we evaluated the performance of an updated POC-CCA test that was developed using a recombinant antibody-based design (recPOC-CCA). We used the G-score grading system to reduce inter- and intra-reader variability and improve intensity estimates of both the original POC-CCA and new recPOC-CCA. Over 850 individuals were recruited across two endemicity settings in Uganda, with three duplicate KKs carried out across three consecutive days, as well as testing with POC-CCA and recPOC-CCA across and within those 3 days. Through a state-of-the-art Bayesian Latent Class Model, we estimated sensitivity and specificity in the field of these diagnostics and optimal cutoffs to meet the Target Product Profile defined by the World Health Organization. The performance of the recPOC-CCA was comparable with the traditional POC-CCA, with a similar probability of meeting the WHO TPP. Importantly, in contrast to the traditional POC-CCA, within-sample variation across three batches of recPOC-CCA was indistinguishable, suggesting little to no batch-to-batch variation. Therefore, the recPOC-CCA test is a strong alternative to the POC-CCA, with similar performance in the field but a more consistent production cycle and no discernible variation between batches. Programmes should consider lower cutoffs in areas with lower intensity of infection to maximize the performance of the diagnostic. At present neither recPOC-CCA nor POC-CCA achieves the WHO TPP required specificity if only used for one day, however, tests on three urine samples collected on subsequent days would likely meet these requirements.

7527

THE SHORT-TERM IMPACT OF *SCHISTOSOMA MANSONI* INFECTION ON HEALTH-RELATED QUALITY OF LIFE: IMPLICATIONS FOR CURRENT ELIMINATION POLICIES

Sergi Alonso[1], Moses Arinaitwe[2], Alon Atuhaire[2], Andrina Barungi Nakansi[2], Joaquín M Prada[3], Emma McIntosh[4], Poppy HL Lamberton[1]

[1]School of Biodiversity, One Health and Veterinary Medicine & Wellcome Centre for Integrative Parasitology, University of Glasgow, Glasgow, United Kingdom, [2]Vector Borne and Neglected Tropical Diseases Control Division, Ministry of Health, Kampala, Uganda, [3]Department of Comparative Biomedical Sciences, Faculty of Health & Medical Sciences, University of Surrey, Guilford, United Kingdom, [4]Health Economics and Health Technology Assessment, School of Health & Wellbeing, University of Glasgow, Glasgow, United Kingdom

The World Health Organisation (WHO) aims to eliminate schistosomiasis as a public-health problem by 2030. However, standard morbidity measures poorly correlate to infection intensities, hindering disease monitoring and evaluation. This is exacerbated by insufficient evidence on *Schistosoma's* impact on health-related quality of life (HRQoL). We conducted community-based cross-sectional surveys and parasitological examinations in moderate-to-high *S. mansoni*-endemic communities in Uganda. We calculated parasitic infections and used EQ-5D instruments to estimate and compare HRQoL utilities in these populations. We employed Tobit/linear regression models to predict HRQoL determinants. Two thirds of the 560 participants were diagnosed with parasitic infection(s) and 49% presented *S. mansoni* infection. Endemic communities reported more health problems and lower HRQoL values than the Ugandan average. High- and moderate-endemicity communities reported similar HRQoL values and health problems, except for the 'pain/discomfort' dimension, where more severe problems were reported in the high-endemicity setting. Importantly, no significant negative association was observed between HRQoL and current *S. mansoni*-infection status/intensity. However, severity of pain urinating (β=-0.106; SE=0.043) and body swelling (β=-0.326; SE=0.005), increasing age (β=-0.016; SE=0.033), reduced socio-economic status (β=0.128; SE=0.032), and being unemployed predicted lower HRQoL. Symptom severity and socio-economic status were better predictors of short-term HRQoL than current *S. mansoni*-infection status/intensity. This is key to disentangling the link between infection(s) and short-term health outcomes, and highlights the complexity of correlating current infection(s) with long-term morbidity. Further evidence is needed on long-term schistosomiasis-associated HRQoL, health and economic outcomes to inform the case for upfront investments in schistosomiasis interventions.

7528

IDENTIFICATION OF SCHISTOSOMICIDAL COMPOUNDS FROM *BALANITES AEGYPTIACA*

Sammy Y. Aboagye[1], Daniel Boamah[2], Jonathan Bisson[3], Shao-Nong Chen[3], Guido F. Pauli[3], David L. Williams[1]

[1]Rush University Medical Center, Chicago, IL, United States, [2]Centre for Plant Medicine Research, Mampong Akwapim, Ghana, [3]University of Illinois, Chicago, Chicago, IL, United States

Schistosomiasis remains an important neglected disease that impacts 78 countries globally. The only existing schistosomiasis therapy, Praziquantel, has limited efficacy against juvenile parasites and there is concern of emerging Praziquantel-resistant parasites. *Balanites aegyptiaca* has been

used extensively in various folk medicines as an antibacterial, anticancer, antimalarial, and anthelmintic agent in many developing countries. We aimed to evaluate the schistosomicidal activity of a *B. aegyptiaca* extract against the multiple developmental stages of *Schistosoma mansoni* worms and to identify the active compound(s) therein. Cercariae were mechanically transformed into skin-stage schistosomula (NTS). Mice were infected with *S. mansoni* by tail exposure to cercariae and juvenile and adult worms were obtained by perfusion 21 and 42 days post infection, respectively. Crude extract was screened against these stages and worm viability was assessed by quantitation of ATP. The crude extract was found to be schistosomicidal against all three stages. The crude extract was fractionated by Biotage C18 column fractionation using MeOH:H_20 gradient resulting in 62 fractions that were pooled based on TLC profiling into 8 fractions for bioactivity assessment. The active fractions identified were pooled and fractionated by dichloromethane-MeOH gradient yielding 50 fractions that were combined into 14 fractions based on TLC profile. Active fractions identified underwent tertiary fractionation by acetonitrile:H_20 yielding 40 fractions. Subsequent screening of these 40 fractions identified 4 fractions with 99%, 82%, 73% and 86% killing, respectively, when tested at 20 µg against NTS. Fractionation is ongoing towards identification of the bioactive compound(s). Our preliminary findings show promise against larval, juvenile and adult worms and provide baseline data to further advance our study towards understanding mechanisms of actions of the compounds.

7529

REAL-TIME PCR ASSAY FOR DETECTION OF *PARAGONIMUS KELLICOTTI* IN HUMAN STOOL

Kurt curtis, Gary Weil, Peter Fischer
Washington University in St. Louis Missouri, St. Louis, MO, United States

The lung fluke Paragonimus *kellicotti* is found throughout most of eastern and central North America infecting mammals that feed on crayfish such as bobcat, raccoon, coyote, mink, and otters. It is closely related to the human pathogen *P. westermani*, which causes paragonimiasis in eastern Asia. *P. kellicotti* can also cause infections in humans if they consume raw crayfish that are the host species for the metacercaria stage of the parasite. The object of this study was to design a real-time PCR assay for detection of P. *kellicotti* DNA in human stool. Known numbers of eggs from adult *P. kellicotti* were added to stool, and DNA was extracted from the spiked stool samples. Real-time PCR was performed with primers and a probe designed to detect a *P. kellicoti* ITS-2 DNA target. The assay detected the target in DNA isolated from a 200 mg stool sample that had been spiked with a single P. kellicotti egg. This is approximately equivalent to detection of 12 fentograms of parasite genomic DNA. We have previously used conventional PCR to detect the P. kellicotti ITS-2 DNA in lung biopsies, cerebrospinal fluid, and sputum from from *P. kellicotti* patients, and the qRT-PCR assay is more sensitive than conventional PCR. However, additional studies are needed to evaluate the sensitivity of this new assay with different types of clinical samples.

7530

UNDERSTANDING INFECTION VERSUS TRANSMISSION DYNAMICS OF *SCHISTOSOMA MANSONI* PRE- AND POST-TREATMENT, AND THE RELATIONSHIP BETWEEN EGG, ANTIGEN AND DNA BASED DIAGNOSTICS

Katherine Hopkinson[1], Moses Arinaitwe[2], Andrina Nankasi[2], Christina L. Faust[1], Jessica Clark[1], Lauren V. Carruthers[1], Diana Ajambo[2], Moses Adriko[2], Fred Besigye[2], Alon Atuhaire[2], Aidah Wamboko[2], Rachel Francoeur[3], Edridah M. Tukahebwe[2], Joaquin M. Prada[4], **Poppy H L Lamberton**[1]
[1]University of Glasgow, Glasgow, United Kingdom, [2]Vector Control Division, Ministry of Health, Kampala, Uganda, [3]University of Chester, Chester, United Kingdom, [4]University of Surrey, Guildford, United Kingdom

Over 240 million people are infected with *Schistosoma*. The World Health Organization has set goals for schistosomiasis elimination as a public health problem by 2030, defined as <1% prevalence of heavy-infections measured by Kato-Katz (KK) in school-aged children. However, KK lack sensitivity, and commonly overestimate drug efficacy. The point-of-care circulating cathodic antigen test (POC-CCA) improves on sensitivity, especially for low intensities and post treatment, but specificity is not 100%. In addition, the relationship between antigens and eggs changes post treatment, resulting in different drug efficacy measures and many individuals who are POC-CCA positive but KK negative. Understanding what proportion of KK negative, POC-CCA positive individuals are true infections, and if they are contributing to transmission, will help inform and guide control programmes. We aimed to estimate the true proportion of school-aged children who are infected with *Schistosoma mansoni* and at risk of morbidity, and what proportion are shedding eggs and contributing to transmission in a high-endemicity Ugandan community. A Bayesian Latent Class Model was developed and fit to data from three days of duplicate KK, miracidia hatching, qPCR of stool and blood spots, and POC-CCA G-scores at pre-treatment, and 3, 9, and 22 weeks post-treatment. Incorporating miracidia hatching data and stool qPCR greatly improved predictions of those shedding eggs, as well as resulting in improved, higher, specificity estimates for POC-CCA. Baseline egg and antigen-based diagnostics were comparable, but at 3 weeks post treatment, egg-based diagnostics lack sensitivity and vastly overestimate clearance, with only a quarter of estimated infections shedding eggs. Miracidial hatching data were the most comparable to model estimates of individuals shedding eggs. In conclusion, after treatment, most infected individuals are not shedding eggs, and therefore not contributing to transmission at that stage. However, egg-based diagnostics overestimate the efficacy of treatment, and more robust diagnostics are needed in order to monitor elimination goal attainment.

7531

COMMUNITY AWARENESS OF FEMALE GENITAL SCHISTOSOMIASIS AND MASS DRUG ADMINISTRATION PARTICIPATION IN THE ABOBO DISTRICT, ETHIOPIA - FINDINGS FROM THE FAST PACKAGE PILOT PROJECT

Alison Krentel[1], Kiflom Hailu[2], Mio Ayana[3], Fikre Seife[4], Daniel Dana[3], Duguay Claudia[1], Kazeem Arogundade[2], Abraham Tamirat Gizaw[3], Aashka Sood[2], Abebaw Tiruneh[3], Tesfahum Begashaw[4], Margaret Gyapong[5], Zeleke Mekonnen[3]
[1]University of Ottawa, Ottawa, ON, Canada, [2]Bruyere research Institute, Ottawa, ON, Canada, [3]Jimma University, Jimma, Ethiopia, [4]Ethiopian Ministry of Health, Addis Ababa, Ethiopia, [5]University of Health and Allied Sciences, Accra, Ghana

Female Genital Schistosomiasis (FGS) is a neglected health issue affecting women and girls in Sub-Saharan Africa. Those with the condition experience physical and social challenges from untreated *Schistosoma haematobium* infections, resulting in urogenital complications. The FGS Accelerated Scale Together (FAST) package is a holistic approach to address FGS by increasing community awareness of FGS preventing new infections by promoting Mass Drug Administration (MDA) and increasing diagnosis and treatment. A baseline cross-sectional study conducted in January 2024 in Abobo District, Ethiopia included 420 participants18 years and above in the community and 400 individuals (15-25 yrs) for urine filtration tests. Baseline-level schistosomiasis prevalence was determined, and mixed-effect logistic regression models were used to assess factors associated with community awareness of schistosomiasis and FGS, and MDA participation. The prevalence of schistosomiasis was 32%, with the disease being more prevalent among males than females (40% vs 30%). Most community participants were aware of schistosomiasis (90%, 378) and have previously participated in an MDA (86%, 361) - however, only 6% (25) of the participants have ever heard about FGS. The mixed-effect logistic regression results highlighted participation in-school MDA was associated with a reduction in the odds of having schistosomiasis [aOR=0.795, P=.044]. As age increases, the likelihood of infection decreases [aOR=.077, P=.034]. Willingness to take Praziquantel preventatively [aOR=2.27, P<.001] and education [aOR=1.25, P=.033] were associated with increased MDA participation. Using risky freshwater sources for domestic purposes [aOR=0.352, P=.025] reduced

odds of hearing about schistosomiasis while higher educational levels [aOR=2.13 P=.01] were linked with schistosomiasis awareness. Effective communication and addressing community perceptions can enhance MDA participation. These baseline findings improve our understanding of community experience and knowledge of schistosomiasis and will shape the FAST Package intervention.

7532

MOVING FROM DISTRICT TO SUB-DISTRICT SCHISTOSOMIASIS IMPLEMENTATION IN SENEGAL: TIME TO CHANGE AND ADAPT STRATEGIES

Rose Monteil[1], Bocar Diop[2]

[1]FHI 360, Dakar, Senegal, [2]MoH, Dakar, Senegal

Schistosomiasis is a major waterborne neglected tropical disease (NTD) that remains major public health problem in Senegal, with an 13.5 million people estimated to be currently at risk of infection. In 1999, the Ministry of Health established the National Schistosomiasis Control Programme in implementing mass drug administration (MDA) among school-aged children To eliminate schistosomiasis as public health problem, there has been a shift in strategy to move from district-wide implementation to a more focal strategy by updating the endemicity at the sub-district level to better target those requiring preventive chemotherapy. Here we present historical and recent schistosomiasis mapping results from Senegal, presented at the district and sub-district level. The first schistosomiasis evaluation was conducted between 1996 and 2003 with 29 districts mapped. Between 2009 and 2012, the PNLB continued mapping and commenced MDA in all endemic districts in 2016. After 4-5 years MDA implementation, an impact evaluation was conducted between 2016 and 2019. More recently, a second impact assessment has been conducted in 37 districts between 2022 and 2024. In summary, multiple surveys have been conducted investigating schistosomiasis in Senegal but to date there is no publication on the national schistosomiasis mapping results. The analysis is still underway as we wait for the 2024 survey results (to be finished at the end of April). In brief, endemicity of 1661 sub-districts and 79 districts will be calculated and presented in district and sub-district maps with a descriptive analysis performed, of national schistosomiasis data at baseline (1996-2003), first impact assessment (2016-2019), and second impact assessment (2022-2024). The number of implementation units requiring PC will be summarized at district level compared to sub-district level with the number of school aged children requiring treatment assessed at district-level compared to sub-district level. This study was aimed to analyze data at sub-district level that could be used to update the endemicity review how this change impacts on drug request needs for better targeted MDA.

7533

PREDICTORS OF SCHISTOSOMIASIS JAPONICUM INFECTION RISK IN SICHUAN, CHINA

Wei William Zou[1], Elise Grover[1], Andrew Hill[1], Bo Zhong[2], Yang Liu[2], Elizabeth J. Carlton[1]

[1]University of Colorado, Colorado School of Public Health, Aurora, CO, United States, [2]Institute of Parasitic Diseases, Sichuan Center for Disease Control and Prevention, Chengdu, China

Schistosomiasis japonicum persists in 450 counties in China despite stringent disease control efforts that began in the 1950s. We conducted a study to identify variables that predict schistosomiasis infection risk along with variable levels associated with peak infection risk in regions targeted for elimination using a machine learning approach. Data were retrieved in 2007, 2010, 2016, and 2019 in Sichuan, China, using multiple surveys. This study included data on 5,004 respondents aged 6 to 96 years old across 2 counties. Generalized boosted regression trees were used to evaluate the association between infection risk and environmental, socioeconomic, demographic, and agricultural features across three spatial scales (individual, household, and village-level). We bifurcated the data to evaluate if key predictors changed over time between 2007-2010 and 2016-2019 because the prevalence of infections declined from 8.93% in 2007 to 1.04% in 2019. The predictive performances of the models were high (AUC=0.88 and 0.91 respectively). Our preliminary analyses suggests that village-level factors were the most important predictors of infection risk, with mean night soil use and the percentage of households with improved sanitation as the most important predictors in 2007-2010 and mean night soil use and area of non-rice crops planted in the summer as the most important predictors in 2016-2019. In 2007-2010, infection risk peaked in villages with >300 buckets of night soil used. In 2016-2019, infection risk peaked in villages with >100 buckets of night soil used and >6 Mus (approx.: 4,000 m2) of non-rice crops planted in the winter. These predictors likely influence the emission of schistosome eggs into the environment and the contact rate between individuals and contaminated surfaces. This study contributes to current management practices of endemic schistosomiasis control in rural China by identifying levels of predictors that best predict high infection risk, as well as optimal spatial scales in which interventions may be implemented.

7534

MORPHOMETRIC TRAITS OF *FASCIOLA HEPATICA'S* INTERMEDIATE HOSTS IN AREAS WITH HUMAN AND ANIMAL FASCIOLIASIS AND STUDY OF PHYSICOCHEMICAL PROPERTIES OF ITS WATER SOURCES

César A. Murga-Moreno[1], **Cristian Hobán**[1], Jhover Diaz[1], David Ruiz-Perez[1], Fabiano Cruzado-Chávez[1], Dayana M. Terrones-Cerna[1], Sandra Quispe[1], Alejandra Hoyos[1], Ana M. Fernández-Sánchez[1], Miguel M. Cabada[2], Pedro Ortiz[1]

[1]Universidad Nacional de Cajamarca, Cajamarca, Peru, [2]University of Texas Medical Branch, Galveston, TX, United States

Trematodiases are transmitted by freshwater snails, mainly limneids distributed worldwide. In the Peruvian Andes, they host trematodes such as *Fasciola hepatica* and some paramphistomids, with the former having the greatest impact on public health. The presence of snails in natural waters used for drinking and irrigation contributes to the transmission of these parasites. This study focuses on the morphometric analysis of Lymnaeidae snail shells and the physicochemical parameters of the water where they dwell. Between March 2023 and March 2024, 656 adult limneid snails and water samples were collected in four rural areas of the province of Cajamarca, Peru. These included Valle Verde/Huayrapongo (VVH) at 2649 m elevation, Otuzco (OTZ) at 2740 m, Chetilla (CHT) at 3055 m and Combayo (CBY) at 3342 m. A quarter of the snails (n = 164) with the best integrity and largest size were selected for evaluation of their shell length (SL), shell width (SW), aperture length (ApL), aperture width (ApW) and aperture area (ApA). Snails from OTZ presented a mean of 8.5 mm in the SL and 4.1 mm in the SW, being significantly larger than those from other areas. The pH of the waters from CHT (7.4) and CBY (7.2) were considerably more neutral than those from VVH (8.7) and OTZ (8.5). The highest turbidity was found in the VVH waters at 329.8 NTU and differed significantly to those of OTZ (16.2 NTU), CHT (1.8 NTU) and CBY (2.6 NTU). No differences were reported for water temperature, which averaged 20.4 °C, and for salinity, which averaged 143.4 ppm. Significance was found in the altitude of CBY with respect to the other study areas, being the highest geographically and influencing the shorter length of the shells. The other traits such as SW, ApL, ApW and ApA suggest a polygenic pattern of inheritance, as they did not show significant differences, while water parameters varied depending on altitude.

7535

COMPARING STOOL PCR, RECOMBINASE POLYMERASE AMPLIFICATION, AND MICROSCOPY TO DETECT *FASCIOLA HEPATICA* INFECTION IN THE RABBIT MODEL.

Carol Alexandra Castro[1], Martha Vanessa Fernandez- Baca[1], Rodrigo Alejandro ore[1], Cristian Hobán[2], Pedro Ortiz[2], Makedonka Mitreva[3], Young-Jun Choi[4], Miguel M. Cabada[5]

[1]Sede Cusco - Instituto de Medicina Tropical Alexander von Humboldt - UPCH, Cusco, Peru, [2]Facultad de Ciencias Veterinarias, Universidad

Nacional de Cajamarca, Cajamarca, Peru., Cajamarca, Peru, [3]McDonell Genome Institute, Washington University, Washington USA., Washington, WA, United States, [4]Departament of Medicine Division of Infectious Diseases,Washington University School of Medicine, Washington USA., Washington, WA, United States, [5]Infectious Diseases Division, Internal Medicine Department, University of Texas Medical Branch, Galveston Texas USA., Galveston, TX, United States

Fascioliasis is an emerging neglected zoonosis worldwide. Communities in the Andean highlands of Peru, where prevalence exceed 10%, are considered hyperendemic. The diversity in transmission patterns and lifecycle complexity of Fasciola pose challenges for early and specific diagnosis the infection. Serology can help in early diagnosis, but limited sensitivity and, particularly, specificity make interpretation difficult. Antigen and DNA detection in stool may identify infection much sooner than microscopy. In this study, we compared real-time qPCR (qPCR) and recombinase-polymerase amplification (RPA) to stool microcopy for the early detection of fascioliasis in the rabbit animal model. Eight *Fasciola* free rabbits at baseline were infected orally with 40 metacercariae of *Fasciola hepatica*. We collected fecal samples before infection and daily starting 15 days post infection (dpi) until the three-day egg count mean was stable in all animals. The stool was tested using quantitative sedimentation microscopy with methylene blue. Stool sedimentation was used to concentrate eggs and DNA extracted from 500ug of fecal sediment using the cetyltrimethylammonium bromide (CETAB). The quantity and quality of the extracted DNA was evaluated by spectrophotometry. We used primers targeting the ITS-1 region of the Fasciola 18s gene. At 49 dpi, 3 rabbit were positive and at 61 dpi all rabbit were positive for Fasciola eggs by microscopy. *F. hepatica* DNA was detected 15 dpi in 3 rabbit using qPCR and in all rabbit at 25 dpi. Using RPA, DNA was detected 15 dpi in 2 rabbit and in all rabbit at 31 dpi. Infection was detected sooner by any of the methods if the number of adult parasites recovered from the animal was higher. Stool qPCR and RPA can detect *Fasciola* infection during the latent phase and several weeks sooner than microscopy.

7536

DETECTION OF *FASCIOLA HEPATICA* DNA IN DIFFERENT SPECIMENS USING A MINIPCR THERMOCYCLER AND LED LIGHT HANDHELD VIEWER

Martha Vanessa Fernandez-Baca[1], Alejandro Castellanos-Gonzalez[2], Maria Luisa Morales[1], Melinda B. Tanabe[2], Pedro Ortiz[3], A. Clinton White[2], Miguel M. Cabada[2]

[1]Universidad Peruana Cayetano Heredia, Cusco, Peru, [2]University of Texas Medical Branch, Galveston, TX, United States, [3]Universidad Nacional de Cajamarca, Cajamarca, Peru

Fasciola hepatica is a trematode causing burdens to livestock & human health. Stool microscopy has a poor sensitivity but is the diagnostic test most used. Real-time PCR (q-PCR) can detect *Fasciola* DNA in clinical & environmental samples with high sensitivity and specificity. In this study, we developed a SYBR Green PCR-based test using a portable miniature thermocycler (miniPCR) and LED light P51 mini-viewer to amplify and detect *Fasciola* (Fh) DNA. For these experiments, we used Fh DNA extracted from clinical (stool) and environmental (water and snails) samples. The differentiation between positive and negative samples was based on the fluorescence produced by SYBR Green after amplification of double-stranded DNA. To increase reproducibility, we used a smartphone application (Prismo Mirage) to quantify the fluorescence detected in P51 viewer. The analytic sensitivity was determined by the limit of detection after serial dilutions and the specificity by cross-reactivity with DNA from related organisms. The sensitivity was 100 fg/µl of *F. hepatica* DNA in water samples and 10 fg/µl of *F. hepatica* DNA in stool and snail samples. The Fasciola miniPCR was 100% specific for *F. hepatica* DNA. These results demonstrate that miniPCR is a molecular diagnostic method that can potentially be deployed to laboratories in endemic areas.

7537

PRE- AND POST-PRAZIQUANTEL TREATMENT ASSOCIATIONS OF *SCHISTOSOMA MANSONI* INFECTION WITH LATENT TUBERCULOSIS AND IMMUNE RESPONSES IN TANZANIA

Khanh Pham[1], Enock Miyaye[1], Daniëlle de Jong[2], Govert van Dam[2], Paul L.A.M. Corstjens[2], Humphrey Mazigo[3], Hyasinta Jaka[3], Jennifer A. Downs[1]

[1]Weill Cornell Medicine, New York, NY, United States, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Catholic University of Health and Allied Sciences, Mwanza, Tanzania, United Republic of

Tuberculosis is the second leading cause of death worldwide, with most active TB cases resulting from reactivation of latent tuberculosis infection (LTBI). Emerging evidence suggests that *Schistosoma* infection may decrease the sensitivity of screening tests that detect LTBI due to helminth-induced, altered immune responses. However, data on whether *S. mansoni* infection, and subsequent eradication, alter responses to LTBI are limited. Data from an ongoing cohort study were analyzed among adults aged 18-50 years living in Tanzania from July 2022 through April 2024. LTBI was determined at baseline and 12 months using the QuantiFERON-TB Gold Plus assay, which included: TB1, TB2, Nil and Mitogen. *S. mansoni* infection was confirmed by stool microscopy plus a serum schistosome circulating anodic antigen of ≥30 pg/mL. We used linear and logistic regression to compare *S. mansoni*-infected and uninfected people. Difference in differences of pre- and post-treatment were compared using Wilcoxon matched-pairs signed-rank test. 148 individuals were enrolled, which included 83 men (56.1%) and 65 women with a median age of 32 years [26-40.5]. Sixty-five people (43.9%) had *S. mansoni* infection. At baseline, there was no difference in LTBI between *S. mansoni*-infected and uninfected people, but those with schistosome infection had lower Mitogen concentration (38.5% versus 23% with Mitogen level<10IU/ml, p=0.03). Compared to persistently uninfected people (n=36), those whose *S. mansoni* infection was eradicated (n=14) at 12 months had subsequent increases in responsiveness to TB1 and Mitogen (TB1 +0.87, p=0.06; Mitogen +2.2, p=0.03). Preliminary data from this ongoing study demonstrate that *S. mansoni* may impair host immune responses to TB antigens. Eradication of schistosome infection at 12 months is associated with increased host immune responses to TB1 and Mitogen. Ongoing data collection may further clarify the longitudinal effects of schistosome infection and anthelmintic treatment on the immune responses to TB, which is particularly important in regions where these two diseases overlap, and co-infections are common.

7538

THE COLONIAL IMPACT ON SCHISTOSOMIASIS RESEARCH, PRESENT DAY INEQUALITIES AND MOVING TOWARDS AN EQUITABLE RESEARCH ENVIRONMENT

Raheema Chunara, Teteh Champion

School of Biodiversity, One Health & Veterinary Medicine, University of Glasgow, Glasgow, United Kingdom

Research into schistosomiasis has been deeply influenced by our shared colonial history, resulting in inequalities that persist to the present day. Despite the burden of this parasitic disease being primarily borne by the Global South, leading research institutions, influential journals, funding bodies, and major players in global health remain concentrated in the Global North. While collaborations between institutions from the Global North and Global South countries are common, issues surrounding power dynamics, longevity, and effectiveness of these collaborations arise. To unravel the complexities of this dynamic, a systematic review delving into the history of schistosomiasis research was undertaken. This review aimed to identify first authors, leading institutions, and the distribution of researchers from the Global North and Global South in published papers related to water, sanitation, and hygiene (WaSH) and schistosomiasis, examining how these dynamics have evolved over time. To further address these inequalities and aid the progression (in both the research environment and wider health

inequalities), it is also imperative to gain crucial insights from researchers in endemic countries as they offer insights into the complexities, barriers, and enablers of these international collaborations. Insights into existing dynamics and challenges were achieved using a mixed-method approach. Surveys, in-depth interviews (IDIs), and focus group discussions (FGD) with researchers from both the Global North and Global South were used to explore researchers' current experiences and help elucidate how research environments can be improved to overcome barriers imposed by colonial legacies. These insights will be presented, and how equitable collaboration between the Global North and South can be contextualized discussed, with tangible actions proposed to close inequality gaps, and improve schistosomiasis research to help control and eliminate this disease.

7539

QUANTIFYING CHANGES IN THE FORCE OF INFECTION OVER 20 YEARS OF MASS DRUG ADMINISTRATION FOR *SCHISTOSOMA MANSONI*

Jessica Clark[1], Christina L. Faust[1], Mafalda Viana[1], Jason Mattiopoulos[1], Moses Adriko[2], Arinaitwe Moses[2], Edridah M. Tukahebwa[2], Narcis B. Kabatereine[3], Michelle Clements[3], Charlotte M. Gower[4], Thomas Crellen[1], Diana Ajambo[2], Andrina Nankasi[2], Candice Rowel[2], Aidah Wamboko[2], David W. Oguttu[5], Fred Besigye[2], Rachel Francoeur[6], Lauren V. Carruthers[1], Alan Fenwick[3], Joanne P. Webster[7], Joaquin M. Prada[8], Poppy H. L. Lamberton[1]

[1]University of Glasgow, Glasgow, United Kingdom, [2]Ministry of Health, Vector Control Division, Kampala, Uganda, [3]Unlimit Health, London, United Kingdom, [4]Centre for Emerging, Endemic and Exotic Diseases, Pathobiology and Population Sciences, Royal Veterinary College, University of London, London, United Kingdom, [5]Ministry of Health, Vector Control Divison, kampala, Uganda, [6]University of Chester, Chester, United Kingdom, [7]4.Centre for Emerging, Endemic and Exotic Diseases, Pathobiology and Population Sciences, Royal Veterinary College, University of London, London, United Kingdom, [8]University of Surrey, Surrey, United Kingdom

Schistosomiasis infects over 240 million people, with the greatest impact on those living in sub-Saharan Africa. Intervention programmes have largely relied on the application of the anthelmintic praziquantel to reduce morbidity and onwards transmission. However, epidemiological evidence indicates that rates of re/infection are as high, and in some locations higher than in previous years despite upwards of 20 years of treatment in some settings. To inform on anthelmintic efficacy and the cost-effectiveness of ongoing control, it is critical to quantify the long-term impact of intervention programmes. To do this, we leverage a longitudinal epidemiological dataset collected over 18 years from school-aged children in three villages with high endemicity of *Schistosoma mansoni* in Uganda. We developed a state-space model that estimates individual-level worm burden from repeated parasite egg counts to investigate whether the mass drug administration programme has reduced the force of infection and what differences exist between these villages, while accounting for challenges such as loss to follow-up and changing cohorts. Our results indicate that the force of infection has marginally reduced over 18 years, with substantial heterogeneity between villages despite their close geographic proximity to one another and Lake Victoria. Owing to the small, though statistically significant, reductions in the force of infection, it is difficult to ascertain whether this is due to repeated mass treatments, or other factors such as i) reduced exposure to infected water sources due to lower fish stocks, ii) education programmes, and/or iii) the implementation of water, sanitation, & hygiene interventions. Future research should aim to quantify the impact of these additional interventions as well as investigate changes to the forceof infection in lower endemicity settings.

7540

ASSOCIATIONS BETWEEN *SCHISTOSOMA MANSONI* INTENSITY, C-REACTIVE PROTEIN (CRP), AND STUNTING AMONG PRESCHOOL-AGED CHILDREN IN UGANDA

Susannah Colt[1], Andrew Edielu[2], Emily L. Webb[3], Hannah W. Wu[1], Patrice A. Mawa[2], Racheal Nakyesige[4], Jennifer F. Friedman[1], Amaya L. Bustinduy[3]

[1]Rhode Island Hospital, Providence, RI, United States, [2]London School of Hygiene and Tropical Medicine Uganda Research Unit, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Uganda Virus Research Institute, Entebbe, Uganda

Schistosomiasis causes linear growth faltering among older children. However, little is known about schistosomiasis-related morbidities in pre-school age children (PSAC). As part of an NIH-funded trial of optimal praziquantel dosing for PSAC in Uganda, we present baseline findings assessing *S. mansoni* infection intensity, systemic inflammatory markers, and risk for stunting. PSAC age 12-47 months with *S. mansoni* infection, diagnosed by Kato Katz in duplicate stool samples, were enrolled from the Lake Albert region. Infection intensity was assessed by eggs per gram of stool (EPG). Plasma C-reactive protein (CRP) was measured by immunoassay. Undernutrition categories of underweight (weight-for-age z score<-2), stunting (length-for-age z score<-2), and wasting (weight-for-length z score<-2) were defined using WHO Anthro. Statistical analyses included multivariate linear and log binomial regression models. A bivariate threshold of $p<0.1$ was used to select covariates and considered age, sex, socio-economic status (SES), non-lake drinking water, malaria coinfection, and HIV coinfection. Among 348 participants, the median *S. mansoni* infection intensity was 72 EPG (IQR 24-258). Sixteen percent of children had malaria and 19.0% were stunted. Fewer than 3% were underweight or wasted. Higher *S. mansoni* infection intensity (EPG) was associated with higher CRP concentrations after adjusting for drinking water, malaria, and HIV (ß=0.08, SE=0.04, p=0.03). Higher CRP concentrations were associated with an increased risk for stunting after adjusting for SES (RR=1.18, 95% CI=1.00-1.40, $p<0.05$). While *S. mansoni* infection intensity was not directly associated with stunting risk, we report that *S. mansoni* may indirectly contribute to stunting via systemic immune activation as captured by CRP. This finding aligns with previously published reports that schistosomiasis contributes to stunting in children via chronic systemic inflammation, which negatively impacts growth factors like insulin-like growth factor 1 (IGF-1). This study offers insight into mechanisms of schistosomiasis-related stunting in children under five years.

7541

MORBIDITY IN PRE-SCHOOL-AGED CHILDREN AND ADULTS IN A *SCHISTOSOMA MANSONI* ENDEMIC COMMUNITY OF LAKE VICTORIA, UGANDA

Rivka May Lim[1], Ruhi Lahoti[1], Amy B. Pedersen[1], Moses Arinaitwe[2], Victor Anguajibi[3], Andrina Nankasi[2], Fred Besigye[2], Joanne P. Webster[4], Poppy HL Lamberton[5]

[1]University of Edinburgh, Edinburgh, United Kingdom, [2]Vector borne and neglected tropical diseases control division, Ministry of Health, Kampala, Uganda, [3]China Friendship Hospital, Kampala, United Kingdom, [4]Royal Veterinary College, Hatfield, United Kingdom, [5]University of Glasgow, Glasgow, United Kingdom

Schistosoma mansoni infection is known to cause damage to the liver, however resource and time constraints limit regular ultrasound screenings in endemic areas. Therefore, the number of eggs in faeces is used as a proxy for morbidity and the high infection intensity (≥ 400 eggs per gram) threshold to inform and evaluate control programs. However, recent evidence has begun to challenge this link between infection intensity and morbidity, urging a revaluation of these control and elimination targets and assumptions. In a cross-sectional survey in Bugoto, Uganda, involving 287 individuals aged 3-74, S. mansoni prevalence and intensity were determined using Kato Katz thick smear microscopy and point-of-care circulating cathodic antigen tests. Ultrasound and the Niamey protocol assessed periportal fibrosis (PPF), portal vein dilation (PVD), and left

parasternal line (PSL) enlargement. Logistic regression models incorporated infection, coinfections, anemia, and symptoms to predict morbidity and infection. PPF prevalence was 9% (B-F) and 4% (C-F), while PVD and PSL prevalence were 34% and 33% respectively. Although 11-14-year-olds had the highest S. mansoni infection intensity, preschool-aged children (PSAC) were more likely to exhibit PVD and PSL morbidities. Current S. mansoni infection showed no association with assessed liver morbidity markers. Our study findings add to the growing evidence indicating a lack of association between current S. mansoni egg count with morbidity markers, which raises significant implications against the use of eggs per gram as a proxy for morbidity within national programs and policy. The age-related distribution of morbidities observed here, with notable burden of PVD and PSL in PSAC, stresses the critical need to both: a) elucidate the impact and progress of apparent 'subtle morbidities' on host health and their interplay with current and past infection status; and b) accommodate and monitor these youngest age classes in treatment and monitoring programmes, if we are to ever truly achieve the revised WHO NTD Roadmap schistosomiasis targets of elimination as a public health problem by 2030.

7542

EFFECTS OF COMMUNITY-LED TOTAL SANITATION ON IMPROVING HYGIENE AND SANITATION IN THREE VILLAGES OF THE EAST REGION, CAMEROON, APRIL - SEPTEMBER 2023

Marius Soho Njenkam[1], Guy Valérie Djumyom Wafo[2], Ange Mague Ymele Takendong[3], Alexis Ngouana Tchinda[1], Winnie Amanda Zouong Nkomba[1], Placide Ankone[1], Flore Balana Esiene[4], Belle Bayong[4], Pricille Anya[4], Gaston Etoundi Mballa[4]

[1]Regional Delegation of Public Health of the East Region, Bertoua, Cameroon, [2]University of Dschang, Ministry of Higher Education, Dschang, Cameroon, [3]Municipality of Fokoué, Dschang, Cameroon, [4]Department for the Fight against Epidemics and Pandemic, Ministry of Public Health, Yaounde, Cameroon

Cameroon faces problems in drinking water and sanitation; access rate was estimated at 3.9% and 34% for drinking water and sanitation services respectively in 2010. East Region is among the regions with the lowest sanitation rate, estimated at 16%. To improve hygiene and sanitation in this region, the Ministry of Public Health with its partners implemented the Community-Led Total Sanitation (CLTS) project in 300 villages. The goal was to bring a change in attitudes and hygiene practices. We described the effects of this strategy in 3 villages of the East region. We conducted a comparative study from April to September 2023 in 3 villages purposely selected (Sandae, Sandji 2 and Bazzama villages) after a 2-year CLTS implementation. We estimated the number of households to be interviewed at 278. We used systematic sampling to select households. In each household, the head of household was interviewed. We used a structured questionnaire to collect socio demographics (age, sex, occupation, education), hygiene facilities (latrines and types, handwashing facilities) and hygiene practices (handwashing, use of soap, use of latrines, open defecation) data. We analyzed data using Excel 2016. In total, 278 heads of households were interviewed. Median age was 41 (18-69) years and sex ratio M:F 3:1. In total, 245 (88.1%) did not attend school and 183 (65.9%) were farmers. At endline, 251 (90.3%) households owned a latrine vs 93 (33.5%) at baseline. The full-bottom latrine was most frequent 251 (90.3%) vs 129 (46.4%) at baseline; 241 (86.7%) had a hand-washing facility vs 318 (51.8%). Among those who owned a latrine, 239 (95.2%) used them regularly with 123 (49%) still in good condition. In total, 19 (6.8%) practice open defecation vs 194 (70%) at baseline and 182 (75.5%) systematically washed their hands after leaving the toilet, compared with 34 (12.7%) at baseline but 4 (1.1%) used soap. CLTS brought enormous changes in sanitation and hygiene practices in these villages. However, some practices need to be improved on latrine utilization and handwashing practices. We recommend a close follow-up to ensure the sustainability of these actions.

7543

HOLISTIC APPROACHES TO WATERBORNE URINARY TRACT INFECTIONS

Hanna Noel Brosky[1], Jill Stewart[1], Valeria Ochoa Herrera[2]

[1]University of North Carolina, Chapel Hill, NC, United States, [2]Universidad San Francisco de Quito, Quito, Ecuador

Water may be an underrecognized but important route of uropathogen transmission causing urinary tract infections (UTIs). This idea is supported by recent reports of the presence of uropathogens in water supplies from multiple countries, and a report of a decrease in UTIs following installation of a new water treatment plant on San Cristóbal Island in Galápagos, Ecuador. Drinking or bathing in contaminated water may expose people to extraintestinal infections caused by *Escherichia coli*, the most common pathogen associated with UTIs. Studies are needed to investigate uropathogenic *E. coli* in drinking water systems, and the links to infectious disease. The hypothesis for this work is that waterborne exposures to *E. coli* are a causative agent of community-acquired UTIs, driven by environmental factors and household water use. Results from this work have the potential to revolutionize our understanding of the etiology of UTIs and the ecology of uropathogenic *E. coli* to subsequently inform interventions to improve water quality and prevent disease.

7544

SPATIAL DISTRIBUTIONS & DIVERSITY OF ENTERIC PATHOGENS IN PUBLIC ENVIRONMENT IN LOW-AND MIDDLE-INCOME NEIGHBORHOODS IN NAIROBI, KENYA

Fanta D. Gutema[1], Bonphace Okoth[2], John Denge[2], Christine Sharon[2], Sheillah Simiyu[2], Blessing Mberu[2], Daniel Sewell[1], Kelly K. Baker[1]

[1]University of Iowa, Iowa city, IA, United States, [2]African Population and Health Research Center, Nairobi, Kenya

The objective of this study was to evaluate the differences in the detection, species diversity, and contamination level of enteric bacterial pathogens between and within low- and middle-income neighborhoods of Nairobi, Kenya. We also assessed the hygienic infrastructure and sanitation conditions in the two neighborhoods. A TaqMan array card assay was employed to analyze soil samples for 19 enteropathogens alongside Enterobacteriaceae culture assays. An observational assessment was conducted during every site visit to document the hygienic infrastructure and sanitation conditions at the sites. We detected at least one enteric pathogen in 81% (130/160) and two and more than two pathogens in 67.5% (108/160) of the soil samples tested. The four most frequently detected pathogens were EAEC (67.5%), ETEC (59%), EPEC (57.5%), and STEC (31%). The detection rate (93% vs. 69%) and mean (5 vs. 4.7) diversity of enteric pathogens were higher in Kibera than in Jericho. Similarly, a wider spatial distribution of the pathogens was found at Kibera public domain sites. On average, diversity in exposure to different enteric pathogens increased by 0.72 and 0.69 species within-site movements in Jericho and Kibera, respectively and by 1.11 and 0.99 for between-site movements in Jericho and Kibera, respectively. Patterns of pathogen detection in public soil varied seasonally in the middle-class neighborhood but remained consistently high throughout the year in the low-income slum. Our study revealed that several enteric pathogens, notably pathogenic *E. coli,* are prevalent in the public environment across both neighborhoods, with a higher contamination rate and spatial-temporal distribution in low-income Kibera. Future studies should focus on identifying the source of contamination and quantifying the role of contaminated environments in enteric infections in children.

7545

MENTAL AND ENVIRONMENTAL HEALTH IN URBAN SALVADOR, BRAZIL: LINKS AND OPPORTUNITIES

Andre Okoye[1], Rashad Parmer[1], Fabiana Almerinda G. Palma[2], Murilo Guerreiro Arouca[2], Federico Costa[2], Amanda K. Gilmore[1], Claire A. Spears[1], **Christine E. Stauber**[1]

[1]Georgia State University, Atlanta, GA, United States, [2]Federal University of Bahia, Salvador, Brazil

Although urban areas have greater access to municipal services such as water and sanitation services, those in densely populated, informal communities experience disparities in distribution, quality, and continuity of services, which can be detrimental to both physical and mental health. For example, densely populated urban favela communities in Brazil often experience high stress related to environmental conditions and exposure to violence. Addressing the association between urban environmental conditions and mental health provides an opportunity to reduce barriers to improved health and quality of life. Mobile health technology (mHealth) has tremendous potential to gather data and may enhance the inclusion of underserved populations in the participatory construction of solutions for these challenging urban environmental problems. Our goal was to examine the association between mental and environmental health in urban communities that are receiving a sanitation intervention in Salvador, Bahia, Brazil. Participants (N=768) in four communities (two sanitation intervention areas and two control communities) completed the SF-12 questionnaire, a standardized questionnaire which examines dimensions of physical and mental health. We found that 60% of participants rated their health as good or better yet 15% responded that they felt discouraged or depressed often. Although there were indicators of strong community cohesion (e.g., 70% of people responded that they felt a desire to help other members of the community), there were also challenges. For example, some cited a lack of trust for others (30%), insufficient presence of community neighborhood associations (20%), concern for violence (28%), and limited infrastructure services (36%) which varied by neighborhood. We also completed focus groups to elucidate the complex links between mental and environmental health in urban areas of Salvador and to assess how the sanitation intervention impacted quality of life. We also looked to identify ways in which mHealth tools could be leveraged to enhance both mental and environmental health in collaboration with these communities.

7546

ACCEPTABILITY, USAGE AND SATISFACTION OF CHLORINE FOR WATER TREATMENT AFTER DOOR-TO-DOOR MASS DISTRIBUTION IN DISPLACED POPULATION OF CABO DELGADO PROVINCE, MOZAMBIQUE

Santinha Juma[1], Mariana Pimenta[2], James Waringa[3], Nelson Sequiao[3], David Prieto[3], **Sergio Lopes**[2], Xavier Badia-Rius[2]

[1]Direcção Provincial de Saúde, Pemba, Mozambique, [2]The MENTOR Initiative, Haywards Heath, United Kingdom, [3]The MENTOR Initiative, Pemba, Mozambique

Cholera is responsible for high mortality in humanitarian emergencies due to overcrowding, malnutrition, lack of healthcare access, sanitation facilities and treatment of drinking water. The province of Cabo Delgado, Mozambique, has been immersed in a severe humanitarian crisis due to conflict and insecurity since 2017 with declared cholera outbreaks. Hygiene promotion campaigns have been implemented since August 2023 including mass door-to-door distribution of chlorine in resettlement sites and host communities of 7 districts of the province. A total of 52,202 bottles of chlorine were distributed to 245,000 people. The aim of this study was to describe the acceptability, usage, knowledge and satisfaction of the use of chlorine as water treatment method after a mass distribution. A cross-sectional survey was conducted in 6 districts after the distribution. A total of 340 people were randomly selected using proportional population size methodology with the premise they had received chlorine. Overall, 76% of participants were women and the largest age group was between 18 and 35 years old (50%). Eighty-nine per cent of participants confirmed they had used chlorine in the previous two weeks. However, out of the 340 households visited, 199 (59%) tested positive for free residual chlorine in their drinking water. Of the positive ones, 20 households did not have the optimal concentration: 7 of them had less than the required (< 0.2 mg/l) and 13 had more than the recommended one (>5.0 mg/l). Eighty-one per cent of the participants who treated their water showed they knew the recommended dose of chlorine to be used. Most of the participants (98%) said they were satisfied with the use of chlorine and 89% said they would use it again. The study is the first one measuring the uptake of chlorine after mass household distribution in displaced population and it showed a high acceptability, knowledge of use, knowledge on the reason to use and the will of using chlorine again. However, discrepancies between the reported usage rate and the positivity of the free residual chlorine test may indicate issues in the usage or storage after the water treatment.

7547

EVALUATING FECAL SLUDGE TREATMENT TECHNOLOGIES IN HUMANITARIAN CONTEXT: A COMPREHENSIVE STUDY IN COX'S BAZAR, BANGLADESH

Mohammad Rafiqul Islam[1], Mohammad Atique Ul Alam[1], Md. Sakib Hossain[1], M. Moniruzzaman[2], Md. Hajbiur Rahman[1], Faisal Chowdhury Galib[1], Md. Shafiqul Islam[1], **Zahid Hayat Mahmud**[1]

[1]icddr,b, Dhaka, Bangladesh, [2]University of Manitoba, Winnipeg, MB, Canada

Efficient treatment of fecal sludge in densely populated settings is essential as it has a direct impact on public health and environment. This study evaluates the performance of selected fecal sludge treatment technologies at the Rohingya camps, Bangladesh. A total of 17 different treatment plants of five different technologies were selected for this study. The treatment technologies were evaluated based on the removal efficiency and standard discharge guideline of different physicochemical and microbiological parameters. Among the treatment technologies, waste stabilization pond (WSP) showed the highest removal efficiency in all parameters except *Escherichia coli*. Upflow filter (UPF) showed good removal efficiency for *E. coli* (99.7%), TSS (95.9%), COD (91.7%), BOD (93.5%) and helminth (93.7%). Decentralized wastewater treatment systems (DEWATS) performed well in the removal of TSS (97.7%), COD (94.4%), BOD (93.9%) and helminth (99.8%). In respect to comparing with the standard discharge guideline, the majority of the treated effluents from WSP were found to be within the guideline values specially for phosphate (61.1 %), TSS (72.2 %) and helminth (66.7 %). In the case of *E. coli* around 43% of treated fecal sludge samples of DEWATS were found within the guidelines, which was higher than all the other technologies. None of the technologies completely follows the national and international guidelines for discharge quality. Therefore, additional treatment options like combining chemical and biological processes to the existing treatment technologies need to be implemented in fecal sludge treatment to effectively ensure safe final discharge into the environment.

7548

EFFECT OF AN ONSITE SHARED SANITATION INTERVENTION ON MARKERS OF ENVIRONMENTAL ENTERIC DYSFUNCTION IN CHILDREN LIVING IN MAPUTO, MOZAMBIQUE

Jackie Knee[1], Trent Sumner[2], Zaida Adriano[3], Claire Anderson[4], Judite Monteiro Braga[5], Drew Capone[6], Veronica Casmo[5], David Holcomb[7], Evgeniya Molotkova[8], Celina Russo[2], Winne Zambrana[4], Rassul Nalá[5], Oliver Cumming[1], Joe Brown[7]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom, [2]Georgia Institute of Technology, Atlanta, GA, United States, [3]We Consult, Maputo, Mozambique, [4]Stanford University, Stanford, CA, United States, [5]Instituto Nacional de Saúde de Moçambique, Maputo, Mozambique,

[6]*Indiana University Bloomington, Bloomington, IN, United States,* [7]*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,* [8]*Virginia Tech, Roanoke, VA, United States*

The relationship between enteric pathogen exposure and long-term health effects like stunting and cognitive deficiencies may be mediated by environmental enteric dysfunction (EED), a subclinical condition characterized by intestinal inflammation, increased permeability, and malabsorption. Reducing exposure through safe water, sanitation, and hygiene (WASH) may limit or delay the onset of EED. We assessed whether access to a shared onsite sanitation intervention affected the concentration of four fecal biomarkers of intestinal inflammation and permeability among children living in Maputo, Mozambique. The Maputo Sanitation trial was a controlled before-and-after study of an urban sanitation intervention in low-income, unplanned neighborhoods of Maputo, Mozambique. We collected stool at baseline (pre-intervention) and 12- and 24-months post-intervention and measured the concentration alpha-1-antitrypsin (A1AT), neopterin (NEO), myeloperoxidase (MPO), and calprotectin (CAL). We assessed the effect of the intervention at 12- and 24-months post-intervention among all children and in a sub-group of children born into study sites post-intervention. After 12 months, the concentration of NEO was higher among intervention children compared with controls (mean difference 0.39 log nmol/L, 95% CI: 0.15 - 0.62). Concentrations of CAL and NEO, both measures of intestinal inflammation, were also higher among children born into intervention sites by the 24-month follow-up visit (CAL mean difference 0.43 log ng/mL, 95% CI: 0.041 - 0.82; NEO 0.38 nmol/L, 95% CI: 0.0079, 0.76). The intervention did not a have statistically significant effect on the concentration of A1AT, the only marker of intestinal permeability. We found no evidence that the intervention reduced the concentration of EED biomarkers among children up to 24-months after the intervention. The lack of a formal case definition and of representative healthy reference concentrations complicates interpretation of our effect estimates, including their potential clinical significance.

7549

RISK FACTORS FOR CHILDHOOD DIARRHEAL DISEASES IN PERI-URBAN AREAS OF OUAGADOUGOU, BURKINA FASO: A HOUSEHOLD SURVEY

Denise Hien[1], Alimatou Hema[1], Jean Sawadogo[1], Ben Idriss Soulama[1], Alphonse Ouédraogo[1], Alfred Bewendtaoré Tiono[1], Sophie Houard[2], Sodiomon Bienvenu Sirima[1]

[1]*Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso,* [2]*European Vaccine Initiative, Heidelberg, Germany*

AbstractDiarrheal diseases represent a significant global public health challenge, particularly in low or middle-income countries, where access to safe drinking water remains a challenge. In Burkina Faso, diarrheal diseases continue to burden the population, especially in peri-urban areas. This study aims to identify the risk factors associated with diarrheal diseases in two peri-urban areas of Ouagadougou, Burkina Faso. A household survey was conducted from April 7 to 16, 2021, targeting mothers/caregivers of children under five. Data collection utilised a structured questionnaire covering socio-demographic and economic household characteristics, as well as maternal knowledge, attitudes, and practices related to diarrheal diseases, safe water access, sanitation, and hygiene. A total of 660 households were surveyed, with respondents averaging 31.39 years of age, and 58.48% having no formal education. Mothers/caregivers predominantly attributed diarrheal diseases to poor nutrition (70.91%) and inadequate hand hygiene (63.33%), while only 30.61% recognised the role of contaminated water. Despite high reported access to drinkable water (98.64%), primarily sourced from public fountains (70.15%), handwashing facilities with water and soap in the same location were lacking in 25.45% of households. Additionally, a significant association (P<0.001) was observed between household economic status and access to a private tap at home. This study highlights the prevailing misconceptions surrounding the causes of diarrheal diseases among mothers/caregivers of children under five in peri-urban areas of Ouagadougou. It underscores the urgent need for targeted interventions addressing knowledge gaps, and improving access to safe water, sanitation, and hygiene practices, particularly among economically disadvantaged households.

NOROVIRUS INFECTION RISKS ASSOCIATED WITH CONSUMPTION OF CONTAMINATED TOMATOES - AN APPLICATION OF A NOVEL QUANTITATIVE MICROBIAL RISK ASSESSMENT (QMRA)-LINKED INFECTIOUS DISEASE TRANSMISSION (IDT) MODEL

Julia S. Sobolik, Elizabeth T. Sajewski, Ben A. Lopman, Juan S. Leon

Emory University, Atlanta, GA, United States

Norovirus is a leading cause of foodborne illness in the United States and worldwide. However, the magnitude of disease risk to a population from consuming produce contaminated with norovirus is not known. To estimate the individual- and population-level risks of consuming norovirus-contaminated tomatoes, we developed a quantitative microbial risk assessment (QMRA)-linked infectious disease transmission (IDT) model to 1) characterize individual risk from consumption of empirically sampled, norovirus-contaminated tomatoes, and 2) simulate norovirus cases in a population from a norovirus-tomato seeding event. Sequence-confirmed norovirus GII.6 strains were isolated from tomatoes collected on Mexican farms and quantified using digital RT-PCR. We used a QMRA model to estimate infection risks (10,000 iterations, mc2d package, 1:100 infectious ratio) based on empirically sampled norovirus concentration data and age-stratified tomato consumption rates. Median infection risks varied by age, with the lowest risk (1.9×10^{-4} per day, 95th percentile range [1.8×10^{-6}, 3.1×10^{-2}]) among children (<6 years), and the highest risk ($1 .4 \times 10^{-3}$ per day, 95th percentile range [3.3×10^{-5}, 1.8×10^{-1}]) among adults (21 to <60 years). These risks were integrated into the IDT model (N=100,000; 50% of population exposed to tomatoes) to simulate a one-time norovirus seeding event. Using the IDT model, a single outbreak from tomato consumption alone lasted four days with a cumulative incidence of 16 cases: 11 symptomatic, 5 asymptomatic. When simulating primary cases resulting from tomato consumption and secondary cases from contact with tomato-infected primary cases, the outbreak lasted 17 days with a cumulative incidence of 42 cases: 29 symptomatic; 13 asymptomatic. This study underscores the utility of integrated risk assessments to evaluate norovirus transmission dynamics across scales, the potential to simulate pathogen- and commodity-specific seeding events, and to inform effective surveillance and mitigation strategies.

7551

PREVALENCE OF ANTIMICROBIAL RESISTANT ENTEROBACTERIA'S IN A COMMUNITY AND IN THE ENVIRONMENT IN SALVADOR, BRAZIL

Davi V R S Eloy, Lee S A Andrade, Hálica R S Borges, João R P C Filho, Luciano K. Silva, Ronald E. Blaton, Mitermayer G. Reis

Oswaldo Cruz Foundation, Salvador, Brazil

We collected 82 community and 77 environment samples between 2023 and 2024, to assess the prevalence of antimicrobial resistant *Escherichia coli*, *Klebisella pneumoniae* and *Enterobacter cloacae* from a neighborhood and a river near the community in Salvador, Brazil. Bacterial isolates were selected based on their characteristics using MacConkey and CHROMagar median culture, and then confirmed with MALDITOF and Vitek. Subsequently, PCR reactions and agarose electrophoresis gel were employed to detect the presence of 13 genes associated with beta-lactamases, particularly those linked to multidrug resistance. We found out that the most prevalent bacteria were *E. coli* (82% in community and 53% in environment) followed by *K. pneumoniae* (18% in community and 37% in environment) and *E. cloacae* (0% in community and 6% in environment). The genes with most frequency in the community and environment was the *bla*TEM with 40% in the community and 37% in the environment. The genes with the least prevalent were *bla*IMP, *bla*VIM and *bla*OXA-48,

both with 0% prevalence. Only 22% of the isolates lacked any resistance associated genes. Furthermore, the antibiotic that showed the most resistance in the analyses was Amoxicillin-clavulanic acid in community and intravenous Cefuroxime in the environment. The most contaminated point with fecal contamination had 6900 CFU/ml in a point closer to mouth of the river. These findings support that antimicrobial resistance is present and increasing worldwide in the environment, needing rapid intervention to slow down this problematic. The prevalence of those bacteria in the environment, besides other associations, is related to the lack of basic sanitation and the traffic between humans and the river. Observing heightened resistance to Amoxicillin-clavulanic acid and intravenous Cefuroxime corresponds with the prevalence of the *bla*TEM gene in the samples, since this gene is related to resistance to cephalosporins and penicillin-like antibiotics.

7552

PIPED WATER INTERMITTENCY AND ITS IMPACT ON WATER QUALITY AT POINT OF USE

Andrea Sosa-Moreno[1], Gwenyth O. Lee[2], Josefina Coloma[3], Gabriel Trueba[4], William Cevallos[5], Karen Levy[6], Joseph NS. Eisenberg[1]

Intermittent water supply (IWS) systems, characterized by services that are unavailable for hours or days at a time, present a risk for water insecurity. IWS often results in pressure fluctuations and stagnation, leading to increased risk of microbial intrusion and proliferation compared with continuous water supply systems. Households that experience water intermittency often store water to compensate for outages, which can lead to contamination. They also tend to distrust the quality of the water, increasing their likelihood of treating drinking water. To explore the association between household piped water intermittency and piped water microbial contamination at the point of use, we collected 1098 piped water samples from 234 households over four visits spaced six months apart in six communities in northern Ecuador. We assessed *E. coli* concentrations using both Colilert (IDEXX) and Petrifilm (3M) tests, obtaining five contamination levels that correspond to WHO risk levels for safe water. IWS patterns, including frequency (days/week without water supply) and duration (hours/day without water supply) of intermittent periods varied across communities. Households in two community-managed systems reported fewer intermittent periods per week but were more likely to have increased contaminated water samples compared to our study community with a centralized system. We did not observe a significant association between household piped water intermittency and piped water contamination at the point of use. However, households reporting more frequent intermittent periods were more likely to provide samples that were stored before collection (OR: 1.3 [95% CI: 1.1-1.5]), and water storage was associated with higher contamination levels (2.9 [1.7-4.9]). We did not observed associations with household water treatment. These findings suggest that while intermittency itself may not directly influence piped water microbial contamination in our study communities, the coping strategies adopted by households to manage IWS, such as storing water, may contribute to the contamination of their drinking water supplies.

IMPROVEMENT AND DISPARITY IN WATER, SANITATION, AND HYGIENE (WASH) IN GHANA: COMPARATIVE ANALYSIS OF 2014 AND 2022 GHANA DEMOGRAPHIC AND HEALTH SURVEY DATA

Provision of safe drinking water, sanitation, and hygiene (WASH) is key in achieving the SDGs by 2030. In achieving this, inequalities are to be considered. In LMICs like Ghana, vulnerable groups disproportionately bear the burden of poor WASH. We assessed Ghana's progress towards provision of WASH and reducing WASH inequalities. We analysed household data from the 2014 and 2022 Ghana DHS. Access to basic WASH intervention was defined using the WHO standard. We estimated the coverage of WASH as a percentage with 95%confidence interval(CI). Concentration index was used to quantify inequality in access to basic WASH interventions. Households in 2014 and 2022 were 11835 and 17933 respectively with a median household size of 3 persons each. Most households were headed by males[2014:66.0%, 2022:63.0%]. From 2014 to 2022, improvements were observed in household access to basic drinking water;84.0%[CI:82.0-86.0] to 87.0%[CI:85.0-89.0], sanitation;21.0%[CI:18.0-23.0] to 23.0%[CI:21.0-26.0] and handwashing facilities; 33.0%[CI:30.0-36.0] to 46.0%[CI:44.0-48.0]. Overall access to basic WASH increased from 6.4%[CI:5.2-7.8] to 15.0%[CI:13.0-17.0] among households. There were significant disparity in household access to basic toilet facilities, drinking water, handwashing facilities, and overall WASH against the poor. Inequality in access to basic WASH interventions was significantly higher in urban households, highest:Greater Accra, lowest:North East region, and increased with educational level, household head gender disparity against female heads was observed in 2014. WASH coverage remains low in Ghana and with high inequality in access to basic WASH facilities across socio-economic status, regions, urban-rural communities, however household head gender disparity was not observed in the current survey. Interventions targeting urban informal settlements need to be considered.
